Initial meetings included workshops to identify what issues could be encompassed into a package of solutions. Possible solutions to address riparian and wetland issues became more apparent although those for managing the drainage system and local road and rail network required further investigation and specialised skills (Lusis 1999c). The Hinchinbrook ICM Reference Group contracted a consultant to prepare, coordinate and complete the ecological and planning reports for all of the issues. The reference group endorsed the report's analysis and recommendations and presented these to the council for review. Hinchinbrook Shire Council approved in principle amendments to the shire planning scheme proposed by the reference group and in December 1998 and January 199 it advertised the proposed changes for public review. The community has endorsed these amendments (Lusis 1999c).

The Ecological Report

The recommendations delivered in the planning report were based on an inventory of pressures, conditions and responses outlined in the ecological report. The solutions developed in the planning report are targeted at these catchment issues. The ecological report found that the Herbert River Catchment contained areas of nationally, regionally and locally significant environmental resources including Wet Tropics World Hertiage areas, Manhogany Glider Habitat and important mangrove and wetland habitat areas. It also found that the integrity of these resources was threatened by natural and human induced environmental pressures, including:

- high rainfall and seasonal flooding;

- exotic flora and fauna species, which flourish in ideal growing and breeding conditions (ie a wet and humid climate and few predators);
- evidence of the expansion of agricultural land use, in contravention of best-practice guidelines;
- Exposure to acid sulfate soils, which may harm native fish species and which is costly to address (Lusis 1999c).

The condition of remaining environmental resources varies widely across the Herbert floodplain and is a direct result of the extent and severity of the pressures experienced. Of particular importance is the Wet Tropics World Heritage Area, located in the Northern extent of the Hinchinbrook Shire, which has the highest level of plant and animal biodiversity in Australia. In some areas this biodiversity extends onto surrounding freehold properties yet the importance of their contribution tends to be understated. Also of importance are the wetlands and mangroves in the catchment, which are of national, regional and local environmental significance (Australian Nature Conservation Agency 1996; Hogan and Graham 1994; Johnson, et al. 1997). In terms of their condition, the distribution of natural vegetation on the floodplain has been dramatically reduced since European settlement. Approximately 35-40% of the natural vegetation of the coastal lowland area has been cleared for crop production or improved pastures (Johnson and Murray 1997). Additionally, the State of the Rivers Report for the Herbert River concluded that the condition of the riparian vegetation was very good to good along 13% of the Herbert River, moderate along 29% and poor to very poor along 58% (Lusis 1999c). The ecological report also included a series of maps, that identified the condition of the wetlands and riparian lands in the Shire as being 'disturbed', 'intact', or 'regrowth'. The Hinchinbrook ICM Reference Group used this information to identify planning solutions to facilitate the protection of 'intact' or 'regrowth' wetland and riparian areas while ensuring the continued expansion of the cane-growing industry.

Several planning and land use management initiatives had been developed in response to current pressures on the environment prior to the linking project. The Catchment Coordinating Committee had responded by producing the Draft Catchment Management Strategy, and with demonstration projects including the development and restoration of wetlands and the establishment of owl nesting boxes. Other land use planning and resource management responses aimed at reducing environmental pressures included the cane land allocation process, and works undertaken by the Herbert River Improvement Trust and Local Water Boards. Despite the existence of such planning and management mechanisms, many of them were not being implemented with a view to minimising pressures on the environment.

1998 Amendments to the Scheme

Although the 1997 scheme was well advanced in its protection of natural resources, the review found that the planning provisions relating to intensive agriculture needed to be strengthened. The suggested changes to the planning scheme also reflected many of the concerns raised by state government, catchment and industry groups in the public consultation phase for the 1997 scheme (refer Appendix 1 for submission summaries). The Scheme amendments included:

- Altering the definition of a rural zone to require land-holders to apply for council approval for intensive agricultural activities under certain circumstances (eg. land designated as fish habitat reserve or mahogany glider habitat.
- Including a definition of intensive agriculture. Intensive agriculture is defined in the scheme as: 'The use of land for intensive production of crops, such as but not limited to sugar cane and horticulture, at rates of production beyond the natural capacity of the land, where the land relies upon the regular and systematic application of fertilisers and other chemicals, and includes the establishment of any infrastructure necessary for the conduct of the use. The definition does not apply to small-scale agriculture conducted on premises or a site less then two hectares in area' (Lusis 1999c)

The Hinchinbrook Shire Strategic Plan was also amended. Amendments included:

- Requiring land-holders, overseen by the council, to maintain conservation values on good quality agricultural land, so as to promote ecologically sustainable primary production; and
- Introducing other provisions to encourage the ecologically sustainable use of natural resources and the protection of environmental systems or features of local conservation value (Lusis 1999c).

The Hinchinbrook Shire Council has also incorporated State Planning Policy 1/92: "Development and the Conservation of Agricultural Land" into the decision-making processes. Consequently agricultural land in the Shire has been classified according to its suitability for agriculture. Land classes 1 to 3 represent land suitable for agriculture with varying limitations, class 4 is marginal land considered unsuitable due to severe limitations and class 5 is considered to be unsuitable due to extreme limitations that preclude its use for agriculture (Hinchinbrook Shire Council 1997). Planning provisions and approval processes now reflect these suitability ratings.

In accordance with the gazettal procedures established under the Integrated Planning Act, the scheme amendments were advertised for 30 business days between November 1998 and January 1999. Council received no submissions and consequently the amendments were gazetted in April of 1999 (Clarke 1999). The council is using its planning scheme to actively apply the ICM principles outlined in the strategic plan. The current planning provisions ensure that future land development or land use changes will be conducted in a sustainable manner (Lusis 1999c). Currently, applications for intensive agriculture trigger a three step assessment process. In step one impact assessment triggers are checked using the geographical data held in the Herbert River Information Centre. In step two, referral coordination triggers are assessed and information requests can be made to the applicant. The final step involves the assessment of the application using either a code assessment or impact assessment procedures. At the time of writing, Council had received 14 code assessment applications since December 1997 and 1 impact assessment application for intensive agriculture since April 1999 (Clarke 1999).

The Herbert River Catchment Management Strategy has been completed and is being reviewed for endorsement by the Queensland Landcare and Catchment Management Council. The strategy will be the framework for the management of the catchment, implemented through objective decision making by the community (Lusis 1999c). The HRCCC's plans include linking with the Hinchinbrook and Herberton shire councils and CANEGROWERS to design best practice drainage systems for new land development, and to promote fish-friendly culvert designs to improve the passage of fish in local creeks (Lusis 1999c).

The Impact of Scheme Amendments

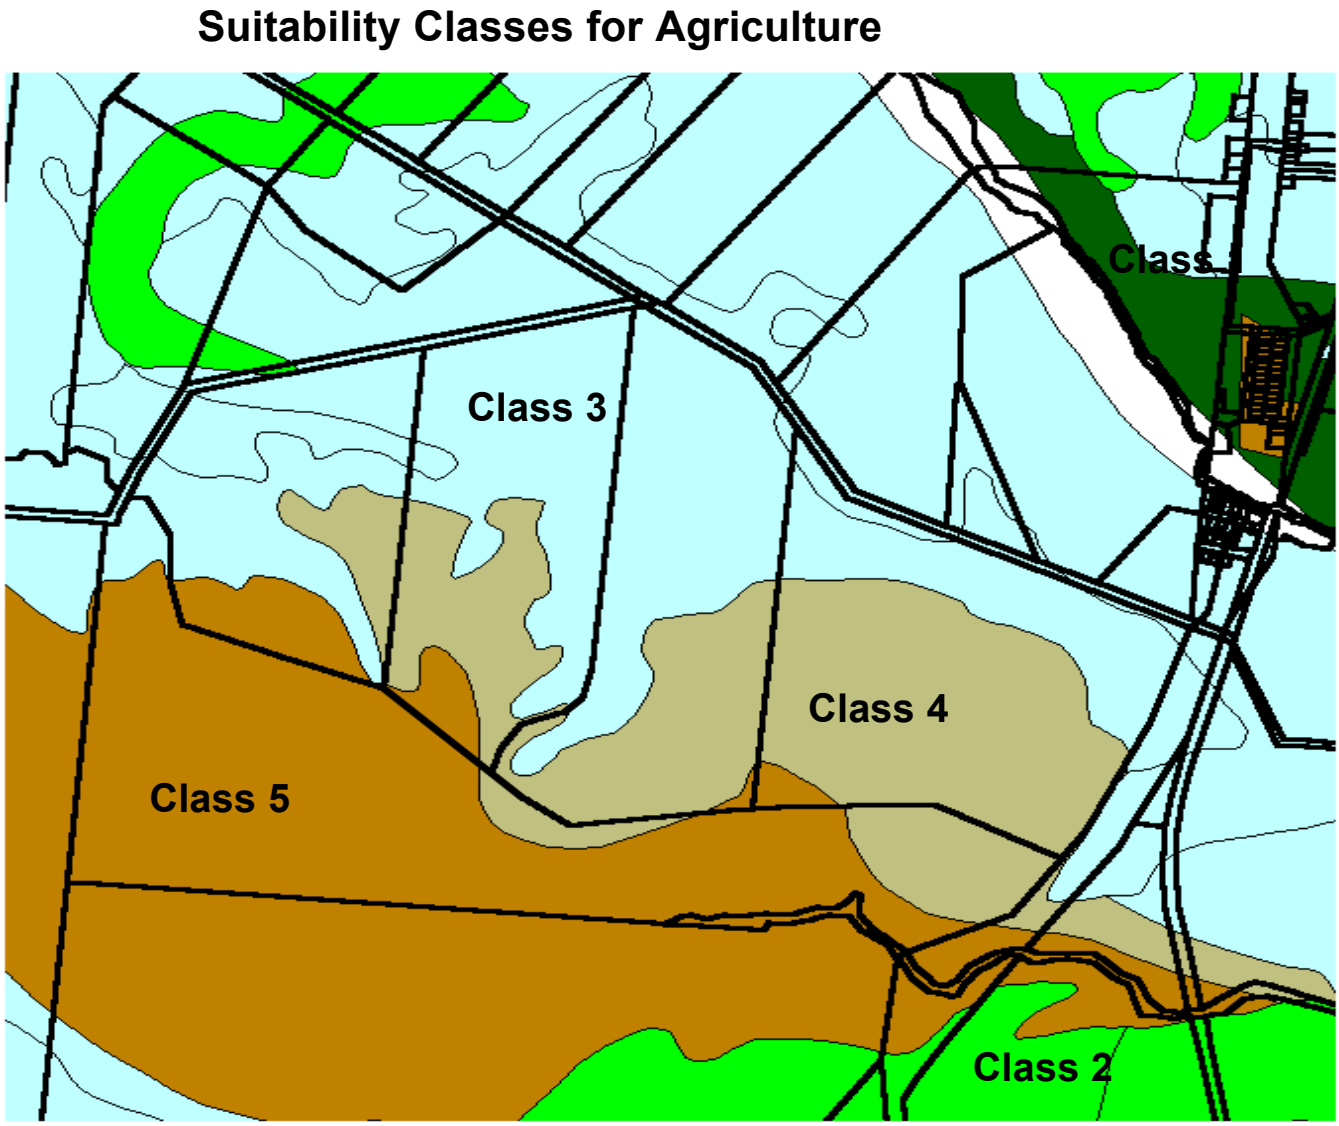
The full impact of the scheme amendments on the development of intensive agriculture in the Shire can be demonstrated using a real development scenario. The development of land for intensive agriculture at Pomona on the Herbert River Floodplain in 1994, 1995 and 1996, prior to the preparation of the 1997 Hinchinbrook Shire Planning Scheme is a particularly relevant example due to environmental issues involved and associated public and media attention. Freehold land at Pomona that had historically been used as a cattle breeding property was subdivided and sold for cane growing purposes (Fig. 2). This land contained known Mahogany Glider habitat, locally significant wetlands and riparian vegetation and environmental issues such as acid sulfate soils (Figs 3 and 4). In Interim Conservation Order was issued on the 25th March 1995 by the Environmental Protection Agency under the Nature Conservation Act. The Hinchinbrook Shire Council had no authority to prevent or condition this land use change given the limited nature of the scheme at the time and its application to the urban parts of the Shire only. Despite the Interim Conservation Order and advice that the land was unsuitable for sugar cane owing to environmental issues, the land was converted to intensive

agriculture. The outcomes of the Pomona land development were instrumental in facilitating the 1996 planning scheme review.

If the current Hinchinbrook Shire Planning Scheme was in place when Pomona was subdivided and developed Council would have had a role in assessing and deciding the application and it is hoped that the outcome would have been different. Under the current scheme the development of Pomona would require council approval, the application being triggered by changing the use of the land from 'agriculture' (cattle breeding) to 'intensive agriculture' (sugar cane growing). Further to this, the subdivision would have also required impact assessment procedures given that the land contains class 4 and 5 soils, a known wetland (identified in Fig 11 of the planning study) and a conservation/interim conservation Order. Referral co-ordination would also be required as the site contained prescribed lands (wetlands). This would have enabled the full impact of the development to be considered by Council and all relevant referral agencies prior to the issue of a decision.

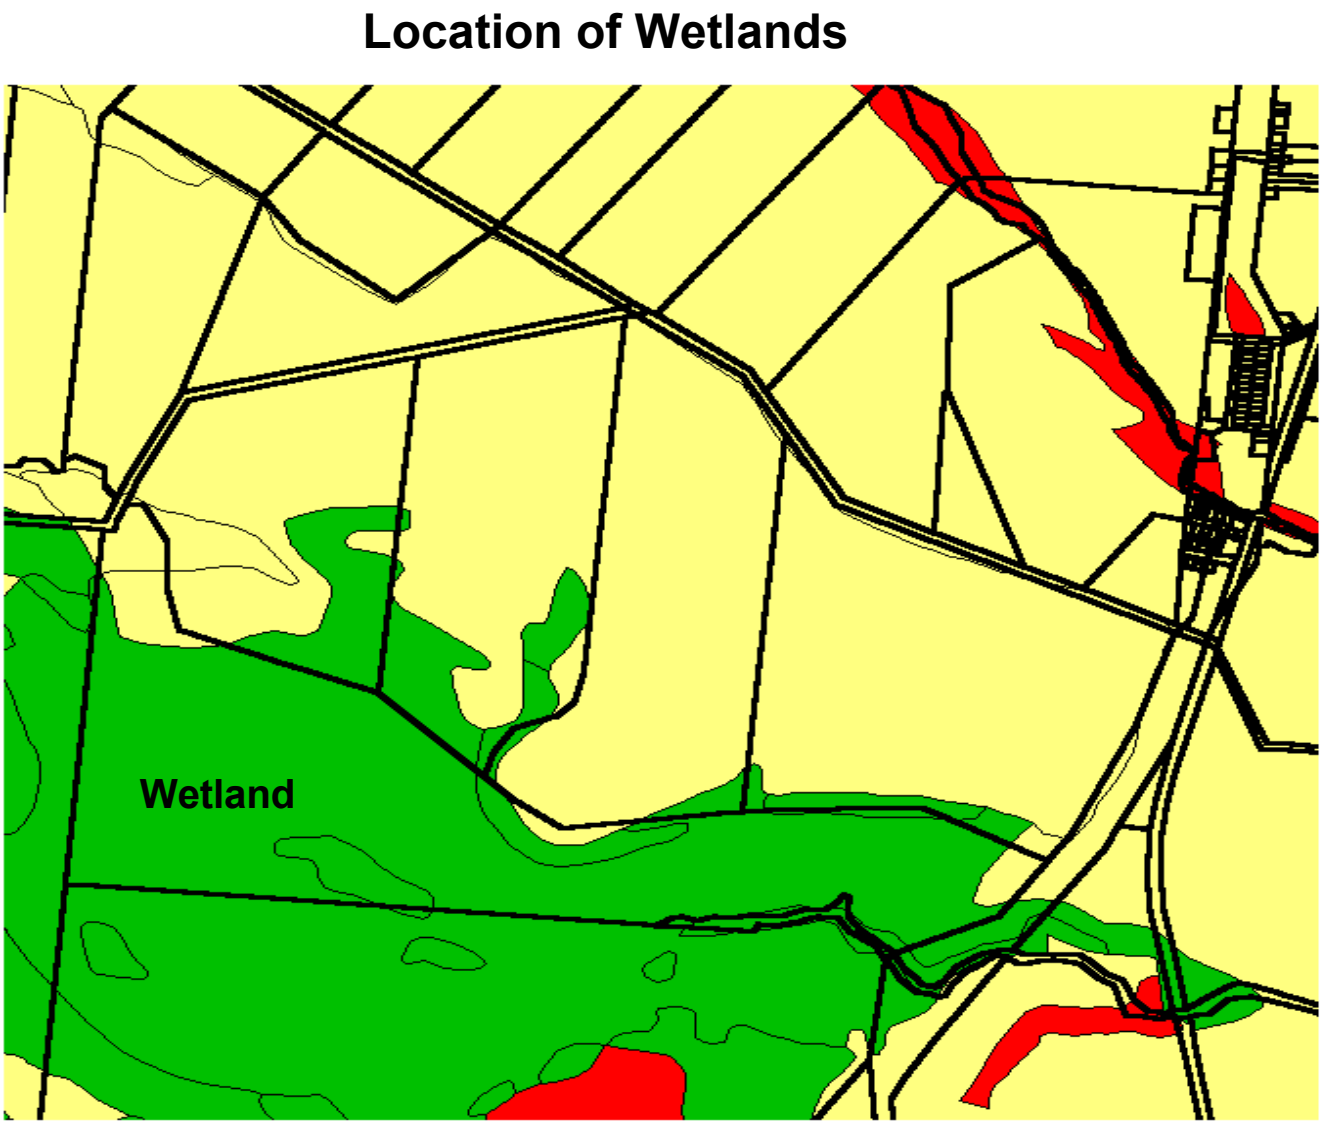
Figure 2: Pomona Subdivision
Source: (Clarke 1999)

Figure 3. Suitability Classes for Agriculture



Source: (Clarke 1999)

Figure 4. Location of Wetlands



Source: (Clarke 1999)

Given that future expansion of the cane industry is forecast for the shire and that in some instances expansion areas may impact adversely on environmental values, it is possible that there will be the refusal of some applications for intensive agriculture.

3.4 Agricultural Planning Process

In addition to achieving the implementation of specific land use strategies to achieve ICM objectives, the process of linking planning schemes and catchment management plans has also improved communication between local government, state government agencies and stakeholder groups within the catchment. It is now leading to the coordination of other separate administrative and organisational processes including the agricultural property development process in the Hinchinbrook Shire.

Work has been undertaken on the agricultural property development process which is a streamlined process led by the Hinchinbrook Shire Council and involving the Department of Natural Resources, the Department of Environment and the Local Sugar Board. (See Fig. 5). The purpose of this integration is to provide landowners with information on planning for a material change of use under IPA, and also to assist cane growers in planning for further assignment or roaming. It relates to the process of preparing property development plans required by both Council under the planning scheme and Local Boards for new cane land allocations. It also establishes a referral process to all relevant agencies at the local level including the Catchment Management Committee (Queensland Department of Natural Resources 1998).

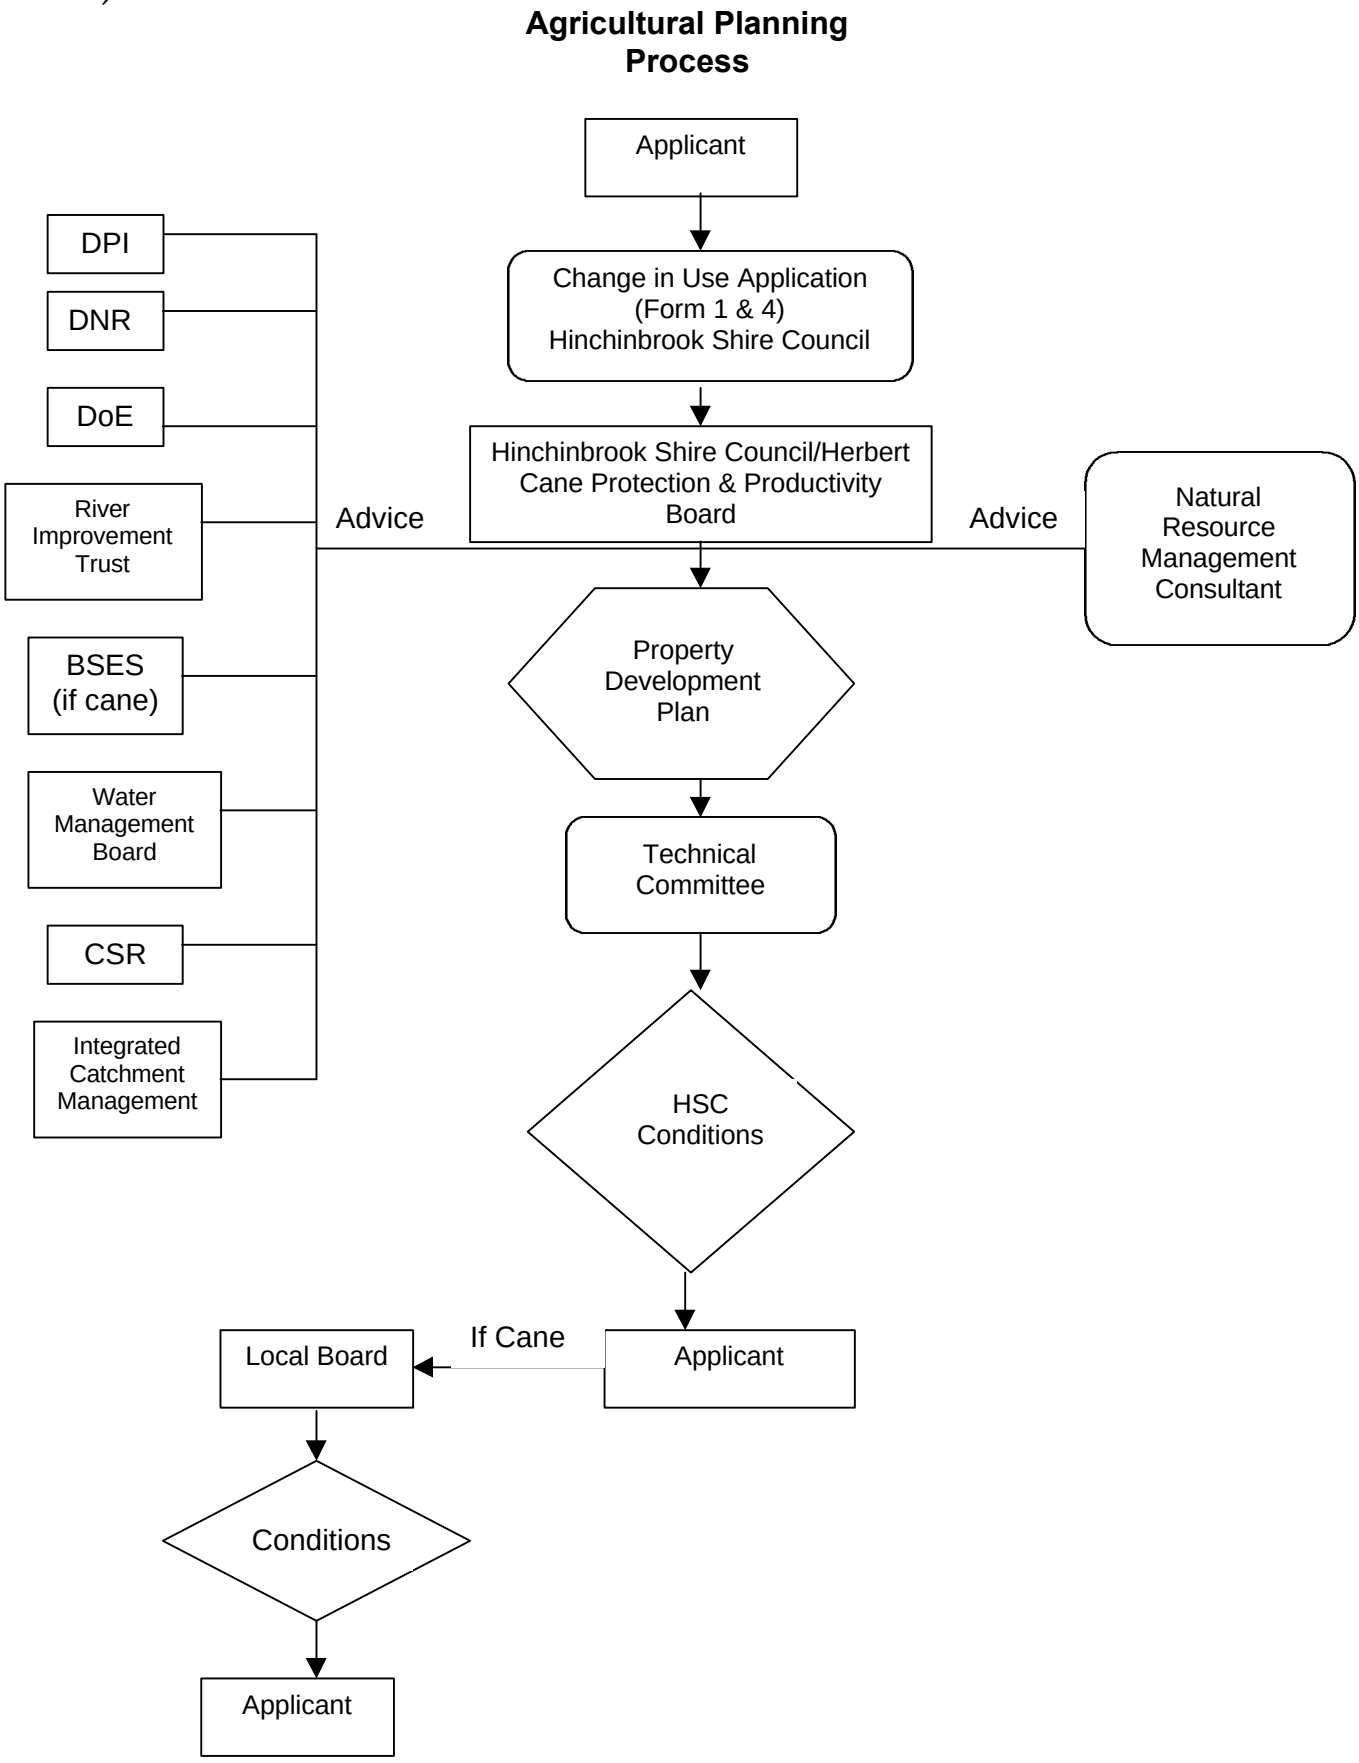
4. ICM Influence on Local Government

Integrated catchment management has had a substantial influence on local government in a relatively short period of time. Some of these changes include an improved awareness of ICM, better coordination between authorities in extending the reach of town planning to achieve ICM strategies as well as the actual implementation of ICM in local planning schemes. Positive benefits also include improved communication between local government and previously unconnected stakeholder groups to provide a wider range of perspectives on resource management issues.

The linking project facilitated many of these changes in four rural catchments in Queensland. The local governments in these catchments have responded by expanding their role in land use planning and management of natural systems. Traditionally local governments have had a limited role in planning in rural areas and in the management of natural resources generally (McDonald and Bellamy 1997). This newly expanded role reflects the increasing demands from the community that environmental concerns and aspirations be acknowledged by land management authorities (Bates 1995). The implication this has for planning is that for the first time local authorities are managing agricultural activities and as a result desirable ecological outcomes can become part of the rural development process. The implication this has for integrated catchment management is that local authorities are regulating land uses to achieve catchment management objectives.

While the linking project has produced improved land planning and management it has only achieved this for a single local authority rather than all local governments within a watershed. In the Herbert River example, the project outcomes have had no influence on the upper catchment to date. The upper catchment is significantly behind the lower catchment in terms of the understanding of planning and ICM issues, open communication between stakeholder groups and level of commitment to resource management. A new catchment management group is forming in the upper catchment. The planning scheme for the Herberton Shire Council is up for review in the year 2000. While there is no doubt that similar results could be achieved in the upper catchment, the results of the lower catchment certainly had the advantage of project faciliators, funding and an extensive geographical information base to prepare the ecological issues report and planning solutions. Without this assistance, achieving such planning and resource management objectives will pose even greater challenges for rural shires, many of which do not have full time planning staff.

Figure 5. Agricultural Planning Process for Hinchinbrook Shire 1998 (Adapted from DNR 1998)



Therefore the expanded role of local governments into planning for catchment management has many challenges for planners. It introduces a whole new set of technical and political dimensions to their work for which they may have little training, no experience and can not call on well-developed precedents to guide the way. It will therefore be a significant learning period for councils, their staff and advisers (McDonald and Bellamy 1997). The underlining planning process will have some similarities with conventional urban based planning in terms of land use control and setting of performance standards and managing the development approval process. The differences will be partly technical in dealing more with ecological and land resources issues but also more complex in that the planning and management will need to be more site and local landscape specific than normally applies to urban planning matters (McDonald and Bellamy 1997). There are serious obstacles too, not the least of which is the potential for councils to be in conflict with land owners over loss of use rights, injurious affectation and potentially the need for compensation. Some of the suggested processes lead councils into unexplored territory, for example the reliance on Property Management Plans and the application of EIA to small land development proposals (McDonald and Bellamy 1997).

5. Local Government Influence on ICM

The amalgamation of catchment management principles and local government planning schemes is particularly important for the achievement of natural resource management in Queensland. It is especially important given that integrated catchment management in Queensland fits into the spectrum of resource use and management models at the policy level. This lack of institutional support for ICM has been a significant barrier to the effective implementation of sustainable catchment management strategies in the past. As one author writes "..the catchment is rarely recognised as the basic unit of management and there are very few examples of truly integrated management of catchment resources in Australia" (Allan and Lovett 1997). As a result, the linkage between catchment management and planning schemes is one step closer to achieving integrated catchment management.

However local government land use planning is not the answer by itself. While it does have enormous scope in achieving catchment management objectives, it is limited by the fact that it can only implement these strategies when a development application is triggered by the planning scheme. The regulation of new developments through the planning process will not effectively deal with existing resource management problems because planning controls have little power to control existing unsustainable land uses or minor variations in those uses. Therefore to effectively achieve integrated catchment management planning schemes and development assessment may need to be integrated with other forms of institutional arrangements to deal with existing use rights.

It is also suggested that further work is required to rationalise the complex and often confusing array of Acts, programs, and policies that impact on resource management at the local, watershed, state and national levels. Examples of were this could occur through legislation at a State level include the River Improvement Trust Act, Water Resources Act, Nature Conservation Act, Environmental Protection Act and the Land Act. Further to this, ICM principles should be incorporated into these arrangements using a systems perspective.

Additionally, the link between local government and land use planning is also not able to solve many of the "bad practices" of resource management agencies with respect to environmental management. In some catchments these "bad practices" are not only preventing the amelioration of environmental issues, but they are in fact a major cause of the problem. Examples include the continued use of major rock wall infrastructures as solutions to flooding and drainage issues and failure of rural land development boards to address environmental issues when issuing rural development permits.

6. Conclusions

Since the inception of integrated catchment management (ICM) in Queensland implementation has been hindered by the inability of catchment management groups to influence land use planning and management. Traditionally ICM principles and catchment management issues have not been incorporated into or addressed by local planning schemes. Fortunately this is changing as partnerships between catchment management groups and local governments are forming and local governments are taking greater responsibility for the implementation of ICM principles and strategies. These partnerships are the result of improved communication between catchment committees and local governments, a better understanding of the principles and objectives of ICM within local government and because of an improved recognition of the role of local government in the management of natural resources. Considerable advances in environmental protection have been made in those shires that have sought to incorporate ICM principles into planning schemes. However Local government land use planning is not the answer by itself. While it does have enormous scope in achieving catchment management objectives, it is limited in that it can only implement these strategies when a development application is triggered by the planning scheme. Therefore to effectively achieve integrated catchment management, planning schemes and development assessment will need to be integrated with other land management arrangements that can deal more effectively with existing unsustainable use rights.

Appendix 1: Summary of the submissions made to the 1997 Hinchinbrook Shire Council Draft Planning Scheme (Source: Interviews conducted with agency representatives December 1996 by K. Vella)

Theme	HRCCC	Canegrowers	DNR	EPA
Commitment and Policy Framework	Planning study failed to recognise the developing catchment management strategy[1]	Activity in connection with sugar cane growing also comes within the scope of industry self regulation.	The broad aim states environmental and economic considerations in a disintegrated rather than integrated manner as proposed by ESD	Plan does not adequately reflect the principles of ESD as described in the national strategy
	Recommends the use of referral agencies for PMP and early discussion of this initiative with relevant agencies to avoid duplication in implementation		The ICM Study should be incorporated into the planning scheme	Plan dids not recognised the legislative responsibilities of other agencies.
			Plan does not recognise State Planning Policies and planning guidelines that seek to protect Good Quality Agricultural Land	No recognition given to many important values[3].
			Environmental and economic costs and benefits of land management are not accurately reflected with respect to ESD	
			Objectives should commit to the sustainable use of natural resources	
Planning	Approves the need to assess development applications on a catchment basis but points out the need to consider cumulative impacts	Need for unsealed roads to be sealed in rapidly expanding cane areas and to improve other public infrastructure to reduce impact on shire roads.	Areas should be designated for rural land using state planning policies and land suitability guidelines.	No link between the plan and planning study
	Would like to see council as influencing future expansion rather than acting as a processing agency for development applications.	Require a flexible width of riparian zones, suggests a 10 metre zone and states unwillingness to support wildlife corridors and stream bank stability zones beyond 10m.	Intensive agriculture areas should not include areas with environmental constraints	Clearing of land must require Council consent
	Would like council to consider cumulative impacts in development assessment		A preferred sequence of development plan and map should be prepared for the town and village areas and for areas that impact on rural lands	Plan frequently uses terminology that is too flexible and open to interpretation particularly in an appeal situation

Theme	HRCCC	Canegrowers	DNR	EPA
Planning (con't)	How will council assess the potential for adverse environmental impacts? Intensive rural industry is not defined in document		Areas with significant conservation values and not protected as a National Park should be so designated on the strategic plan map	Attempts to incorporate ICM however the sections that detail how these will be implemented fall short on delivering on the aims. No reference made to the ICM committee or strategy, the River Improvement Trust or the Herbert River Management Plan.
	Encourages proposals to use PMP and suggest guidelines for the use of PMPs.		The plan should provide for the role of other state departments in determining environmental impact.	Rural zone is large and extends onto wetland areas. It should reflect the data in the HRIC and suitability should be reassessed.
	Tightening up of scheme provisions from "council may require" to "council will require" to provide more certainty to the public and developers.		The word sustainable needs to be included in the scheme in reference to rural industries	Some constraints to rural development have not been recognised [4].
	Would have liked council to engage in greater community consultation especially on some contentions issues and suggested a series of informative articles in the Newspaper.		All applications adjacent to watercourses should be subject to a 40m buffer on a major water course and 20m on a minor water course.	Not all forests are available for harvesting
	Conservation designation does not include most of the areas identified under the Mahogany Glider Conservation Plan, significant wetlands and other significant remnant habitat areas.		Riparian corridors and conservation areas should be included in a network of open space/conservation	Lack of development control in the villages of Lucinda and Taylors beach, which are surrounded by conservation zones.
				Industrial zone does not recognise the need for buffers esp. adjacent to conservation areas.
Implementation	Identify and map areas inappropriate for development.	Notes the Strategic Plan adoption of ICM and implementation through the appraisal of soils and agricultural suitability and suggests the use of the Herbert River Information Centre as a guide to assist in land use planning and decision-making.	Good quality agricultural land should be mapped and identified in the planning scheme.	Many objectives are not supported by implementation strategies.

Theme	HRCCC	Canegrowers	DNR	EPA
Implementation (con't)		Incorrect statistics on the value of the sugar industry and mill crushing capacity. In accurate references to the Sugar Industry Infrastructure Package (SIIP)[2]	Terms such as 'may' and 'should' and need tightening up to provide more certainty	Recognises attempts to conserve significant vegetation or habitat types and recognise and protect natural assets and resources however the sections that detail how these will be implemented fall short on delivering on the aims. Major focus is on public land, no commitment to protecting conservation values on public land.
		Could identify, map on GIS and advertise areas on the floodplain where development would be inappropriate.	Council needs to specifically state how it will assess applications, particularly with respect to the catchment system	
			Development Standards need to be made for particular uses	
			The use of the word 'encourage' in the plan needs to be supported by appropriate criteria.	
			Council should liase with DNR with regards acquisition for conservation purposes	
			Further clarification is needed between definitions of intensive agriculture, agriculture and other rural activities.	
Measurement and Evaluation			Development standards need to be set for particular uses	
Other		Canegrowers representatives on committee did not view cane growing as intensive agriculture		Strategic Plan Map filled with errors ie: land designated as rural was National Park, World Heritage boundaries omitted.
		Evidence of salt water intrusions to the ground water resource incorrectly referenced to Peter Sheedy.

Assessing the Institutional Arrangements for Sugar Cane Expansion and Environmental Management in the Herbert River District, Queensland, Australia

Part 1: Principles and Process

Dr Dan Shrubsole

1995-1996 Visiting Research Fellow, CSIRO, Division of Tropical Crops and Pastures

Assistant Professor, Department of Geography, Faculty of Social Science, University of Western Ontario, London, Ontario, Canada, N6A 5C2, ph: 519 679 2111 ext. 5016, fax: 519 661 3750

Originally Published as:
Shrubsole, D. (1997). *Assessing the Institutional Arrangements for Sugarcane Expansion and Environmental Management in the Herbert River District, Queensland, Australia. Final Report.* CSIRO Tropical Agriculture, Brisbane.

FOREWARD: This draft report is provided to all respondents in the examination of how environmental issues are addressed in the expansion of sugar cane land in the Herbert River District. It is hoped that you can comment on the accuracy of the facts, and the desirability and feasibility of the initial conclusions and recommendations. Based on your comments, a revised and final document will be completed.

In 1994, CSIRO, Division of Tropical Crops and Pastures (DTCP) received funding from LWRRDC (project CTC7) to examine Integrated Catchment Management in the Herbert River Catchment. One component of that research initiative focused attention on the institutional aspects of resource management. In that regard, this review examines the sugar cane assignment process in the lower Herbert River catchment. It was not commissioned by any agency, but rather emerged from my ongoing interest in water and land-related management issues.

I am grateful to all respondents who took time from their busy schedules to share their thoughts with me. During the research, the staff at the Ingham CANEGROWERS office - Peter Sheedy, Allan Ancliff, Wayne Thomas, Gail Alloway, Sharon Fighera, Leona Gangemi, Natalee Agostinelli and Cathy Bowrey - made me feel very welcome. I also received comments from Jenny Bellamy, Allan Dale, Andrew Johnson and Dan Walker of CSIRO, and Geoff McDonald and Carl Smith of the University of Queensland. Let me stress, however, that the interpretations and conclusions are mine; I take full responsibility for them.

EXECUTIVE SUMMARY

This report considers the institutional context for the management of sugar cane land with a specific focus on how environmental considerations are incorporated into the process. It highlights the following:

(1) Integrated resource management in the sugar industry involves an understanding of at least three perspectives: (i) linkages among biophysical processes, (ii) linkages among society, environment and economy, and (iii) linkages within and among relevant institutional arrangements.
(2) Ecologically sustainable development (ESD) principles advocated by the 1992 *Intergovernmental Agreement on the Environment* and the CANEGROWERS *Caring for the Environment* (1995) share four resource management principles: balance, ecosystem, partnership and flexibility. These principles are the benchmarks used to evaluate the current assignment process in the Herbert River District.
(3) Relevant institutional arrangements which influence the cane assignment process, and that process itself are reviewed. The discussion concludes that since 1993 the Local Boards in the Herbert River District have incorporated environmental considerations into its decision making through: (i) forming an *ad hoc* technical review committee in 1995, (ii) requiring all applicants to submit a property management plan, and (iii) developing conditions of assignment.
(4) No radical changes to existing processes are recommended. However, improvements must be made. A set of recommendations are made on the basis of findings from the Herbert River District. Their applicability on a state-wide basis should be considered carefully. It is believed that more effective decision making can be achieved by enhancing the consistency among the four management principles - a balanced perspective, ecosystem management, developing partnerships and allowing for flexibility - and current decision-making processes. In addition, the breadth of principles should be broadened. In this context, the following preliminary recommendations are made:

To enhance **balanced** management, consider:

Recommendation #1: That the *ad hoc* technical review committee and Local Board members review how to improve the present referral process. Locally based conflict resolution mechanisms should be established and applied before the formal involvement of the Queensland Sugar Corporation or Sugar Industry Tribunal. These should be codified in the *Sugar Industry Act* and/or *Sugar Industry (Assignment Grant) Guidelines*.

Recommendation #2: Providing for the earlier consideration of environmental factors in the cane assignment process through existing mechanisms such as "Continuous Crushing Agreements" and corporate policies.

Recommendation #3: Reducing the perceived need for pre-emptive clearing by adjusting the timing of the assignment process. In the Herbert River District, this would see the announcement of assignment grants in the February-March period.

To enhance **ecosystem management**, consider:

> **Recommendation #4: Carefully reviewing the proposed Sugar Industry Infrastructure Package** (SIIP) projects to ensure that future management options are not unduly constrained.
>
> **Recommendation #5:** Immediately undertaking a catchment management plan for the entire lower Herbert River area. In evaluating alternatives, it should consider environmental, social and economic impacts on surface, ground, coastal and related land-based resources. It should consider both structural and non-structural alternatives and incorporate, wherever possible, natural channel design and restoration techniques. This study should also examine the establishment of a drainage board for the entire lower catchment.

To enhance **partnerships**, consider:

> **Recommendation #6:** Better informing the Shire of the assignment process and its outcomes. This should be done through the appointment of a shire representative to the Local Boards who shall have voting rights on expansion decisions.

To enhance **flexibility**, consider:

> **Recommendation #7:** Undertaking an audit within the next three years, which examines the compliance and enforcement of conditions of assignment. Effective and regular monitoring should be specified as a Queensland Sugar Corporation responsibility required under the *Sugar Industry Act*.

To **broaden the base of principles**, consider:

> **Recommendation #8:** Developing mechanisms, which place more responsibility on applicants and the industry for determining the nature and extent of acid sulphate soils before review of an individual application.
>
> **Recommendation #9:** Developing and applying an environmental impact assessment screening mechanism that identifies applicants who must more adequately consider farm management and environmental issues with the submission of their application.

And finally, to increase the legitimacy and credibility of ecologically sustainable development within the Queensland sugar industry and resource management agencies;

> **Recommendation #10:** Senior government, Queensland Sugar Corporation, corporate, CANEGROWERS, and non-government officials provide leadership in the formulation and application of ecologically sustainable development.

It is hoped these suggestions promote discussions which strengthen the practice of ecologically sustainable development in the sugar industry.

1. INTRODUCTION

This report describes how environmental issues are considered in the sugar cane assignment process in the Herbert River District, identifies strengths and weaknesses, and suggests alternative approaches in the future. This introductory section provides background to the report, the focus, the approach taken, and the organisation of the report.

1.1 Background

This report is an independent review of the environmental management and cane land allocation. As a faculty member in the Department of Geography, University of Western Ontario in Canada, my main research interests have concerned the institutional arrangements for water management in Canada, the conservation authority program in Ontario, the use of regulation in floodplain management and diffuse source pollution control, and impact assessment. Between 1 July 1995 and 30 June 1996, I held a Visiting Research Fellowship with the CSIRO, Division of Tropical Crops and Pastures which had a five-year LWRRDC-funded (project CTC7) program to assess the implementation of Integrated Catchment Management (ICM) in the Herbert River catchment.

A number of activities were associated with the research. In the first year, the research team formulated a framework to organise the design and conduct of subsequent activities (Bellamy *et al.*, 1995). One component of that framework focused attention on the institutional arrangements for resource management. This report considers the institutional aspects of cane assignment and resource management in the Herbert River District. It is believed that an understanding of present strengths and weaknesses will provide a solid foundation for improvements.

This review involved several stages. Initially, a review of water-related legislation and material about the Herbert River catchment was undertaken. These readings, and discussions with local and regional resource managers and CSIRO staff lead to a decision to concentrate on cane expansion and drainage issues. The support of the local CANEGROWERS office in Ingham was requested and received. Their support was conditional upon the research respecting the privacy and confidentiality of both applicants and interview respondents. They and many interview respondents expressed a desire to review the report in draft form. This preliminary document fulfils that request. All interview respondents are invited to provide their opinions on this draft report. On this basis, a final report will be prepared and circulated. This triangulation of sources should enhance the relevance and accuracy of information.

Notwithstanding my deep appreciation for all the cooperation and assistance received, I emphasise that this report represents an independent and personal appraisal of resource management and the sugar cane expansion process in the Herbert River District. It is hoped that it can promote debate about present practices which can provide for more effective management in the future.

1.2 Focus and Approach

Initially, the research goal was to examine the relationship between drainage problems and the cane assignment system within the Herbert River area for the period 1993 - 1995. However, a formal review of assignment applications by an *ad hoc* committee comprised of CSR Ltd., Bureau of Sugar Experiment Stations (BSES), Queensland Department of Primary Industries (QDPI), and Queensland Department of Environment and Heritage (QDEH) officials was introduced

into the 1995 review process (*i.e.*, the 1996 assignment grant). Extending the study period to include the 1996 award allowed for an examination of the perceived effectiveness of that review mechanism. A decision was also made to extend the breath of the issues covered by incorporating selected measures of economic, social and environmental factors. In this manner, the relative importance of the environment could be measured. It is also consistent with the legal definition of environment in Queensland (Duncan, 1993). Thus, this report embraces a wider range of issues for the 1993-1996 period.

The review was conducted between October 1995 and May 1996. In that period, the work had several components. Relevant literature and legislation were reviewed. The permit files located at the CANEGROWERS Ingham office for the period 1993-1996 were examined. This information was entered into a GIS database at the CSIRO Davies Laboratory in Townsville. The Queensland Sugar Corporation (QSC) provided computer-based assignment (Sugar Corporation Assignment Register (SCAR)) data which was also incorporated into the analysis. Interviews were held with over 30 people from relevant government, industry and non-governmental organisations, and selected local landowners. Interviews were conducted with individuals at both local and state-wide levels to place the activities in the Herbert River District into a broader context.

At the same time, research was also being conducted on Integrated Catchment Management in the Herbert River. In that regard, a questionnaire survey was developed with Prof. Geoff McDonald (co-investigator) of the University of Queensland, with the assistance of Jenny Bellamy, James Butterworth, Andrew Johnson, Geoff Syme and Dan Walker of CSIRO. In November 1995, surveys were distributed to all ICM Coordinators and Chairs within Queensland, and all Catchment Coordinating Committee members in the Johnstone and Herbert Rivers. That work is reported on in full in a separate document (McDonald and Shrubsole, forthcoming). However, relevant elements of this material have been incorporated into this present report.

1.3 Report Organisation

This report contains the main findings and conclusions regarding the context for, and the nature of, the existing process. During the interviews, a diversity of perceptions was expressed about the nature of integrated resource management, and the responsibilities of various government and non-government participants in sugar cane assignment. The second chapter examines relevant background material, particularly as it relates to the Herbert River District and the concept of integrated resource management. The similarities and differences between government and CANEGROWERS views of sustainable resource management are outlined in the third chapter. Chapter four describes the institutional arrangements for resource management which influence sugar cane assignment, while the actual assignment process is reviewed in the fifth chapter. Based on an examination of the current management principles (Chapter 3) and the decision-making process in the Herbert River District (Chapters 4 and 5), observations and recommendations are made in the sixth chapter.

2.0 BACKGROUND

2.1 The Problem in Brief

The sugar cane industry is an important element of the Queensland landscape. Since the 1990s, the amount of land devoted to cane farming has increased by approximately 20,000 ha per year, and in 1995 over 470,000 ha were used for that purpose (QDPI, 1995). Concern has been

expressed about this rapid growth and its potential environmental impacts (Johnson *et al.*, 1996). These impacts include erosion and sedimentation, loss of riparian vegetation, damage to coastal wetlands, and diffuse sources of nutrient pollution and heavy metals (Brodie, 1984; Bramley and Johnson, 1995; Johnson *et al.*, 1996). Since recent expansions have often occurred on relatively more marginal land, resource managers must ensure that only appropriate areas are developed and effective farm practices applied to ensure its long-term sustainability. There is also concern regarding the effectiveness of existing institutional arrangements to meet this challenge (Johnson *et al.*, 1996). Most cane is grown along the eastern coast of Queensland and northern New South Wales where soil and climate conditions are favourable. However, this area of Queensland is very well known for its wet tropical rainforest and the offshore Great Barrier Reef. There are floodplain issues and coastal wetlands that require careful management. In short, there is increased pressure for institutional arrangements to resolve these and other land use conflicts effectively, and to prevent environmental degradation.

Traditionally, land suitability was the predominant natural resource issue considered in examining cane land expansion (Belcher and Dalton, 1983; Dawson *et al.*, 1983; Capelin, 1987). In addition, expansion rates of the past were very modest compared with current levels. The 30% increase in the amount of land devoted to cane growing growth since 1991 has strained the capacity of both private and public agencies (QDPI, 1995; CANEGROWERS, 1995). For instance, Local Boards were created in the 1920s to, in part, control the level and location of sugar cane production, and to prevent the growing and commercial harvest of sugar cane (Industry Commission, 1992). It has achieved these objectives through regulating cane growing and harvesting through a regulatory mechanism called the 'assignment system'. Local Boards are now being asked to extend their traditional perspective and meet the environmental expectations, social responsibilities, and legal requirements of the 1990s.

The future demands placed on Local Boards and other resource management agencies are expected to increase. More frequent and possibly intense resource management conflicts may further test the ability of decision makers to provide equitable, efficient and effective processes and outcomes. QDPI (1995) predicts a 25% increase in cane land area between 1994 and 2003. Given the potential for and significance of environmental, economic and social impacts, and the high potential for resource conflicts in this coastal area, there is a need for integrated resource management within the sugar cane industry.

2.2 The Case Study Area - The Herbert River District

The Herbert River District has been one of the most rapidly expanding areas within the state. The following are selected facts and widely held perceptions of the Herbert River District which were contained in relevant documents, the Victoria and Macknade Annual Reports, provided through the Herbert River Catchment Coordinating Committee questionnaire responses, or offered during the interviews. The intent is to provide a 'snapshot' of key elements that have influenced sugar cane assignment. These include:

- Cane farming and milling have been longstanding and the dominant regional economic activities. Two CSR mills are in the area - Victoria and Macknade - each with its own Local Board. Since 1991, the area has been one of the most rapidly expanding cane-growing areas in the country (QDPI, 1995). QDPI (1995) predicts a further 36% increase will occur between 1994 and 2003 raising the assigned area from 46,730 ha to 63,360 ha. Soil surveys identify another 60,000 ha of land well suited and available for sugar cane growing (Wilson and Baker, 1990).
- The relationship between growers and millers throughout Queensland is often associated with conflict. The season length, division of proceeds from the sugar product, and transport

issues have been particular points of longstanding dispute.

- Technological innovation has played an important role in increasing productivity and decreasing harvest costs. Herbert River growers have increasingly used laser levelling rather than bedding on the paddocks. Based on anecdotal evidence, some respondents suggested that this shift, which has largely taken place during the study period, has increased the effective growing area by between 3%-8%. Green cane harvesting is used by over 98% of farmers in the region (QDPI, 1995). It reduces production costs, provides the return of some nutrients to the soil through trash blanketing, and reduces erosion. BSES, CSIRO and CSR Ltd. continue to develop varieties of cane to increase productivity.
- The area has a long history of drainage problems. Compared with the past, drainage problems in the 1990s have not been as significant for most growers due to below average rainfalls.
- In the Herbert River District, environmental issues related to sugar cane expansion became very prominent in 1995. In that year, assignment was granted in an area known as Pomona land holding. During land clearing, the area was found to be an important habitat for an endangered species, the Mahogany Glider (QDEH, 1995). A conservation order was placed on the site, and later a draft conservation plan was prepared. There was a significant level of uncertainty and conflict among industry, government and non-government participants concerning this development. At present, a drainage permit under the *Water Resources Act 1989* has been applied for by the proponents, and is under review by the Queensland Department of Natural Resources (QDNR).
- Ortho-photography, sponsored by a range of private and public agencies has just been completed. Before that time, only topographic and cadastral maps were easily available to most resource managers. A Herbert River Information Resource Centre is being established in Ingham as a shared GIS facility for public and private resource managers. When established, it should provide better information from which resource management decisions can be made (Johnson and Walker, 1996).
- Elections in 1996 saw new governments formed at both federal and state levels. Their commitment to ecologically sustainable development is unclear at this time. The federal government's intention is to reduce its overall spending by $8 billion over the next two years. The state government has reorganised the administrative arrangements for resource management. The new Department of Natural Resources (QDNR) reflects the amalgamation of the Natural Resources Section of the former QDPI and the former Department of Lands. The remaining QDPI focuses of production issues. Essentially the former Department of Environment and Heritage (QDEH) remains intact but its name has been changed to Environment (QDoE), as is the case with the former Department of Housing, Local Government and Planning (QDHLGP) which is now called Planning and Local Government (QDPLG). Given potential funding cuts and new administrative arrangements, the nature of integrated resource management, and the adequacy and role of future water and related land planning is unclear.

2.3 Integrated Resource Management and the Sugar Cane Industry

Integrated management must be considered in the context of geographic scale and the nature of the management issues. Interview respondents suggested at least three key perspectives from which 'integrated' resource management can be applied to the sugar industry.

2.3.1 Integrated Resource Management as Linkages among Environmental Resources

Integration may be seen as considering the interaction among water, land and other environmental resources (Mitchell, 1990). This perspective recognises that many water problems have their origins on the land, and many land problems have their causes in too little or too much

water. In the Herbert River District, longstanding resource issues have concerned inadequate land drainage which has limited crop productivity, and flooding which has inflicted damages to the town of Ingham and crop losses (Cameron McNamara, 1984). Emerging resource issues concern the impacts associated with the drainage of coastal wetlands, the management of known and potential acid sulphate soils, and the maintenance of riparian corridors for wildlife. Solutions to these problems require, in part, an adequate understanding of biophysical systems. Inadequate information could see decisions made which might lead to poor outcomes including the transfer of problems from one property owner to another, the inefficient expenditure of public and private funds, or significant negative environmental.

2.3.2 Integrated Resource Management as Environment-Economy-Social Linkages

A second perspective of integrated resource management was advocated by the Brundtland Commission. It considers linking natural resources to economic and social development aspects (Mitchell, 1990). The sugar industry is Australia's third largest exporting industry, with production in 1995 estimated to be 5.1 million tonnes of raw sugar, worth approximately $2 billion (Aus.). Australia continues to rely heavily on the agricultural sector to generate export earnings (Daniels, 1992). If Australians are to maintain their traditional high standard of living, there is a continued and increased need for export-generating sectors of the economy to raise foreign capital through trade. This need must be balanced against social and environmental considerations.

Economic and social factors must also be considered at a regional scale. The Queensland sugar industry supports over 6,350 growers and 25 sugar mills (CANEGROWERS, 1996). Sugar cane farming and milling dominate the regional economies of the smaller rural communities in which they are located (McGovern *et al.*, 1988). If farmers and mills were unable to be competitive in the global market, the resulting regional dislocation of people and economic loss could be substantial. Without appropriate alternatives to increase production, farmers could employ farm practices which degraded the environment (Epps and Crittenden, 1992). Alternatively, some farmers could sell their operations to other farmers or utilise their land for other enterprises. In this scenario, the future of the family farm is uncertain. Its maintenance is one basic tenet of the industry.

2.3.3 Integrated Resource Management as Effective Institutional Arrangements

The need for effective institutional arrangements represents a third view of integrated resource management. According to the Brundtland Commission, achieving sustainable development posed a problem for institutions, whether national or international, which were created on the basis of "narrow preoccupations and compartmentalised concerns" (WCED, 1987, 10). It maintained that since the interconnected nature between economic and ecological systems (like those associated with the sugar industry) was unlikely to change, policies and institutions must, if sustainable development is to be achieved. Such an adjustment is "one of the chief institutional challenges of the 1990s and beyond" (WCED, 1987, 10). These comments are relevant to resource management in Queensland where there is a complex web of laws, policies and agencies. In addition, there is separation between resource development and resource management activities as illustrated by the 1996 division of responsibilities between the former QDPI for agricultural production and the new Department of Natural Resources for resource management. Providing an integrated resource management approach from this fragmented arrangement is a longstanding challenge for governments world wide, and is a key theme in this report.

3.0 THE INTENT OF ECOLOGICALLY SUSTAINABLE DEVELOPMENT: GOVERNMENT AND CANEGROWERS PERSPECTIVES

3.1 Government View of Ecologically Sustainable Development

Historically, there has been inadequate regard for environmental considerations by public and private resource managers at Commonwealth, state and regional levels. With the publication of *Our Common Future (Brundtland Report)* in 1987, this situation is changing. For instance, all levels of Australian Government signed an *Intergovernmental Agreement on the Environment* (1992) to pursue the following principles:

(1) Decision-making processes should effectively integrate both long and short-term economic, environmental and equity considerations.
(2) Where there are threats of serious or irreversible environmental damage, lack of full scientific certainty should not be used as a reason for postponing measures to prevent environmental degradation.
(3) The global dimension of environmental impacts of actions and policies should be recognised and considered.
(4) The need to develop a strong, growing diversified economy which can enhance the capacity for environmental protection should be recognised.
(5) The need to maintain and enhance international competitiveness in an environmentally sound manner should be recognised.
(6) Cost effective and flexible policy instruments should be adopted, such as improved valuation, pricing and incentive mechanisms.
(7) Decisions and actions should provide for broad community involvement on issues which affect them (Australia, 1992, 8).

The Agreement commits all levels of government to ecological sustainable development (ESD) principles. These and other principles were endorsed at the 1992 Earth Summit (Grubb *et al.*, 1993).

3.2 CANEGROWERS' View of Ecologically Sustainable Development

The key participants in the sugar industry have responded to the need for ecologically sustainable development (Industry Commission, 1992; Senate Standing Committee on Industry, Science and Technology, 1989). Provisions within the *Sugar Industry Act 1994* and assignment regulations, which are administered by the Queensland Sugar Corporation (QSC), mention that environmental, social and economic aspects must be considered in determining the desirability and feasibility of applications for cane land expansion (QSC, 1991). Major sugar-related research and development is the responsibility of the Bureau of Sugar Experiment Stations (BSES). Financed by growers and millers, BSES approves cane varieties to be grown in mill areas, provides extension services to farmers, and conducts research into the growing of cane. It has encouraged farmers to adopt environmentally friendly practices and identifies sustainable resource use as an important principle (Briody, 1994).

Sugar cane research has tended to focus on biophysical aspects of the plant. CSR Ltd. has had an ongoing sugar cane varietal program. More recently, QDPI and CSIRO have intensified their sugar-related research, and a CRC for Sustainable Sugar Production has been established. The latter will devote some research effort into socioeconomic aspects of the industry.

CANEGROWERS and the Australian Sugar Milling Council are the two main industry associations. CANEGROWERS is a statutory organisation representing all cane growers in

Queensland and is financed by a grower levy based on cane supplied. It adopted an environmental policy in 1990. In 1995, this policy was revised in the document *Caring for the Environment* which embraced the following principles:

(1) Industry and farm management practices should enhance the efficient and sustainable use of soil and water, safeguard public health, help preserve natural resources and desirable flora and fauna, and combat feral animals such as wild pigs;
(2) Concerns about the environment should not be treated in isolation from economic and social considerations;
(3) Preservation of the environment is everyone's concern and the cost should be borne equally within the community;
(4) Individual land holders are best placed to address issues as part of voluntary publicly-funded programs as well as R&D projects;
(5) Where sensible precautions are taken and best technology used, farmers should be free of bureaucratic interference in the everyday running of their properties;
(6) Farmers should be active participants in an open consultation process between government, industry and the community;
(7) Primary producers have rights and obligations;
(8) Government has a role in providing information, education and incentives to encourage active and self-regulatory environmental management of farms; and
(9) Unacceptable behaviour by individuals should be discouraged.

These principles are of particular relevance to this paper because they represent a clear statement of intent from the growers.

3.3 Differences in Principles: Defining the Precautionary Principle and Bounding Management Strategies

While there are commonalities, there are at least three significant differences between the *Intergovernmental Agreement* and *Caring for the Environment* principles (Table 1). The first concerns agreeing on the breadth and depth of the balanced, ecosystem, partnership, flexibility principles. For instance, the *Intergovernmental Agreement* highlights the need for a global perspective in ecosystem management, while the CANEGROWERS are more concerned for providing efficient farm operations by controlling feral animals as well as a healthy environment. While these types of differences are important, it is more appropriate to consider differences and similarities in a broader context.

In general terms, the other two important differences pertain to the precautionary principle, and how management strategies should be bounded. During the interviews, a wide range of views was expressed concerning the nature of these concepts. The following discussion reviews their meaning and implications for the sugar industry.

3.3.1 The Precautionary Principle

The precautionary principle has been used by decision makers to consider the impacts of policies, programs, and projects. Although it has been applied since the 1950s in Germany, its inclusion as Principle 15 in the U.N.-sponsored Rio Declaration on the Environment and Development (Earth Summit) has raised its international profile and popularity. That document rationalised and defined the principle as follows:

> In order to protect the environment, the precautionary approach shall be widely applied by States according to their capabilities. Where there are threats of serious or irreversible damage, lack of full scientific certainty shall not be used as a reason for postponing cost-effective measures to prevent environmental degradation.

Table 1
Comparing and Contrasting Intergovernmental Agreement **and** Caring for the Environment **Resource Management Principles**

Principle	Specific Statement
Precautionary	*Intergovernmental Agreement* • where there are threats of serious or irreversible environmental damage, lack of full scientific certainty should not be used as a reason for postponing measures to prevent environmental degradation
	Canegrowers • where sensible precautions are taken and best technology used, farmers should be free of bureaucratic interference in the everyday running of their properties
Balance	*Intergovernmental Agreement:* • develop a strong, growing diversified economy which can enhance the capacity for environmental protection should be recognised • decision-making processes should effectively integrate both long and short-term economic, environmental and equity considerations
	Canegrowers: • concerns about the environment should not be treated in isolation from economic and social considerations
Partnerships	*Intergover*nmental Agreement: • decisions and actions should provide for broad community involvement on issues which affect them • the need to maintain and enhance international competitiveness in an environmentally sound manner should be recognised
	Canegrowers: • preservation of the environment is everyone's concern and the cost should be borne equally within the community • farmers should be active participants in an open consultation process between government, industry and the community • primary producers have rights and obligations • unacceptable behaviour by individuals should be discouraged
Ecosystem	*Intergovernmental Agreement:* • the global dimension of environmental impacts of actions and policies should be recognised and considered
	Canegrowers: • industry and farm management practices should enhance the efficient and sustainable use of soil and water, safeguard public health, help preserve natural resources and desirable flora and fauna, and combat feral animals such as wild pigs
Flexibility	*Intergovernmental Agreement* • cost effective and flexible policy instruments should be adopted, such as improved valuation, pricing and incentive mechanisms
	Canegrowers • government has a role in providing information, education and incentives to encourage active and self-regulatory environmental management of farms • individual land holders are best placed to address issues as part of voluntary publicly-funded programs as well as R&D projects

The *Intergovernmental Agreement* fails to specify the use of "cost-effective measures". However, the document maintains that in applying the principle:

> public and private decisions should be guided by: careful evaluation to avoid, wherever practicable, serious or irreversible damage to the environment; and an assessment of the risk-weighted consequences of various options.

While this statement suggests a pragmatic use of the precautionary principle, the predominant view among interview respondents is that it should always prevent resource development. While this is a legitimate view, it is not necessarily the case.

The precautionary principle recognises the importance and the types of uncertainty in resource management (Table 2). The challenge is to apply appropriate management processes and decisions in the face of uncertainty which meet peoples' needs. Collingridge (1983) outlined two strategies, hedging and flexing, as ways of making decisions in the context of uncertainty and ignorance (Table 2).

Table 2. Defining Different Kinds of Uncertainty in Resource Management

Risk:	system parameters are well known. Range of outcomes and the odds are known and can be predicted.
Uncertainty:	major system parameters are known. Range of outcomes is known but the odds are not.
Ignorance:	scientists will be surprised by the outcomes because they do not know. Do not know what questions should be asked.
Indeterminacy:	scientific knowledge is inadequate. Causal chains are open. Understanding is not possible.

(after Wynne, 1992; Mitchell, 1995; Young, 1995)

Hedging involves avoiding the worst-case scenario. This popular and traditional strategy in the face of all types of uncertainty emphasises minimising damage when the worst possible outcome occurs. However, this strategy is likely to be inappropriate in cases of ignorance. In these situations, Collingridge (1983) suggested a strategy of flexing. Flexing assumes that under circumstances of ignorance, no decision can be known to be right or wrong with any degree of confidence. Therefore, it is prudent for managers to monitor these decisions, and be prepared to modify them. According to Mitchell (1995, 5), "if resource managers approach situations with a view to being flexible, and are prepared to monitor and modify decisions, then they can afford to take chances and do not have to follow the cautious approach encouraged by hedging."

Young (1995, 20) suggested that it meant "all options need to be explored when considering significant irreversible action with unpredictable future consequences. Further, such actions should only be undertaken when large social costs would otherwise be incurred by the current generation." Rather than stopping all resource development, applying the precautionary principle has more to do with changing the balance of decision-making power. It emphasises the responsibility of resource developers must take in either: (i) demonstrating that their initiatives will not cause harm, or (ii) providing the means to compensate potentially impacted communities or people (O'Riordan, 1995). These comments suggest that responsible decision making is an important element of the precautionary principle. Some mechanisms which can achieve this goal include: monitoring changes in resource capital, placing the onus of responsibility on proponents, developing safe minimum standards, enhancing community consultation and education, and providing anticipatory approaches to resource management. Thus, applying the precautionary approach is particularly relevant for those who view integrated resource management as effective institutional arrangements.

3.3.2 Bounding Problems and Solutions

It is important to consider how the scale of a problem can influence management strategies. The *Intergovernmental Agreement* favours community-based initiatives (largely through economic instruments) which are placed in the context of global initiatives and international competitiveness. CANEGROWERS places relatively more importance on individual farmers who voluntarily incorporate best management practices which are supported by communities and the government (Table 1). Both perspectives are essential for ecologically sustainable development.

In water management, most people would advocate the catchment as the most appropriate geographical unit to practice an ecosystem approach. However, the size of catchments varies according to one's perspective. They can be considered as the land area draining the entire eastern seaboard or a single catchment (*e.g.*, the Herbert River), or a subcatchment (*e.g.*, Cattle Creek). In Canada, a 'nested' catchment approach addresses the need to understand linkages among biophysical processes with the development of appropriate implementation mechanisms along a continuum of scales (Royal Commission, 1992).

A mix of reinforcing geographic scales and implementing mechanisms will most likely lead to effective management. For instance, water quality standards established on relative loads (*e.g.*, parts per million) fail to address the total amount of residuals entering the environment. While individual farmers or other potential contributors may be complying with relevant government regulations, an increase in the total number of farming operations could increase the total load to the environment and result in significant impacts. In short, a 'problem' does not exist at the block level, but is present at the ecosystem or community level. In this example, the nested ecosystem approach should consider both the total loads and relative contributions of individual operations. A second example pertains to drainage works. Increased productivity can often be best achieved through large-scale drainage works which are beyond the capacities of an individual farmer. However, the desirability and feasibility of these projects must consider the impacts on upstream and downstream landowners, the environment, and the economy. The nested catchment approach can be incorporated into integrated resource planning initiatives.

Integrated planning is one mechanism to guide the activities of both individuals and communities. The key issue is to recognise that many environmental problems transcend property and administrative boundaries. Effective resource management will likely require a mix of approaches involving the coordination of voluntary individual efforts, the establishment of community-based bodies such as Catchment Coordinating Committees and Landcare groups, the participation of non-governmental organisations, local and state agency planning efforts, and government incentives and regulations.

3.4 Similarities in Government and Canegrowers Principles

While differences in management principles exist, the *Intergovernmental Agreement on the Environment* and *Caring for the Environment* share some general elements (Table 1). These are the need for balance, ecosystem, partnership and flexible approaches.

A **balanced** perspective recognises the economic, social, and environmental aspects of resource development and management. However, a key concern pertains to the relative weight given to each element. Past management efforts have usually favoured short-term economic gains over long-term factors. In providing for balance, mechanisms should be in place to provide for compromise and tradeoffs among this legitimate mix of dimensions. Conflict resolution mechanisms should enhance management efforts. At what point in the planning process these mechanisms are utilised is also important.

Responsibility for environmental and resource management is often shared between private and public managers at international, national, state, regional, local and individual property scales. **Partnerships** respond to this reality and should ensure the equitable treatment of all these participants. People and groups who have a legitimate concern should have an opportunity to influence the formulation and implementation of resource management and development decisions. Information among participants can also be exchanged.

An **ecosystem** approach appreciates the complexity of relationships among and within environmental, social, and economic systems. Rather than focusing attention on one element of the environment, attention is often turned to considering how human health or other broad measures of quality are affected by the natural and social environment. To implement this approach, attention is often given to watersheds or bioregions. Environment and natural resource management is often ill-suited to administratively-based boundaries. While it is not feasible to form agencies exclusively based on 'natural' boundaries, it is appropriate to plan on the basis of ecosystems and incorporate this information into appropriate implementing documents (*e.g.,* policies, strategic plans, legislation, regulation). It is in this context where the nested catchment approach can enhance practice.

Our understanding of the environment and human interactions with it is continually evolving. Social and personal attitudes and behaviours are also dynamic. Political and economic circumstances can change almost overnight on the basis of the future's market in New York, an announcement from the central bank, or the results of an election. Since these types of changes must be accommodated in individual, community and government management strategies, there is a need for **flexibility**. Research and education can aid this process. Monitoring should be an important element of management, particularly in the light of ignorance (Table 2), so that progress can be assessed and appropriate modifications made.

3.5 Summary

While there may be some difference in specifically interpreting these general principles, it is important to identify and appreciate the degree of similarity. However, stating these four principles is one thing; translating them into appropriate planning and operational processes is another. The degree to which the sugar cane assignment process supports the implementation of these principles is used as a benchmark for this study.

4.0 INSTITUTIONAL ARRANGEMENTS FOR ENVIRONMENTAL MANAGEMENT INFLUENCING CANE LAND ASSIGNMENT

4.1 The Legacies of the Past

In making the transition to ecologically sustainable development, both the sugar industry and Queensland public resource management agencies must contend with how past efforts influence future activities. One member of a 1992 Industry Commission into the sugar industry described that industry as follows:

For all my working life I have been engaged in the examination of agricultural policy in Australia. I have found it harder to fathom what goes on in the sugar industry than to come to grips with any other rural industry.

> This is partly because there has been less information available on the sugar industry than on other rural industries. Traditionally the Queensland sugar industry and Queensland Governments have not been attracted to openness in providing information...But the difficulty in coming to terms with the sugar industry is largely the policy arrangements are so complex, and that there are interactions between elements of the arrangement [not easily understood] (Edwards, 1993, 1).

While I found both the industry and government respondents to be quite candid and open during interviews, many people are unfamiliar with this experience and maintain the perceptions of the

past. This legacy detracts from future initiatives which are based on the principles of partnership and balance.

The water management record of the Queensland government before 1989 emphasised a structurally focused, development approach (Fenwick, 1985). While many of these projects contributed to increased growth, many interview respondents questioned the efficiency and effectiveness of this approach. In this pre-1989 period, some landowners in the lower Herbert River built levees and other flood and drainage works which failed to comply with the requirements of the *Water Resources Act*. These landowners were not sanctioned for these violations. In the words of several government officials, senior managers and relevant ministers did not support assertive legal enforcement. An unfortunate legacy of this period is the perception held by some landowners that they can, in the future, alter surface water flows without government approvals and penalties. The scale of these individual works is inadequate and contributes to significant conflicts between neighbours. Any efforts to achieve effective partnerships must address this problem. People must know the 'rules of the game' and be assured that these will be followed and enforced.

The climate for the rapid expansion of sugar cane land was, in part, stimulated by the *Sugar Industry Act 1991* (amended in 1994). It required a minimum expansion of 2.5% (about 10,000 ha) per year between 1991 and 1995 which has been exceeded (QSC, 1995). After 1995, the QSC will determine the extent of any expansion. There was an awareness that this growth must be managed. To that end, the Minister for Primary Industries, who is responsible for the activities of the QSC, committed:

> officers of his department [to be] readily available to provide assistance and advice as required (Briody, 1992, 5).

There were no additional resources provided to QDPI or other agencies in the Herbert River area to specifically address this need. Thus, any government involvement in sugar cane expansion has been done with existing or fewer resources.

The need to incorporate these agencies into the assignment process has been emphasised by the QSC (1993, 7):

> Where the need arises, Local Boards should liaise with the Queensland Department of Primary Industries, Land Use and Water Resource Groups, Drainage Boards and the Bureau of Sugar Experiment Stations in respect of proposed new land and where necessary, are to attach as conditions of the grant assignment, any **land use restrictions** imposed by such authorities. The Corporation has informed relevant organisations of the expansion and requested them to make officers available for consultation with Local Boards as necessary.

Interviews with regional public agency officials suggested that they have not been informed about this request through normal administrative channels. In the Herbert River District, they perceive their lobbying of the Local Boards as the key factor which prompted the 1996 formation of the *ad hoc* technical review committee.

A more recent aspect of the management legacy pertains to the 1989 state election. At that time, a new State Government was elected and committed itself to providing more effective resource management. It focused attention on formulating new resource management policies, and adjusting administrative arrangements. In 1996, a new government was elected. While it has provided for new administrative arrangements, its commitment to the *Intergovernmental Agreement*

on the Environment is uncertain. The following sections discuss the basis and nature of government involvement which significantly influences the sugar cane expansion process.

4.2 Queensland Department of Primary Industries (QDPI)

In 1989, the new state government responded, in part, to the need to implement sustainable development by enhancing the institutional capacity to implement resource programs. The Department of Forests and the Water Resources Commission were amalgamated into the Department of Primary Industries (QDPI). During the study period, QDPI influenced sugar cane growing through legislation, programs, and policy statements. It administered the *Water Resources Act 1989* which provides for the:

- construction, control and management of works with respect to water conservation and protection, irrigation, water supply and drainage;...and
- protection and improvement of the physical integrity of water resources.

Drainage boards which have been formed in some portions of the lower Herbert River are guided by this statute. QDPI provided a rural extension services program which focused on the production, financial, and resource management aspects of farm activities. Interested cane farmers could avail themselves to this service on a voluntary basis. Policy statements, such as "Land Use Practices for Wet Tropical Floodplains" represent the third mechanism available to QDPI and other agencies (QDNR, 1996). The intent is to guide the drainage of agricultural land on the wet tropical coast; it is not legally binding. Management principles, land assessment, farm planning, drainage requirements and design, and implementation and management arrangements are discussed.

These legislative, farm extension and floodplain policy guideline functions were transferred to the newly created Department of Natural Resources (QDNR) following the 1996 agency reorganisation. The remaining QDPI maintained responsibilities for regulating mangrove clearing under the *Fisheries Act*. The Queensland Department of Lands (QDOL) was also merged into the new QDNR. Since 1991, the QDOL was required through an amendment to the *Lands Act* to consider the environmental implications of leasing and selling Crown lands (Duncan, 1993). Cane land expansion in the Herbert River District often involved the purchase or lease of Crown land. In selling and leasing Crown Lands, the Federal *Native Title Act* requires adequate consultation with an 'accredited' body. In the Herbert River District, this body is the Central Queensland Indigenous Land Council.

4.3 Queensland Department of Environment and Heritage (QDEH)

The Queensland Department of Environment and Heritage (QDEH - now Environment (QDoE) after the 1996 agency reorganisation) is charged with promoting the conservation, management and wise use of the environment for the long-term public benefit. That agency conserves vegetation and wildlife species by declaring public and private lands as protected areas under the *Nature Conservation Act 1992*. It may enter into agreements with private landowners to protect designated areas. Acquisition may be negotiated between the agency and a landowner. These areas are designated on the basis of supporting rare and threatened wildlife, critical wildlife habitat, a protected area (*e.g.*, National Park), or areas of significant nature conservation interest.

This legislation is relevant to the Herbert River District. In 1995, an interim conservation order under the *Nature Conservation Act 1992* was placed on the Pomona land holding because the clearing of the forest area for cane growing would "have a significant detrimental effect" on the Mahogany Glider. A *Draft Mahogany Glider Conservation Plan* was prepared (QDEH, 1995). It

outlined over 28,000 ha of critical habitat requiring protection. Much of this area is suitable for sugar cane growing, and some of it has already been assigned. Funding for this $6 million initiative was provided from the Sugar Coast Environmental Rescue Package Agreement (SCERP). That Commonwealth-State program was to provide a total of $16 million over a 3-year period for the acquisition of land, and the development of intergovernmental management initiatives, public education programs and landowner assistance measures. With the expected cuts to Commonwealth budgets and the potential impacts on state initiatives, it is unclear whether the announced total of $16 million will be secured. However, the adequacy of the $16 million is questionable given that 37.5% of the entire amount was dedicated to the Mahogany Glider program alone.

Some interview respondents maintained that QDoE could use the *Environmental Protection Act 1994* to influence land clearing and farming by placing a "duty of care" on farmers to protect the environment. The efficacy of this approach is unknown. On the one hand, the *Act* uses the term "environmental harm" to embrace a wide range of impacts, it refers to "contaminant" and excludes land clearing for agricultural development as a regulated activity. These provisions suggest that the development of land for agricultural production are not regulated by the *Act*. On the other hand, the court could view the storage of acid sulphate soils in farm ponds as a "contaminant" exclusive from land clearing activities. The final outcome of litigation will reflect, in large part, several issues: (i) if the activity causing environmental degradation was defined as a "land clearing activity"; (ii) if acid sulphate water is defined as a "contaminant"; (iii) if the relevant water quality criteria (yet to be defined under the legislation) has been violated; (iv) a demonstrable lack of due diligence by a landowner (yet to be defined in an Agricultural Code of Practice), and (v) the significance of environmental harm resulting from this activity.

There is no question that the *Environmental Protection Act 1994* will be more relevant in managing specified farming practices. Farming practices which create air emissions (*e.g.*, cane burning), discharge water which contravene stormwater quality standards, contaminate land or groundwater through the use of pesticides, or exceed specified noise levels could be prosecuted.

4.4 Local Government

The Queensland Department of Planning and Local Government (QDPLG) ensures that the requirements of the *Local Government (Environment and Development) Act* are met. Local governments are responsible for implementing the *Act* in a manner consistent with goals and objectives stated in its strategic plan.

The Hinchinbrook Shire adopted its first strategic plan in 1984. It identifies a "rural zone" which predominates all other land uses and promotes a climate for cane land expansion. Under law, permitted development (*i.e.*, consistent with the zoning) is considered "as a right" which precludes the shire reviewing proposals and initiating environmental assessments. Cane land expansion within the rural zone is not referred to the Shire. Therefore, it receives very little information and has very little influence regarding the cane expansion process and its final decisions. The development of sugar-related rail and road systems impact on shire drainage works. Roads will be maintained by the Shire. These developments are treated "as a right" which precludes their formal review through the impact assessment provisions of the *Local Government (Planning and Development) Act*. Other legislation related to transport development provides for Shire participation in these areas.

However, a key point concerns how cane land expansion affects changes to land valuation, drainage flows and road maintenance costs - all responsibilities of the Shire. Yet, local government is poorly informed of the assignment process and its outcomes.

The strategic plan is being reviewed at present. Many respondents believe that the new plan should protect riparian corridors and other significant biophysical features through zoning. While this might be desirable, it faces some practical problems. On the one hand, any rezoning of rural land which allowed alternate forms of development (*e.g.*, tourism, urban) could contravene Queensland's State Planning Policy on Agricultural Land. On the other hand, if existing rural areas were 'down zoned' (*i.e.*, precludes land development allowed under the former plan) to provide for nature conservation, compensation must be awarded to the landowner. Funding for this award is the sole responsibility of local government and could take the form of rate relief. Given the relatively higher concern for coastal areas versus inland water environments, the revised plan may give more importance to the former than the latter. These factors constrain the ability of local government to declare protected areas. It must consider these and similar initiatives in the context of other legitimate social and economic concerns.

The proposed *Planning, Environment and Development Assessment Bill* (PEDA) will streamline local planning. A 'whole of government' approach to the review of development proposals is to enhance the efficiency and effectiveness of responses from relevant state agencies. The general intent suggests that development applications submitted to local governments will be circulated to relevant agencies for comment. These responses, which will be required within specified time frames, will be reviewed, and more timely and appropriate decisions made. While that initiative is not being actively pursued by the present state government, interview respondents suggested that the intent of this legislation will be embraced through existing administrative mechanisms. The outcome will likely see more timely decision making and more decision-making responsibility will be placed on local governments.

The Herbert River Improvement Trust is essentially another arm of local government. Having a jurisdictional area embracing the Hinchinbrook Shire, this agency consists of two local counsellors and a QDNR representative. While it is primarily concerned with instream erosion and flood protection, it could play a modest role in water and related land management. In the Hinchinbrook Shire, a river improvement notice of 10 m adjacent to specified water courses has been applied to subdivision proposals on land. For $110.00 fee, this notice is attached on the land title which prevents alteration of the channel and the clearing of the adjacent corridor. This mechanism provides for secure land tenure under the Herbert River Improvement Trust and precludes clearing or development within the designated area. The primary objective is to ensure major water courses are maintained for rural and urban drainage purposes.

4.5 Integrated Catchment Management

The Queensland Government released *Integrated Catchment Management* (ICM) in 1991 as a means of considering

> the management of land, water and related biological resources in order to achieve the sustainable and balanced use of these resources. It provides a framework for fostering cooperation and coordination between many land holders and other resource users, community groups and government agencies involved in the use and management of land and water resources (Queensland, 1991, 1).

While it was recognised that other government initiatives such as the proposed State Conservation Strategy, State-wide environmental programs (*e.g.*, Landcare), and broad regional

strategies such as the Far North Queensland 2010 Growth Management Strategy and Coastal Protection Strategy would be important activities, ICM was to involve all sectors of the community and thereby achieve integrated and coordinated action. ICM was also to focus on several important issues, rather than a single issue base, in achieving an integrated perspective. The final product of the ICM process is a Catchment Strategy which prioritises catchment issues, and identifies appropriate implementation mechanisms. This catchment strategy could develop codes of practice or other mechanisms which could influence cane land expansion or related activities such as drainage or irrigation practices.

Implementation of ICM would foster a 'whole of government' approach by providing a strategy which was consistent with policies and guidelines of all levels of government. Three options for implementation were identified. The preferred choice would see the Catchment Coordinating Committee (CCC) seek the voluntary adoption of catchment management strategies by land holders and resource users, community action groups, and government agencies. Presumably, the strategy development process would educate resource managers about the need for specified resource management activities. Where voluntary implementation was jeopardised, CCCs could request the appropriate state minister (*e.g.*, QDPI, QDoE, QDNR, QDPLG) to have local and state agencies consider catchment management strategies in their routine operations. The final option would see the establishment of a catchment trust or similar statutory body for specified issues such as soil conservation, floodplain management, or river improvement. This issue was considered in the 1994 document *The Sustainable Use and Management of Queensland's Natural Resources* (QDPI, 1994b).

In 1993, a Herbert River Catchment Coordinating Committee (HRCCC) was formed and a coordinator hired. Sugar cane expansion has been one important issue identified by HRCCC members, and will be addressed in its forthcoming catchment strategy.

4.6 Other Legislative Requirements

The outcomes of the previously noted Hinchinbrook Shire Strategic Plan review and HRCCC planning are unclear. This uncertainty also extends to some other recent legislative initiatives in Queensland. The *Coastal Protection and Management Act* and the *Wet Tropics Management Act* will likely identify wetlands and riverine environments on a selected basis. Under the former, control districts, defined as the foreshore and up to 400 m inland or up to 1 km inland along estuarine deltas or all coastal wetlands or dune systems, will be formed in the future. The latter has seen the recent release of a *Draft Wet Tropics Management Plan* which proposes the protection of other sensitive areas (Wet Tropics Management Authority, 1995). When a local land use scheme is adopted, information from these and other relevant Commonwealth and State initiatives should be incorporated into relevant municipal planning documents. State agencies will also have to have regard for these statements.

The Commonwealth Government is involved through funding programs such as the previously mentioned SCERP. In 1992, it funded in cooperation with the State Government and the sugar industry a Sugar Industry Infrastructure Package (SIIP). Each mill area formed committees consisting of millers and farmers to determine which projects would be nominated for funding. The Herbert River District was successful in its application, and a preliminary engineering study has identified 8 drainage projects worthy of more detailed engineering design. That study also advocates the formation of a single drainage board to provide for an adequate level of maintenance. That single board would replace the existing fragmented arrangement, but would not extend to the entire cane growing area of the lower Herbert River.

Requirements of the *Endangered Species Protection Act 1992*, *World Heritage Properties Conservation Act 1983*, and the *Environment Protection (Impact of Proposals) Act 1974* may also influence the development of new cane lands.

4.7 Summary

The arrangements influencing the expansion of cane land and associated farming practices are fragmented. Concern has been expressed concerning the adequacy and effectiveness of these institutional arrangements to protect the special resources of the offshore Great Barrier Reef and the adjacent wet tropical rainforests, and the less publicised but important coastal wetlands and floodplain areas. This complex set of arrangements could also confuse a public who are unaccustomed to this high level of government involvement. It is this type of concern which prompts the suggestion for a 'whole of government' approach in reviewing the environmental aspects of development proposals. Providing for effective institutional arrangements from this fragmented resource management approach supports the four principles shared by government and the CANEGROWERS - balance, ecosystem, partnership and flexibility.

5.0 PUTTING INTENT INTO PRACTICE: THE INSTITUTIONAL ARRANGEMENTS FOR CANE LAND ASSIGNMENT

5.1 **The** Sugar Industry Act 1994

Before 1991, growth in the sugar industry was controlled through a series of international agreements and tariffs. In Australia, the Sugar Board provided a highly centralised decision-making structure. This arrangement changed in 1991 with the passage of the *Sugar Industry Act 1994*. That statute provided for annual minimum increases in assignment of 2.5% (about 10,000 ha) between 1991 and 1995, and greater flexibility in the administration of the *Act*. Some of this flexibility was achieved by delegating increased decision-making responsibility to Local Boards. However, the centralised administration of the Central Sugar Cane Prices Board meant that they were not that active. Under the tenure of the Queensland Sugar Corporation (QSC), this situation has changed.

A detailed review of the assignment system can be found in ABARE (1991) and Industry Commission (1992). In brief, sugar cane or land assignment was introduced in 1926 to control the level and location of sugar cane production, and to preclude the growing and commercial harvesting of cane (Industry Commission, 1992). Until 1991, cane land expansions were 'planned for' by the Sugar Board. Assignments were originally specified in terms of particular plots of land on a designated farm, and growers could not easily get permission to change assignments even within existing farm boundaries. This requirement was changed in 1991. Cane can now be grown on any part of an assigned area. While growing on unassigned land is not prohibited, mills are not obliged to accept it and the grower receives a penalty price of $1 per tonne.

Mill and farm assignments continue to control the size and rate of growth at state and local levels. At a local level, these regulations match cane production with a mill's crushing capacity and transport infrastructure, so that expansion does not penalise existing growers (Industry Commission, 1992). Improvements and expansion of the transport network and mill infrastructure occur regularly in response to market conditions, and provide opportunities for cane land expansion. At a state level, regulations should ensure markets for the sugar products.

5.2 Considerations in Granting Assignment

Section 12 of the *Sugar Industry Act 1994* identifies the principal objectives of the QSC as:

- ensuring that the policies for the Queensland sugar industry are successfully implemented;
- enhancing the efficiency, competitiveness and access to markets of the Queensland raw sugar industry;
- enhancing the long-term economy of the Queensland sugar industry
- enhancing the benefits flowing from the Queensland sugar industry to cane growers and mill owners and to the economy of Queensland; and
- encouraging initiative and innovation among cane growers and mill owners and others involved in the Queensland sugar industry (QSC, 1995, 4).

While the QSC is responsible for implementing the *Sugar Industry Act 1994*, it has delegated much of the responsibility for mill-area decision making to the 25 Local Boards in Queensland. These bodies are constituted under the *Act* with the objective of ensuring the efficient participation of mill owners and canegrowers in the production and milling of cane. As noted earlier, each Local Board comprises an independent chair, two mill representatives, and two mill supplier representatives. The *Primary Producers' Organisation and Marketing Act 1926* established CANEGROWERS as the formal grower body for sugar cane (excluding marketing functions) (CANEGROWERS, 1995). It is the Local Board which acts as an 'agent' for the QSC, and receives and determines applications for new and increased assignment (Briody, 1995). Powers to rescind assignment are reserved by QSC on the advice of the Local Board.

QSC's statutory objectives are oriented toward economic considerations, although the 'long-term economy' of the industry can be achieved, in part, through effective natural resource management. Direct reference to the environment in the *Sugar Industry Act 1994* is found in Sections 144(2)(c) and 147(4)(a)(iii) which require environmental issues to be part of the decision-making process. Reference to the environment is also found under the *Sugar Industry (Assignment Grant) Guidelines* which are established under Section 29(b) of the *Sugar Industry Act 1994*. The guidelines should be viewed as QSC policy which must be complied with by all Local Boards. All respondents from the Macknade and Victoria Local Board were keenly aware of their obligations under the *Act* and *Guidelines*. Section 6 of the *Guidelines* outlines general considerations in granting assignment, and includes the following implicit and explicit references to the environment.

(b) the principal objectives of the Corporation mentioned in section 12 of the Act; and
(c) any view expressed by the relevant Local Board on a relevant local matter; and
(e) the capacity of the proposed assignment's land for producing commercial crops of sugar cane when subjected to correct agricultural practices; and
(f) the prospects of preparing and using the proposed assignment's land without undue damage to the environment...

In addition, Section 8(1)(e) of the *Sugar Industry (Assignment Grant) (No.2) Guideline 1995* indicates that an application will be granted if the QSC and Local Board are satisfied that the proposed assignment land is:

> able to be prepared and used for the growing of sugar cane without undue damage to the environment.

The Local Board is also to consider the efficient and cost-effective delivery of sugar cane to the receiving mill. For applicants who do not hold an existing assignment, their willingness and capacity to develop the land in a timely manner (usually a 2-year period), and their place of

residence is appraised. Thus, environmental, economic and social factors are the basis of the final assignment decisions.

5.3 Cane Assignment Process in the Herbert River District

As noted earlier, there are two CSR mills operating in the Herbert River District - Victoria and Macknade. Each has its own Local Board and shared the same chairman during the study period. During that time, the cane assignment process has evolved continually in two significant aspects: (i) more responsibility for awarding assignment has been delegated from the QSC to Local Boards; and (ii) the formal consideration of environmental aspects has become more apparent. Table 3 outlines the most recent expansion application process and its timing for the 1996. To place the activities of the Local Board in context, the process has been divided into four stages (Table 3). Stage 3 is the formal assignment process as defined under the *Sugar Industry Act 1994*. However, important decisions made by corporations and governments (Stage 1), and by millers and growers (Stage 2) define the desirability and feasibility of any expansion activity. Successful applicants make the assignment effective in stage 4.

5.3.1 Stage 1: International and Corporate Contexts

The context for expansion reflects, in large part, perceived market opportunities and the corporate (miller's) perception regarding the desirability and feasibility of mill expansion. With regards to the former, a "World Market Prospects" report is prepared by the QSC's marketing agent CSR Limited. It considers the world demand for and supply of sugar, and significant world and national legislative initiatives (*e.g.*, GATT, U.S. Farm Bills, European Union Agricultural Policies) to identify market opportunities for Australian products. This report is circulated to local boards, millers, CANEGROWERS and other relevant organisations. The feasibility of increasing mill capacity will reflect corporate goals and capabilities, the opportunities for cane land expansion, and infrastructure needs (*e.g.*, rail lines, roads, bridges). Decisions to increase mill capacity are most often made a few years prior to implementation.

5.3.2 Stage 2: Continuous Crushing Agreement

In the Herbert River District, a "Continuous Crushing Agreement" between the CANEGROWERS and CSR significantly influences the regional industry's development. It establishes the harvesting period, production and crushing capacities, future growth, and transport planning for the regional sugar industry. This agreement has implications for expansion planning and resource management. Factors external to the industry which pertain to the availability of sugar cane land (*e.g.*, zoning in shire plan, national parks) can influence plans to expand cane farming.

The 1995 Agreement specifies the harvest season as starting on the Monday between June 19 and June 25 (unless extraordinary circumstances arise), with a target season length of 20 weeks and 3 days (*i.e.*, ending by November 15). This period is coincident with a high level of sugar content in the stalks (as measured by commercial cane sugar (ccs)), and before the summer rains prevent easy access onto paddocks. The average sugar content ranges from around 10 ccs at the beginning and end of the season to 16 ccs in the middle. After harvesting, ccs within the sugar cane quickly decreases. To reduce this loss, which is one basis for payment to growers, harvesting and processing must be effectively scheduled. This factor is particularly important in the Herbert River District since the mills are not centrally located in the cane growing areas. Like most cane growing areas, most cane transport is done on mill-owned and maintained 2' gauge railways. The "Continuous Crushing Agreement" guides railway development by tying it to cane assignment. Since the transport of the cane from delivery points to the mills via the rail system is the miller's responsibility, both CANEGROWERS and the mills must be confident that the transport

network can deliver the cane in a very timely manner. The implicit objective is to match sugar cane production with transport and crushing capabilities.

Table 3
Herbert River District - Cane Expansion Process: Stages, Timing, Key Decisions and Selected Significant Participants Which Influence Decision Making

Stage	Timing (1995)	Decisions	Participants and Means of Influencing Decision Making
Stage 1	2 - 5 years ahead	International Agreements National Trade Policies Corporate Goals QSC/CSR 'Prospects' Report	Governments and Corporations * international agreements * other sugar-producing nations * perceived market opportunities * corporate goals and expectations * export infrastructure (*e.g.*,terminals)
Stage 2	yearly	Continuous Crushing Agreement	Millers and CANEGROWERS * mill goals relative to corporate goals * mill capacity for growth * transport capacity for growth * existing grower expectations * availability of suitable land with agricultural zoning
Stage 3 (formal assignment process)	Aug. 1	Call for Applications through print media	QSC and Local Boards * *Sugar Industry Act*
	Aug. 31	Received by Local Board	applicant * goals, experience and capabilities
	Sept. 1-31	Refer to *ad hoc* Technical Review Committee and required field inspections	financial institutions/family sources * loan conditions (if required)
		Agreement on desired mill allocation	QDPI/QDoE/QDNR/QDPLG * *Water Resource Act* * *Fisheries Act* * *Nature Conservation Act* * *Environmental Protection Act* * *Lands Act* * *Local Government (Planning and Environment) Act* * *State Development and Public Works Organisation Act*
	October	QSC notified of total applicant demand and desired mill allocation	
		QSC consults with industry and QDPI Minister	
		Farm and Mill Allocations Determined	Hinchinbrook Shire: * strategic plan * River Trust
	Nov./Dec.	Applicants Notified	HRCCC: * strategic plan
Stage 4	within next 2 years	successful applicants make assignment effective	QDPI/QDEH/QDNR * *Water Resource Act* * *Environmental Protection Act* * extension services

Some biophysical properties of sugar cane present management challenges. When a sugar crop is planted, it may be 12 to 18 months before it is harvested. Over that time, loan payments must be made. In the Herbert River District, real estate agents suggested that existing cleared cane land could sell for $3,000 to $5,000 per hectare, while uncleared land demanded $2,500 to $4,000 per hectare. These costs can impose a heavy burden for new and rapidly expanding operations, and provide opportunities for financial institutions to influence the nature and extent of expansion.

Given the wide array of viewpoints which prevail upon the formal assignment process (Table 3), there is a need for effective institutional design.

Biophysical aspects of the sugar cane present other management challenges. Maximum sugar output can be achieved in the middle of the growing season when ccs is highest. However, the realisation of this objective requires enormous increases in existing mill crushing capacities to handle the crop before it deteriorates. For the rest of the year, the mill remains idle. Under present economic conditions, milling representatives suggested that this situation is not viable. To increase the productive use of mill facilities, CSR Ltd. has, since 1993, operated on a continuous basis - 7-days-per-week, 24-hours-per-day during the harvest season. The present June to November harvest period represents a tradeoff between benefits of spreading the cost of milling capital over a longer season and the reduction in sugar yield at the beginning and end of the season. This means that if cane production exceeds crushing capacity, the length of the harvest season must be extended when ccs is dropping. While the "Continuous Crushing Agreement" provides compensation to farmers in these circumstances, extending a harvest season can cause conflict. In the following year, a shortened growing season due to the preceding late harvest lends to smaller cane sizes which attract lower prices. Short cane is also more susceptible to flood damage which is most likely during the summer period (December - February). Thus, compensation must be seen in light of the potential economic losses to farmers and the ability of the mill to pay.

The "Continuous Crushing Agreement" provides a basis for long- and medium-term planning at the regional level. In the Herbert River District, it notes that over an unspecified period, the amount of assigned land could reach 100,000 ha (Agreement, 1995). In planning for forthcoming expansions, it was agreed:

> ... to work together to determine a forecast area of new land to be harvested in the following year by early July in each year. Based on this area and the cultivated area recorded for the current season, and using the five year average rotation for harvest, [which included the estimated area for harvest for the current season] the district forecast area for harvest in the next year can be determined; and that
> ... CSR undertakes that crushing capacity will be available for the processing of the whole district crop yielding up to 83 tonnes per hectare over the forecast area for the harvest determined ... at CCS levels of up to 14.0 units, within the target season length stipulated ... provided that the target season length may be extended [under specified circumstances] (Agreement, 1995, 3).

Expansion in the Herbert River District is based on CSR's ability to transport and crush sugar cane grown at an estimated yield of 83 tonnes per hectare. Existing growers must feel secure in the mill's ability to crush the crop, and CSR must be assured that farmers can deliver the agreed amount of cane.

5.3.3 Stage 3: Formal Assignment Process

International markets and "Continuous Crushing Agreements" set the context for increasing assignment. The *Sugar Industry Act 1994* outlines the requirements of the formal assignment process. The QSC places an advertisement in regional newspapers across the state and the CANEGROWERS magazine (Table 3). Interested readers apply to the relevant Local Board which receives and reviews the applications following the previously mentioned QSC guidelines.

During the study period, the application form required information concerning the:

- type of application (*e.g.*, new or increased)
- applicant's address

- new grower or current assignment information (*e.g.*, mill, existing assignment, increase sought, spare land available)
- location of increased assignment (*e.g.*, previously assigned or new land)
- land tenure (*e.g.*, lease or freehold)
- evidence of title and any land use restrictions
- land cover (*e.g.*, cleared, uncleared, partly cleared, under cane)
- development program (*i.e.*, when planting of cane will occur)

The state agencies and relevant statutes, programs, and policies described in the previous chapter influence individual applicants, and the decision-making process (Table 3). Before 1994, participation from government agencies and drainage boards was almost nonexistent. In 1994, QDPI with some informal input from QDEH provided some comments. A more visible and multi-agency mechanism was used in the review of 1996 applications. An *ad hoc* technical committee comprising representatives from QDPI, QDEH, BSES, and CSR Ltd. considered the environmental impacts of the application based on: (i) available 1995 ortho-photo mapping, (ii) soil surveys and other available mapping, (iii) local knowledge, (iv) information provided on the application, and (v) a property management plan which was required from all applicants for the first time in 1996. In preparing these property management plans, some applicants received detailed assistance from QDPI, others more informal assistance from BSES or CSR field staff, while others submitted rough sketches of their properties. All plans focused on land management issues.

Representatives from the Local Boards and *ad hoc* technical review committee conducted site inspections for properties of significant concern. Final recommendations were made by the *ad hoc* committee and were forwarded to the Local Boards. After considering which applications met the guidelines, the advice of the *ad hoc* technical committee and having reached agreement on mill capacity, the Local Boards advised the QSC regarding: (i) the total level of applications; and (ii) the amount of expansion it is prepared to approve (Table 3). This information for all mill areas was presented by the QSC to industry groups and the Minister for QDPI (as required by statute), and a final decision was made by the QSC. Applicants were notified in writing by the QSC.

Unsuccessful assignment applicants may appeal to the Sugar Industry Tribunal, or apply in subsequent years. Successful applicants have two years to make assignments effective (*i.e.*, delivering sugar cane to the mill) (Stage 4, Table 3). Twelve month extensions may be given. Farmers will be required to abide by regulations and codes of practice established under the *Environmental Protection Act*. If drainage works (as defined by statute) or irrigation waters are required, applications under the *Water Resources Act* must be submitted to QDNR for review. QDPI and QDNR provide extension services to farmers.

For the 1996 award, the call for applications was made on 1 August and decision announced by 31 December at the latest (Table 3). For the 1997 award, the QSC announced that applications must be submitted to Local Boards by 31 June 1996. Local Boards are to notify the QSC by 31 July of the total applicant demand and the desired mill application. Applicants will be notified in late September of final decisions.

6.0 INITIAL OBSERVATIONS ON THE CANE LAND EXPANSION PROCESS

Australian resource managers need to demonstrate clearly how their decision-making processes facilitate effective, efficient and equitable outcomes. To address this challenge, the Macknade and Victoria Local Boards have (i) formed the *ad hoc* technical review committee (in 1996), (ii)

required applicants to submit a property management plan with applications (in 1996), and (iii) developed an evolving list of conditions of assignment (Table 4). This list initially embraced drainage and soil conservation issues. It now encompasses wildlife and water quality issues. This evolution illustrates an appreciation of the functional aspects of resources, to one which embraces some ecosystem values as well.

Table 4. Evolution of Environment-Related Conditions of Assignment: 1993-1996

General Concern	Specific Condition	Applicable Year 1993	1994	1995	1996
Administrative	- failure to comply with any condition may result in assignment being rescinded	*	*	*	*
	- all requirements with all or any relevant State legislation applying to a particular location, development, proposal or project must be met				*
Drainage	- works must comply with the Rural Drainage Plan (1984) or other approved standards	*	*	*	*
	- growers may be required to cooperate in formation of community-based drainage or soil conservation schemes	*	*		
	- plans for works must be in accordance with the plan submitted at the time of application		*		*
	- any works within or connecting to a watercourse, lake, or spring must be authorised by a relevant licence or permit under the *Water Resources Act 1989* prior to the works being undertaken		*	*	*
	- areas known to be preferential flood overflow paths are excluded				*
Land and Water	- areas of acid sulphate soil may not be used for cane growing			*	*
	- development must comply with "Interim Guidelines for Development on Floodplains"			*	
	- following areas excluded: - mangrove swamps naturally subject to tidal inundation - areas below 3 m contour are excluded - areas below 9.5 m contour in Pomona Subdivision in Cattle Creek catchment - riparian zones of 20 m along water courses and drainage lines, and 40 m along major watercourse				* * * *
Soil	- land holders are encouraged to seek and adopt advice from DPI on soil conservation measures for slopes >3^{o}			*	
	- land holders must seek and adopt advice from DPI on soil conservation measures for slopes >3^{o}				*
	- areas of class 4 and 5 DPI land suitability excluded				*
Wildlife	- 20 m riparian zone of native vegetation must be maintained on each side of existing watercourses as a habitat corridor for the Mahogany Glider				*

Since the cane expansion process has been constantly developing, no radical changes to existing processes are recommended at this time. However, improvements must be made. One way of enhancing current performance is to provide greater consistency between the general intent of the four shared management principles noted in the *Intergovernmental Agreement on the Environment* and *Caring for the Environment* - balance, partnerships, ecosystem, and flexibility (Table 1) and the formal assignment process (Table 3). Inconsistencies can lead to frustration, confusion, and detract from public and governmental support. It is also appropriate to consider the broadening the management base from four to five principles by embracing the precautionary principle. Given the upcoming review of the sugar industry, it is appropriate to provide a wide and firm basis for discussion. Subsequent monitoring and research will better determine the need for additional modifications, or more radical reforms.

The following discussion highlights some initial key aspects associated with the assignment **process**. An evaluation of **practice** will be provided in a subsequent report. The five principles of balance, ecosystem, partnerships, flexibility and precautionary principle guide the following discussion and its recommendations.

6.1 Enhancing Balanced Management

Balanced management meant appreciating the environmental, social and economic dimensions of resource development and management. This issue is closely linked with the partnership principle. This paper distinguishes between these two concepts by suggesting that balanced management considers issues of how and when that goal is achieved. Partnership refers to who is involved in the management process.

6.1.1 The How: The Ad hoc Committee

The formation of the *ad hoc* technical review committee and the development of the conditions of assignment reflect the Local Boards' primary responses to changing circumstances. However, concern exists regarding the relative merit given to environmental considerations against social and economic concerns. While this issue will be examined in the subsequent report, it is appropriate to note that eleven applicants were denied increased assignment in 1996. However, none of these were among the six which were refused assignment by the Local Board. This discrepancy suggests that economic and social considerations are given relatively more importance in cane assignment than environmental aspects. It can also imply a lack of credibility and the high level of uncertainty, indeterminacy and ignorance in the technical aspects of resource management (Table 2).

This situation could suggest that the efforts of the technical review committee were ill-spent. On a more positive and cooperative note, the list of conditions recommended for the 1996 assignments by the *ad hoc* technical review committee was accepted by the Local Boards. Some members of the *ad hoc* technical committee were generally satisfied with the process, while others expressed some level of frustration. It is desirable and feasible to improve the process within the existing administrative framework.

It is suggested that members of the *ad hoc* technical review committee and Local Boards learn from this initial experience. A fundamental issue concerns the effective communication between the two groups. For instance, while the information provided from the *ad hoc* technical review committee identified the potential for negative impacts, perhaps their significance was not demonstrated clearly to the Local Boards. In particular, discussions should focus on: (i) how the assignment conditions effectively mitigate against significant environmental impacts and meet the

requirements of the *Sugar Industry (Assignment Grant) Guidelines*; and (ii) how final award decisions reflect an appropriate balance among environmental, social and economic factors.

Another fundamental aspect concerns enhancing the credibility of the *ad hoc* committee and providing more effective conflict resolution mechanisms. In six instances, assignment was granted against the advice of the *ad hoc* technical committee. The basis of these awards is unclear to members of the *ad hoc* committee, and fundamental conflicts between these groups remain unresolved. This situation may contribute to an escalation of conflict. Mechanisms to exchange views and resolve conflicts are absent from the existing process. The Local Board is not required to explain discrepancies between itself and the *ad hoc* technical committee.

Available conflict resolution mechanisms are channelled through the QSC in the form of: (i) administrative 'pressure' applied by the QSC; or (ii) a formal appeal by the Sugar Industry Tribunal. These approaches are inconsistent with the principle of partnership. Alternative dispute resolution and locally based administrative mechanisms should be incorporated into the *Sugar Industry (Assignment Grant) Guidelines*, or legislative changes to the *Sugar Industry Act*. If these locally based mechanisms fail, decisions can be made through existing mechanisms - the QSC and Sugar Industry Tribunal.

If the current situation is not addressed, these conflicts could prompt the need for more radical changes to the membership, responsibilities and powers of Local Boards, and their relationship with advisory bodies.

Recommendation: That the *ad hoc* technical committee and Local Board members review how to improve the present referral process. Locally based conflict resolution mechanisms should be established and applied before the formal involvement of the QSC or Sugar Industry Tribunal. These should be codified in the *Sugar Industry Act* and/or *Sugar Industry (Assignment Grant) Guidelines*.

> **Action required by:** QSC, CANEGROWERS, Local Board and *ad hoc* Technical Review Committee members.

6.1.2 The When: Better Late than Never ?

Prior to the formation of the *ad hoc* technical review committee, there were few opportunities for views outside of the sugar industry to be expressed. That committee's formation provides only modest opportunities to significantly influence decision making. This problem reflects two issues: (i) higher levels of decision making occur in the absence of meaningful stakeholder involvement; and (ii) as a result, environmental issues are considered only when assignment allocations are considered. In the context of the sugar cane assignment process (Table 3), there are limited opportunities for 'the environment' to be considered in Stages 1 and 2. Environmental factors are incorporated at Stage 3 through either the influence of state and local agencies, or the *ad hoc* technical review committee. This situation limits the influence of environmental interests over the cane assignment process.

At present, Stages 1 and 2 of the assignment process favour economic and corporate goals (Table 3). Once these goals are established, they tend to 'drive' the cane assignment process (Table 3). The outcome of this decision-making structure relegates the 'environment' to an accommodative or reactive position relative to these primarily economic considerations. Social issues such as the viability of the family farm and the impact of road developments on municipal operations are not systematically considered at any stage of the assignment process. In providing for balance management, it is appropriate to consider why, when and how this principle is achieved.

The sugar industry's recent experience with 'the environment' suggests that a 'crisis' (*e.g.*, Mahogany Glider), or an 'opportunity' (*e.g.*, SIIP) provide a need for intermittent interaction among a broad range of participants. Unfortunately, destructive conflict is often associated with a 'crisis' and frustrates balanced decision making. Funding opportunities often require the quick submission of a proposal which precludes raising a wide range of issues. In the Herbert River SIIP discussion, participants were essentially presented with a 1984 engineering study as the only feasible proposal which could feasibly meet Commonwealth and State Government submission dates. In both 'crisis' and 'opportunistic' circumstances, discussions essentially focus on addressing "what will be done". In these decision-making environments, it is difficult to raise issues which consider "what should or could be done".

In resource management, three levels of questions can be asked: (i) what should be done (normative planning); (ii) what could be done (strategic planning); and (iii) what will be done (operational planning) (Smith, 1993). The structure and practice of environmental management within the sugar industry suggests that 'environmentalists' who have limited input into assignment decisions will ask normative and/or strategic planning questions (Stage 1 and 2), while the industry is asking operational ones (Stage 3). This incongruity can lead to frustration and conflict. The *ad hoc* technical review committee provides little assistance in raising the level of debate because it is essentially concerned with operational rather than strategic issues. Social impacts are overlooked in the existing process. There is no representation from the Social Impact Assessment Unit (Queensland Department of Family Services) or shire on the ad hoc technical committee which could assist in this aspect of a balanced review.

The "Continuous Crushing Agreement" is the key strategic planning document which guides cane expansion in the Herbert River District. At present, it essentially matches projected increases in crushing and transport capacity to production capacity. When a conflict concerning assignment has occurred, "environmentalists" have sometimes questioned why the assignment was granted in the first place (i.e., strategic question). In contrast, the 'sugar cane industry' has asked how what mitigative measures might protect environmental values (i.e. operational question). This difference illustrates the difficulties in embracing environmental values late in planning processes. Once economic goals (*e.g.*, mill capacities) are established, it becomes difficult to raise other legitimate issues and perceive to be 'constructive'. In addition, these discussions are intermittent, rather than ongoing. If decisions are to be more balanced, there is a need for the cane allocation process to effectively consider the 'environment' as well as social aspects earlier in the decision-making process, and on an ongoing basis.

This situation could be addressed to some extent by broadening the foundation of the "Continuous Crushing Agreement". For instance, medium-term expansions could better incorporate environmental and social issues which identify both constraints and opportunities for growth. The recent establishment of the Herbert Resource Information Centre should facilitate this type of planning. In addition, through the CANEGROWERS, shire and the Queensland Department of Family Services, social issues related to the role of the family farm, as well as economic and environmental considerations could guide medium term expansions. This mix of issues could be incorporated into mill expansion and transport planning activities. In this manner, the Local Boards can better consider and communicate to potential applicants the relative weight that both the industry and existing cane growers give to specific decision criteria. In this manner, it could make an explicit statement that ensuring the viability of family farms would be given preference, or that future expansion would favour specific locations. At a corporate level, CSR could ensure that its corporate strategy embraces 'green' values. The

common element in these initiatives is to introduce environmental and social issues earlier in the cane assignment process.

Participation in the "Continuous Crushing Agreement" could be broadened to incorporate the views of relevant government agencies, local government, and the public. The desirability and effective management of cane expansion could be considered from economic, environmental and social perspectives. In this manner, the sugar industry would enhance the development of a balanced perspective in Stage 2 (Table 3), and ideally reduce current levels of frustration, time, and resources required to resolve conflicts.

Recommendation: Providing for the earlier consideration of environmental and social factors in the cane assignment process through existing mechanisms such as "Continuous Crushing Agreements" and corporate policies.

> **Action required by:** QSC, Local Boards, Local Mills, CANEGROWERS, Corporate Interests.

Related activities will be considered in the adoption of ecosystem and partnership approaches.

6.1.3 Altering the Timing of the Proces s

Decision making processes should not unintentionally provide for negative outcomes. Announcing final assignment decisions in the summer months as was done in 1995 (Table 3) can have such an effect. For many growers in the Herbert River District, land clearing is perceived to be most convenient, easiest, and cheapest in February - March while the harvest is three months away and the ground is moist. This period also provides sufficient time to plant a crop and harvest it in the next season.

Between 1993-1996, specific announcement dates have varied. They have primarily reflected administrative requirements rather than an applicant's needs and environmental conditions. This timing, when combined with a farmer's potential need to make payments on loans and a perception that Local Boards favour applicants who can provide cane to the mill quickly, often promotes land clearing and planting before the announcement of assignment grants (*i.e.*, pre-emptive clearing). This perception is created, in part, by the application form which asks the area of land which is cleared, uncleared, partially cleared and under cane.

The review of applications for the 1993-1996 period suggests that many applicants have substantial areas of partially cleared or cleared land (50%+), and some applicants (10%-15%) have some cane planted at the time of application. Pre-emptive clearing can negate or reduce the applicability of subsequent conditions placed on an approved assignment. If the application were refused, it places a farmer in more financial difficulty.

One adjustment would be to impose penalties for the pre-emptive clearing of land through the assignment system. However, this approach alone would not respond to the needs of applicants. The high level of enforcement required is beyond the capacities of existing public agencies to staff and would be contrary to the partnership principle (Table 1). A more consistent approach to reduce pre-emptive clearing is by announcing assignment decisions when farmers are most likely to undertake these activities.

It was noted earlier that 1997 applications are due 30 June 1996, and assignment awards will be announced in September 1996. While this adjustment could assist in reducing pre-emptive clearing, it is unclear how effective it will be in the Herbert River District. The majority of local

interview respondents specified that announcements should be made in the February period. Since soil moisture, precipitation patterns and farmer practices vary throughout the state, the most effective approach may require application and announcement dates to be based on a regional or mill basis. This represents a shift from the present practice which applies the same administrative timing across the state. Its feasibility should be considered in the context of essential administrative requirements.

Recommendation: Reducing the perceived need for pre-emptive clearing by adjusting the timing of the assignment process. In the Herbert River District, this would see the announcement of assignment awards in the February.

Action required by: QSC.

6.2 Enhancing Ecosystem Management

Ecosystem management pays particular attention to linkages among biophysical processes and how human activities affect them. One precept of environmental planning is to prevent problems rather than react to them. Conditions of assignment should address this goal by preventing and mitigating against the negative impacts associated with land clearing and subsequent farming activities (Table 4). The cane assignment process should ensure that: (i) proposed expansions do not significantly degrade the existing environment, and that; (ii) successful applicants do not cause off-site problems by interfering with the drainage of other properties, and degrade the natural environment. To achieve these ends, the assignment process should consider a broad range of environmental issues and mitigative measures.

The development of more conditions reflects, in large part, the participation of QDPI and QDEH in the assignment process since 1994, and the response of the Local Boards to demonstrate a recognisable duty of care. While these intentions are well founded, its effective delivery is difficult as illustrated by the management of drainage issues in the lower Herbert River.

6.2.1 Responding to Drainage Problems of the 1970s

The *Hinchinbrook Rural Drainage Study* (1984) has been consistently referred to in conditions of assignment granted between 1993 and 1996 (Table 4). That study's objectives were "to achieve a consistent standard of drainage which would increase rural production and to define required works, their location, cost and benefits to be achieved from the works, and subsequent management and operation leaving only detailed design and documentation necessary to implementation" (Cameron McNamara, 1984, 1-1). These ends were achieved by classifying the lower catchment according to the perceived need, scale and feasibility of structural drainage works. This categorisation, based on site inspections, interviews with relevant private and public resource managers, questionnaire responses from growers, public meetings and 1981 cane productivity data, was used to screen potential areas. Of the three categories established, only two were subjected to detailed drainage design and subsequent benefit-cost and environmental impact analysis, and review of institutional alternatives. The report provided economic analysis on 9 structural alternatives and recommended that a drainage board be formed under the *Water Resources Act*. Since these areas contain parts of catchments, it is unclear how adequately this delineation promotes effective drainage or catchment management. The use of the catchment has been a longstanding principle in water management.

At present, these recommendations form the basis of the more detailed drainage design and institutional analysis being conducted through the Sugar Infrastructure Improvement Package (SIIP). Initiated in 1992, this Commonwealth-State agreement is to enhance the sugar industry's performance. If sufficient landowner support is achieved within the lower Herbert River catchment, the desirability and feasibility of these proposed works and the formation of a unified drainage board can be considered.

Recommendation: Carefully reviewing the proposed Sugar Industry Infrastructure Package (SIIP) projects to ensure that future management options are not unduly constrained.

Action required by: SIIP Board, QDNR, Drainage Boards, HRCCC.

6.2.2 Responding to Drainage Problems of the 1980s and A voiding More in the Future
Much of the land assigned between 1993 and 1996 was not considered for detailed study in 1984 *Hinchinbrook Rural Drainage Study*. Since then, there has been no systematic assessment of the current needs and structural and non-structural drainage alternatives in the lower Herbert River catchment. While property management plans can use 'rule-of-thumb' guidelines to consider individual farm drainage problems, there is no effective plan which considers the cumulative impact of these individual land use changes. In addition, many applicants are only providing sketch maps of their planting intentions, and do not seek professional assistance. This is often not a problem. However, some areas will require drainage works which do not connect to water courses (and do not require a permit). Some successful applicants, such as those in the Pomona and Wharps land holding areas, will require drainage permits under the *Water Resources Act 1989*. Downstream landowners may be concerned that these works could significantly increase inundation of their properties. Increased drainage conflicts among landowners could occur without effective management processes. If drainage permits were denied, farmers would be unable or have some difficulty in recouping financial returns from their full assignment. This situation could promote the use of inappropriate agricultural practices to increase productivity.

If recent rainfall patterns which have been generally below average are maintained, this will not be a pressing issue. However, if precipitation patterns return to more typical distributions and amounts, landowners experiencing acute drainage problems could lobby for the extension of cost-sharing (*e.g.*, SIIP) initiatives to solve their problems. An alternative view suggests that effective cane land assignment should have precluded cane growing in these areas. Effective planning could avoid these difficulties.

Current Commonwealth Government activities (e.g., Coastal Management plans, Conservation plans) will not address the geographic area relevant to the Herbert River sugar industry. In addition, the shire plan will most likely provide more support to the protection of these coastal areas relative to riverine issues. The outcome and impact of the draft plan written by the HRCCC are unclear at present. However, it is primarily focused on operational rather than normative issues.

A proactive resource management document, which considers among other things the desirability and feasibility of cane land expansion, is required. The concept of the 'nested' ecosystem approach could be applied so that needs of the sugar industry at regional and other geographic scales are addressed, and a link between riverine and coastal resources made. This information could be incorporated into the "Continuous Crushing Agreement" and provide for more proactive resource management.

Recommendation: Immediately undertaking a catchment management plan for the entire lower Herbert River area. In evaluating alternatives, it should consider environmental, social and economic impacts on surface, ground, coastal and related land-based resources. It should consider both structural and non-structural alternatives and incorporate, wherever possible, natural channel design and restoration techniques. It should also examine the establishment of a drainage board for the entire lower catchment.

Action required by: CSR and Local Mills, Hinchinbrook Shire, QDNR, CANEGROWERS, Drainage Boards, HRCCC.

6.3 Enhancing Partnerships

There are many resource managers who are influenced by sugar cane assignment decisions. It is appropriate that their legitimate interests are considered so effective tradeoffs can be made and information shared.

6.3.1 Membership of the Local Board

Environmental issues are addressed through the *ad hoc* technical review committee. Mill and grower issues are effectively considered through existing mechanisms. However, an important level of government is essentially excluded from the process. Local rates should reflect land converted from other uses to cane growing. Expansion into new areas will often require road construction, which will eventually be maintained by local ratepayers. Roads and rail lines will affect drainage. All these items are of significance to the Hinchinbrook Shire. At present, no formal mechanism provide it with information concerning the list of applicants or final decisions.

As noted earlier, River Improvement Trusts can have notices placed on a land title when subdivision plans are approved. In the case of the Herbert River Improvement Trust, the shire is the only participating municipality. Given the concern over the maintenance of riparian corridors and the past legacy of individual and unapproved drainage works, it is appropriate to consider similar mechanisms for the assignment process. The impact on local rates would be negligible. Possible cross-sanctions with the *Water Resources Act 1989* and the *Transport Planning and Coordination Act 1994* could also be provided. The consideration of social and economic aspects could be broadened and deepened through the Shire's participation. More timely notices concerning rate changes can be provided.

Recommendation: Better informing the Shire of the assignment process and its outcomes. This should be done through the appointment of a shire representative to the Local Boards who shall have voting rights on expansion decisions.

Action required by: QSC, CANEGROWERS, Local Mills, Shire.

6.4 Enhancing Flexibility

While the list of conditions is a visible response, the effectiveness of its implementation will be unclear without effective monitoring. At present, enforcement is to be achieved primarily through the voluntary reporting of potential violations by individuals. This approach will be most effective for drainage and the maintenance of wildlife corridors which can affect adjacent landowners and are evident. However, failure to comply with elevation-based or soil-type based conditions is more difficult to detect. The recent introduction of the conditions makes it untimely to consider their effective implementation. However, this question must be addressed in the future.

Recommendation: Undertaking an audit within the next three years, which examines the compliance and enforcement of conditions of assignment. Effective and regular monitoring should be incorporated as a QSC responsibility required under the *Sugar Industry Act*.

Action required by: QSC, CANEGROWERS, mills, Local Boards.

6.5 Embracing New Principles: Shifting the Burden of Responsibility

It was noted earlier that applying the precautionary principle had more to do with shifting the burden of responsibility onto the proponents rather than stopping all forms of resource development. One element of the precautionary principle would support the previous recommendation to improve monitoring. However, more could be done to support the application of the precautionary principle through transferring more responsibility to proponents.

In the context of acid sulphate soils, government agencies have provided mapping at a scale of 1:100,000. However, more detailed field studies are required to determine the presence and nature of specific on-farm problems. Present circumstances provide little direction regarding appropriate actions to be taken by applicants in response to this problem. However, it is reactive rather than proactive, and does not place primary responsibility clearly on the applicant.

Recommendation: Developing mechanisms, which place more responsibility on applicants and the industry for determining the nature and extent of acid sulphate soils before the review of an individual application.

> **Action required by:** CANEGROWERS, mills, and BSES to determine: (i) need for industry sponsored surveys which further the existing information base; and (ii) the need for and basis of cost-sharing arrangements which support appropriate soil tests during the application process. Relevant government agencies (*e.g.*, QDPI, QDoE, QDNR) and research organisations (*e.g.,* CSIRO) should participate in these discussions. This could be an important research frontier.

At present, many applications ranging in size from less than 1 ha to over 1,700 ha are made with little consideration of environmental issues. Without an effective water management plan for the entire lower catchment, a screening mechanism should be developed which requires the submission of a detailed property management plan which addresses drainage and environmental considerations. This screen would identify those applicants who would be affected by this additional requirement, and could be based on such factors as location (*e.g.*, relative to specified habitats, soil types, water courses), area of existing assignment and/or area of assignment applied for.

Recommendation: Developing and applying an environmental impact screening mechanism that identifies applicants who must more adequately consider environmental and farm management issues with the submission of their application.

6.6 Concluding Comments: Dealing with the Legacies of the Past

The management of natural and economic resources represents one of the most intractable issues confronting public and private managers. Catchment boundaries and bioregions rarely coincide with the administrative boundaries of government agencies and mill areas. Many political units claim jurisdiction over particular aspects of a resource, and landowners claim rights of use. If

these multiple interests are to be accommodated effectively, it is important to legitimise a common set of principles in a clear manner. What appears to have been lacking in the past and to a lesser extent at the present, is demonstrable leadership regarding the management of both the sugar industry and the natural resources which support it.

The Queensland Sugar Corporation must accept full responsibility to ensure that all aspects of the *Sugar Industry Act 1994* are met. If the technological and administrative changes in the Herbert River District typify the activities of the other 23 mill areas, this will be a challenging task. It has provided for some positive action through its 1994-1995 review of bulk sugar terminal activities to ensure compliance with new Queensland legislation (QSC, 1995), and administering the environmental requirements of the cane assignment regulations.

However, while it has a specific set of legislative objectives and developed assignment regulations, a clear vision of its commitment to sustainable resource management is lacking. This vision could enhance the credibility and legitimacy of ecologically sustainable development. Once established, senior executives should mention these principles in speeches and annual reports. Since the QSC reports to the Minister of Primary Industry, it is appropriate that it embraces the ESD principles outlined in the 1992 *Intergovernmental Agreement on the Environment.*

The industry must take a leadership role if the difficult issues confronting the effective implementation of conditions of assignment are to be addressed effectively. Present conditions of assignment suggest that failure to comply with restrictions may see the award revoked. This places responsibility for enforcement on the Local Board and QSC. These are new roles for these organisations. Leadership at the QSC, CANEGROWERS and mills can establish an expectation that compliance is expected by all farmers. In this manner, farmers who operate without conditions on their assignment should address relevant considerations as though they were in place.

This type of widely based, voluntary action could engender very strong public support. In its absence, public support will be nurtured through compliance and enforcement data. The recommended audit should provide insight into both voluntary compliance and enforcement measures. Those findings will reflect on the leadership qualities of the sugar industry, and identify the need for evolutionary and revolutionary change in its management of natural resources.

Political leadership is also required. The recent change of government at State and Commonwealth levels has provided for some uncertainty regarding their commitment to ESD principles. Needed is strong and sustained political commitment. Such leadership may be provided through 'external' pressures such as the 1992 Earth Summit. It may also be generated from locally based initiatives such as ICM. A return to a tradition of not enforcing the legal requirements of the *Water Resources Act* and other statutes would be most unfortunate, and represent the unfair treatment of citizens.

Recommendation: Senior government, Queensland Sugar Corporation, corporate, CANEGROWERS, and non-governmental officials provide leadership in the formulation and application of ecologically sustainable development.

Many recommendations made in this report encourage and require an organisational culture, in both government and industry, where cooperation and collaboration can occur. However, another essential ingredient is required. Leaders from all relevant participating agencies - senior politicians and officials from government, corporate, and non-governmental sectors - must send

out signals that cooperation and collaboration are wanted and expected. Without this commitment, the most sophisticated arrangements to promote evolutionary change and improvement will fail. This leadership is also required to assist in forming effective community partnerships which overcome the legacy of remote and ineffective resource management by both industry and state government agencies. Without leadership, there is a danger that rather than providing for substantive and constructive change, ecologically sustainable development will be a thin coat of green paint masking the resource development practices of the past.

If the cane assignment system is to provide effective management in the years ahead, adjustments have to be made. It is hoped this report will contribute to that end.

Executive Summary

In 1994, CSIRO received funding from the Land and Water Resources Research and Development Corporation (LWRRDC) to examine the implementation of Integrated Catchment Management (ICM) in the Herbert River catchment of north Queensland, Australia. Support for related work was also provided by the CRC for Sustainable Sugar Production. A common component of these research initiatives focused attention on the institutional aspects of resource management in the sugar industry. In that regard, this report examines the sugarcane assignment process in the Herbert River district during the period 1993-1996.

Data and Information Review (Chapters 1-4)

Since the early 1990s, significant expansion in both growing area and milling capacity has occurred in the Australian sugar industry. In 1998 over 507,000 hectares of land were used for cane growing in Queensland. Despite the significant economic benefits of sugar production, there is a growing unease about sugarcane development because it is perceived to be a major cause of ecological impact. These impacts include erosion and sedimentation, loss of riparian vegetation, damage to coastal wetlands, and diffuse sources of nutrient pollution and heavy metals. Legislatively stipulated growth of new cane lands has fragmented the landscape and encouraged, in many cases, the use of marginal lands.

Changing circumstances have transformed the cane assignment process from what was once generally perceived as a 'routine' process with a 'predictable' outcome, to one characterised by conflict, uncertainty and complexity. The ability of stakeholders involved in cane expansion to effectively deal with 'environmental issues' remains problematic. All levels of Australian government have endorsed the principles of Ecologically Sustainable Development (ESD). Sugar producers have produced similar documents (*e.g.* CANEGROWERS' *Caring for the Environment* Statement) and support the use of Codes of Practice. There appears to be recognition of the problem and the need for solutions by all participants. However translating these documents into action has proven difficult and the industry's ability to effectively guide recent and future cane farm expansion impacts is unclear.

The purpose of our research was to evaluate the sugarcane assignment process in the Herbert River district from 1993-1996 in terms of its compliance with the principles of ESD. This required an explicit set of criteria against which judgments about performance could be made. While the definition of ESD has been popularised, it's meaning and measurement have been elusive. ESD principles advocated by the 1992 *Intergovernmental Agreement on the Environment* and the CANEGROWERS *Caring for the Environment* (1995) share five resource management principles: balance, ecosystem, partnerships, flexibility and the precautionary principle. These principles were the benchmarks used to evaluate the assignment process in the Herbert River district.

Assessing the Sugarcane Assignment Process in the Herbert River District (Chapter 5)

During the study period, 525 applications for assignment, covering an approximate area of 16,000 ha, were submitted to the Victoria and Macknade Local Boards for approval. It was feasible to link information from complete application forms with a companion spatial database for 472 applications (89.9%) of the total application pool. These applications encompassed an area of 15,013ha or about 94% of the total 15,994ha area applied for. During the study period, 472 applications were spatially represented and comprised an area of 15,013ha. From this total, 355 (75%) applicants were awarded their entire request, 92 (20%) were awarded less than their request, and 22 (5%) were denied. Of the 15,013ha applied for, 12,165ha were awarded, representing an 81% approval rate. 1,962ha were not awarded on the basis of an applicant being granted less than 100% of their request. In addition, 887ha were denied an award. All applications that were denied occurred in 1996 and represented an area of 2,736ha. Since the 1996 application pool contains applications that were denied, the analysis pays particular attention to it. These results are analysed in terms of each of the five resource management principles described previously.

Over 70% (8,655ha) of the awards granted during the study period occurred on land that both the Local Board and Environmental Advisory Committee (EAC) were deemed suitable by both bodies. About 7% (741ha) of the land was granted on land that both groups perceived as unsuitable. Of concern is the 2,768ha of development that occurred in the area of disagreement. This represented about 20% of

development during the entire study period. More importantly, in 1996, over 1,400ha of the total assignment of 3,601.5ha (38.8%) were located in this region. In the absence of an open and transparent decision-making process and effective conflict resolution mechanisms, cane expansion in these areas may alarm government officials (and interested members of the public) who are concerned with drainage and habitat issues. It is these considerations that the Local Boards and EAC disagree on.

These data and development patterns raise concerns about how effectively the sugarcane assignment process supports the principles of ESD. Changes to existing institutional arrangements are required if ESD is to be achieved. A set of recommendations is made on the basis of findings from this study in the Herbert River district. Their applicability on a statewide basis should be considered carefully. It is believed that more effective decision making can be achieved by enhancing the consistency among the five management principles - a balanced perspective, ecosystem management, developing partnerships and allowing for flexibility, the precautionary principle - and current decision-making processes. In this context, the following recommendations are made:

Enhancing Ecosystem Management
Recommendation: Legislative and voluntary initiatives be undertaken to reduce the clearing of valued habitats. Reduce the perceived need for pre-emptive clearing by adjusting the timing of the assignment process. In the Herbert River district, this would see the announcement of assignment awards in the February. Require applicants to obtain clearing permits from QDNR prior to receiving assignment on freehold land or leasehold land.

Action required by: Local Boards (Cane Protection Boards), QDNR and Shire.

Enhancing the Principle of Balanced Decision Making
Recommendation: Provide for the earlier consideration of environmental and social factors in the cane assignment process through existing mechanisms such as "Continuous Crushing Agreements" and corporate policies.

Action required by: Local Boards (Cane Production Boards), CANEGROWERS, and CSR.

Enhancing the Partnership Principle
Recommendation: That the Environmental Advisory Committee and Local Boards members improve the present referral process. Industry wide, basic legislative amendments should support more effective communication between Environmental Advisory Committees and Local Boards. These should be codified in sugar industry legislation.

Action required by: Minister for Primary Industries, CANEGROWERS, Local Boards (Cane Production Boards) and Environmental Advisory Committee.

Recommendation: Better incorporate the Shire and other relevant participants into the assignment process. This could be accomplished through an effective referral process, observer status on Local Boards, full voting rights on Local Boards, or other appropriate mechanisms.

Action required by: Minister for Primary Industries, Local Boards (Cane Production Boards), CANEGROWERS, CSR and Shire.

From Flexibility to Adaptability
Recommendation: Immediately undertake discussions among all relevant parties that will develop an effective environmental monitoring network within the next two years. Within the next three years, conduct an environmental impact audit to examine the compliance, enforcement and effectiveness of Conditions of Assignment. Within the next five years, complete an environmental management audit. Effective and regular environmental monitoring should be required under the sugar industry legislation.

Action required by: CANEGROWERS, Mills, Local Boards (Cane Production Boards), QDNR, QDPI, QEPA, Shire, BSES, CSIRO and other research organisations.

Enhancing the Precautionary Principle
Recommendation: Develop mechanisms that place more responsibility on applicants and the industry for determining the nature and extent of acid sulphate soils before the review of an individual application.

Action required by: CANEGROWERS, mills, and BSES to determine: (i) need for industry sponsored surveys which further the existing information base; and (ii) the need for and basis of cost-sharing arrangements which support appropriate soil tests during the application process.

Relevant government agencies (*e.g.* QDPI, QEPA, QDNR) and research organisations (*e.g.* CSIRO) should participate in these discussions. This could be an important research frontier.

Recommendation: Develop and apply an environmental impact screening mechanisms that identify applicants who must more carefully consider environmental and farm management issues with the submission of their assignment application.

Action required by: Local Boards (Cane Production Boards), relevant government agencies, CANEGROWERS.

Recognising Legacies of the Past and Dealing with the Future

This report outlines some of the issues related to the cane assignment process and environmental management. Effective responses to the changes, uncertainties, complexities and conflicts that will continue to be part of the sugar industry's future lie in innovative administrative mechanisms, planning initiatives, and scientific research. Thus, there are conceptual and practical shortcomings in present responses that suggest the need for changes to the sugar assignment process. While the industry is currently in a phase of reduced expansions, it needs to be adequately prepared for future expansions when economic conditions become more favourable. We argue that ESD in the sugar industry requires a better integration of economic, social and environmental considerations. Hence, this report outlines a number of responses that the sugar industry may wish to consider in future planning.

The industry must take a leadership role if the importance placed on the environment and sustainability is to be realised. Present Conditions of Assignment suggest that failure to comply with restrictions may see the award revoked. This places increased responsibility for enforcement on the Local Board (Cane Production Board). These are new roles for these organisations. Leadership by the Local Board (Cane Production Board), CANEGROWERS and mills can establish an expectation that compliance is expected and required by all farmers. This type of widely based, voluntary action could engender very strong public support. In its absence, public support will be nurtured through compliance and enforcement. The recommended audit should provide insight into both voluntary compliance and enforcement measures. Those findings will reflect on the leadership qualities of the sugar industry, and identify the need for evolutionary and revolutionary change in its management of natural resources.

The policy environment for ESD in the context of the sugar industry will continue to respond to changing political, economic, social and environmental considerations. While the manner in which resources are managed will vary, public expectations for, and support of, effective environmental management policies will remain. In this regard, the principles for ESD will form the basis for the development of new and improved initiatives. The efficient and equitable allocation of new land for cane production must be central in these. The challenge for the sugar industry is to embrace, rather than resist, the inevitable trend toward greater public intervention in its affairs. In response, government must provide a stable environment in which locally relevant decision-making can occur and in which appropriate and viable monitoring, cost-sharing and regulatory arrangements can be supported. The Australian sugar industry must continue to develop its own capacity to plan for expansion (and contraction). Such planning must be a continuous activity rather than a single exercise. Further, the industry must develop its own strategic view on where and how sugarcane will be grown – both at regional and whole of industry levels. This view will need to be based on the best available scientific information and full utilisation of the products of its substantial investment in environmental R&D.

Many recommendations made in this report encourage and require strong leadership. Without a visible commitment to ESD, the most sophisticated institutional innovations that promote positive change will fail. Without leadership, ESD will be relegated to a thin coat of green paint masking the resource development practices of the past.

1 ECOLOGICALLY SUSTAINABLE DEVELOPMENT AND THE AUSTRALIAN SUGARCANE GROWING INDUSTRY

1.1 Environment and Economy - Integrative or Conflicting Forces?

Many people believe that the 'environment' is and will increasingly be an important issue in the 21st century. In this regard, the idea of sustainable development has attracted considerable interest since the Brundtland Commission (also known as the World Commission on Environment and Development (WCED)) identified it in 1987 as the driving force behind its 'global agenda for change' entitled *Our Common Future.* The concept was defined as development that "meets the needs of the present without compromising the ability of future generations to meet their own needs" (WCED, 1987: 43). A fundamental aspect of sustainable development is the belief that economic and ecological concerns must be seen as interdependent systems rather than opposing forces. In the words of the Brundtland Commission, "economy is not just about the production of wealth, and ecology is not just about the protection of nature; they are both equally relevant for improving the lot of humankind" (WCED, 1987: 38). Although the concept of integrating economic and environmental considerations into decision making appears attractive, the WCED believed that it would be difficult to achieve because it required government leaders, the private sector and people to adopt a very different mindset. Part of the needed adjustment focused on the institutional arrangements for resource management.

The following statements from *Our Common Future* illustrate some of the challenges to and requirements of future 'sustainable' institutional arrangements:

- Effectively implementing sustainable development would require immediate and decisive political action ... to begin managing environmental resources to ensure both sustainable human progress and human survival.
- The objective of sustainable development and the integrated nature of global environment/development challenges pose problems for institutions, national and international, that were established on the basis of narrow preoccupations and compartmentalized concerns. The challenges are both interdependent and integrated, requiring comprehensive approaches and popular participation.
- Most of the institutions facing those challenges tend to be independent, fragmented, working to relatively narrow mandates with closed decision processes. Those responsible for managing natural resources and protecting the environment are institutionally separated from those responsible for managing the economy. The real world of interlocked economic and ecological systems will not change; the policies and institutions must.
- The other great institutional flaw in coping with environment/development challenges is governments' failure to make the bodies whose policy actions degrade the environment responsible for ensuring that their policies prevent that degradation.
- The ability to anticipate and prevent environmental damage requires that ecological dimensions of policy be considered at the same time as the economic, trade, energy, agricultural and other dimensions. They should be considered on the same agendas and in the same national and international institutions.
- Making the difficult choices involved in sustainable development will depend on the widespread support and involvement of an informed public and of non-governmental organisations, the scientific community and industry.

These statements identify some of the changes required to traditional management approaches, and particularly the importance of designing effective institutional arrangements to achieve sustainable outcomes. The reality is that in some instances, achieving sustainable development will require a fundamental rethinking and readjustment of the way in which government and industry organize themselves. At other times, changes at the margins of existing institutional arrangements (*e.g.* legal, financial, economic, administrative, organisational) will suffice. However,

the demand for change comes at a time when many public resource management agencies are dealing with budget cuts and there is often a sense of retreat or retrenchment.

It could also be argued that recent and current international economic forces could further undermine governments' ability to effectively manage growth and development. For instance, globalisation has challenged all levels of governments, but particularly national governments, to meet the challenges posed from the emergence of global corporations, and the increasing influence of supranational institutions such as the General Agreement on Tariffs and Trade (GATT) and the North American Free Trade Agreement (NAFTA). Global economic forces in the 1980s have "brought the formerly distinct worlds of trade and environment into contact and, all too frequently, conflict" (Esty, 1994: 2). This "either environment or economy" view is in stark contrast to integrative perspective advocated by the concept of sustainable development. Furthermore, expanded trade, under initiatives such as the NAFTA, could result in negative environmental outcomes. These problems include pollution spillovers into developed countries from increased industrial activity in developing countries; lower environmental standards and a loss of sovereignty in developed countries as laws and regulations are "harmonised" at compromise or baseline levels; limitations on the ability of developed countries to use trade measures to support international environmental agreements; and marketplace disadvantages for facilities in developed countries that compete against plants located in "pollution havens" - resulting in job losses or downward pressure on developed countries' environmental standards (Esty, 1994: 2). Global trade could cause environmental harm by promoting economic growth that results in an unsustainable use of resources and wasteful production.

Since the 1980s, globalisation and ecologically sustainable development (ESD) are two paradigms that have changed the manner in which humans interact with each other and with their environment. In the context of agriculture in developed countries, the WCED (1987) maintained that:

- Production in industrialised countries has been highly subsidised...[and] has encouraged the overuse of soil and chemicals, the pollution of both water resources and foods with these chemicals, and the degradation of the countryside.
- The financial and economic burden of subsidies must be reduced.
- In general, patterns of government intervention [in agriculture] suffer three basic defects. First, the criteria that underlie the planning of these interventions lack an ecological orientation and are often dominated by short-term considerations. The second defect is that agricultural policy tends to operate within a national framework with uniform process and subsidies, standardised criteria for the provision of support services, indiscriminate financing of infrastructure investments, and so forth. The third defect...lies in incentive structures. In industrialised countries, overprotection of farmers and overproduction represent the accumulated result of tax relief, direct subsidies, and price controls.

According to McMicheal (1994), the recent globalisation of agriculture is characterised by the creation of national regulatory bodies that exercise less regulatory control, agricultural liberalisation, increasing specialisation in food production, the development of niche markets for both fresh and produce foods, and an increase in contract farming.

The dilemma confronting the reform of existing institutional arrangements comes from changes at both conceptual and practical levels. On the one hand, sustainable development suggests institutional arrangements must consider environment, economy and society as interdependent systems. However, the conditions that have guided resource management have changed and are still changing due to domestic and global forces, and their financial support has been often eroded. In short, within this changing social and economic system, the role and capacity of public agencies to effectively guide development are often perceived to be uncertain at best and ineffective at worst.

People expect the environment to sustain life, support community and economic activities, and look beautiful. Balancing these expectations and meeting people's needs are a challenge at the best of times. The natural environment is critical to agriculture's economic and social success. Multinational corporations as well as farm families are dependent on the environment to support their well being. Although the economic benefits of agricultural development are clear, the stresses that are placed on the environment are often subtle and not immediately evident. However, they can be profound. These impacts include land degradation (*e.g.* clearing overstocking, cropping on marginal land, irrigation and exotic species) and water issues (*e.g.* scarcity, quality and nutrient loads, waste water disposal, rising groundwater and associated salinisation, and pollution of coastal waters) (Commonwealth, 1996).

These comments suggest the complexity of dealing with many environmental issues. According to Dovers (1997), it is important to distinguish between systemic and non-systemic sustainability problems. Systemic problems are characterised by causes that are deep within modern society. Effective responses to these problems have serious implications for modern society, such as energy use, settlement and transport structure, agricultural practices, resource consumption and lifestyle. Global examples include climate change, biodiversity loss and poverty. In contrast, non-systemic sustainability problems are discrete and smaller. They may be solved by adjustments at the margins of individual or social behaviour. These problems are illustrated by the more routine tasks of management such as the issuing of a permit, integrated catchment management, or fisheries management (Dovers, 1997). The focus of this document embraces both of these problems. Sugar is an internationally traded commodity that is dominated by large corporations. Expansion of the area of sugarcane land in Queensland has been traditionally viewed as a 'routine' activity that required a permit. However, changing circumstances, that will be described later, have transformed what was once generally perceived as a 'routine' process with 'predictable' and 'negligible' outcomes and impacts, to one fraught with conflict, uncertainty and complexity. An issue arising from this situation is to identify the changes required in the present institutional arrangements that would provide for more sustainable outcomes.

1.1.1 The Australian Sugar Industry

The international sugar trade illustrates the tension among economic, social and environmental concerns. Sugar is a global commodity. National governments and multinational corporations have participated in sugar growing and trade for centuries. In Australia, the sugar industry is one of its largest rural industries, producing in 1996/1997 approximately 5.3 million tons of raw sugar, worth in excess of $2 billion to the Australian economy. The institutional arrangements for the Australian sugar industry have changed significantly, in part, due to global forces. In 1991, the *Sugar Industry Act* repealed and replaced what had been previously a fragmented array of statutes that pertained to the sugar industry. One significant feature of the *Act* was its requirement for an annual expansion of 2.5% (approx. 10,000ha statewide between 1991 and 1996). It also included provisions that, for the first time, required 'the environment' to be considered in these decisions. Since the 1990s, approximately 20,000 hectares per year have been converted, and in 1998 over 507,000 hectares of land were used for cane growing.

The ability of all participants involved in expansion of cane growing area to effectively deal with 'environmental issues' is unclear. The rhetoric from both the government and the sugar industry seems positive, as illustrated in the advancement of ESD principles. For instance, all levels of Australian government have endorsed the principles of sustainable development in signing an *Intergovernmental Agreement on the Environment* (1992). Sugar producers have produced similar documents and support the use of *Codes of Practice*. There appears to be recognition of the problem and the need for solutions by all participants. However, making statements is one thing, translating them into effective action is often quite another. If the rhetoric is not realised by effective actions, the environmental, economic and social consequences could be substantial at national, regional and local scales.

Sugarcane is grown along 2,100 km of coastline from Grafton in northern New South Wales to Mossman in north Queensland (Figure 1.1). Small industries have recently commenced on the Atherton Tablelands in north Queensland and the Ord River district in Western Australia. In these areas, soil and climate are favourable for sugarcane growing. However, significant portions of the eastern coast of Australia retain very high ecological, social and cultural values. Despite the economic benefits of sugar production, there is a growing unease about sugarcane development because it is perceived by some people to be a major cause of ecological impact. These impacts include erosion and sedimentation, loss of riparian vegetation, damage to coastal wetlands, and impacts of diffuse sources of nutrient pollution and heavy metals (Brodie *et al.*, 1984; Industry Commission, 1992; Bramley and Johnson, 1995; Johnson *et al.*, 1996; 1999a). The development of the legislatively stipulated growth of new cane lands has fragmented the landscape and encouraged the use of marginal lands (Johnson *et al.*, 1997; 1999b). The Sugar Industry Working Party (1990) estimated that 16,080 hectares of land, or about 5% of the land used for sugarcane crops, is farmed in marginal or unsuitable areas. In the face of increased global competition, this situation could become worse. Despite the pronouncements that both the sugar industry and Australian governments embrace ESD, their ability to effectively guide the recent, and potentially future high levels of sugarcane farm expansion and avoid/minimise negative impacts is unclear.

The institutional arrangements that are often perceived to be part of the problem, as well as a vital part of the solution, are generally poorly understood. This is particularly true for the sugar industry in Queensland. For instance, one member of a 1992 Industry Commission inquiry into the sugar industry described the industry as follows:

> For all my working life I have been engaged in the examination of agricultural policy in Australia. I have found it harder to fathom what goes on in the sugar industry than to come to grips with any other rural industry. This is partly because there has been less information available on the sugar industry than on other rural industries. Traditionally the Queensland sugar industry and Queensland Governments have not been attracted to openness in providing information...But the difficulty in coming to terms with the sugar industry is largely the policy arrangements are so complex, and that there are interactions between elements of the arrangement [not easily understood] (Edwards, 1993: 1).

Knowledge about the nature and processes that operate within the sugar industry are central in understanding both problems and solutions. This requires a focus upon institutional arrangements. These are interpreted to be the interaction among:

- legislation and regulations;
- policies and guidelines;
- administrative structures;
- economic and financial arrangements;
- political structures and processes;
- historical and traditional customs and practices; and
- key participants or actors (Mitchell, 1990).

It is important to understand changes at all these levels in order to grasp the impacts of these activities on the environment and on people. This focus on institutional arrangements is consistent with the views of the WCED (1987: 62), which maintained that implementing sustainable development would require a change in attitudes and objectives and in the institutional arrangements at every level. Without this reorientation of institutional attitudes, little progress could be achieved. The WCED (1987: 63) also believed that implementing sustainable development required:

> Community knowledge and support, which entails greater public participation in the decisions that affect the environment. This is best secured by decentralising the management of resources upon which local communities depend and giving these communities an effective say over the use of these resources.

Figure 1.1 Sugarcane producing areas in Queensland.

At first glance, the institutional arrangements that have guided the recent expansion of sugarcane in Queensland exhibit a number of these qualities. Despite the consolidation and liberalisation of the sugarcane industry on 1991, there remains significant regulatory and local control over the growing and harvest of cane. Local Boards comprised of industry (sugarcane millers) and growers are, to a significant degree, responsible for controlling the level and location of sugarcane

production, and promoting the growing and commercial harvest of sugarcane (Industry Commission, 1992). This process is known as "assignment". Although these bodies have existed since the 1920s, the *Sugar Industry Act 1991* (and the new *Sugar Industry Bill 1999*) requires them to consider both economic and environmental factors in allocating land. Thus, Local Boards and the assignment process are characterised by local participation through a mix of industry and grower representatives, and consideration of both environment and economy.

These characteristics of sustainable development operate within the context of a global sugar trade. However, there appears to be a fundamental contradiction between the growing concern about the importance of the environment, and the need for effective institutional arrangements to implement ESD in a global economy. The precise role and responsibility of the private sector in managing this growth during this period of less regulation are indeterminate.

ESD of agricultural resources raises many complex issues. There is uncertainty in economic, social and environmental conditions. These contexts can change quickly and result in the removal or appearance of obstacles to effective implementation. Some impacts are site specific, while others are more general in nature. Thus, there appears to be no simple answers or single correct solutions. An integrated set of responses to address the uncertainty, complexity, change and conflict that are associated with agricultural resources in general, and sugarcane growing specifically, is required. This report seeks to answer these questions within the context of the cane land allocation in the Queensland sugar industry in order to determine the extent to which ESD is operating at a local level, and what marginal changes are feasible to improve present performance

1. 2 Report Organisation

The second chapter in this document examines the history of the sugar trade from both global and Australian perspectives. The concept of ESD from global and Australian viewpoints is developed in the third chapter. Five principles that provide the evaluative framework are identified and described. The research methodology and the case study region are also described in Chapter 3. The fourth chapter explains the current relevant institutional arrangements for natural resource management in the State of Queensland, and for sugarcane assignment. The last chapter uses the principles of ESD to assess current performance. It also highlights the conclusions and discusses the implications of the findings for future practice and research.

2 THE SUGAR INDUSTRY – PAST AND PRESENT: GLOBAL AND AUSTRALIAN INITIATIVES AND POTENTIAL ENVIRONMENTAL IMPACTS

2.1 Introduction

This chapter outlines some important historical aspects of sugar trade and Australia's sugar industry. The second part of the chapter reviews the environmental impacts of developing cane lands and growing sugarcane. In this manner, a context to appreciate the need for and direction of current initiatives is provided.

2.2 The World Sugar Trade

For centuries, sugar has evoked "strong social, political, geographical and emotional" attachments, and has been the cause and prizes of wars (Hannah and Spence, 1996: 20). It is a sweetener and source of energy, and has been widely traded since at least the 14th century. Although it was viewed as a spice and luxury in 17th century Britain, it is now a basic part of many diets. Between 1900 and the present, world demand has grown from 8 million tons to 155 million tons. Initially obtained exclusively from sugarcane grown in the Polynesian Islands of the South

Pacific, sugar is now produced from a variety of sources (*e.g.* sugar beet and synthetic sweeteners) in over 120 countries or territories.

Table 2.1 contains some statistics for the world trade of sugar for the period 1955 to 1998. Two distinct periods can be noted from these data. The first is characterised by rapid growth in net imports between 1955 and 1980. During this period, the pattern of imports changed with developing countries increasing their share of world imports from 26% to 44% between 1975 and 1980. The second period (1980-present) has seen world trade reach a near steady state of about 23 million tons annually. However, the distribution of demand has changed. Developed countries have imported less sugar. This decline has almost been matched by an increase in imports by developing countries. These data suggest that world markets have undergone significant structural changes. Australia, as the world's largest net exporter, has a heightened interest in these trends. The significant structural factors that all sugar producers have faced include: (a) volatile changes in world trade patterns and price, (b) the introduction of substitute products, and (c) domestic trade developments.

Many countries, including Australia, are highly dependent on sugar for export revenue. In response to the high level of volatility of world sugar prices (Table 2.1), a number of multilateral and intergovernmental agreements were negotiated between 1950 and 1998 (Figure 2.1). The general intent was to "keep the world free market sugar price within stated ranges" (Hannah and Spence, 1996: 136). For instance, International Sugar Agreements (ISAs) were negotiated in 1953, 1958, 1968 and 1977. Their general objective was to provide "a reasonable price, not exceeding the cost of production, including a reasonable profit of efficient producers" (Hannah and Spence, 1996: 23). For a variety of reasons, including the impacts associated with the Cuban Revolution (1959), the dissolution of the USSR (1991) and the implementation of national policies, they generally failed to meet their price objectives.

Table 2.1 World net imports of sugar 1955-1998.

Year	Total (M t)	Developed Countries	Developing Countries	Net Imports as % of World Consumption	Price US cents/lb (1985=1.00)
1955	11.70	8.90 (76%)	2.80 (24%)	31.2	N/A
1960	16.75	12.96 (77%)	3.79 (23%)	34.7	9.18
1965	17.15	12.88 (75%)	4.27 (25%)	30.8	5.58
1970	18.40	12.94 (73%)	4.71 (27%)	25.1	9.44
1975	23.06	13.53 (74%)	4.87 (26%)	24.7	28.00
1980	23.06	12.79 (56%)	10.27 (44%)	26.1	25.00
1985	23.01	11.29 (49%)	11.64 (51%)	23.5	4.06
1990	23.14	10.33 (47%)	12.22 (53%)	21.3	8.73
1995	22.87	7.18 (31%)	15.69 (69%)	20.1	8.47
1998	22.93	4.50 (19%)	18.43 (81%)	18.6	4.81

(Sources - Hannah and Spence, 1996: Licht, 1998)

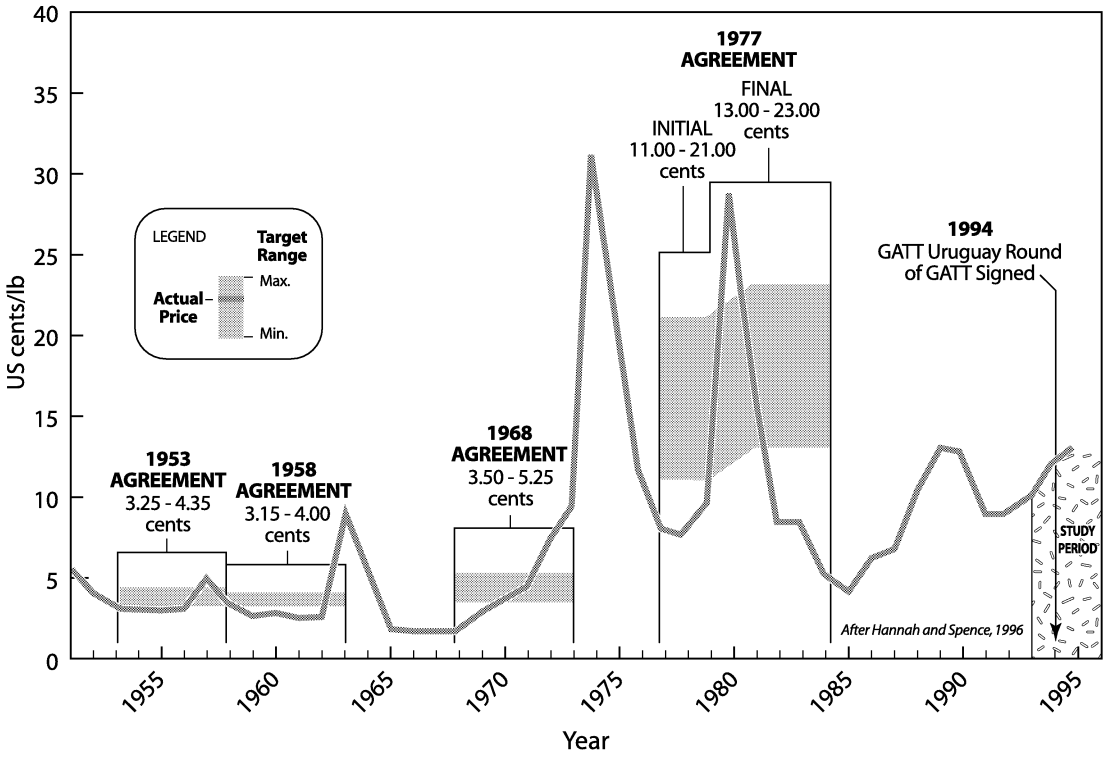

Figure 2.1 The price of sugar: target and actual from International Sugar Agreements to GATT.

Some insight concerning the complexity, volatility and difficulty in managing sugar prices through these international agreements is provided by activities between 1974 and 1989 (Figure 2.1). In 1974, the ISA price was targeted in a range between $0.035/lb and 0.0525/lb while the actual price peaked at $0.64/lb (US). The 1984 price was supposed to be between $0.13/lb and 0.23/lb, while the actual price plunged to $0.03/lb (US). The major reasons for this volatility relate to changing national policies in the United States and European Community (EC), and declining consumer demand. In response to the extremely high price of 1974, the EC established policies that: (i) increased the price support for domestically produced sugar; and (ii) increased domestic production quotas. These initiatives transformed the EC from a net importer to a major sugar exporter by 1980. In addition, the high sugar price in 1974 also led the United States and Japan to encourage the production of alternative sweeteners such as high fructose corn syrup (HFCS). Other importing countries unable to afford the world price embarked on expansion programs (Hannah and Spence, 1996). Collectively, these initiatives resulted in a major increase in sugar production. However, the demand for sugar did not keep pace, and declined in developed countries. Although demand for imports increased in developing countries, the substantial imbalance between supply and demand resulted in the precipitous decline in prices. Sugar stocks from the early 1980s were not cleared and world prices remained depressed until 1989. In the early and mid-1990s, prices rose in response to decreasing demand from Asia and decreasing volumes of world sugar stocks due to production declines in Europe and South America. However by late 1998, world sugar prices had again declined substantively as the effects of the Asian Economic Crisis, devaluation of Eastern European currencies and increased production in South America and Western Europe substantially raised sugar stocks.

Since the mid-1970s, sugar has lost a significant portion of its market share to sweeteners such as corn syrup and high fructose corn syrup (HFCS). In the 1980s, HFCS consumption grew rapidly, in part because of import barriers to sugar, and domestic programs in the United States, Europe and elsewhere for beet and sugarcane. Between 1980 and 1997, HFCS consumption in the United States grew from 14% to 40%. Part of this increase was the result of decisions made by Coca-Cola and Pepsi to use HFCS rather than sugar (CANEGROWERS, 1999). Indeed, the

focus of the competition has shifted from one tuned to sugar derived from cane versus beet, to the production of 'sweeteners' from a wide variety of natural and artificial sources. Future sugar consumption is likely to be influenced by a combination of factors including: the price of sugar and alternative sweeteners, per capita incomes, population growth, sugar availability, government policies, consumer preferences and technological advances.

Fluctuations in the demand and price of sugar also impact multinational corporations and individual farmers. CSR is Australia's largest manufacturer of raw and refined sugars and operates two refining mills in the Herbert River district, the location of the case study for this research paper. The Colonial Sugar Refining Company (CSR) was formed in 1855 to refine sugar and soon after diversified into raw sugar milling. It has been exposed to the impacts of price fluctuations. For instance, after diversifying into natural gas and oil exploration in 1977, CSR's survival was based largely on profits from its sugar and building material divisions. However, this support was undercut with the previously mentioned severe drop in sugar prices in the early 1980s. It struggled until corporate and management restructuring turned its fortunes around in 1985. While CSR was addressing its corporate problems during the late 1970s and early 1980s, many cane farmers were living below the poverty line and accused the company of mismanaging the industry in which it played a dominant role (Bright, 1998).

Since January 1985, there have been no further ISAs with economic clauses. Instead, the International Sugar Organisation (ISO) provides information, statistics and analysis and a forum for intergovernmental policy discussion. This reflects two important shifts from historical approaches. First, current economic and political beliefs suggest that the free market is best able to govern the market. Interventionist policies, such as the ISAs, are viewed as "bad". Second, there has been more price stability in the market since 1988 (Figure 2.1). During the study period, a increase in sugar prices would prompt many existing cane growers to consider expanding their holdings, and new farmers to enter the industry. This recent period of relative price stability has been assisted by the ISO which makes markets more transparent through its information providing and facilitation roles. Hence, the perceived need for ISA-type arrangements is diminished. However, the historical pattern of sugar price volatility suggests that the recent period of stability will not be an enduring one.

It is also important to appreciate the role and linkage between international and national sugar policies. At present, national policies are significant and are responsible for subsidizing about 25% of the world's sugar production. There are several forms of national policy instruments and include the following (Hannah and Spence, 1996):

1. *Border measures* that control import levels, and differentiates domestic prices from international prices.
2. *Domestic production measures* that range from guaranteed prices, production quotas, and subsidies on domestic production, inputs or credit, deficiency payments, and export subsidies.
3. *Domestic consumption measures* primarily in the form of price controls or rationing systems.

The need for domestic policies relates to the significantly higher cost of producing sugar from beet than from cane. They are also believed to be necessary to protect farmers and consumers from price volatility. Both developed and developing countries have established domestic policies to serve both international as well as national interests. During the era of International Sugar Agreements, domestic policies were also established in order that a nation's exports could meet its export target. At a national level, public policy goals such as redistributing income, reducing the economic burden on resource-based industries, preventing the de-population of rural areas and achieving self-sufficiency in food production could be pursued through sugar policies (Hannah and Spence, 1996; Johnson *et al.,* 1998).

The traditional protection afforded sugar and other industries through domestic policies has recently been viewed as unfair and inappropriate. The primary objectives of the 1994 GATT Uruguay Round on agriculture related to increasing the market access commitment of individual countries, decreasing the use of tariffs and domestic support for agriculture, and reducing the subsidies provided to exported agricultural products. Signatory countries are required to import a minimum share of 3% of their domestic market in 1995, rising to 5% by the end of 2000. Non-tariff barriers and variable import levies are to be replaced by a base rate tariff. Tariffs are to be reduced. These changes should have minimal effects on existing sugar policies. In Queensland, the tariff on raw and white sugar was removed in July 1997. The tariff had been reduced from \$115 t^{-1} in 1989 to \$55 t^{-1} immediately prior to its removal. However, the reduction of internal price support, border protection and export subsidies for sugar commodities by other nations was expected to produce a \$10 million to \$40 million annual benefit to Australia (CANEGROWERS, 1999). This promise of growth combined with the increasing price for sugar provide significant incentives for both farmers and the sugar refining industry to expand its production capabilities.

2.3 Australian Sugar Policy

Commercial sugar production in Australia commenced in the 1870s, and is now one of Australia's largest export industries (Sugar Industry Working Party, 1996) (Table 2.2). The State of Queensland accounts for around 95% of production and all of Australia's raw sugar exports (Industry Commission, 1992). The industry is very competitive in the global market. Although world demand has remained relatively constant at 23 Mt since 1975, Australia's share has grown from 2.7 t to 4.7 t (Table 2.2). This growth has been achieved in "one of the most restrictive regulatory regimes of any Australian industry"(Industry Commission, 1992: 1). The nature and rationale for this arrangement are the focus of the following section.

Table 2.2 Selected statistics for the Queensland sugar industry 1955-1998.

Year	Area Assigned (ha)	Area Harvested (ha)	Cane Crushed (t)	Sugar Produced (t)
1955	241,220	147,927	8,754,124	1,158,389
1960	240,673	132,535	8,824,393	1,346,026
1965	302,977	197,387	13,762,451	1,921,031
1970	301,544	211,518	16,438,360	2,371,097
1975	299,017	245,795	21,068,863	2,715,398
1980	333,209	274,259	22,540,369	3,148,999
1985	359,472	288,359	23,003,606	3,208,610
1990	372,119	323,441	23,929,650	3,353,969
1995	477,257	364,079	35,292,688	4,620,532
1998*	516,132	382,839	37,117,798	4,745,378

(* - Forecast; Source – Australian Sugar Milling Council)

All sugar industry activities - cane growing, milling and marketing - in Australia have been regulated through a series of Commonwealth and State legislative statutes and regulations. Most existing controls were granted between 1901 and 1939, largely by the Commonwealth Government to protect the new industry from international forces. Initial import protection was established in 1901 through the *Customs Act 1901* as a condition for Queensland joining the Commonwealth of Australia. This protection was increased under the *Regulation of Sugarcane Prices Act* and *Sugar Acquisition Act of 1915* as a wartime measure, with an embargo placed on the import of sugar, the introduction of fixed domestic pricing, and a monopoly acquisition and marketing structure of Queensland sugar. By 1922, Australia was a net exporter of sugar.

In 1923, the Sugar Board was established under the *Sugar Acquisition Act.* This legislation required the Sugar Board to acquire and market all raw sugar produced in Queensland (Industry Commission, 1991). At the same time, a system known as 'land assignment' was introduced to

control the location and amount of sugarcane produced. Conditions of Assignment established that cane was only grown on assigned land, and that the growers were required to deliver all cane from that land area to a specified mill. It is this process that is of central concern to this report. Mills were obligated to accept all cane produced on assigned land. Pricing and delivery arrangements were outlined in accompanying regulations. According to the Industry Commission (1992: 2),

> In retrospect, it is easy to understand why many in the [sugar] industry supported regulation. Growers feared the regional economic power of millers and, as the industry expanded, both growers and millers feared that overseas buyers could exploit the industry. Regulations were also seen as a means of reducing risk and stabilising producer incomes, and as a way of maintaining established growers the higher prices attainable from domestic sales.

The Commonwealth/Queensland sugar agreements were renewed at five-year intervals. The Queensland Sugar Board carried out the marketing of sugar in both Queensland and New South Wales, and the Commonwealth price support continued in the form of an embargo on imports of sugar and its close substitutes. These pricing arrangements were reviewed in 1970 and a new formula to establish annual adjustments to domestic sugar price was introduced.

Early expansion of the industry led to continued growth in exports. These exports to mainly unprotected markets (*i.e.* countries that did not sign ISAs or other international agreements) led to lower grower returns and a consequent push for further controls to safeguard established growing and milling interests. The two pool pricing system incorporating mill peaks was designed to discourage cane growing on unassigned land and to ensure higher returns to established growers. Further controls on industry expansion were introduced in 1937 after Australia acceded to the first International Sugar Agreement. It specified restrictions on export volumes, and as a result 'penalty' prices for sugar produced on unassigned land was announced ($1 per ton). Although the regulatory aspects of the ISA lapsed in 1984, Australian policy continued to evolve, reflecting the balance between bargaining strength of the sugar industry, and changing national and international market conditions. By 1984, the nature of the industry had changed dramatically. Producers now had better access to market information on which to base production and marketing information. There was also a closer integration between the global and domestic sugar economies (Hannah and Spence, 1996).

In 1990, there were 37 laws related to the sugar industry as well as numerous regulations that controlled the Australian sugar industry. As noted earlier, practically every aspect of the industry, including areas of the land on which cane could be grown was regulated. Criticisms of this approach generally related to the constraints it placed on the industry's capacity to maintain its viability and international competitiveness by (ABARE, 1991; Industry Commission, 1992; Hungerford, 1996):

- restricting inputs of the land they raised the costs of growing cane;
- inducing more intensive production methods that increased the demand placed on the land;
- excluding some people to enter sugarcane farming, and preventing some existing growers from growing as much as they wished;
- acting as a disincentive to the development of an export-oriented refinery industry; and
- preventing growers, millers and other participants firms from seeking out and exercising market opportunities.

On this basis, there was a strong view that Australia's sugar industry was in need of reform by the late 1980s.

2.4 1991 Sugar Industry Reforms

The *Sugar Industry Act 1991* repealed and replaced nearly all of the 37 existing laws pertaining to the sugar industry. Three of the most significant changes related to the administrative

arrangements for assignment, the minimum level of expansion to be achieved, and the consideration of environmental issues in the assignment process. Previously, sugarcane had to be grown on a specified area and location of land, and delivered to a specific miller. Under the new *Act,* cane could be grown anywhere on the cane grower's property. In addition, the *Act* provided for more flexibility in the transfer of assignment within a grower's own land holding, between growers and between mills. This easing of assignment regulations enables cane growers to have a greater measure of freedom to determine their own farm management practices.

Another important aspect concerned the requirement for annual expansion of 2.5% annually (about 10,000 ha) state wide between 1991 and 1995, and greater flexibility in the administration of the *Act.* Some of this flexibility was achieved by delegating increased responsibility to Local Boards. These bodies, comprised of millers and growers with a neutral Chair, were created in 1926 to administer, in part, the cane assignment process. Until 1991, cane land expansions were 'planned for' by the Sugar Board and reflected Australia's ability, under international agreements (*e.g.* International Sugar Agreements) to export sugar. Between 1991 and 1995, the area under assignment had to grow at an unprecedented rate of 2.5% per year. It is this level of expansion, combined with the ability of Local Boards and relevant public agencies to control the environmental impacts of this development that are sources of significant concern. It would also place significant demands upon the mills to increase their capacity to crush cane. Under the *Sugar Act 1991* (amended in 1994), sugarcane grown on assigned land must continue to be accepted for refining by the designated mill.

Provisions within the *Sugar Industry Act 1991* and assignment regulations, which are administered by the Queensland Sugar Corporation (QSC), mention that environmental, social and economic aspects must be considered in determining the desirability and feasibility of applications for cane land expansion (QSC, 1991). This report examines the implementation of these requirements and regulations in the Herbert River district. The specific requirements will be described in Chapter 4.

Despite the 1991 changes in Australia's sugar industry, the economic, political and technological uncertainties that have confronted it in the past will remain. For instance, both domestic and export markets are not stable. A decline in the consumption of products, such as beer, can decrease the demand for sugar (Hungerford, 1996). The increased use of alternative sweeteners can also erode domestic and foreign markets. Other countries, particularly the US and EU continue to provide their agricultural industries with quotas, tariffs and price support. The potential re-emergence of Cuban sugar onto the US market and increased competition from new sugar industries (*e.g.* Thailand) would impact exporting nations. This point highlights the complexity and uncertainty of integrating environmental and economic considerations of a global commodity.

2.5 Sugar and the Environment

During the late 1980s and early 1990s, there was a growing realisation that expansion in the area of cane growing and cane growing itself had the potential to cause significant environmental damage. This was because of the industry's increasing size, its coastal location, and its intensive use of fertiliser, chemicals and irrigation water. Severe soil erosion has long been recognised as a potential threat to long-term productivity of sloping land growing sugarcane, with soil losses in excess of 200 t ha^{-1} reported in the Mackay region (Sallaway, 1979) and in excess of 500 t ha^{-1} on the wet tropical coast (Prove and Hicks, 1991). The adoption of green cane harvesting-minimum tillage practices has been an important step in decreasing sediment supply to the coastal zone from sugarcane lands. However, the practice has received only partial acceptance by the industry. Despite the fact that in many areas soil erosion remains a problem, the precise rate and impact of sediment delivery from catchments in which sugarcane is grown to estuarine and marine

environments remains poorly understood (Pailles *et al.*, 1993; Pailles and Moody, 1995; Wasson, 1996).

QDNR (1998) identified the following impacts of agricultural development in cane growing regions:

- changes to natural drainage systems, flood flows and flood peaks;
- the clearing of natural vegetation and consequent loss of native fauna habitats;
- changes on groundwater levels;
- decline in water quality;
- siltation of watercourses and the Great Barrier Reef lagoon;
- the introduction of weeds and exotic plants and animals; and
- reduction in habitat and thus reduction in populations of fish and crustaceans.

The major sources of diffuse source pollution (*e.g.* fertiliser and pesticides) have generally increased in magnitude in recent years and have been predominantly associated with expansion in the area of land supporting sugarcane. Recent research (Bramley and Johnson, 1995; Mitchell *et al.*, 1995) has shown that nutrient concentrations in streams in selected sugar catchments are generally below national guidelines (ANZECC, 1992) for freshwater. Exceptions were generally associated with peak flow events. Although nutrient levels are currently low, understanding of ecosystem behaviour is not sufficiently developed to allow the assimilative capacity of these waters to be predicted with certainty. Furthermore, while an increasing amount is known about the fate and behaviour of nutrients, information on accession, persistence and behaviour of pesticides is sparse. Current knowledge suggests that the periodicity, volume and intensity of rainfall influence the downstream effects of agricultural production. Hence, minimisation of diffuse source pollution is likely to depend on carefully matching actual land use to land use suitability.

Development of land and water resources for new cane assignment has had a large negative impact on riparian vegetation, freshwater wetlands, swamps, billabongs and waterholes in most cane growing areas. Results from the CANEGROWERS environmental audit indicated that 70% of the farms surveyed had a riparian zone classed as moderate (<15m) or worse (GHD, 1996). Mangrove areas have largely remained intact, although some clearing did occur in the 1960s and 1970s. Large areas of riverine rainforest with patches of Eucalypts and the riverine rainforest have also been cleared in most cane growing regions. For example, in the Johnstone Rivers system, there has been a 60% reduction in the area of coastal wetlands between 1951 and 1992 (Russell *et al.*, 1995). On the Herbert River floodplain, Johnson *et al.* (1997; 1999a, b) have shown a 60% decrease in the area of Melaleuca dominated vegetation patterns (including a 40% decrease since 1943), and a 50% decrease in riparian rainforest patterns since European settlement.

The development of new sugarcane land may require additional irrigation works (*e.g.* Burdekin, Mackay, Isis, Maryborough), or drainage infrastructure (*e.g.* Herbert) that have two potential impacts. First, environmental impacts associated with irrigation may include salinity, rising water tables, salt intrusion and water resource depletion. Drainage works can result in acid sulphate soil problems and discharge of tail water into coastal ecosystems. These negative impacts can be transferred to existing and/or adjacent landowners. Second, the financing of these works must also be considered. According to the Queensland Department of Primary Industry (1993: 2),

> In the current climate of economic rationalism and application of the 'user pays' principal, governments are becoming increasingly reluctant to finance the entire costs of such projects. Even when the infrastructure is paid for by the state, many farms are too small, or the farmers too indebted, to support further investment in irrigation.

As will be detailed later in this report, the Queensland Government subsidises drainage works. Issues of fairness related to who pays and who benefits from these projects are significant. For instance, drainage works may be required to support upstream sugarcane farming. However, the

financing of a drainage project could see existing downstream farmers supporting a portion of these costs while seeing negligible, if any, benefit. This example reinforces the need to effectively link environmental, economic and social considerations in decision making.

3 ECOLOGICALLY SUSTAINABLE DEVELOPMENT: EVALUATIVE FRAMEWORK, METHODS AND CASE STUDY AREA

3.1 Ecologically Sustainable Development

The ideas of the Brundtland Commission were furthered in 1992 at the Earth Summit in Rio de Janeiro. Two outcomes from meeting were *Agenda 21* and the Rio Declaration. The former is "perhaps best seen as a collection of agreed negotiated wisdom as to the nature of problems, relevant principles, and a sketch of desirable and feasible paths towards solutions, taking into account, national and other interests" (Grubb *et al*., 1993: 17). In general, it supports the Commission's initial thoughts – economic, social and environmental systems were linked; intragenerational and intergenerational issues must be stressed; and policy and institutional reform were critical. These should provide the basis for ongoing discussions on international environment-development issues that could have implications for national, state and local levels of government.

Australian governments articulated their sustainable development principles under the term 'ecologically sustainable development' (ESD). In 1992, the Commonwealth Government adopted a *National Strategy for Ecologically Sustainable Development* in order to pursue the following objectives:

- to enhance individual and community welfare by following a path of economic development that safeguards the welfare of future generations;
- to provide equity within and between generations; and
- to protect biological diversity and maintain essential ecological processes and life support systems.

It is difficult to argue against the intent of these policy objectives. However, no strong consensus exists on how to best achieve them. Key questions concern who should take action (*e.g.* level of government, private sector, individuals), what action should be taken (*e.g* market mechanisms, regulations, voluntary, privatisation, nationalisation), and how urgent action is needed. These are difficult questions to answer definitively.

However, the vision of ESD in Australia is very clear. It aims to "meet the needs of Australians today, while conserving our ecosystems for the benefit of future generations" (COAG, 1992: 1). It is important to distinguish between the process and outcome of ESD. In the context of pursuing resiliency, Dovers (1997: 304) suggested the following distinction.

> *Sustainability* is the ability of a natural, human or mixed system to withstand or adapt to, over an indefinite time scale, endogenous or exogenous changes perceived as threatening. *Sustainable development* is a pathway of deliberate endogenous change (improvement) that maintains or enhances this attribute to some degree, while answering the needs of the present population.

Thus, sustainable development is the process that delivers sustainability. It is the process of decision making that is the focus of this report and forms the basis of the evaluation framework.

3.2 Evaluation Framework

The purpose of the research was to evaluate the sugarcane assignment process in the Herbert River district in terms of its compliance with the principles of ESD. This required an explicit set of criteria against which judgments about performance could be made. While the definition of sustainable development has been popularised, it's meaning and measurement have been elusive. However, a review of *Our Common Future*, and the Earth Summit Agreements identifies at least

five principles that should characterise sustainable development. These principles, which are modified from Mitchell (1995), are balance, ecosystems, partnerships, flexibility, and the precautionary principle (Table 3.1). Combined, these principles support the integration of environment and economy that the Brundtland Commission sought. These are discussed further below.

Table 3.1 Sustainable development principles as reflected in the Rio Declaration and *Agenda 21*.

Principle	Statement from Rio Declaration and Agenda 21
Balance	– integrate environment and development into decision making
Ecosystem	– environmental protection shall constitute an integral part of the development process – reduce and eliminate unsustainable patterns of production and consumption – conserve biodiversity
Partnerships	– meet the development needs of present and future generations – access of information held by public authorities, opportunities to participate in decision-making processes – enhance development, adaptation, diffusion and transfer of technologies – special attention to developing countries, indigenous people, women, youth
Precautionary Principle	– where there are threats of serious or irreversible damage, lack of full scientific certainty shall not be used as a reason for postponing cost-effective measures to prevent environmental degradation
Flexibility	– enact effective legislation – supportive and open economic system – market incentives, environmental accounting – integrated land planning – combat deforestation – biotechnology – promote sustainable agriculture and rural development

3.2.1 Balance

Integration between environment and economy was a central component of the Brundtland Report. A balanced perspective recognises the economic, social, and environmental aspects of resource development and management. However, a key concern pertains to the relative weight given to each element. Past management efforts have usually favoured short-term economic gains over long-term factors.

For this study, an important qualitative aspect of balance pertains to the level of decision making where environmental and economic issues are considered clearly and directly. Smith (1993) identified three levels of decision-making based on the type of question/problem being asked/solved.

- Normative planning asks questions related to "What should be done?"
- Strategic planning considers "What could be done?"
- Operational planning asks "What will be done?"

Ideally, environment-economy issues should be considered at all levels. In the context of the sugar industry, initiatives such as the GATT, the *Sugar Act 1991*, and Local Government Strategic Plans could be considered normative and strategic level documents. The cane assignment process is an operational level of decision making.

3.2.2 Ecosystem Approach

An ecosystem approach appreciates the complexity of relationships among and within environmental, social, and economic systems. Rather than focusing attention on one element of the environment, attention is often turned to considering how human health or other broad measures of quality affect the natural and social environment. To implement this approach, attention is often given to watersheds or bioregions. Environment and natural resource management is often ill suited to administratively based boundaries. While it is not feasible to form agencies exclusively based on 'natural' boundaries, it is appropriate to plan on the basis of ecosystems and incorporate this information into appropriate implementing documents (*e.g* policies, strategic plans, legislation, and regulation). In the context of the sugar industry in the Herbert River district, the ecosystem approach considers at least three key perspectives.

The first perspective considers the interaction of biophysical processes. In the Herbert River district, long-standing resource issues have concerned inadequate land drainage which has limited crop productivity, and flooding which has inflicted damages to the town of Ingham and crop losses (Cameron McNamara, 1984). Emerging resource issues concern the impacts associated with acid sulfate soils, the maintenance of riparian corridors for wildlife, and decreasing biodiversity through the loss of some remnant ecosystem types on the coastal lowlands (QDEH, 1995; Johnson *et al.,* 1998). Solutions to the problems require, in part, an adequate understanding of biophysical systems. Inadequate information could see decisions made which might lead to poor outcomes including not only environmental problems, but the transfer of problems from one property owner to another, or the inefficient expenditure of public and private funds. From this perspective, the comprehensiveness and appropriateness of the Conditions of Assignment should be considered.

The second perspective of the ecosystem approach suggests that institutional arrangements work in a coordinated manner. For instance, it is not uncommon to have fragmented responsibilities for water management. One agency may be responsible for drainage, another with fisheries, another with soil erosion, and yet another with water quality. The Brundtland Commission noted this tendency. The solution to the problems associated with a fragmented approach does not necessarily imply a 'consolidation of responsibilities' that simply transfers an inter-agency problem to an intra-agency one. Since the interconnected nature between economic and environmental systems is unlikely to change, policies and institutional behaviour must. Such an adjustment is "one of the chief institutional challenges of the 1990s and beyond" (WCED, 1987).

These comments are relevant to resource management agencies in Queensland where there is a complex web of laws, policies and agencies (Johnson *et al.*, 1998). In addition, there is separation between resource development and resource management activities as illustrated by the division of responsibilities that occurred in 1996 between the former Queensland Department of Primary Industries for agricultural production and the then new Department of Natural Resources for resource management. Providing for an integrated resource management approach that allows for adequate information of biophysical processes, and provide for the effective administration is a long-standing challenge for governments worldwide. The issue of administrative fragmentation will be addressed under the partnership principle. The third ecosystem approach perspective focuses attention on environment-economy-society linkages. A noted earlier, this aspect is addressed under the balance principle.

3.2.3 Partnerships

As discussed, responsibility for environmental and resource management is often shared between private and public managers at international, national, state, regional, local and individual property scales. Partnerships respond to this reality and should ensure the equitable treatment of

all these participants. People and groups who have a legitimate concern should have an opportunity to influence the formulation and implementation of resource management and development decisions. Information among participants should also be exchanged.

The Brundtland Report and the Earth Summit suggest that a participatory planning approach is an essential component of a democratic society. In the context of this report, participation not only includes the involvement of citizens, but of other relevant public and private resource management agencies. In providing for effective participation, mechanisms should be in place to provide for conflict resolution.

Kernaghan (1994) provides insight on the meaning and types of partnerships used in Canada. "So-called true partnerships promote empowerment in that they involve a sharing of decision-making power between or among partners" (Kernaghan, 1994: 61). However, this definition excludes many other interactions between resource managers where there is little power sharing. This shortcoming prompted Kernaghan (1994: 61) to provide a second definition of partnership that embraced a "relationship involving the sharing of power, work, support and/or information with others for the achievement of joint goals and/or mutual benefits." Thus, understanding the nature of the relationships and power sharing among participants is crucial in understanding partnerships.

The character of participation is one important component in understanding relationships and power sharing. Three types of decision-making styles typify resource management agencies in historical and contemporary contexts (Figure 3.1). A well-established type is "Decide-Announce-Defend" (Figure 3.1a). When a public agency becomes aware of a problem, it considers solutions through the use of "rational planning methods". This form of decision making provides almost no opportunities for partnership to form since there is very little sharing of information or work. Instead, the key public agency would announce a solution "which solved the problem" and fulfilled its legislative requirements. Unfortunately, historical inertia, financial arrangements and legal requirements often skewed the range of adjustments that were considered. If the proposal were controversial and groups attacked it, a public dispute was 'created' and forced the public agency to defend its interests. Information meetings, lobbying and media campaigns illustrate some of the efforts which proponents might undertake in order to gain public and political support. Regardless of the outcome, these are adversarial strategies and provide little opportunity to form future partnerships.

The "Solomon Trap" is a second common type of decision-making (Carpenter and Kennedy, 1988) (Figure 3.1b). This approach seeks to identify relevant stakeholders and to obtain their views. Through forums such as public meetings, focus groups, polls and surveys, a resource management agency consider how the public views the economic, social and environmental implications of alternative solutions. What is less clear is the basis upon which such input is incorporated into the proposal.

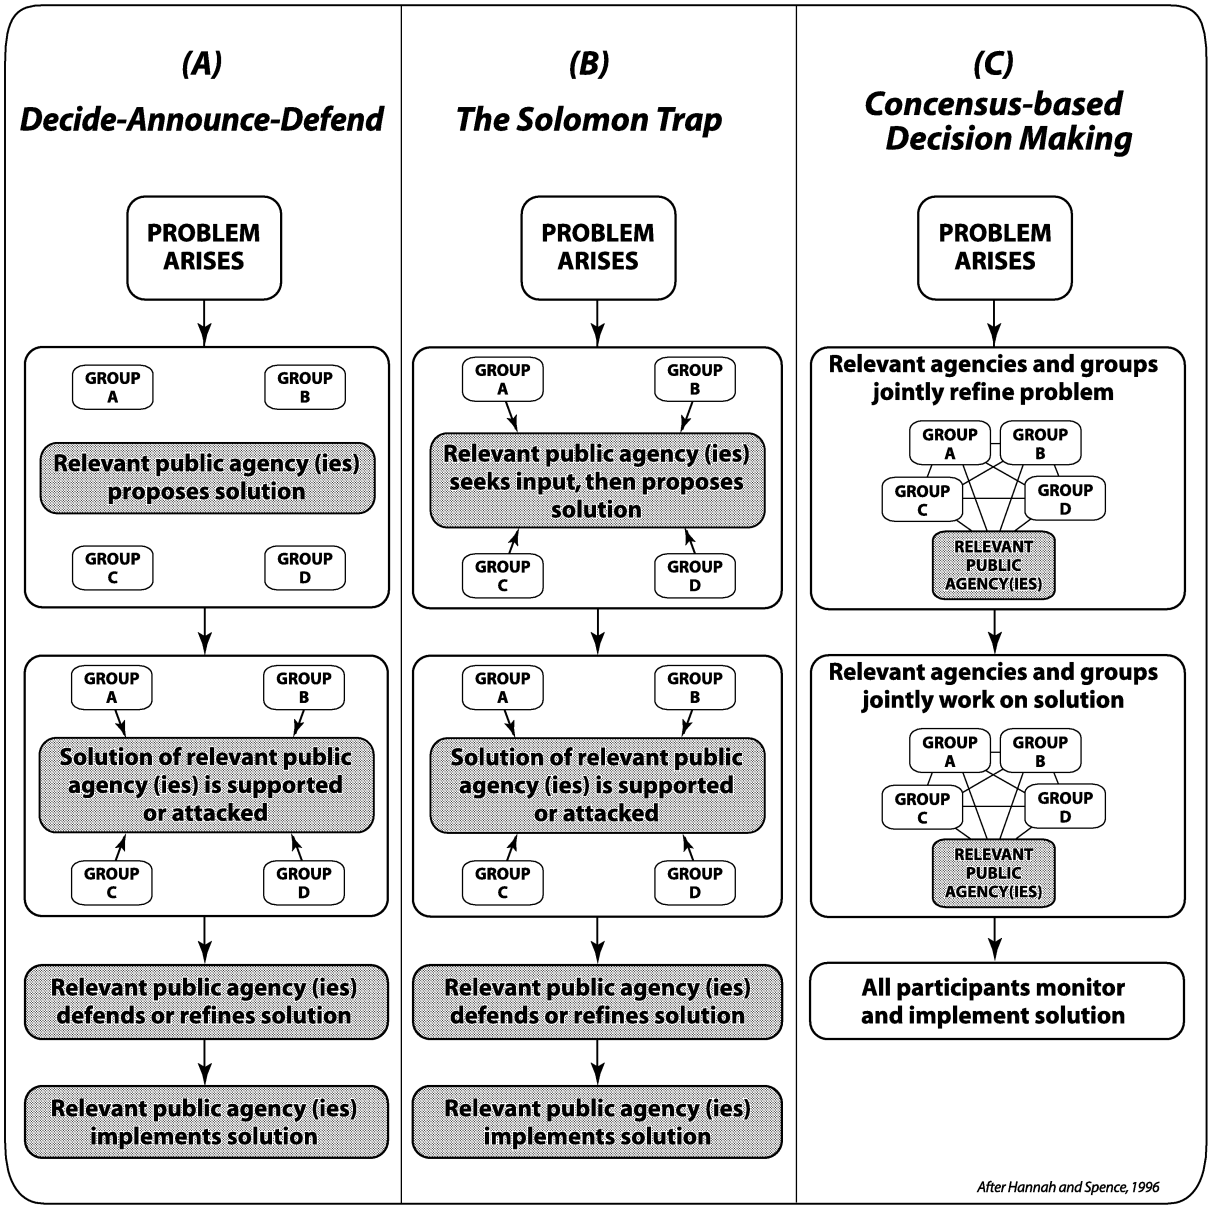

Figure 3.1 Three common participatory approaches to resource management.

Unfortunately many public agencies do not enjoy the same level of esteem afforded the Bible's King Solomon who threatened to cut a baby in two and give the halves to two women each of whom claimed to be the mother. In this way, he believed it would be possible to determine the identity of the real mother, because she would not agree to the baby being cut in half. While King Solomon was seen as possessing divine wisdom because he did not kill the child and was able to distinguish the true mother, a resource agency may be surprised that its efforts to obtain public input are unappreciated and that its judgment is questioned. After the public agency announces the solution that in its view best serves the public interest, some stakeholders may be dismayed that their key concerns were inadequately addressed. According to Carpenter and Kennedy (1988), this disappointment can turn into feelings of betrayal. Some participants may disagree with the solution offered. As with the "Decide-Announce-Defend" approach, a public agency may expend significant efforts in justifying its proposals to the public and politicians, but ends up in a "Solomon Trap" because many interests may be dissatisfied with the decision.

The "Solomon Trap" represents a limited form of partnership because the relationship is essentially focused on the one-way exchange of information. Relatively little effort and opportunity to establish ongoing partnerships exist, and there is little sharing of decision-making

power. In this approach, partnerships often develop from *ad hoc* and reactive responses to particular problems.

Consensus-based decision making represents a third and more complete form of partnership (Figure 3.1c). At present, a key participant who could represent a range of people (*e.g.* a public agency, private user or non-governmental organisation) perceives a problem. That participant will work with key public and private agencies/groups in order to define the problem, identify appropriate solutions and implement relevant programs.

In a collaborative partnership such as this, the role of the key public agency is significantly different from the previously noted decision-making styles in that:

- It is a facilitator rather than the focal point for making a decision. All participants share information among themselves, define the nature of the problem, identify possible solutions, and suggest appropriate means of implementation.
- Efforts are focused on problem solving. In both the 'Decide-Announce-Defend" and "Solomon Trap", public agencies could end up devoting significant energies to defending their position. These efforts can be stressful on organisations and people.
- Differences among participants are resolved through direct meetings. Public agencies no longer serve to explain, justify, interpret or judge the full range of views of other participants. These responsibilities are shared with each stakeholder.
- Participants shape the problem-solving process. Since the collective experience in developing effective, efficient and equitable procedures is limited, some trial-and-error is taking place. In addition, a well-formulated process can change due to evolving external and internal pressures (*e.g.* new government, fiscal circumstances, environmental crisis, changing problem definition, and change in participants or membership).

These traits are one measure of partnership. Other aspects are also relevant. First, a general consensus exists that partnerships are best served when involvement occurs early in the decision-making process throughout the entire process, and after the decision is made. Partners should not be asked to simply ratify a decision that has already been determined (Mitchell, 1990). Second, there should be sufficient time for partners to consider information provided to them. Third, when there are disagreement, partners should, at a minimum, explain the rationale supporting their decisions. Ideally, effective conflict resolution processes are established to settle these disputes.

3.2.4 Flexibility

Our understanding of the environment and human interactions with it is continually evolving. Social and personal attitudes and behaviours are also dynamic. Political and economic circumstances can change almost overnight on the basis of the future's market in New York, an announcement from the central bank, or the results of an election. Since these types of changes must be accommodated in individual, community and government management strategies, there is a need for flexibility. This principle is illustrated in the reliance on the mix of policy instruments advocated in the Rio Declaration (Table 3.1). It also suggests that monitoring be established in order that learning and adapting are achieved.

3.2.5 The Precautionary Principle

The precautionary principle has been used by decision-makers to consider the impacts of policies, programs, and projects. Although it has been applied since the 1950s in Germany, its inclusion as Principle 15 in the Rio Declaration has raised its international profile and popularity. That document rationalised and defined the principle as follows:

> In order to protect the environment, the precautionary approach shall be widely applied by States according to their capabilities. Where there are threats of serious or irreversible damage, lack of

> full scientific certainty shall not be used as a reason for postponing cost-effective measures to prevent environmental degradation.

The precautionary principle recognises the importance and the different types of uncertainty in resource management (Table 3.2). The challenge is to apply appropriate management processes and decisions in the face of uncertainty.

Table 3.2 Defining different kinds of uncertainty in resource management.

Type	Definition
Risk	System parameters are well known. Range of outcomes and the odds are known and can be predicted.
Uncertainty	Major system parameters are known. Range of outcomes is known but the odds are not.
Ignorance	Scientists will be surprised by the outcomes because they do not know. Do not know what questions should be asked.
Indeterminacy	Scientific knowledge is inadequate. Causal chains are open. Understanding is not possible.

(Source: Wynne, 1992; Mitchell, 1995; Young, 1995)

Rather than stopping all resource development, applying the precautionary principle has more to do with changing the balance of decision-making power. It emphasises the responsibility of resource developers must take in either: (i) demonstrating that their initiatives will not cause harm; or (ii) providing the means to compensate potentially impacted communities or people (O'Riordan, 1995). These comments suggest that responsible decision making is an important element of the precautionary principle. Some mechanisms which can achieve this goal include: monitoring changes in resource capital, placing the onus of responsibility on proponents, developing safe minimum standards, enhancing community consultation and education, and providing anticipatory approaches to resource management. Thus, applying the precautionary approach is particularly relevant for those who view integrated resource management an effective institutional arrangement. Research and education can aid this process.

3.3 Data collection and synthesis

In applying the framework previously outlined to an evaluation of the cane assignment process in the Herbert River district, data were obtained from five sources:

1. Written records of applications for assignment;
2. Spatial data indicating biophysical and land use characteristics of the lower Herbert River district;
3. A statistical analysis of the relationship between the granting or rejection of assignment applications and key biophysical, economic and social parameters;
4. A geo-statistical analysis of the relationship between the granting or rejection of assignment applications and key locational parameters; and
5. Interviews with key sugar industry and government respondents at local and state levels.

3.3.1 Applications for Assignment

Cane assignment application files located at the CANEGROWERS Ingham office for the period 1993-1996 were examined. A total of 525 applications were submitted to that office during the study period (Table 3.3).

Table 3.3 Number of applications for assignment for each mill area in the Herbert River district.

Year	Victoria Mill Area	Macknade Mill Area	Herbert District Total
1993	189	27	216
1994	61	22	83
1995	79	19	98
1996	107	21	128
Total	436	89	525

A copy of an application form is contained in Appendix 1. These forms provided information about:

- the location of the property;
- the type of application;
- the mill area (Macknade or Victoria);
- the total area applied for; and
- the proposed planting schedule to make the assignment effective.

Final decisions, area granted for assignment and any conditions the Local Board placed on the assignment were recorded. Correspondence among relevant participants concerning environmental aspects associated with an application was noted.

The 525 applications covered an approximate area of 16,000 ha. It was feasible to link information from complete application forms with the spatial database (that is described below) for 472 applications (89.9%) of the total application pool. The complete applications encompassed an area of about 15,000ha or about 94% of the total area applied for. In addition to incomplete information, difficulties were also encountered in linking some applications to the Digital Cadastral Database (DCDB) layer (particularly in the vicinity of Helen's Hill). Despite these problems, the available record is believed adequate to reasonably assess the cane assignment process in the **Herbert River district** between 1993 and 1996.

3.3.2 Spatial data

A range of data were collected and collated to underpin the evaluation. Table 3.4 lists the key spatial data sets utilised, their source and accuracy. It is important to note that although some of the errors presented may seem insignificant in terms of catchment scale analysis, they can become a larger problem when they are compounded with other small errors over a large area. Hence the following need to be acknowledged when considering the general utility of the data collected.

1. *All spatial data is of limited accuracy*. This is due to the fact that instruments recording distances and angles have inherent accuracy limitations. It is also because databases are primarily an abstract or generalisation of the actual geographic feature they are representing. Digitising errors are often relatively minor when compared to the process of cartographic abstraction itself. Classic examples of this include soil and vegetation mapping.
2. *The precision of GIS processing tends to exceed the accuracy of the data*. In principle, data should be expressed in a precision that reflects the accuracy of the data collected.
3. We have methods for describing the positional accuracy of point features, but little has been developed for abstract features. More comprehensive modeling will be required if we are to develop methods for describing *accuracy within spatial databases and track its propagation through complex GIS processes*.
4. *Ideally there would be a set of confidence limits on all GIS products*, resulting from descriptions of error in the database and its propagation through the GIS process. In some situations this would be difficult to determine as multiple-source data sets may be manipulated and overlayed, in this case warnings may replace confidence limits to steer unwary users away from meaningless results.

Table 3.4 Spatial data collected to underpin the evaluation of the cane assignment process in the Herbert River district.

Dataset	Description	Source	Accuracy
Digital Cadastral Database (DCDB)	Digital database of cadastral features in Queensland. Collected on a local government area boundary basis. Contains both linework (*e.g.* property boundaries) attribute data (*e.g.* tenure).	Queensland Department of Natural Resources	Attribute accuracy approximately 98%. Linework, average horizontal accuracy is estimated to be +/- 50m, with 60% of the linework within +/- 25m and approximately 10% of linework outside the accuracy of +/- 50m.
Land Cover	Land cover of the lower Herbert River catchment was visually interpreted from scanned and rectified 1:25000 aerial photography acquired for 1943, 1961, 1970, 1977, 1988 and 1992 and 1:10000 digital orthophotography acquired in 1993, 1994 and 1995. An unsupervised classification of SPOT Panchromatic and MSS imagery was used to map land cover in 1996. Land cover boundaries were mapped onto a geo-referenced digital base in ARCINFO GIS.	Classification drew on previous vegetation (Tracey, 1982; Blackman *et al.* (1992); Perry, 1995) and soil surveys (Wilson and Baker, 1990; Heiner and Grundy, 1994)	Spatial accuracy ±7m for 1:25000 aerial photography, ±1m for 1: 10000 ortho-photography and ±10m for SPOT imagery. Classification of units and boundaries not inspected in 1996 was undertaken by extrapolation from equivalent photographic units. Final accuracy of ±10m in the horizontal for map.
Land Suitability for Sugarcane	Based on a combination of geology, soil, vegetation and climate data, this dataset is the output of applying a simple rule base to determine biophysical suitability for sugarcane growth.	Queensland Department of Natural Resources (Wilson and Baker 1991)	Scale of publication is 1:100000 with a horizontal accuracy of +/- 50m.
Mahogany Glider Habitat	Habitat mapping for mahogany gliders based on detailed vegetation mapping and field trips.	Queensland Department of Environment	Maximum scale of use 1:50000, with horizontal accuracy of +/- 25m.
Mangrove Vegetation	Mangrove vegetation boundaries were interpreted from air photos as per details for land cover	Johnson *et al.* (1997) and Perry (1995)	As per land cover mapping.
Height 3m Above Sea Level	Represents the 3m ASL contour. Generated using elevation data and the ArcInfo Grid module's function: CONTOUR. The elevation data was gridded prior to having contours extracted.	Base data derived from Herbert Mapping Project	Contours within 95% accuracy of known spot heights with accuracy of +/-1m. The grid cell size used was 250m.
Height 9m ASL - Cattle Creek	As per above but geographic extent located only on the Cattle Creek sub-catchment.	Base data derived from Herbert Mapping Project	Contours within 95% accuracy of known spot heights with accuracy of +/-1m.

Table 3.4 cont.

Dataset	Description	Source	Accuracy
Slope Greater Than 3%	Dataset was generated using the gridded elevation data and the ArcInfo Grid module using the SLOPE function.	Base data derived from Herbert Mapping Project	It was not possible to verify the accuracy of this dataset.
Acid Sulfate Prone Soils	A qualitative assessment derived from a rule base incorporating soil type, elevation, distance from coast and geomorphology.	Based on data from Wilson and Baker (1991)	Scale of mapping was 1:100000 with a horizontal accuracy of +/- 50m.
Lakes, Lagoons & Wetlands	This dataset delineates lakes, wetlands, swamps, lagoons and billabongs defined in the land cover mapping.	QDoE, Herbert Mapping Project	As per land cover data.
Stream Buffers – 10, 20 and 40m	Dataset was generated using Herbert Mapping Project stream data and the BUFFER command in ArcInfo. Only selected major and minor streams were included, reflecting the true stream protection laws which only include named streams.	Base data derived from Herbert Mapping Project	Relative linework accuracy of +/-5m.
Flood Mapping	Linework for the coverage of the 1967 and 1977 floods was intended as a guide to the full extent of the inundation area.	Cameron McNamara (1980)	It was not possible to verify the accuracy of this dataset.
Drainage Board Boundaries	The data provides the areal extent of gazetted drainage boards.	Queensland Department of Natural Resources	Maximum scale of use 1:50000, with horizontal accuracy of +/- 25m.
Location of Cane Assignment	Location of farms was determined using the Sugarcane Assignment Register (SCAR) database in conjunction with the DCDB, linked using the lot, plan and parish attributes. Cane blocks from the Herbert Mapping Project were used to determine the location of cane block. Data describing sugarcane assignment applications over the 1993 to 1996 period were then linked to the Victoria Mill and Macknade Mill datasets. Links were established according to the year cane was planted and the area applied for. Corrections were made according to the advice of local cane inspectors.	Queensland Sugar Corporation	Linework accuracy as per the DCDB. Positional accuracy is estimated to be approximately 90%.

These considerations suggest that GIS processes and results need to be kept in context with the system from which they were derived, the methods and instruments that were used to record the feature and the system in which the results will be applied. Many of the features represented in this study are more continuous than exactly bounded into distinct classes, and so have inherent limitations.

3.3.3 Spatial analysis of land cover data

A spatial analysis of land cover in the lower Herbert River catchment was also undertaken. A number of key indices were calculated in ARCINFO to quantify changes in shape, size and spatial pattern of vegetation units. These indices have been successfully used in a number of similar studies:

- *Edge:area ratio*, which quantifies the amount of irregularity in the shape of remnant stands of vegetation (Sharpe *et al.*, 1981);
- *Forest island dissection index* (DI), which compares the amount by which any one "island" (or in GIS terms, polygon) of vegetation is more dissected than another and, therefore, would have a greater edge to interior. Any index greater than 1 is a measure of such irregularity in comparison to an index of 1, which is circular in shape (Sharpe *et al.*, 1981). DI can be represented by the following equation:

$$\mathrm{DI} = \frac{p}{\left(2\sqrt{p\,a}\right)}$$

  where p = island perimeter (metres) and a = island area (ha)
- *Landscape dissection index* (DL), which measures the cumulative edge:area ratio for the entire landscape (Sharpe *et al.*, 1981). DL can be represented by the following equation:

$$\mathrm{DL} = \sum_{i=1}^{n} \frac{p}{\left(2\sqrt{p}\sum_{i=1}^{n} a\right)}$$

  where p = total perimeter (metres) and a = total area of the forest island (ha);
- *Island distribution index* (IDI), which measures landscape aggregation and is similar in logic to the nearest neighbour statistic. IDI emphasises the pattern of islands in the landscape. IDI = 1 in a randomly distributed population, < 1 in an aggregated population and approaches uniformity if the value is close to 2.1491, where islands would have maximum spacing, in which case they are regularly distributed in a hexagonal pattern (Bowen and Burgess, 1981). IDI can be represented by the following equation:

$$\mathrm{IDI} = 2\overline{r_c}\,(l\,p)$$

  where $\overline{r_c}$ = mean centroid-to-centroid distance from a forest island to its nearest neighbour and λ = density of forest islands (number per ha)
- *Diversity* ($H^{/}$) and *Evenness* (E) indices which compare changes in richness and landscape apportionment (Medley *et al.*, 1995). $H^{/}$ and E can be represented by the following equations:

$$H^{/} = -\Sigma P_i \ln P_I$$

  where P_i represents the proportion of total area (or entropy measure) in category *i* of each land cover/use type

$$E = H^{/} / \ln s$$

  where s = total number of land cover/use categories
- Number and density of islands (*i.e.* number per unit area) and cover class as a % of total area measure landscape pattern.

3.4 Statistical Analysis

A survey of approved sugarcane assignments was carried for the years 1993-1996. The results of this survey were used to determine the relative importance of a number of factors on the final assignment decision. For each year two mills, Macknade and Victoria, were recorded on a farm basis as follows:

- Approval rate (0, <100%, 100%);
- Amount applied for; and
- Current assignment.

Farms were also categorised according to the tenure description and an assignment application type. In the first two years, there were farms with an Approval Rate of 0 or <100%; in the third year (1995). All farms (excepting one) were recorded with the value of 100% for Approval Rate; and in the fourth year (1996), Approval Rate took all three values (o, <100%, 100%). Also available in the fourth year were the proportions of Applied For to be planted in Years 1 and 2 and a Recommendation from the Environment Advisory Committee. Further geographical details were available for some farms for that year and they consisted of:

- Nearest rail distance;
- Distance to Victoria Mill; and
- Distance to 1996 centroid of whole cane district.

For each of the years 1993, 1994 and 1996, a multinomial logistic regression was performed, relating the Approval Rate to the various factors available for each year. A separate analysis was performed for the two mills. Table 3.5 summarises the scheme used to simplify the fitting of the logistic equation. The Approval Rate was coded (0,1,2) corresponding to the approval ratings (0, <100%, 100%). The continuous and discrete predictor variables were coded as 0,1 variables according to whether the variable was less than or equal to a critical value (given the value 0) or greater than the critical value (given the value 1), as follows:

Table 3.5 Description of predictors.

Factor	Variable Description	Critical Value
A	Applied For – 93,94	10
	Applied For – 96	50
T	Type	2
D	Land Tenure	1
R	Recommendation	2
C	Current Assignment	2
Y1	Year 1 % Applied For	0.5
Y2	Year 2 % Applied For	0.5
NR	Nearest Rail	3000
DV	Distance to Victoria Mill	20000
D96	Distance to 1996 Centroid	400

A further factor PY was constructed taking the value 0 if there was only one year intended for planting the amount Applied For, or 1 if there were two or three years planned for planting.

3.5 Geo-Statistical Location Analysis

When dealing with spatially distributed phenomena, it is often useful to provide a visual representation of the distribution. This can be done with the use of the standard deviational ellipse or the ellipse of dispersion. The standard deviational ellipse gives a graphical

representation of an area with a radius of one standard deviation along each axis around the centroid. In this case, the land cultivated with sugarcane. The methodology for the calculation of the standard deviational ellipse with the cross of dispersion involves a number of steps. The following description is derived from Kellerman (1981).

The ellipse is centred on the unweighted centroid, which is sometimes also called the spatial mean. In the case of this research there are no weights associated with the pixel coordinates, so the centroid is simply the mean of the X and Y coordinates.

The two dimensional extension of the standard deviation defined in univariate statistics is the standard distance (d). Equation 3.1 shows that the standard distance is the square root of the sum of the variances of the X and Y coordinates. With s_Y^2 being the variance of the Y coordinate and s_X^2 being the variance of the X coordinate.

Equation 3.1

$$d = \sqrt{s_X^2 + s_Y^2}$$

The standard deviation ellipse has the property that the larger arm is the line that minimises the squared deviations between the point coordinates and the axis (just like a linear regression line). The minor axis (the smaller arm) has the maximum sum of squared deviations from the point coordinates to the axis. This is necessary to ensure the major and minor axes are at right angles to each other. In statistical terms the two axes are uncorrelated.

To draw the standard deviation ellipse it is necessary to determine the degree of rotation " from the original X axis. This can be derived from the formula:

Equation 3.2

$$\tan(2\alpha) = \frac{2\,\mathrm{cov}(X;Y)}{s_X^2 - s_Y^2}$$

where cov(X;Y) is the covariance of X with Y (Equation 3.2). Once α is calculated the length of the axes of the ellipse can be calculated.

The length of the arms of the ellipse centred on the centroid (Equations 3.3 and 3.4) are:

As required the sum of the squared distances from the data points to the longer axis will be minimised and will be maximised to the shorter axis.

Equation 3.3

$$sX' = \sqrt{sX^2\cos^2\alpha + sY^2\sin^2\alpha + 2\,\mathrm{cov}(X;Y)\sin\alpha\cos\alpha}$$

Equation 3.4

$$sY' = \sqrt{sX^2\sin^2\alpha + sY^2\cos^2\alpha + 2\,\mathrm{cov}(X;Y)\sin\alpha\cos\alpha}$$

There are a number of formulas for the area of the ellipse but the general one (equation 3.5) is:

Equation 3.5

$$A = \tfrac{1}{2}\pi d^2$$

3.6 Interviews

The fifth source of data was interviews directed to officials involved in assignment and/or land and water planning at local and state levels. The purpose was to gain a better understanding of the sugarcane industry and natural resource management. The interviews provided an opportunity to gain insight into the experience and knowledge of managers involved directly in the implementation of relevant programs. Respondents were asked to describe their role in sugarcane management, their views on the strengths and weaknesses or current practices, and alternatives to address weaknesses. Throughout the research, ongoing communication with many of these respondents also provided clarification and understanding about the programs.

3.7 The Case Study Area: Herbert River District

The evaluation of the cane assignment process utilised a case study approach. Its major advantages relate to its ability to show historical and causal processes. This enables researchers to answer 'how' and 'why' questions (Stoecker, 1991). It also provides for a policy relevant setting to consider practice rather than a theoretical one. In this manner, this report hopes to provide useful feedback to line managers. The weakness of the case study approach is its potential lack of objectivity and difficulty in providing generalisation (Stoecker, 1991). Since no accurate measure of independent variables or control groups is often possible, this approach usually relies on retrospective or post-program evaluations. These shortcomings may compromise the reliability of the research when used as the primary means of analysis. However, since there has been a dearth of studies that have assessed the environmental aspects of the cane assignment process, it is appropriate to utilise the case study approach.

The Herbert River catchment drains an area of approximately 10,000 km^2 to the Coral Sea and is the largest of the river systems located in Australia's sub-humid to humid tropical north east (latitude 15-19^0 S, longitude 145-146^0 E) (Figure 3.2). The Herbert River rises at an elevation of approximately 1,070m and has a total length of 340 km. The catchment has three distinct geomorphic sections: the upper catchment (6,000 km^2), the intermediate catchment (1,000 km^2) and the lower catchment (3,000 km^2). In the upper catchment, the topography ranges from level alluvial plains to rugged, deep incised ranges. In the western parts, the land is generally gently undulating while in the eastern portion of the upper catchment, the topography rises irregularly and reaches altitudes over 1,000 m. The middle catchment consists of a deep gorge before entering the lower catchment. The lower catchment consists of a coastal plain flanked by mountains in excess of 1,000m high, but commonly at 600m to 900m with steep slopes. It is the 3,000 km^2 lower catchment bounded to the north by the Cardwell Range and by the Seaview Range to the south that is relevant to this study. The catchment normally experiences warm humid to sub-humid summers and mild dry winters. Large rainfall and temperature gradients exist across the catchment and variability of rainfall is also very high. Mean annual rainfall is 1,370 mm and ranges from in excess of 4,000 mm in the coastal ranges to 750 mm in the extreme west. Approximately 74% of the mean annual rainfall occurs from December to March, decreasing to a minimum in the June to October period.

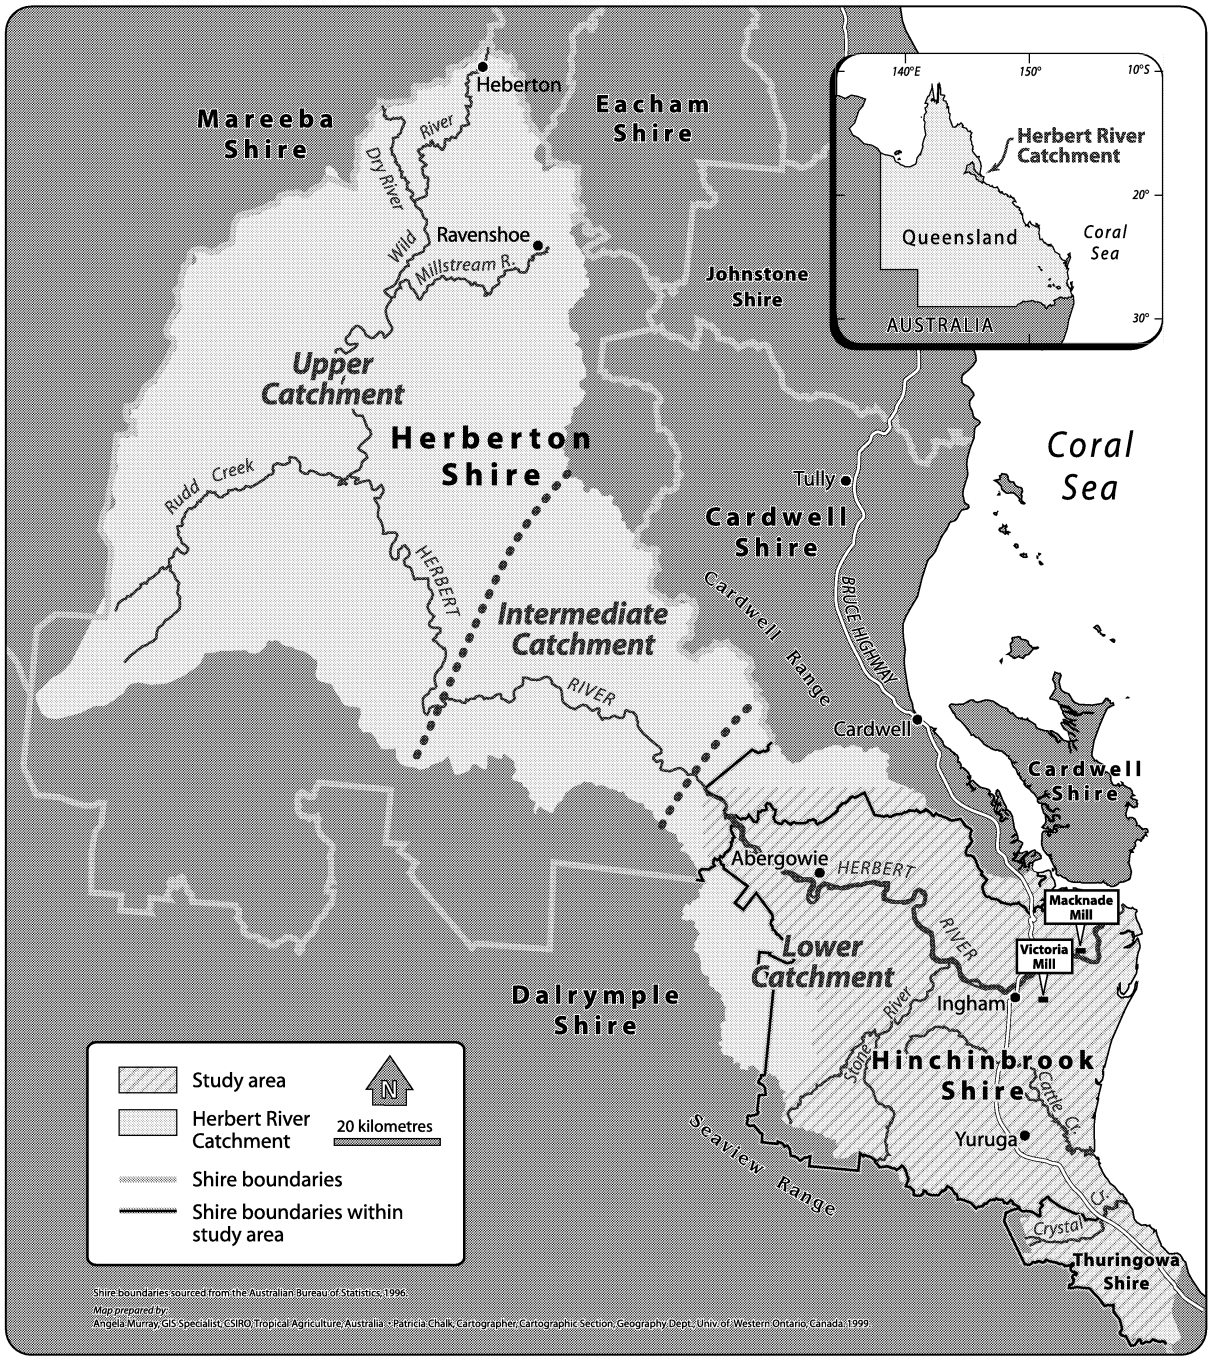

Figure 3.2 The Herbert River Catchment.

Large areas of the upper catchment remain under natural vegetation and are used for extensive beef cattle grazing, while much of the lower catchment has been cleared for crop production or exotic pastures. Agricultural and pastoral production are the largest users of land in the catchment. Natural vegetation in the lower catchment consists predominantly of open Eucalyptus and Melaleuca woodlands, with areas of open grassy plains and dense Melaleuca wetlands (Figure 3.3). Rainforest patterns occur on the creek and river levees. In terms of arable agricultural production, the sugar industry located in the lower catchment is dominant, with approximately 70,000ha of sugarcane under cultivation. Other important industries are plantation forestry, beef cattle and small crops such as pineapple, melon and pumpkin. Small areas are utilised for mining (in the upper catchment only) and industrial activities, or are alienated for urban development.

Two main shires are located in the catchment – Herberton and Hinchinbrook. The catchment has two major population centres (Ingham and Ravenshoe) and a total population of

approximately 20,758 people (1996 Census), of whom 66% are located in the lower catchment. The administrative boundary of the Hinchinbrook Shire is coincident with the lower Herbert River catchment, and it is this region that is of primary relevance to this study. Communities, such as Abergowrie, Halifax and Macknade, have their roots in the sugar industry. Ingham is the major centre with a population of 15,600 people. Thuringowa is a municipality located south of Crystal Creek. It is dominated by population centres on the western and northern limits of Townsville City (Figure 1.1). Sugarcane is grown in both Thuringowa and Hinchinbrook Shires.

The sugar industry in the Herbert River district has approximately 65,000ha of land supplying cane to two sugar mills (Victoria and Macknade) and is the largest intensive agricultural industry in the catchment. Cane is grown mainly in the area surrounding the mills and extending along the Herbert River to Abergowrie and along the Stone River to Upper Stone. Cane has also extended south from Yuruga to Crystal Creek (Johnson and Murray, 1997). The area of cane grown and the amount of sugar produced in Queensland have increased substantially since World War II and most particularly since 1991 (Figure 3.4). The Herbert River district has been one of the most rapidly expanding areas within the state. In 1998, the Herbert River district accounted for approximately 17% of the total assigned area in Queensland and produced about 18% of total sugar. The 30-year average yield per harvested area is 79.3 t/ha for the Victoria mill area, and 77.4 t/ha for the Macknade mill area. The 30-year average commercial cane sugar content (ccs) for Victoria mill area is 13.48 and 13.31 for Macknade Mill. The 30-year average sugar yield for Victoria Mill is 11.23 t/ha and 10.43 for Macknade Mill. Sugarcane with its many varieties will grow well on a wide range of soils. No simple soil/crop yield relationship is evident. However, in general, higher yields and/or lower production costs are associated with well drained and relatively fertile soils, while poorer yields are associated with very wet or the very dry soils. The variation in yield for any given soil reflects both seasonal variation as well as individual farmer expertise (Johnson and Murray, 1998).

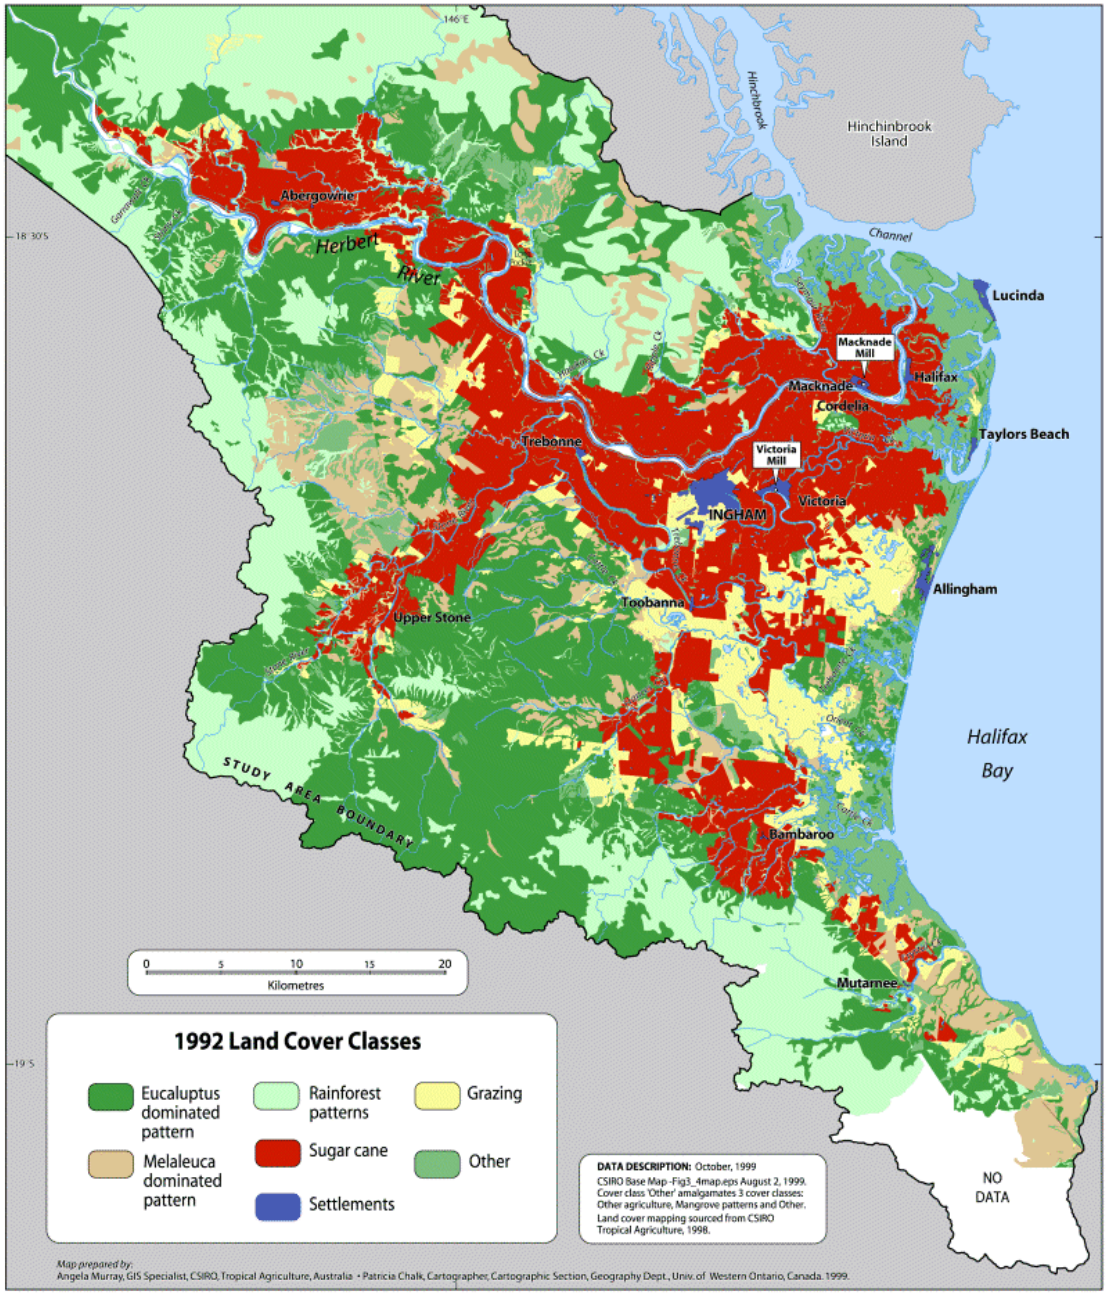

Figure 3.3 Land cover in the Herbert River catchment (1992).

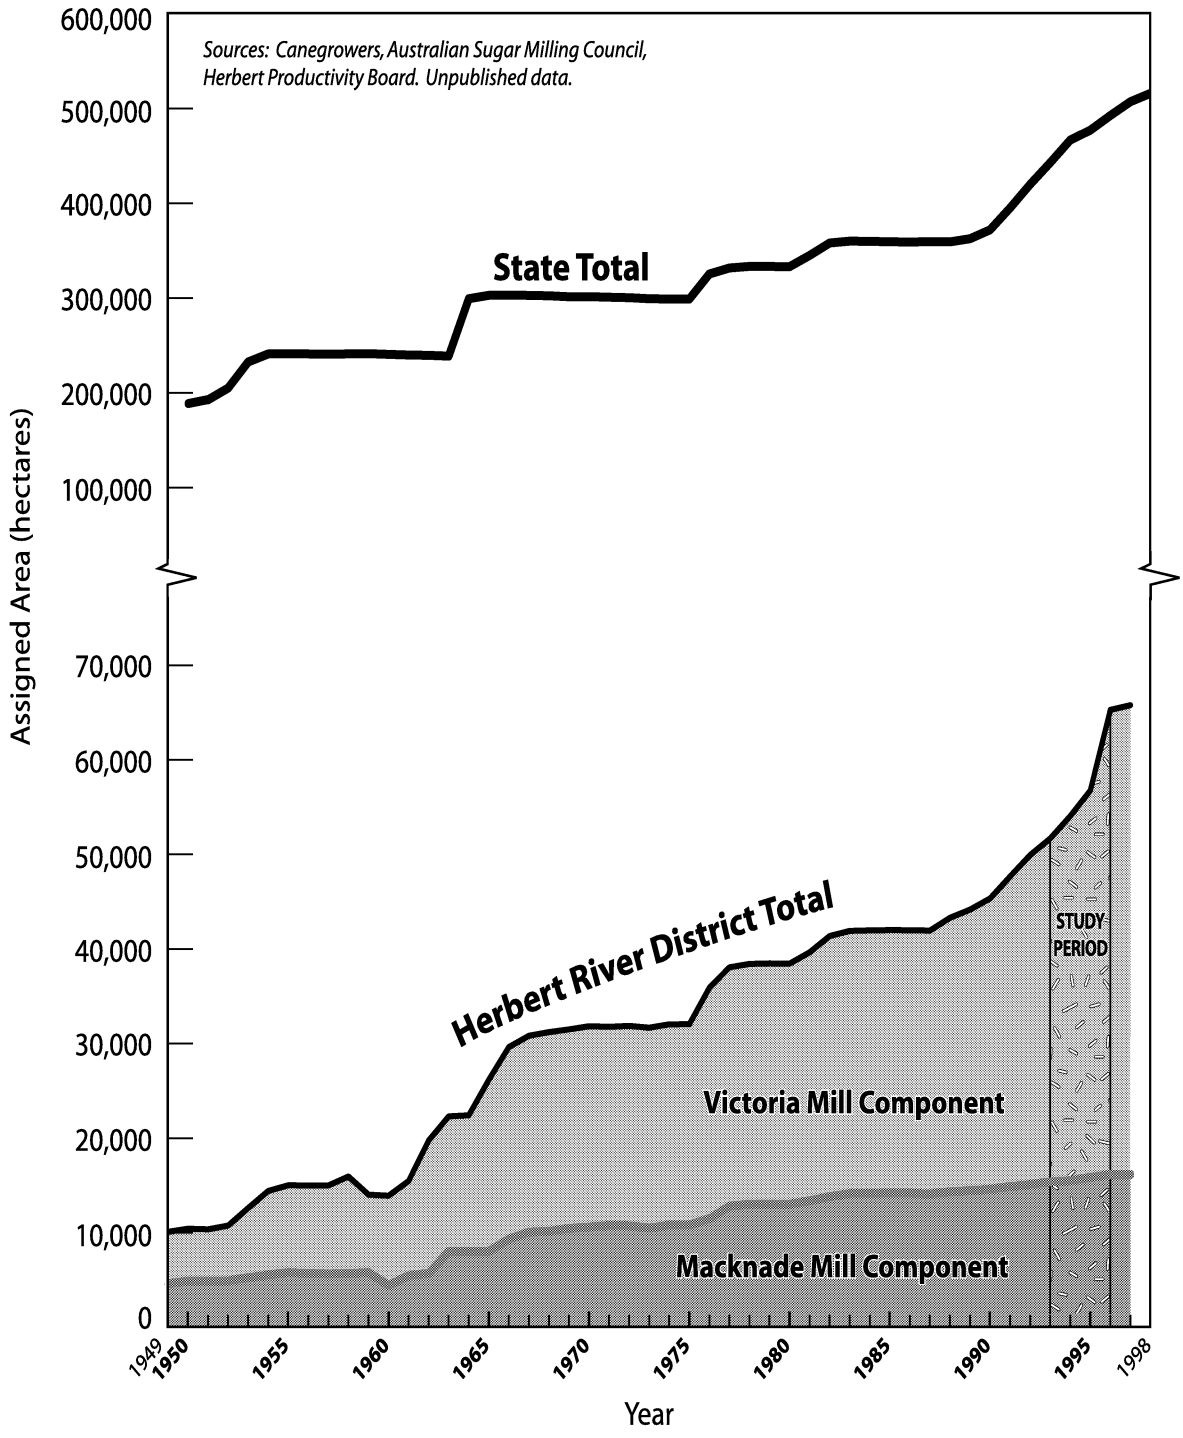

Figure 3.4 Growth in the assigned land in Queensland and the Herbert River district.

3.9 Sugar in the Regional Economy

The sugar industry has been the dominant economic force in the Herbert River district since the mid-1870s. The industry has had a similar impact on most populated coastal regions of eastern Australia north of 30^0 S. Table 3.6 describes the distribution of employment by industry sector in the Hinchinbrook Shire. Approximately 95% of the Herbert sugar industry in contained within the boundaries of the Hinchinbrook Shire. Table 3.7 shows that the contribution of the Herbert sugar industry to output and employment in the regional economy of North Queensland, while relatively small, is comparable to a number of manufacturing sectors in the regional economy, including Wood and Paper manufacturing, Machinery and Appliances and Non-metal manufacturing.

Table 3.6 Industry employment in the lower Herbert 1990/91 and 1995/96.

The effect of the Herbert district sugar industry on regional employment in north Queensland region can be disaggregated into the number of jobs generated directly by the industry, and those resulting from flow-on effects. Direct employment includes those persons employed in the growing and milling of sugarcane. The flow-on employment results from the industry support effects generated by sugar industry purchasing of goods and services from each of the sectors defined in the input-output table. Tables 3.8 and 3.9 show the industrial significance of Herbert sugar industry in terms of output and employment effects respectively

Table 3.8 Estimated output effects of the Herbert sugar industry on the north Queensland regional economy ($000s).

Table 3.9 shows the industrial significance, in terms of employment, of the Herbert sugar industry on the regional economy of North Queensland. Robinson *et al.* (1999) estimates that 1,367 people are employed directly in the sugar industry and approximately 1,936 additional people are employed in the regional economy in industries supporting the sugar industry in the Herbert district. It is estimated that approximately 3,304 people are employed directly or in industries supporting the sugar industry. The employment multiplier (2.417) estimates that for every additional person employed in the industry, a further 1.417 people are employed in other industries in the regional economy.

Table 3.9 Estimated employment effects of the Herbert District sugar industry on the regional economy (number of persons employed).

3.10 Key Natural Resource Management Issues

This regional summary is supplemented below by a selection of facts and widely held perceptions of issues affecting the sugar industry in the Herbert River district obtained from relevant sugar industry documents and survey responses from the Herbert River Integrated Catchment Management Coordinating Committee. The intent is to provide a 'snapshot' of key elements that have influenced sugarcane assignment. These include:

- Since 1991, the area has been one of the most rapidly expanding cane-growing areas in the country (QDPI, 1995). Soil surveys (Wilson and Baker, 1990) identify another 40,000ha of land well suited and available for sugarcane growing. This potential for expansion will have to be considered in the context of environmental and economic considerations.
- The relationship between growers and millers throughout Queensland is often associated with conflict. Season length, division of proceeds from the sugar product, and transport are issues of long-standing dispute.
- Technological innovation has played an important role in increasing productivity and decreasing harvest costs. Herbert River growers have increasingly used laser levelling rather than bedding of paddocks. Green cane harvesting is used by over 98% of farmers in the district (CANEGROWERS, 1998). It reduces production costs, provides the return of some nutrients to the soil through trash blanketing and reduces erosion. BSES and CSR continue to develop varieties of cane to increase productivity.
- The area has a long history of drainage problems. Compared with the past, drainage problems in the 1990s have not been as significant for most growers due to below average rainfalls. During the study period, precipitation during the spring and the summer harvest season provided ideal conditions for sugarcane growing (Figure 3.5). Farmers could easily access fields and the sugar content of the cane could be expected to be relatively higher than usual. However, wet years in 1998 and 1999 have again raised the profile of drainage issues. An attempt is being made to address these issues in the lower catchment through the development of a Master Land and Water Management Plan as part of Stage II of the Sugar

Industry Infrastructure Package (SIIP).

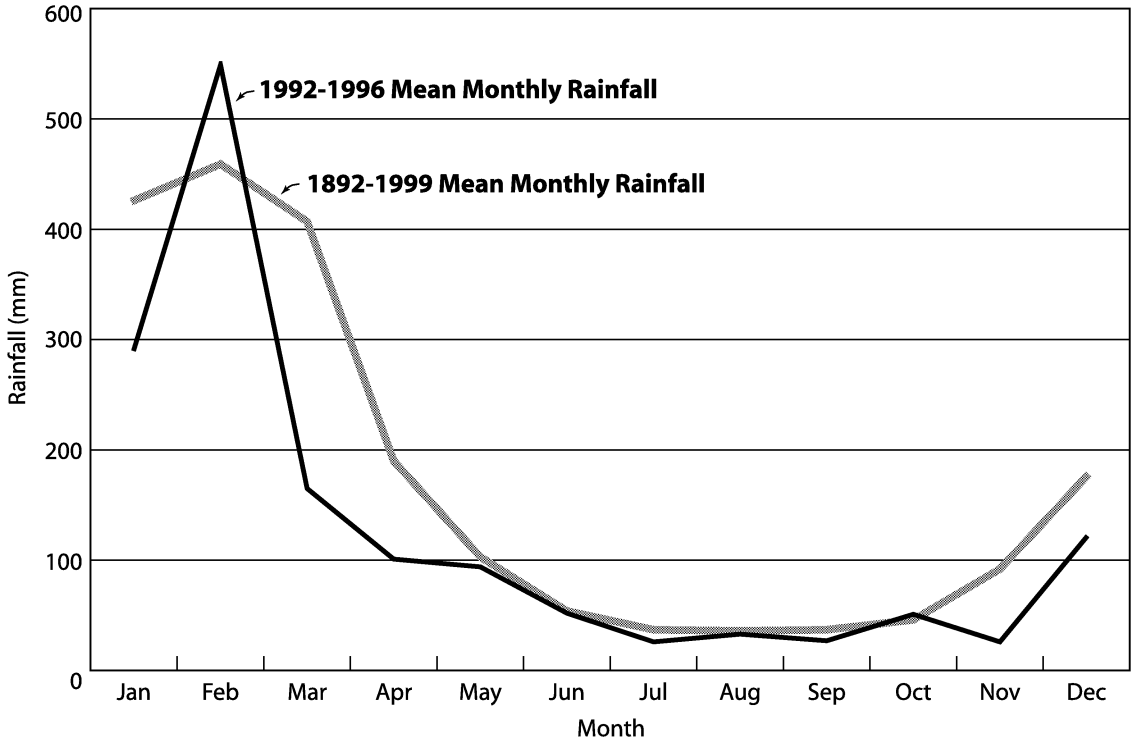

Figure 3.5 Precipitation in the Ingham area: historical and recent patterns.

- In the Herbert River district, environmental issues related to sugarcane expansion became very prominent in 1995. In that year, assignment was granted in an area known as Pomona land holding, which was identified as an important habitat for an endangered species, the Mahogany Glider (QDEH, 1995). A conservation order was placed on the site, and later a draft conservation plan was prepared. There was a significant level of uncertainty and conflict among industry, government and non-government participants concerning this development. The proponents applied for a drainage permit under the *Water Resources Act* 1989. Following a series of reviews by the HSC, QDEH and QDNR, assignment was granted on the area and immediate surrounds. The land was planted to cane, however as expected, the crop there has performed very poorly in the wet years of 1997 and 1998 (QDNR).
- Acquisition of digital ortho-photography at a scale of 1:10,000 was completed in 1997 by the Herbert Mapping Project. A range of private and public agencies sponsored the project. Before that time, only topographic and cadastral maps at 1:50,000 scale were easily available to most resource managers. A Herbert Resource Information Resource Centre was established in Ingham in 1997 as a shared GIS facility for public and private resource managers. The HRIC has exceeded all expectations in terms of its impact on the District and has played a major role in enhancing access of stakeholders to available information (Johnson and Walker, 1997).
- Elections in 1996 saw new governments formed at both federal and state levels. Their commitment to ESD differed markedly, with the Federal government implementing the Natural Heritage Trust in support of the environment, while Queensland reduced support to catchment management and increased spending on water infrastructure. The state government re-organised the administrative arrangements for resource management by forming the Department of Natural Resources (QDNR). It reflects the amalgamation of the Natural Resources Section of the former QDPI and Department of Lands. The remaining QDPI focuses on production issues. The former Department of Environment and Heritage (QDEH) had its name changed to Environment (QDoE), as was the case with the former Department of Housing, Local Government and Planning (QDHLGP) which was called

Planning and Local Government (QDPLG).

- Elections in 1998 saw a new Government in Queensland and the incumbents returned federally. The new Queensland government retained QDNR, but split QDEH in to the Queensland Department of Environment and a newly formed Environmental Protection Agency. QDLGP was renamed, Department of Communication, Information Local Government and Planning and the new *Integrated Planning Act* was formally gazetted by State Parliament. State policy on the environment has benefited from the change, with the new regime actively exploring options for operationalising their ESD commitments.

A 1992 workshop associated with the Herbert River Catchment Coordinating Committee (HRCCC) identified a number of natural resource management issues including flooding, sedimentation, bank erosion, major river course changes, rural drainage, tourism and recreation, biological issues (including wildlife habitats), and water quality and quantity issues. These issues were perceived to result in the loss of valued land, loss of agricultural production, damage to roads, rail lines and other infrastructure, access difficulties and loss of tourism and recreational opportunities.

Sugarcane expansion can have a direct and indirect effect on some of these issues and impacts. For instance, inappropriate rail line development could increase flood levels and increase flood losses and infrastructure damage. On the other hand, tours of sugarcane fields and operations could be part of a "Herbert River Tourist Experience". Thus, sugarcane can be a positive or negative contributor to these issues and impacts.

3.11 Summary

A number of factors should be considered in the research. First, the Herbert River area represents about 10% of the total sugarcane growing area in Australia. Second, during the study period, precipitation patterns were lower than usual and promoted high sugar content in sugarcane. This factor combined with relatively high prices, a well-developed rail network, the availability of suitable land, and the need to expand the land base by 2.5% per year made additional sugarcane development in the Herbert River district both desirable and feasible, from grower and miller perspectives. During the study period, 525 applications covering an area of 16,000ha were made. Spatial representation of the data was possible for 472 of the applications, which reflects about 15,000 ha. The economic importance of the sugar industry to the regional economy cannot be overstated. However, there are concerns that future sugarcane expansion should not detract from the ecological integrity of the area. The next chapter describes the institutional arrangements that were responsible for managing this sugarcane expansion.

4 THE INSTITUTIONAL ARRANGEMENTS FOR ENVIRONMENTAL MANAGEMENT IN THE SUGARCANE ASSIGNMENT PROCESS

4.1 Introduction

This chapter is organised into three sections. The first describes how public resource management agencies have influenced water and land management during the study period as well as major initiatives that have occurred between 1996 and 1999. The second section examines the cane assignment process. The final section reviews two significant government and industry statements in order to assess the appropriateness of the evaluative framework.

4.2 Legacies of the Past: Resource Management by Public Agencies in Queensland

The water management record of the Queensland government before 1989 emphasised a structurally focused, development approach (Fenwick, 1985; Smith, 1998). While many of these

projects contributed to increased economic growth, many interview respondents questioned the efficiency and effectiveness of this approach. In this pre-1989 period, some landowners in the lower Herbert River built levees and other flood and drainage works which failed to comply with the requirements of the *Water Resources Act 1989*. These landowners were not sanctioned for these violations. According to several government officials, senior managers and relevant ministers did not support assertive legal enforcement. An unfortunate legacy of this period is the perception held by some landowners that they can, in the future, alter surface water flows without government approvals and penalties. The scale of these individual works is often inadequate to solve problems and/or the solutions contribute to significant conflicts between neighbours. Any efforts to achieve effective partnerships must address this problem. People must know the 'rules of the game' and be assured that these will be followed and enforced.

The belief that Australian exports could grow between $10 million and $40 million annually as a result of the Uruguay GATT Agreement encouraged a climate for sugarcane expansion. Rapid expansion was also stimulated by the *Sugar Industry Act 1991* (amended in 1994) provisions that required a minimum expansion of 2.5% (about 10,000 ha) per year between 1991 and 1995. It was exceeded in 1995 (QSC, 1995) (Figure 3.4). After 1995, the Queensland Sugar Corporation (QSC) would determine the extent of any expansion. However, it realised at the outset that this growth had to be managed. To that end, the Minister for Primary Industries, who is responsible for the activities of the QSC, committed:

> Officers of his department [to be] readily available to provide assistance and advice as required (Briody, 1992: 5).

There were no additional resources provided to QDPI or other agencies in the Herbert River district to specifically address this need. Thus, any government involvement in sugarcane expansion was done with existing or fewer human and financial government resources. In addition, neither Victoria nor Macknade Mills hired additional field staff to supervise the expansion activities during the study period.

The need to incorporate public resource agencies into the assignment process was emphasised by the QSC (1993: 7):

> Where the need arises, Local Boards should liaise with the Queensland Department of Primary Industries, Land Use and Water Resource Groups, Drainage Boards and the Bureau of Sugar Experiment Stations in respect of proposed new land and where necessary, are to attach as conditions of the grant assignment, any land use restrictions imposed by such authorities. The Corporation has informed relevant organisations of the expansion and requested them to make officers available for consultation with Local Boards as necessary.

Interviews with regional public agency officials suggested that they were not well informed about this request through normal administrative channels. In the Herbert River district, they perceive their lobbying of the Local Boards as the key factor that prompted the 1996 formation of the Environmental Advisory Committee. Details about this group will be provided later in this chapter.

A more recent aspect of the management legacy pertains to the 1988 state election. At that time, a new State Government was elected and committed itself to providing more effective natural resource management. It focused attention on formulating new resource management policies, and adjusting administrative arrangements. That tradition appears to have been followed by subsequent governments (at least in print). Commonwealth governments have also advocated the need for ESD. The following sections discuss the basis and nature of government involvement that significantly influences the sugarcane expansion process.

4.3 Queensland Departments of Primary Industries (QDPI) and Natural Resources (QDNR)

In 1989, the new state government responded, in part, to the need to implement sustainable development by enhancing the institutional capacity to implement resource programs. The Department of Forests and the Water Resources Commission were amalgamated into the Department of Primary Industries (QDPI). During the study period, QDPI influenced sugarcane growing through legislation, programs, and policy statements. It administered the *Water Resources Act 1989* which provides for the:

> Construction, control and management of works with respect to water conservation and protection, irrigation, water supply and drainage;..and protection and improvement of the physical integrity of water resources.

This statute guides drainage boards, which have been formed in some portions of the lower Herbert River (Figure 4.1). QDPI provided a rural extension service program, which focused on the production, financial and resource management aspects of farm activities. Participation in this service was voluntary. Policy statements, such as "Land Use Practices for Wet Tropical Floodplains" represent the third mechanism available to QDPI and other agencies (QDNR, 1996). This document was being prepared during the study period and was endorsed in January 1998 (QDNR, 1998). The intent is to guide agricultural land development, and more specifically drainage at the farm level, on Queensland's wet tropical coast. However, it is not legally binding. Management principles, land assessment, farm planning, drainage requirements and design, and implementation and management arrangements are discussed. Local Sugarcane Assignment Boards (Local Boards) are encouraged to utilise the document in order to guide their decision-making.

The *Herbert River Flood Management Study* was undertaken between 1978 and 1980 by Cameron McNamara on behalf of the Herbert River Improvement Trust. The goal of the study was to recommend a program of short and long-term proposals that conform to an overall flood management strategy. The area inundated from Herbert River flooding was defined as the study area. The recommended flood mitigation options consisted of additions to the natural levees over a 10 km length of the lower Herbert River with associated floodgates and overflow structures to contain the river in this reach up to the 1 in 3 year flood. Land drainage problems to the north and south of the river are compounded by backup flows from the Herbert River during flood events and the inability of these areas to drain into the river during high water levels. Floodgating of creeks draining these areas was recommended to prevent backflows (Rudd *et al.*, 1985).

The study recommended that the following set of structural and non-structural measures be implemented:

- Partial containment of the Herbert River to prevent up to 1 in 3 year flood events spilling into the adjacent floodplain over a 20 km length of river.
- Protection of the town of Ingham by an upstream training levee system and a flood by-pass channel.
- Upgrading of the flood forecasting and warning system.
- Floodplain zoning.
- Floodproofing of construction in the floodplain.
- Flood education measures.

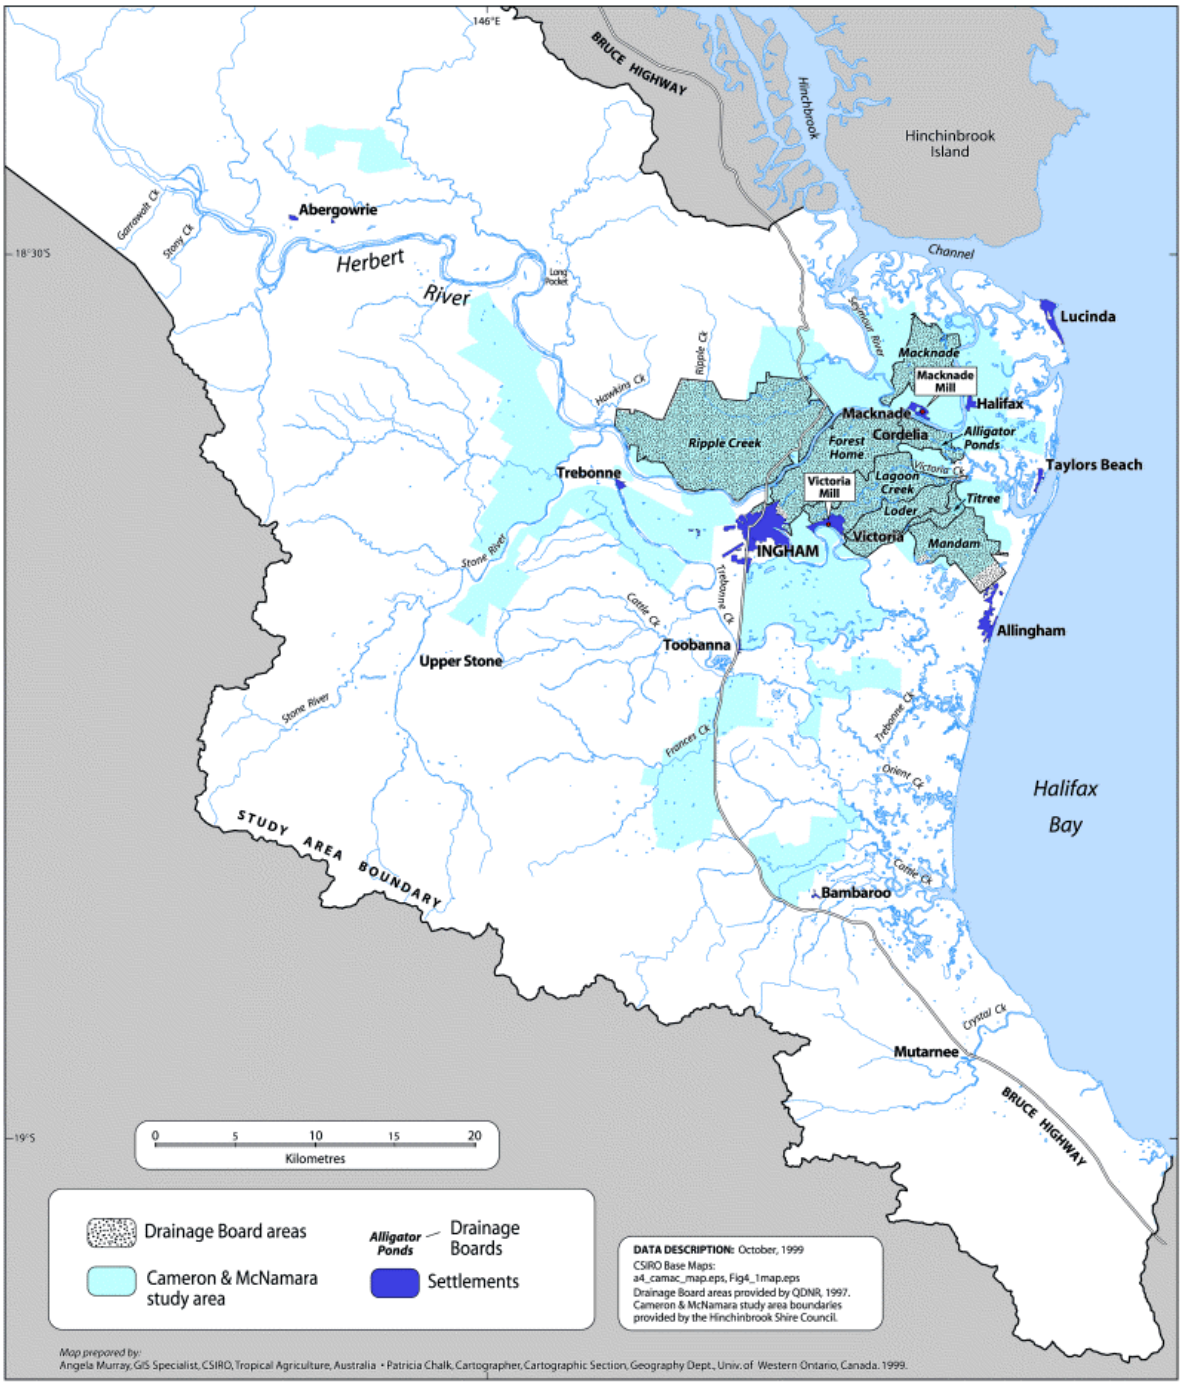

Figure 4.1 Drainage Boards and the Cameron-McNamara study boundaries.

The recommendations of most interest to this present review of cane assignment process pertain to the partial containment of flood flows. Some construction associated with this recommendation was completed and includes the floodgates on Catherina Creek (which drains the Forestholme sump) and Ripple Creek. These projects drain these two sump areas and prevent back up water from entering the sumps, and the levee system along the Herbert River (Rudd *et al.*, 1985). Drummond (1993) suggests that existing levees may have resulted in increased water levels downstream of the Anabranch.

The *Hinchinbrook Rural Drainage Plan* was prepared between 1981 and 1984 on behalf of the Hinchinbrook Shire Council. The Plan covered many of the drainage areas both existing and proposed. The plan recommended works in association with the four existing drainage boards totaling $1.2 million. Much of that work has not been implemented (Drummond, 1993).

The main issues for each drainage area were:

- Ripple Creek Drainage Area: the drainage plan recommended the construction of a controlled overflow from Ripple Creek to the Seymour River. It is proposed to incorporate the adjacent drainage area serviced by the informal Seymour Drainage Committee upon amalgamation of the Boards.
- Forestholme Drainage Area: Attention has been focussed on the controlled outlet capacity to Alligator Ponds and the urban contribution to runoff as being the main limitations to improved performance of this scheme.
- Mandam Drainage Area: Runoff from significant areas outside the gazetted boundary and the overflows from Palm Creek cause major difficulty in this scheme. The board has to date undertaken significant work to enhance the capacity of its existing outlet to Mandam Creek. The Rural Drainage Plan recommends the construction of an additional outlet to Victoria Creek.
- Loder Creek Drainage Area: The key limitation to the drainage performance of this scheme is the capacity of Lagoon Creek downstream of its confluence with Loder Creek (Drummond, 1993).

The *Hinchinbrook Rural Drainage Plan* (Cameron McNamara, 1984) has been consistently referred to in Conditions of Assignment granted between 1993 and 1996 (Table 4.1). That study's objectives were "to achieve a consistent standard of drainage which would increase rural production and to define required works, their location, cost and benefits to be achieved from the works, and subsequent management and operation leaving only detailed design and documentation necessary to implementation" (Cameron McNamara, 1984: 1-1). These ends were achieved by classifying the lower catchment according to the perceived need, scale and feasibility of structural drainage works. This categorisation, based on site inspections, interviews with relevant private and public resource managers, questionnaire responses from growers, public meetings and 1981 cane productivity data, was used to screen potential areas. Of the three categories established, only two were the subject of detailed drainage design and subsequent benefit-cost and environmental impact analysis, and review of institutional alternatives. The report provided economic analysis on nine structural alternatives and recommended that a drainage board be formed under the *Water Resources Act*. Since these areas contain parts of catchments, it is unclear how adequately this delineation promotes effective drainage or catchment management (Figure 4.1). The use of the catchment has been a longstanding principle in water management.

At present, these recommendations form the basis of the more detailed drainage design and institutional analysis being conducted through the Sugar Infrastructure Improvement Package (SIIP). Initiated in 1992, this Commonwealth-State agreement is to enhance the sugar industry's performance. If sufficient landowner support is achieved within the lower Herbert River catchment, the desirability and feasibility of these proposed works can be considered. The formation of a single Water Management Board is a requirement of SIIP. A key outcome of the process will also be the development of a Master Land and Water Management Plan for the lower Herbert

These legislative, farm extension and floodplain policy guideline functions were transferred to the newly created Department of Natural Resources (QDNR) following the 1996 agency reorganisation. The remaining QDPI maintained responsibilities for regulating marine habitat (*e.g.* mangrove) clearing under the *Fisheries Act 1994*. Draft Guidelines for a "Fish Habitat Code of Practice" were prepared in 1999 by QDPI (Fisheries Group) in cooperation with CANEGROWERS (Tapsall *et al.*, 1999). The intent is to provide 'strategic permits' to farmers for regular maintenance works (*e.g.* slashing and mowing of existing roads; spot spraying and blanket spraying; trimming trees along existing farm roads; and medium impact de-silting of drains in areas of marine habitat). After QDPI (Fisheries Group) review, individual permits may be issued for major excavations of existing drains, the construction of new drains; and new land

clearing or re-assignment in designated areas. One-day workshops will be held for landholders and contractors who undertake work. Completion of the workshop will be a requirement for permit approval.

Table 4.1 Evolution of the Conditions of Assignment: 1993-1996.

General Concern	Specific Condition	Applicable Year 1993	1994	1995	1996
Administrative	– failure to comply with any condition may result in assignment being rescinded	*	*	*	*
	– all requirements with all or any relevant State legislation applying to a particular location, development, proposal or project must be met				*
Drainage	– works must comply with the *Rural Drainage Plan* (1984) or other approved standards	*	*	*	*
	– growers may be required to cooperate in formation of community-based drainage or soil conservation schemes	*	*		
	– plans for works must be in accordance with the plan submitted at the time of application		*		*
	– any works within or connecting to a watercourse, lake, or spring must be authorised by a relevant license or permit under the *Water Resources Act 1989* prior to the works being undertaken		*	*	*
	– areas known to be preferential flood overflow paths are excluded				*
Land and Water	– areas of acid sulphate soil may not be used for cane growing			*	*
	– development must comply with Interim Guidelines for Development on Floodplains			*	
	– following areas excluded:				
	– mangrove swamps naturally subject to tidal inundation				
	– areas below 3m contour (generally unsuitable)				*
	– riparian zones of 10m along courses and drainage lines, or lesser widths as adopted by HRCCC				*
	– adherence to QDPI Guidelines for Sustainable Development on Floodplains is recommended				*
					*
Soil	– land holders are encouraged to seek and adopt advice from DPI on soil conservation measures for slopes >3% slope			*	
	– land holders must seek and adopt advice from DPI on soil conservation measures for slopes >3%				*
	– areas of class 4 and 5 DPI land suitability excluded				*
Wildlife	– 100m riparian zone of native vegetation must be maintained on each side of existing watercourses as a habitat corridor for the Mahogany Glider				*

The Queensland Department of Lands (QDOL) was also merged into the new QDNR. Since 1991, the QDOL was required through an amendment to the *Lands Act* to consider the environmental implications of leasing and selling Crown Lands (Duncan, 1993). Cane land expansion in the Herbert River district has involved the purchase or lease of Crown Land. In selling and leasing Crown Lands, the Federal *Native Title Act* requires adequate consultation with an 'accredited' body. In the Herbert River district, this body is the Central Queensland Indigenous Land Council. To date, no native title claims have been lodged over agricultural land in the Herbert.

One impending change is the introduction of a *Natural Resource Management* Bill (Maher & Associates and MacDonald, 1998). A discussion paper released in 1994 identified the following

objectives:

- to provide for the equitable and efficient allocation of State owned or controlled water, forest and fisheries resources;
- to maintain the availability of natural resources for the economic development of rural industries;
- to maintain and enhance the quality of natural resources and to protect them from degradation;
- to minimise or prevent the environmental impact of natural resource use; and
- to enhance the economically efficient and effective use of natural resources.

One significant suggestion in the Discussion Paper was the introduction of statutory-based Natural Resource Management Plans in order to:

- determine the allocations of State owned or controlled water, forest and fisheries resources in a local area such as a catchment or district;
- define use/management practices for water resources, State Forests and fisheries; and
- define use/management practices for Special Management Areas in both freehold and leasehold land (Maher & Associates and MacDonald, 1998). Other management mechanisms under consideration include Codes of Practice and the use of voluntary NRM Agreements where individuals wish to protect privately owned or managed natural resources.

At the time of writing, no definitive action had been taken on the NRM Discussion Paper.

4.4 Queensland Environmental Protection Agency (QEPA)

The Queensland Environmental Protection Agency (formerly the Department of Environment between 1996 and 1998) and formerly the Department of Environment and Heritage (QDEH) (before a 1996 agency reorganisation) is charged with promoting the conservation, management and wise use of the environment for the long-term public benefit. That agency conserves vegetation and wildlife species through a range of mechanism provided by the *Nature Conservation Act 1992*. For instance, it may enter into agreements with private landowners to protect designated wildlife areas. Acquisition may be negotiated between the agency and a landowner. These areas are designated on the basis of supporting rare and threatened wildlife, critical wildlife habitat, a protected area (*e.g.* National Park), or areas of significant nature conservation interest.

This legislation is relevant to the Herbert River district. In 1995, an interim conservation order under the *Nature Conservation Act 1992* was placed on the Pomona land holding because the clearing of the forest area for cane growing would "have a significant detrimental effect" on the Mahogany Glider. A *Draft Mahogany Glider Conservation Plan* was prepared (QDEH, 1995). It outlined over 28,000ha of critical habitat requiring protection. Much of this area is suitable for sugarcane growing, and some of it has already been assigned. Funding for this $16 million conservation plan was provided from the Sugar Coast Environmental Rescue Package Agreement (SCERP). A Commonwealth-State program supported by CANEGROWERS, SCERP aimed to provide a total of $16 million over a 3-year period for the acquisition of land, and the development of intergovernmental management initiatives, public education programs and landowner assistance measures. With the expected cuts to Commonwealth budgets and the potential impacts on state initiatives, it is unclear whether the announced total of $16 million will be secured. The adequacy of the $16 million is also questionable given that 75% of the entire amount was dedicated to the Mahogany Glider program alone.

Some interview respondents maintained that QDoE could use the *Environmental Protection Act 1994* to influence land clearing and farming by placing a "duty of care" on farmers to protect the environment. Under the *Act*, an Environment Protection Policy on air, noise, water and waste management is to be developed, and a specific reference is made to a Code of Practice for

Agriculture. The latter is being drafted currently with the participation of the agricultural sector (that includes the sugar industry) and will be discussed later in this chapter. The efficacy of this approach is unknown. On the one hand, the *Act* uses the term "environmental harm" to embrace a wide range of impacts, it refers to "contaminant" and excludes land clearing for agricultural development as a regulated activity. These provisions suggest that the development of land for agricultural production is not regulated by the *Act*. On the other hand, the court could view the storage of acid sulphate soils in farm ponds as a "contaminant" exclusive from land clearing activities. The final outcome of litigation will reflect several issues including: (i) if the activity causing environmental degradation was defined as a "land clearing activity"; (ii) if acid sulphate water is defined as a "contaminant"; (iii) if the relevant water quality criteria (yet to be defined under the legislation) has been violated; (iv) a demonstrable lack of due diligence by a landowner (yet to be defined in an Agricultural Code of Practice); and (v) the significance of environmental harm resulting from this activity.

There is no question that the *Environmental Protection Act 1994* will be more relevant in managing specified farming practices. Farming practices which create air emissions (*e.g.* cane burning), discharge water which contravene stormwater quality standards, contaminate land or ground water through the use of pesticides, or exceed specified noise levels could be prosecuted. In 1997, an Environmental Protection Policy for water was introduced. It could support the development and implementation of catchment-wide plans.

The *Coastal Protection and Management Act 1995* manages the coastal zone and development on it from an ecological perspective. It supports the preparation of regional coastal management plans from about 6km offshore to above the high water mark. Provisions are to be incorporated into the Strategic Plans of local government. Under the *Act*, control districts may include (Maher & Associates and McDonald, 1998):

- tidal rivers and lands up to 100m from the highest astronomical tide mark (HAT);
- land up to 1km inland from HAT at a river estuary/delta;
- islands; and
- foreshores up to 400m above HAT.

A coastal management plan for the Cardwell/Hinchinbrook Region has been developed.

4.5 Queensland Department of Communication, Information, Local Government and Planning and the Hinchinbrook Shire

This department was formerly the Queensland Department of Planning and Local Government (QDPLG). It and its predecessors ensured that the requirements of the *Local Government (Environment and Development) Act* are met. Local governments are responsible for implementing the *Local Government (Environment and Development) Act* in a manner consistent with goals and objectives stated in its strategic plan. In 1998, the state passed the *Integrated Planning Act 1997* that provides for the development of State Planning Policies. These will be implemented through local government plans and the Integrated Development Assessment System (IDAS). Ecological sustainability as well as traditional planning goals will be pursued through coordinated planning, managing the development process, and the effect of development of the environment (Maher & Associates and MacDonald, 1998).

The IDAS is part of *IPA*. IDAS purports to provide a procedure through which up to 60 different types of approval may eventually be delivered in a "one-stop shop" for developers. In order to achieve this outcome, the IDAS provides an avenue through which State agencies act as referral agencies for applications made to local government that raise issues falling within their jurisdiction. According to Maher & Associates and MacDonald (1998), it will provide a "whole of government" approach to the review of development proposals, requests for information,

public notification, decision making and dispute resolution. Key to the success of the process is the performance of "assessment managers" and "referral agencies". The assessment manager administers and processes an application, and has a major role in final decision making. While the assessment manager will vary from case-to-case, local government will assume this as a default option.

Two types of referral agencies are identified in IDAS. A "concurrence agency" can request relevant information, identify conditions of approval that must be incorporated into the final application which the assessment manager must include if approving, and refuse the application under specified circumstances. As of December 1998, the Environmental Protection Agency (formerly the Department of Environment and Heritage), the Department of Employment, Training and Industrial Relations, and the Queensland Fire and Rescue Authority have become concurrence referral agencies with respect to some development applications that fall within their jurisdiction. "Advice agencies" must be consulted, but the assessment manager is not bound by any comments provided to them (Maher & Associates and MacDonald, 1998). Responses from all referral agencies will be required within specified time frames to support more timely decision making. Implementation of *IPA* will be phased in over a five-year period.

The Hinchinbrook Shire adopted its first plan in 1984. Unfortunately, it cannot be considered 'strategic'. It identified a "rural zone" which dominated all other land uses and promoted a climate for poorly planned cane land expansion. Under law, permitted development (*i.e.* consistent with the zoning) is considered "as a right" which precludes the shire reviewing proposals and initiating environmental assessments. Cane land expansion within the rural zone is not referred to the Shire. Rather than providing a strategic vision, it controlled the "subdivision of land, as distinct from the subsequent use of land" (Sinclair Knight Merz, 1998: 7). In short, the Shire received very little information and had very little influence regarding the cane expansion process and its final decisions. The development of sugar-related rail and road systems impacts on shire drainage works. In addition, the Shire eventually maintains roads developed for sugarcane transport. Since these developments were treated "as a right", they were not reviewed through the impact assessment provisions of the *Local Government (Planning and Development) Act.* Other legislation related to transport development provides for Shire participation in these areas. It is the 1984 plan that was in force during the entire study period. During the late 1990s, there were significant developments at both state and local levels that have provided for more strategic planning. These are discussed below.

Thuringowa Shire adopted its plan in 1988 and was revised in 1996. Like the Hinchinbrook Plan, the old plan failed to effectively guide rural development, and specifically sugarcane expansion south of Crystal Creek (Figure 3.2). In particular, it had a very strong focus on urban development issues. No attempt was made at integrating rural water and land management issues into the assessment of planning proposals and development applications. At present, Thuringowa Shire is preparing a planning scheme that will comply with the new *IPA* legislation and will replace its 1996 Shire Plan. The statement of proposals is to be advertised in November 1999.

A revised local planning scheme for Hinchinbrook Shire was gazetted in December 1997. It embraces many of the themes contained in *IPA.* Considerable emphasis was placed on integrating water and land management issues into the assessment of planning proposals and development applications. According to Vella (1999), the new strategic plan enables Hinchinbrook Shire to better influence development throughout the entire area, not just Ingham. The goal of the plan is to:

> provide a framework to facilitate the continuing use and development of the Shire's resources according to sound environmental and catchment management practices, and, to promote the diversification of the Shire's economic base, for the long-term benefit of the Community (Hinchinbrook Shire Council, 1997 as cited by Vella, 1999: 18).

Three environmentally related objectives support this goal statement:

1. Catchments and subcatchments within the Herbert River catchment will be identified.
2. No adverse environmental impacts are to be associated with the development and use of land within any catchment identified in (1) above. This will achieved by having regard for and implementation of the goals of ICM.
3. Sensitive and sustainable land use practices will be promoted through the development process.

Vella (1999: 19) maintains that:

> this will be implemented by requiring and encouraging "all development and land uses…to adopt sound management practices so as to minimise, mitigate and contain the impacts on the land, water and biological resources of the catchment system." Additionally, "the Council may refuse to support any proposal which would prejudice the long-term values of the resources within the catchment system affected."

Five land use classes were established: Public purposes, Rural, Town, Village and Special Activities. Although no direct zoning mechanism was established to conserve natural resources, agricultural land uses and wetland conservation are to be regulated.

Protection of the environment from agricultural activities is to be achieved by changing the definition of a rural zone. This provision requires landholders to apply for Shire approval for intensive rural activities under the following circumstances:

- The land is classified as Class 4 or 5 agricultural land; or
- The land is classified as Class 1,2 or 3 and contains one or more of the following features:
  - (a) a known wetland as identified in the Plan;
  - (b) a parcel of land the subject of a Conservation Order or Interim Conservation Order under the *Nature Conservation Act 1992*; or
  - (c) a fish habitat reserve as defined in the *Fisheries Act 1994*; or
  - (d) an Active Coastal Area as described in the Strategic Plan
  - (e) Wet Tropics World Heritage Area; or
  - (f) an area of known Mahogany Glider habitat as identified in the Plan, and not included in a Conservation Order or Interim Conservation Order; or
  - (g) land below the RL 3.0 metres AHD contour; or
- The land in abutting a fish habitat reserve as defined in the *Fisheries Act 1994*.

Intensive agriculture is defined as:

> The use of land for intensive production of crops, such as but not limited to sugarcane and horticulture, at rates of production beyond the natural capacity of the land where the land relies upon the regular and systematic application of fertilizers and other chemicals, and includes the establishment of any infrastructure necessary for the conduct of the use. The definition does not apply to small-scale agriculture conducted on premises or a site less than two hectares in area.

Thus, an impact assessment approach is to be utilised in enhancing environmental management in the Hinchinbrook Shire.

The new planning scheme also requires landholders, overseen by council, to maintain conservation values on good quality agricultural land, so as to promote ecologically sustainable primary production. It also introduces other provisions that encourage the sustainable use of natural resources and the protection of environmental systems or features of local conservation value.

The Herbert River Improvement Trust is essentially another arm of local government. Having a jurisdictional area embracing the Hinchinbrook Shire, this agency consists of two local councilors and a QDNR representative. While it is primarily concerned with in-stream erosion and flood protection, it could play a modest role in water and related land management. In the

Hinchinbrook Shire, a river improvement notice of 10m adjacent to specified watercourses has been applied to subdivision proposals on land. For a $110.00 fee, this notice is attached on the land title that prevents alteration of the channel and the clearing of the adjacent corridor. This mechanism provides for secure land tenure under the Herbert River Improvement Trust and precludes clearing or development within the designated area. The primary objective is to ensure major watercourses are maintained for rural and urban drainage purposes. The 1994 NRM Discussion Paper suggests that River Improvement Trusts could become NRM statutory bodies and assume a range of water-related responsibilities.

4.6 Integrated Catchment Management

The Queensland Government released *Integrated Catchment Management* (ICM) in 1991 as a means of considering:

> the management of land, water and related biological resources in order to achieve the sustainable and balanced use of these resources. It provides a framework for fostering cooperation and coordination between many land holders and other resource users, community groups and government agencies involved in the use and management of land and water resources (Queensland, 1991: 1).

While it was recognised by the government that other initiatives, such as the proposed State Conservation Strategy, state-wide environmental programs (*e.g.* Landcare), and broad regional strategies such as the Far North Queensland 2010 Growth Management Strategy and Coastal Protection Strategy would be important activities, ICM was to involve all sectors of the community and thereby achieve integrated and coordinated action. ICM was also to focus on several important issues, rather than a single one, in achieving an integrated perspective.

The final product of the ICM process is a Catchment Strategy that ranks catchment issues, and identifies appropriate implementation mechanisms. This document was in the process of being written during the study period. It was released in November 1998. The Herbert River Catchment Coordinating Committee's objectives were to:

- Coordinate government agencies and the community to pursue common goals.
- Seek community involvement in catchment management.
- Identify and rectify natural resource degradation.
- Promote the wise use of all natural resources within the catchment.
- Identify key indicators of biodiversity and monitor as a measure of catchment health.
- Encourage the retention of significant natural habitats within the catchment (HRCCC, 1998: 2).

The eight-chapter plan covers issues related to land, water, stream and habitat management as well as implementation. Concerning land management, key issues included:

- inappropriate land use allocation and its impacts on resources and natural systems;
- impacts of land management on productivity; and
- impacts on other values of land and adjacent land and water resources.

The fragmentation of habitat, poor water quality and quantity monitoring, and the loss of wetlands were other issues identified in the strategy. Many of the principles and recommendations noted in the strategy formed the basis for the previously described Hinchinbrook Strategic Plan. Thus, implementation of the strategy is underway. An opportunity exists for the catchment strategy to develop Codes of Practice or other mechanisms that could influence cane land expansion or related activities such as drainage or irrigation practices.

4.7 Other Legislative Requirements

The outcomes of the previously noted Hinchinbrook Shire Strategic Plan review and HRCCC planning are unclear. This uncertainty also extends to some other recent legislative initiatives in Queensland, such as the *Wet Tropics Management Plan* that proposes the protection of other sensitive areas (Wet Tropics Management Authority, 1995). When a local land use scheme is adopted, information from these and other relevant Commonwealth and State initiatives should be incorporated into relevant municipal planning documents. State agencies will also have to have regard for these statements.

The Commonwealth Government is involved through funding programs such as the previously mentioned SCERP. In 1992, it funded in cooperation with the State Government and the sugar industry a Sugar Industry Infrastructure Package (SIIP). The Herbert River district was successful in its application, and a preliminary engineering study has identified eight drainage projects worthy of more detailed engineering design. That study also advocates the formation of a single drainage board to provide for an adequate level of maintenance. That single board would replace the existing fragmented arrangement, but would not extend to the entire cane growing area of the lower Herbert River. At the time of writing, agreement had not been reached on a single drainage board. Similarly, a number of proposed works were in doubt due to concerns voiced by the QEPA, QDPI Fisheries and Environment Australia.

4.8 The Queensland Sugar Industry

4.8.1 The Sugar Industry Act 1991

Before 1991, growth in the sugar industry was controlled through a series of international agreements and tariffs. In Australia, the Sugar Board provided a highly centralised decision-making structure. This arrangement changed in 1991 with the passage of the *Sugar Industry Act 1991*. That statute provided for annual minimum increases in assignment of 2.5% (about 10,000 ha) between 1991 and 1995, and greater flexibility in the administration of the *Act*. Some of this flexibility was achieved by delegating increased decision-making responsibility to Local Boards. However, the centralised administration of the Central Sugarcane Prices Board meant that they were not that active. Under the recent tenure of the Queensland Sugar Corporation (QSC), this situation has changed.

A detailed review of the cane assignment system can be found in ABARE (1991) and Industry Commission (1992). In brief, sugarcane or land assignment was introduced in 1926 to control the level and location of sugarcane production, and to preclude the growing and commercial harvesting of cane (Industry Commission, 1992). Until 1991, cane land expansions were 'planned for' by the Sugar Board. Assignments were originally specified in terms of particular plots of land on a designated farm, and growers could not easily get permission to change assignments even within existing farm boundaries. This requirement was changed in 1991. Cane can now be grown on any part of an assigned area. While growing on unassigned land is not prohibited, mills are not obliged to accept it and the grower receives a penalty price of $1 per ton. Mill and farm assignments continue to control the size and rate of growth at state and local levels. At a local level, these regulations match cane production with a mill's crushing capacity and transport infrastructure, so that expansion does not penalise existing growers (Industry Commission, 1992). Improvements and expansion of the transport network and mill infrastructure occur regularly in response to market conditions, and provide opportunities for cane land expansion. At a state level, regulations should ensure markets for the sugar products.

4.8.2 Considerations in Granting Assignment

Section 12 of the *Sugar Industry Act 1991* identifies the principal objectives of the QSC as:

- Ensuring that the policies for the Queensland sugar industry are successfully implemented.

- Enhancing the efficiency, competitiveness and access to markets of the Queensland raw sugar industry.
- Enhancing the long-term economy of the Queensland sugar industry.
- Enhancing the benefits flowing from the Queensland sugar industry to cane growers and mill owners and to the economy of Queensland.
- Encouraging initiative and innovation among cane growers and mill owners and others involved in the Queensland sugar industry (QSC, 1995: 4).

While the QSC is responsible for implementing the *Sugar Industry Act 1991*, it has delegated much of the responsibility for mill-area decision making to the 25 Local Boards in Queensland. These bodies are constituted under the *Act* with the objective of ensuring the efficient participation of mill owners and cane growers in the production and milling of cane. As noted earlier, each Local Board comprises an independent chair, two mill representatives, and two mill supplier representatives. It is the Local Board which acts as an 'agent' for the QSC, and receives and determines applications for new and increased assignment (Briody, 1995). Powers to rescind assignment are reserved by QSC on the advice of the Local Board. The *Primary Producers' Organisation and Marketing Act 1926* established CANEGROWERS as the formal grower body for sugarcane (excluding marketing functions) (CANEGROWERS, 1995).

QSC's statutory objectives are oriented toward economic considerations, although the "long-term economy" of the industry can be achieved, in part, through effective natural resource management. Direct reference to the environment in the *Sugar Industry Act 1994* is found in Sections 144(2)(c) and 147(4)(a)(iii) that require environmental issues to be part of the decision-making process. Reference to the environment is also found under the *Sugar Industry (Assignment Grant) Guidelines* which are established under Section 29(b) of the *Sugar Industry Act 1994*. The guidelines should be viewed as QSC policy that must be complied with by all Local Boards. All respondents from the Macknade and Victoria Local Boards were keenly aware of their obligations under the *Act* and *Guidelines*. Section 6 of the *Guidelines* outlines general considerations in granting assignment, and includes the following implicit and explicit references to the environment:

> - the principal objectives of the Corporation mentioned in section 12 of the *Act*; and
> - any view expressed by the relevant Local Board on a relevant local matter; and
> - the capacity of the proposed assignment's land for producing commercial crops of sugarcane when subjected to correct agricultural practices; and
> - the prospects of preparing and using the proposed assignment's land without undue damage to the environment...

In addition, Section 8(1)(e) of the *Sugar Industry (Assignment Grant) (No.2) Guideline 1995* indicates that an application will be granted if the QSC and Local Board are satisfied that the proposed assignment land is:

> able to be prepared and used for the growing of sugarcane without undue damage to the environment.

The Local Board is also to consider the efficient and cost-effective delivery of sugarcane to the receiving mill. For applicants who do not hold an existing assignment, their willingness and capacity to develop the land in a timely manner (usually a 2-year period) and their place of residence is appraised. Thus, a mix of environmental, economic and social factors is the basis of the final assignment decisions.

4.9 The Cane Assignment Process in the Herbert River District 1992-1996

As noted earlier, there are two CSR mills operating in the Herbert River district – Victoria and Macknade (Figure 3.2). Each has its own Local Board and shared the same chairman during the study period. As the previous discussion indicated, between 1992 and 1996 the sugarcane assignment process was changed in two specific aspects. First, more responsibility for awarding

assignment was delegated by the QSC to Local Boards. Second, the formal consideration of environmental considerations had become a legal requirement.

Before the Local Board considers an application, decisions made by governments and corporations at international, national and local levels establish a context for local awards (Figure 4.2). Millers and growers also make decisions that influence the assignment process. Together, these considerations define the desirability and feasibility of any expansion activity. Applicants who are awarded assignment must make it effective within a three-year period. Each level of the decision-making context is considered below.

4.9.1 International Agreements

The context for expansion reflects, in large part, perceived market opportunities and the corporate (miller's) perception regarding the desirability and feasibility of mill expansion (Figure 4.2). Traditionally, these opportunities were influenced through a series of International Sugar Agreements (ISAs) with the objective of controlling price volatility and overall supplies. The GATT is now the mechanism that will guide trade in the future.

A significant economic signal for the Australian sugar industry is the annual "World Market Prospects" report that is prepared by the QSC's marketing agent CSR. It considers the world demand for and supply of sugar, and significant world and national legislative initiatives (*e.g.* GATT, U.S. Farm Bills, European Union Agricultural Policies) to identify market opportunities for Australian products. This report is circulated to local boards, millers, CANEGROWERS and other relevant organisations. The feasibility of increasing mill capacity will reflect corporate goals and capabilities, the opportunities for cane land expansion, and infrastructure needs (*e.g.* rail lines, roads, and bridges). Decisions to increase mill capacity are most often made a few years prior to implementation. These are all economically oriented messages.

4.9.2 Continuous Crushing Agreement

In the Herbert River district, a "Continuous Crushing Agreement" between the CANEGROWERS and CSR significantly influences the regional industry's development (Figure 4.2). It establishes the harvesting period, production and crushing capacities, future growth, and transport planning for the regional sugar industry. This agreement has implications for expansion planning and natural resource management. However, factors external to the industry which pertain to the availability of sugarcane land (*e.g.* zoning in shire plan, wetlands) can influence plans to expand cane farming.

The 1995 Agreement specifies the harvest season as starting on the Monday between June 19 and June 25 (unless extraordinary circumstances arise), with a target season length of 20 weeks and 3 days (*i.e.* ending by November 15). This period is coincident with a high level of sugar content in the stalks (as measured by commercial cane sugar (ccs)), and before the summer rains prevent easy access onto paddocks. The average sugar content ranges from around 10 ccs at the beginning and end of the season to 13.5 ccs in the middle (Figure 4.3). After harvesting, ccs within the sugarcane decreases quickly. Since ccs is one basis for payment to growers, it is important to minimise this loss through the effective scheduling of harvesting and processing. This factor is particularly important in the Herbert River district since the mills are not centrally located in the cane growing areas. Like most cane growing areas, most cane transport is done on mill-owned and maintained narrow gauge railways. The "Continuous Crushing Agreement" guides railway development by tying it to cane assignment. Since the transport of the cane from delivery points to the mills via the rail system is the miller's responsibility, both CANEGROWERS and the mills must be confident that the transport network can deliver the cane in a timely manner. The implicit objective is to match sugarcane production with transport and crushing capabilities.

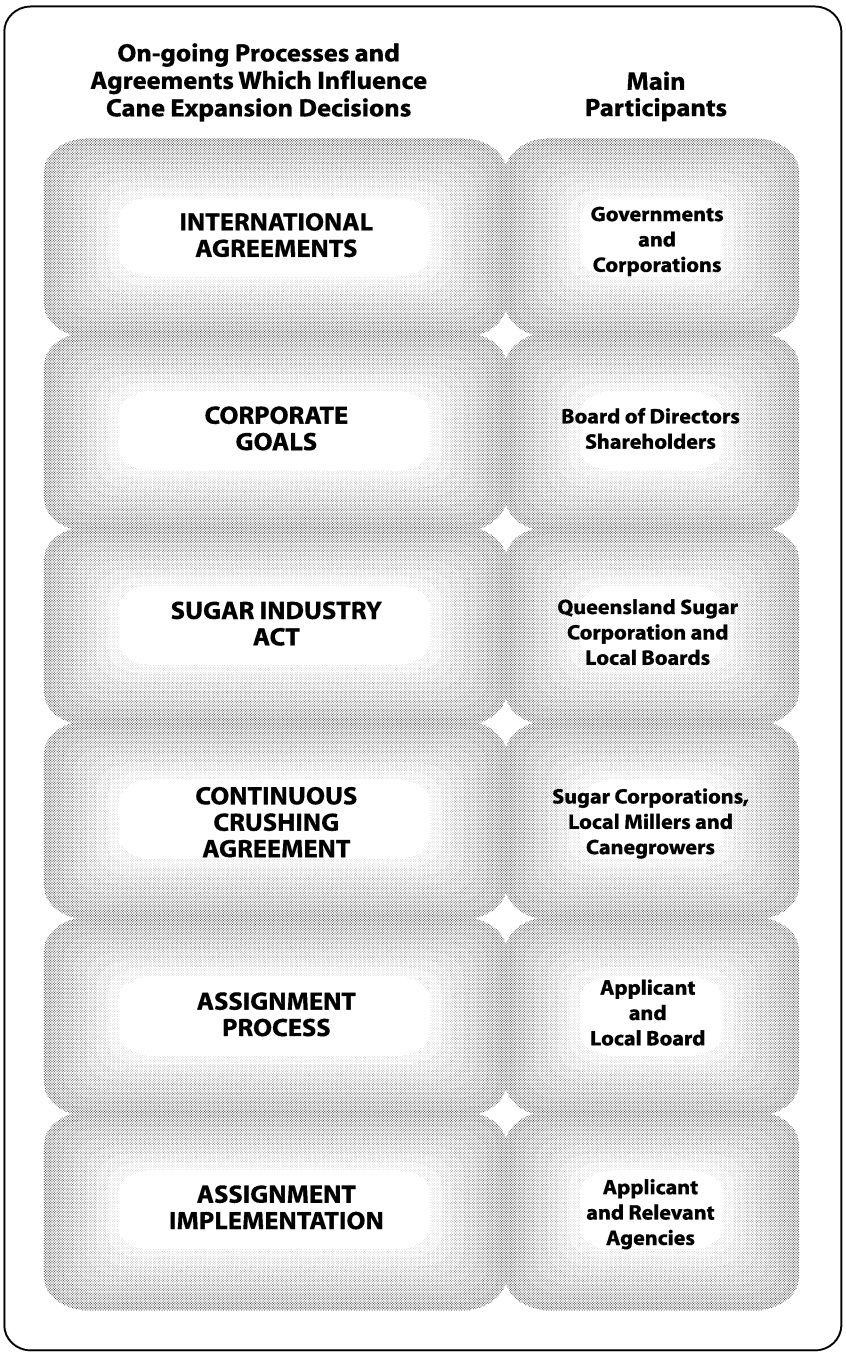

Figure 4.2 Decision-making context and the assignment process.

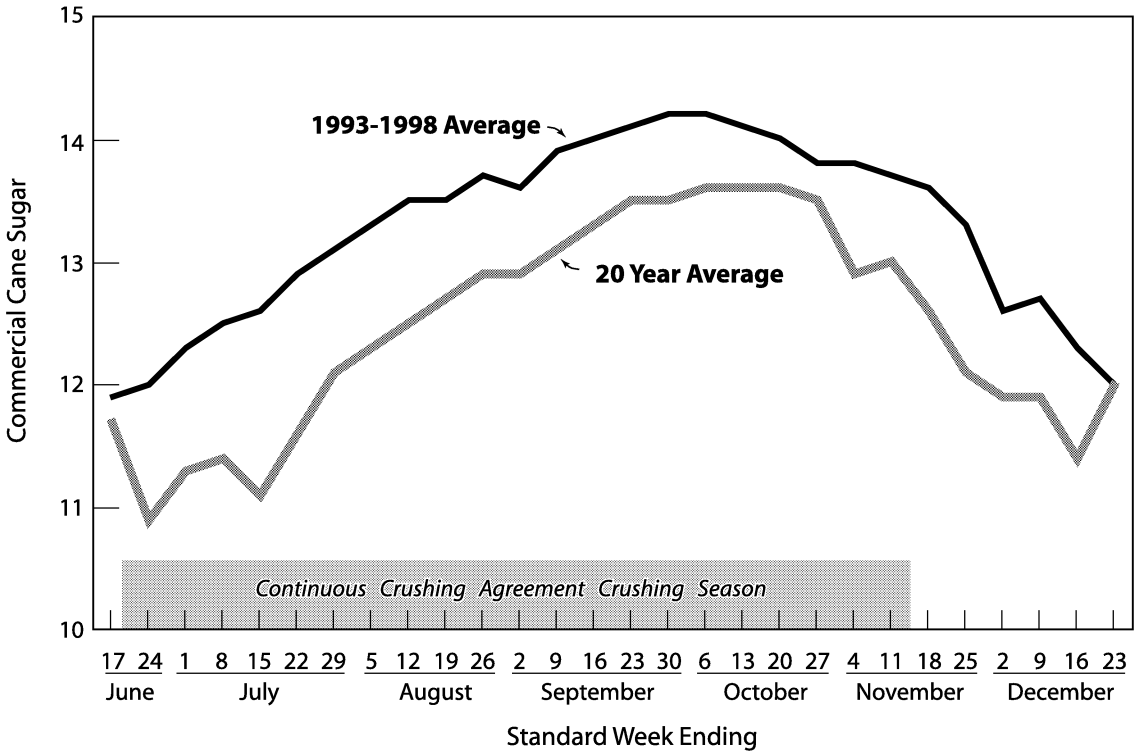

Figure 4.3 Average Commercial Content of Sugar (CCS) in the Herbert River district.

Growing sugarcane presents a number of other management challenges. When a sugar crop is planted, it may be 12 to 18 months before it is harvested. Over that time, loan payments must be made. In the Herbert River district, real estate agents and QDNR staff suggested that existing cleared cane land could sell for $10,000 to $12,000 per hectare, while uncleared suitable land demanded $2,500 to $6,000 per hectare. These costs can impose a heavy burden for new and rapidly expanding operations, and provide opportunities for financial institutions to influence the nature and extent of expansion. Given the wide array of viewpoints that prevail upon the formal assignment process, there is a need for effective institutional design.

Other biophysical aspects of the sugarcane crop present management challenges. Maximum sugar output can be achieved in the middle of the growing season when ccs is highest (Figure 4.3). However, the realisation of this objective requires enormous increases in existing mill crushing capacities to handle the crop before it deteriorates. For the rest of the year, the mill remains idle. Under present economic conditions, milling representatives suggested that this situation is not viable. To increase the productive use of mill facilities, CSR has, since 1993, operated on a continuous basis - 7-days-per-week, 24-hours-per-day during the harvest season. The present June to November harvest period represents a compromise between benefits of spreading the cost of milling capital over a longer season and the reduction in sugar yield at the beginning and end of the season. This means that if cane production exceeds crushing capacity, the length of the harvest season must be extended when ccs is dropping. While the "Continuous Crushing Agreement" provides compensation to farmers in these circumstances, extending a harvest season can cause conflict. For instance, after an extended harvest season, the following year sees a shortened growing season that leads to smaller cane sizes that attract lower returns. Short cane is also more susceptible to flood damage that is most likely to occur during the summer period (December - February). Thus, compensation must be seen in light of the potential economic losses to farmers and the ability of the mill to pay.

Expansion in the Herbert River district is based on CSR's ability to transport and crush sugarcane grown at an estimated yield of 83 tons per hectare. Existing growers must feel secure in the mill's ability to crush the crop, and CSR must be assured that farmers can deliver the agreed amount of

cane. These themes are the essence of the "Continuous Crushing Agreement".

4.9.3 Formal Assignment Process

Figure 4.4 illustrates the assignment process that generally applies to the Herbert River district during the study period. International markets and "Continuous Crushing Agreements" set the context for the formal assignment process. As will be noted shortly, the process shown in Figure 4.4 complies with the environmental requirements of the *Sugar Industry Act 1991*.

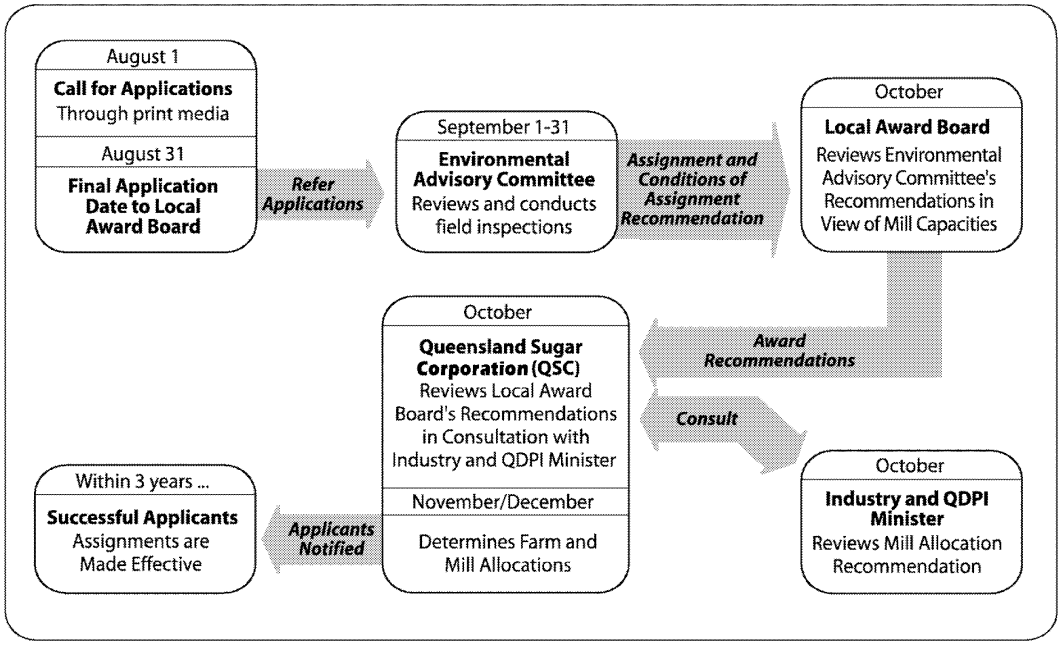

Figure 4.4 Formal sugarcane assignment process

The QSC places an advertisement in regional newspapers across the state and the CANEGROWERS magazine. Interested readers apply to the relevant Local Board that receives and reviews the applications following the previously mentioned QSC guidelines. During the study period, the application form required information concerning the:

- type of application (*e.g.* new or increased);
- applicant's address;
- new grower or current assignment information (*e.g.* mill, existing assignment, increase sought, spare land available);
- location of increased assignment (*e.g.* previously assigned or new land);
- land tenure (*e.g.* lease or freehold);
- evidence of title and any land use restrictions;
- land cover (*e.g* cleared, uncleared, partly cleared, under cane); and
- development program (*i.e.* when planting of cane will occur).

The state agencies and relevant statutes, programs, and policies described in the previous chapter influence individual applicants, and the decision-making process. However, the Local Board essentially makes the final decision. Before 1994, participation from government agencies and drainage boards was almost non-existent. In 1994, QDPI with some informal input from QDEH provided some comments. A more visible and multi-agency mechanism was used in the review of 1996 applications.

By 1996, an Environmental Advisory Committee (EAC) comprising representatives from QDPI, QDEH, BSES, and CSR considered the environmental impacts of the application based on: (i) available 1995 ortho-photo mapping, (ii) soil surveys and other available mapping, (iii) local

knowledge, (iv) information provided on the application, and (v) a Property Management Plan which was required from all applicants for the first time in 1996. In preparing these Property Management Plans, some applicants received detailed assistance from QDPI, others more informal assistance from BSES or CSR field staff, while others submitted rough sketches of their properties. All plans focused on land management issues.

Representatives from the Local Boards and Environmental Advisory Committee conducted site inspections for properties of significant concern. Final recommendations were made by the Environmental Advisory Committee and were forwarded to the Local Boards. After considering which applications met the guidelines, the advice of the Environmental Advisory Committee and having reached agreement on mill capacity, the Local Boards advised the QSC regarding: (i) the total number of applications; and (ii) the amount of expansion it was prepared to approve. This information was presented by the QSC to industry groups and the Minister for QDPI (as required by statute), and a final decision was made by the QSC. Applicants were notified in writing by the QSC.

The evolution of the referral process is one visible mechanism to address the need to consider environmental considerations. A second innovation was realised in the incremental development of environment-related Conditions of Assignment (Table 4.1). In the 1993 assignment, the Conditions of Assignment related to the environment did not exist. By 1996, the list of conditions embraced traditional drainage issues, as well as land and water, soil and wildlife values. A key issue concerns how these conditions are monitored and enforced.

Unsuccessful assignment applicants could appeal to the Sugar Industry Tribunal, or apply in subsequent years. Successful applicants had two years to make assignments effective (*i.e.* delivering sugarcane to the mill). Twelve-month extensions could have been given. Farmers were required to abide by regulations and codes of practice established under the *Environmental Protection Act 1994*. If drainage works (as defined by statute) or irrigation waters were required, applications under the *Water Resources Act 1989* must be submitted to QDNR for review. QDPI and QDNR provided extension services to farmers.

For the 1996 award, the call for applications was made on 1 August and a decision announced by 31 December at the latest. For the 1997 award, the QSC announced that applications must be submitted to Local Boards by 31 June 1996. Local Boards are to notify the QSC by 31 July of the total applicant demand and the desired mill application. Applicants were to be notified in late September of final decisions. It is the process shown in Figure 4.4 and some of its outcomes that is the subject of the evaluation.

4.10 The Evaluative Framework Revisited

Prior to employing the evaluation framework, it is appropriate to identify its suitability to assess the major participants – both private and government - in the sugarcane assignment process. This section describes government and CANEGROWERS' views of ESD according to the five principles of balance, partnerships, ecosystem, flexibility, and precaution.

4.10.1 Government View of ESD

Historically, there has been inadequate regard for environmental considerations by public and private resource managers at Commonwealth, state and regional levels. With the publication of *Our Common Future (Brundtland Report)* in 1987, this situation changed. For instance, all levels of Australian Government signed an *Intergovernmental Agreement on the Environment* (1992) to pursue the following principles (Australia, 1992: 8):

(1) Decision-making processes should effectively integrate both long and short-term economic, environmental and equity considerations.

(2) Where there are threats of serious or irreversible environmental damage, lack of full scientific certainty should not be used as a reason for postponing measures to prevent environmental degradation.
(3) The global dimension of environmental impacts of actions and policies should be recognised and considered.
(4) The need to develop a strong, growing diversified economy that can enhance the capacity for environmental protection should be recognised.
(5) The need to maintain and enhance international competitiveness in an environmentally sound manner should be recognised.
(6) Cost effective and flexible policy instruments should be adopted, such as improved valuation, pricing and incentive mechanisms.
(7) Decisions and actions should provide for broad community involvement on issues which affect them.

The Agreement commits all levels of government to ecological sustainable development (ESD) principles. These and other principles were endorsed at the 1992 Earth Summit (Grubb *et al*., 1993).

4.10.2 CANEGROWERS' View of ESD

The key participants in the sugar industry have responded to the need for ESD (Industry Commission, 1992; Senate Standing Committee on Industry, Science and Technology, 1989). Provisions within the *Sugar Industry Act 1994* and assignment regulations, which are administered by the Queensland Sugar Corporation (QSC), mention that environmental, social and economic aspects must be considered in determining the desirability and feasibility of applications for cane land expansion (QSC, 1991). CANEGROWERS and the Australian Sugar Milling Council are the two main industry associations. CANEGROWERS is a statutory organisation representing nearly all cane growers in Queensland and is financed by a grower levy based on cane supplied. Although CANEGROWERS has been interested in 'environmental' issues for some time, it has been particularly active since the completion of a 1996 audit of the canegrowing industry in Queensland (GHD, 1996). The audit contained over 150 recommendations, many of which have been acted on. Some of these initiatives are described below.

In 1997, CANEGROWERS endorsed a Code of Practice that met government guidelines. This initiative supports the sustainable and efficient use of resources and minimises off-farm impacts (including movement of sediment, nutrients and chemicals) (CANEGROWERS, 1999). These guidelines were endorsed by the QDoE (now QEPA) as a Code of Practice under the *Environmental Protection Act 1994*. The *Code of Practice for Sustainable Cane Growing in Queensland* has been distributed to all cane growers in Queensland. Through its extension program, the Bureau of Sugar Experiment Stations (BSES) is supporting its implementation. Major sugar-related research and development is also the responsibility of the BSES. Financed by growers and millers, BSES approves cane varieties to be grown in mill areas, provides extension services to farmers, and conducts research into the growing of cane. It has encouraged farmers to adopt environmentally friendly practices and identifies sustainable resource use as an important principle (Briody, 1994). Sugarcane research has tended to focus on biophysical aspects of the plant. CSR has had an ongoing sugarcane variety program. More recently, QDPI, QDNR and CSIRO have intensified their sugar-related research, and a CRC for Sustainable Sugar Production established. The latter will devote some research effort into socioeconomic aspects of the industry.

The environmental audit also prompted the development of an Environmental Management Strategy (EMS). The four objectives of the EMS are to:
(1) Adopt agricultural practices that minimise off-farm impact and ensure the sustainable and efficient use of soil and water resources.

(2) Achieve a balance between cane growing and the protection of natural systems and fostering biodiversity.
(3) Achieve appropriate use, storage and disposal of agricultural chemicals and farm waste.
(4) Raise the level of communication on environmental maters so as to ensure that:
    - cane growers have reliable information on which to base decisions which result in adoption of best management methods which meet legislative requirements and that they have a clear understanding of the impact which cane growing practices have on the environment; and
    - industry bodies, government agencies, community groups and conservation organisations are adequately informed on CANEGROWERS' environmental policy and initiatives directed at maintaining a profitable, sustainable cane growing industry.

CANEGROWERS adopted an environmental policy in 1990. In 1995, this policy was revised in the document *Caring for the Environment* that embraced the following principles:
(1) Industry and farm management practices should enhance the efficient and sustainable use of soil and water, safeguard public health, help preserve natural resources and desirable flora and fauna, and combat feral animals such as wild pigs;
(2) Concerns about the environment should not be treated in isolation from economic and social considerations;
(3) Preservation of the environment is everyone's concern and the cost should be borne equally within the community;
(4) Individual landholders are best placed to address issues as part of voluntary publicly-funded programs as well as R&D projects;
(5) Where sensible precautions are taken and best technology used, farmers should be free of bureaucratic interference in the everyday running of their properties;
(6) Farmers should be active participants in an open consultation process between government, industry and the community;
(7) Primary producers have rights and obligations;
(8) Government has a role in providing information, education and incentives to encourage active and self-regulatory environmental management of farms; and
(9) Unacceptable behaviour by individuals should be discouraged.

While the principles of environmental management have evolved since that time, they provide a benchmark against which the activities in the Herbert River district may be assessed.

The milling sector has also developed environmental initiatives. For instance, CSR (1998) has developed an environment policy that commits it to;
- always seeking to comply with all laws and business decision making;
- fully integrating environmental considerations into business decision making;
- ensuring that its people work in an environmentally responsible manner;
- contributing to the development of industry and regulatory standards;
- measuring its impacts and setting goals for improvement; and
- maintaining good relations with its neighbours, the community and regulators.

Even though these statements are not binding on any of these participants, they represent a shift towards more sustainable management.

In considering the suitability of the evaluative framework, the statements from government and CANEGROWERS are of particular relevance to this report. Although it is a promotional document, *Caring for the Environment* clearly indicates that the Queensland cane growing industry recognises its responsibilities towards the environment. It is also reasonable to obtain statements that are applicable to the study period 1993-1996. Industry and government statements serve as a benchmark against which intent and process can be assessed.

Table 4.2 links specific statements from the *Intergovernmental Agreement on Ecologically Sustainable Development* and *Caring for the Environment* with the five principles – ecosystem, balance, partnerships, flexibility and precaution - that support the concept of sustainable development. There are at least three significant differences between the *Intergovernmental Agreement* and *Caring for the Environment* principles. The first concerns agreeing on the breadth and depth of the balanced, ecosystem, partnership, and flexibility principles. For instance, the *Intergovernmental Agreement* highlights the need for a global perspective in ecosystem management, while CANEGROWERS are more concerned for providing efficient farm operations by controlling feral animals as well as a healthy environment. While these types of differences are important, it is more appropriate to consider differences and similarities in a broader context. In general terms, the other two important differences pertain to the precautionary principle, and how management strategies should be bounded. During the interviews with government and industry officials, a wide range of views was expressed concerning the nature of these concepts. Despite these differences, there are many areas of similarity and the CANEGROWERS appear to be committed to more effective resource management as reflected in the completion of an environmental audit of the canegrowing industry in 1996.

Table 4.2 Comparing and contrasting resource management principles in the *Intergovernmental Agreement* and *Caring for the Environment.*

Principle	Specific Statement
Precautionary	*Intergovernmental Agreement:* • Where there are threats of serious or irreversible environmental damage, lack of full scientific certainty should not be used as a reason for postponing measures to prevent environmental degradation. *CANEGROWERS:* • Where sensible precautions are taken and best technology used, farmers should be free of bureaucratic interference in the everyday running of their properties.
Balance	*Intergovernmental Agreement:* • Development of a strong, growing diversified economy which can enhance the capacity for environmental protection should be recognised. • Decision-making processes should effectively integrate both long and short-term economic, environmental and equity considerations. *CANEGROWERS:* • Concerns about the environment should not be treated in isolation from economic and social considerations.
Partnerships	*Intergovernmental Agreement:* • Decisions and actions should provide for broad community involvement on issues that affect them. • The need to maintain and enhance international competitiveness in an environmentally sound manner should be recognised. *CANEGROWERS:* • Preservation of the environment is everyone's concern and the cost should be borne equally within the community. • Farmers should be active participants in an open consultation process between government, industry and the community. • Primary producers have rights and obligations. • Unacceptable behaviour by individuals should be discouraged.
Ecosystem	*Intergovernmental Agreement:* • The global dimension of environmental impacts of actions and policies should be recognised and considered. *CANEGROWERS:* • Industry and farm management practices should enhance the efficient and sustainable use of soil and water, safeguard public health, help preserve natural resources and desirable flora and fauna, and combat feral animals such as wild pigs.
Flexibility	*Intergovernmental Agreement* • Cost effective and flexible policy instruments should be adopted, such as improved valuation, pricing and incentive mechanisms. *CANEGROWERS:* • Government has a role in providing information, education and incentives to encourage active and self-regulatory environmental management of farms. • Individual landholders are best placed to address issues as part of voluntary publicly funded programs as well as R&D projects.

In 1999, CANEGROWERS (1999) committed Local Boards to develop and publish environmental and land use guidelines in order that the suitability of proposed new cane production areas can be assessed. QDNR and QDoE are to be consulted in the development of the guidelines. The guidelines will also comply with other relevant statutes.

The initiatives noted above focus on a variety of activities that have occurred since 1996. In order to provide for a fair assessment, it is appropriate to consider developments prior to 1996 in order that comments may be framed in an appropriate context.

4.10.3 CANEGROWERS' Environmental Audit of the Queensland Canegrowing Industry

CANEGROWERS and the rest of the sugar industry are aware of the need for effective action in terms of their ESD obligations. Part of their response was the completion of an environmental audit of the canegrowing industry (GHD, 1996). In order to establish an industry perspective on the potential for environmental impacts of cane assignment, the following section reviews the findings of an environmental audit that was commissioned by the CANEGROWERS Council and released in 1996 (GHD, 1996). This completion of the audit is consistent with the temporal perspective provided in this research effort. The audit's findings were based on 180 interviews and 130 farm audits completed along the entire sugarcane-growing coast from Rocky Point to Mossman (Figure 1.1). Interview respondents included a wide range of interested parties – industry organisations, local, State and Commonwealth Government, research organisations, Landcare and Integrated Catchment Management groups, conservation groups, recreation and commercial fishermen, and a range of other community and aboriginal groups. A significant majority of respondents (63%) and the majority from each sector interviewed perceived that "current environmental management practices within the sugarcane growing industry needed improvement" (GHD, 1996: 4).

Farm expansion was perceived as having potentially high impact by a majority of respondents. Specific issues concerned:

> the clearing of land for expansion affecting habitat values and critical ecosystems; 49% of all respondents believed this was a high priority issue. The growing of sugarcane on riverbanks was seen to be adversely affecting the riparian or vegetation corridors which are critical for river health, bank stability and fauna habitats; 56% of all stakeholders believed riparian zones are a high priority management issue… (GHD, 1996: 5).

Respondents from community groups in the Herbert River district commented that the river was "seen as merely a culmination of a [series] of open drains with swamp grasses, battered creeks and straightened creeks" (GHD, 1996: 5). The farm audit generally concurred with this portrayal of river systems and further stated that the

> riparian zone issue and the value of retaining these areas needs to be better understood by the industry in terms of water quality… Riparian zones should be revegetated with native species, as they provide good pollution, nutrient and sedimentation sinks as well as ameliorating water salinity problems (GHD, 1996: 15).

The report noted that the destruction of riparian vegetation is regulated under Section 70 of the *Water Resources Act 1989* and can be an offence under the *Land Amendment Act 1992*.

The impact of cane growing on endangered species and fauna/flora is an issue that is closely related to riparian corridors. There was a perception among non-farming interview respondents that "the government, rather than encouraging sustainable farming, [was] promoting expansion beyond sustainable limits through infrastructure development packages. These packages are often for weirs or drainage schemes which conservationists consider to be environmentally suspect, or for expansion onto marginal areas" (GHD, 1996: 6). These structures interfere with natural flows, downstream flushing, groundwater levels, and fish migration. Expansion onto

marginal land was defined as land that needed some form of amelioration before it was suitable for farming (*e.g.* drainage, excessive fertiliser application). It was also perceived that the exposure of acid sulphate soils and exacerbation of existing sodic soils were problems associated with the development of marginal lands. Drainage problems were also believed to be associated with land leveling practices that prevented natural run off and recharge of creeks and watercourses (GHD, 1996).

Concerning wetlands, the report noted that these should not be drained since this further exacerbates local hydrologic problems. Creeks and waterways should not be blocked off or straightened without appropriate permits such as those provided under the *Water Resources Act 1989*. Concern was also expressed over acid sulphate soils and erosion. The report recommended that

> the management and identification of acid sulphate soils needs to be better understood by growers in all regions. It was recommended that CANEGROWERS develop a code of practice for growers relating to management of acidic and element-deficient soils (GHD, 1996: 16).

The authors also advocated the development of management practices for soil erosion in drains and for the protection of riparian zones.

Interviews with farmers suggested that government policies are also unwittingly contributing to habitat loss, and consequent soil and water degradation.

> These policies include the opening up of marginal land…to crop production. Some growers indicated that perceived pressure from industry organisations to increasing production was influencing many growers to utilise marginal land (drain wetlands, open up saline areas, cut down Melaleuca swamps, etc) and in combination with government export policies and price of crops, results in over-intensive use of the land (GHD, 1996: 20).

Non-farmer respondents questioned the integrity of the assignment process and perceived that Local Boards acted "too quickly" (GHD, 1996: 6). "In the past, QDoE and QDPI have had little input into the outcomes of the system. No mechanisms were reported in place to halt and address potential undue environmental damage. It was believed that the potential of vertical expansion was not adequately assessed on current land prior to the granting of additional assignment on new land" (GHD, 1996: 6).

The report commented on the unfortunate lack of data and the inadequate implementation of on-farm management practices to mitigate against water quality impacts. It was believed that these shortcomings posed "a risk to the industry" (GHD, 1996: 12). The report recommended that:

> Increased monitoring of water quality in local creeks and waterways should be facilitated or encouraged by local CANEGROWERS' offices in order to counter negative perceptions of the effects of nitrification, sedimentation, turbidity and salinity of water resources.

Awareness and compliance with existing government regulations, industry codes of practice and Australian Standards were considered low. In terms of who should undertake further action to protect the environment, farmers preferred the Department of the Environment (48%), individual growers (22%), voluntary conservation agreements (16%), and rate relief (14%). Unfortunately, more precise information concerning the feasibility of these alternatives was not provided.

To a large extent, the audit maintained that growers throughout the state were suffering the legacy of poor past management practices that reflected a time when environmental regulation, community awareness and scientific information on the beneficial aspects of riparian zones were not well known. In summary, the CANEGROWERS' audit suggests that all participants – government, the industry, growers and the public – must change practices that have contributed to a lamentable "legacy of the past" that provides a poor foundation for popular public support.

In reflecting on the findings of the audit, CANEGROWERS (1999: 38), suggested that it was disappointed by the audit and commented:

> As the industry's understanding and appreciation of environmental issues has matured it has become evident that some of the audits [156] recommendations reflect an imperfect understanding of sugarcane growing, some recommendations are repetitive and some important issues are not covered in any of the recommendations.

CANEGROWERS committed itself to responding to the audit, in part, to identify outstanding issues that may need to be addressed and their level of priority. It is hoped that this current research effort can assist in furthering some of the ideas contained in the audit, provide the CANEGROWERS some food for thought as they consider their response to the audit, and in these ways contribute to improving the practice of ESD throughout the sugar industry.

5 ASSESSING THE SUGARCANE ASSIGNMENT PROCESS IN THE HERBERT RIVER DISTRICT

5.1 Introduction

This chapter is divided into nine sections. Prior to examining the assignment process itself, we provide a brief review of those government initiatives initiated since 1996 (Section 5.2). This discussion will focus on the *Integrated Planning Act 1997* and the *Sugar Bill 1999*, and will establish the need for additional improvements to the assignment and land use planning processes. The nature of the data is also described (Section 5.3). The remainder of the chapter considers two issues: (i) an evaluation of the cane assignment process and selected outputs during the study period 1992-1996 (Sections 5.4 - 5.8); and (ii) an assessment of the adequacy of the current (*i.e.* 1999) institutional arrangements for environmental management in the sugarcane assignment process (Section 5.9). Where these are deficient, alternative measures that could ensure a more sustainable process are identified. The evaluation and the determination of adequacy are guided by selected measures of ecosystem (Section 5.4), balance (Section 5.5), partnerships (Section 5.6), flexibility and adaptability (Section 5.7) and the precautionary principle (Section 5.8). These five principles reflect the underlying principles of ESD. Summary comments and implications are noted (Section 5.9).

5.2 Is there a need for change in the cane assignment process?

Since 1996, land use and cane assignment planning processes affecting sugar industry development have undergone significant changes. Prior to 1993, both planning systems operated in a relatively separate manner with only the Hinchinbrook Shire Plan having an indeterminate influence on assignment activities (Figure 5.1). In addition, the *Water Resources Act* played a role in guiding drainage activities after assignments had been granted. However, as noted in Chapter 4, the shortcomings of the statute combined with the lack of enforcement reduced its ability to influence activities.

By 1999, a large number of initiatives had been undertaken that impacted on both land use planning and cane assignment (Figure 5.2). At a local level, amendments to the *Planning and Development Act* (*IPA*) and the re-writing of the Hinchinbrook Shire Plan were two of the most significant changes. These adjustments combined with new and revised regulations, particularly those established under the *Environmental Protection Act* and *Fisheries Act*, will influence both cane planning and the implementation of assignments. Thus, there is a greater degree of direct interaction between land use planning and cane assignment. The cane growing industry has also become more responsive to environmental concerns. It has worked with government agencies and others to establish an Environmental Strategy and Codes of Practice (Figure 5.2). Given the nature and degree of these changes, it is appropriate to question the need for further reform of the assignment process.

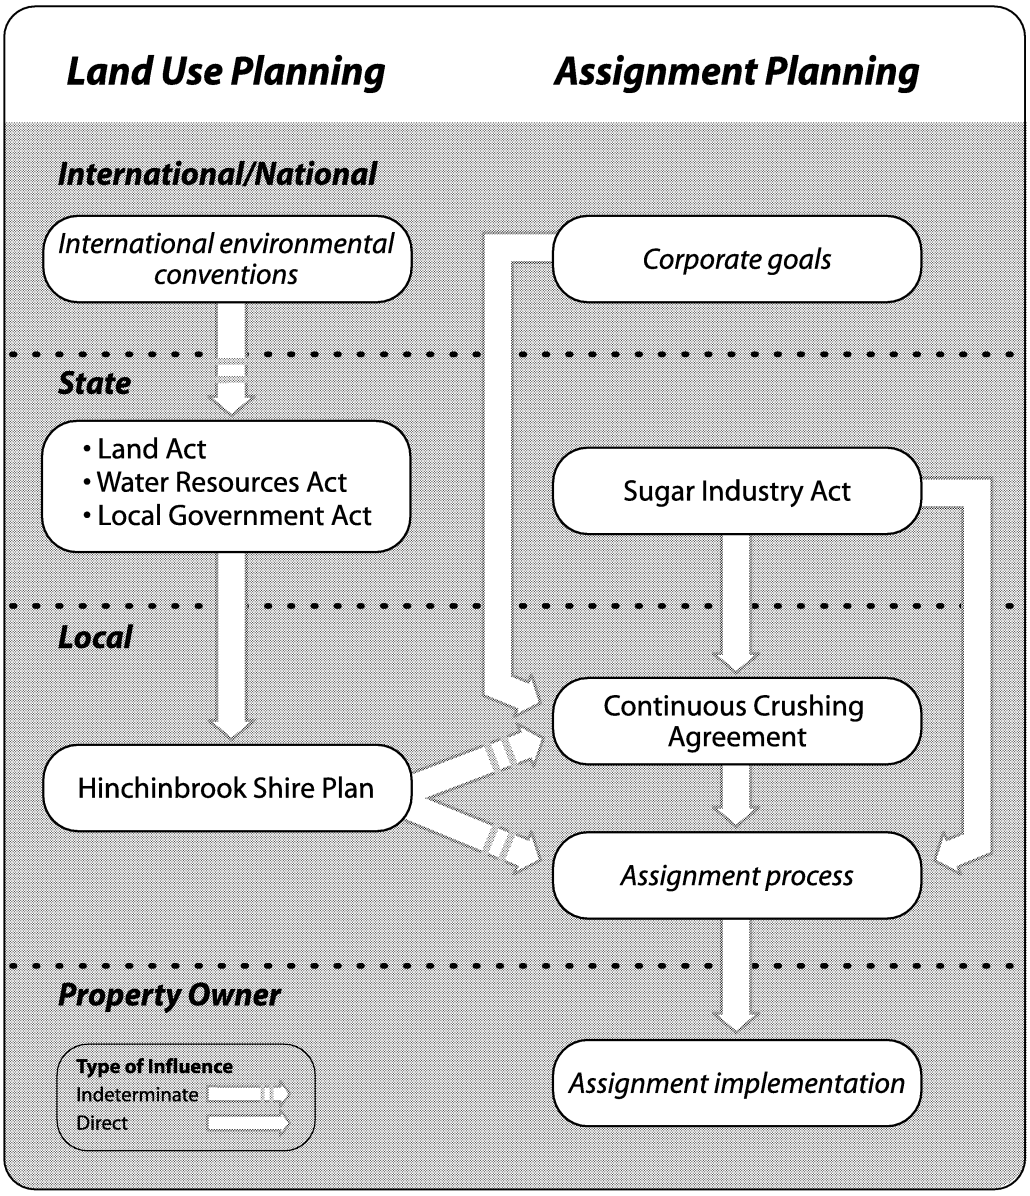

Figure 5.1 Land use planning and assignment planning (1991).

Very briefly, the four points noted below support this need:

1. Many recent changes, such as regulations under the *Fisheries Protection Act 1994* and the development of Codes of Practice and Environmental Protection policies, are focused at the operational level of planning. However, they are often perceived as reactive rather than proactive. Their frequent use, particularly on newly assigned marginal lands, prompts the question; "Why was this land assigned in the first place?". Environmental Protection Policies and recommendations contained in documents such as, *Land Use Practices in Wet Tropical Floodplains* and *Codes of Practice* are an important part of the solution that ensures that an appropriate "duty of care" is achieved. However, they are part of a package that must incorporate strategic and normative level responses too.

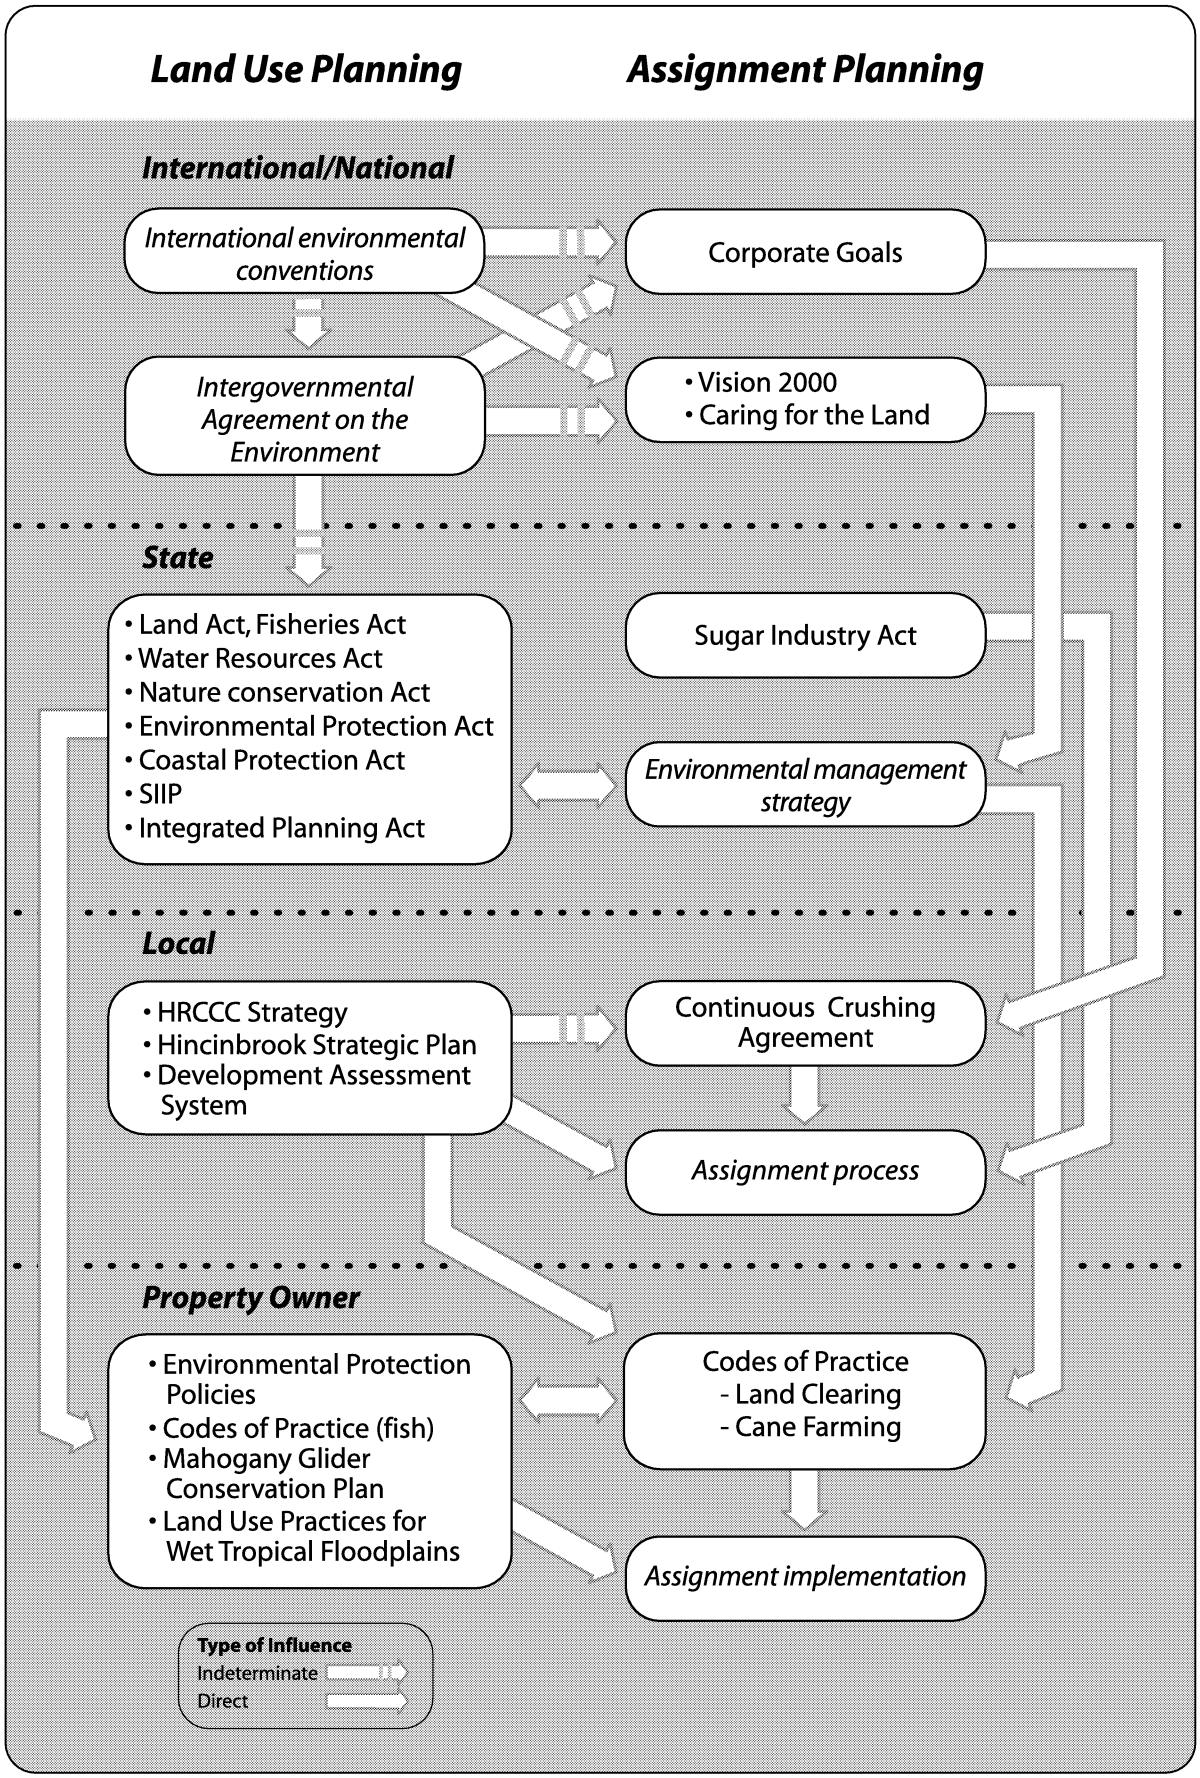

Figure 5.2 Land use planning and assignment planning (1999).

2. There have been a number of advances at normative and strategic levels. All levels of government – national, state and local – have supported their statements about the need for ESD with legislation and/or strategic planning initiatives. The draft Cardwell/Hinchinbrook Coastal Management Plan, as well as the revised *Hinchinbrook Shire Strategic Plan* provide legislative support for initiatives. The *Mahogany Glider Conservation Plan*, and the Herbert River Catchment Coordinating Committee's Strategy will influence land use planning and development in the Hinchinbrook Shire (Figure 5.2). The intent is to implement many of the provisions contained in these documents in local government Planning Schemes. Future sugarcane assignments should be excluded from areas identified as 'valued' or 'sensitive' in these documents. The extent to which recent changes influence corporate goals and the "Continuous Crushing Agreements" is unclear. It appears that decisions made at these levels will continue to drive the need for increased assignments. Indeed, the link between Corporate Goals and the Continuous Crushing Agreement remains indeterminate (Figure 5.2). Thus, integrating economic and environmental decision-making remains a challenge.
3. The introduction of the *Integrated Planning Act 1997* and the reformulation of the *Hinchinbrook Shire Strategic Plan* are fundamental guides for future resource management activities. The *IPA* has allowed the Shire to require landholders wishing to conduct intensive agricultural activities, such as cane farming, to obtain the its prior approval. While this mechanism could provide benefits, it appears to be focused on development control rather than strategic planning. Indeed, the intent of *IPA* appears to be primarily focused on streamlining decision-making processes, rather than enhancing its effectiveness. Initial reviews of *IPA* suggest the following items require further attention (Barker, 1997; England, 1999; Moon, 1998):
   - The technical aspects of development studies must be rigorous. Existing descriptions fail to clarify if an impact assessment versus an environmental reporting approach will be adopted. If the former intent were desired, proponents must ensure that the need for development is clearly demonstrated; that the magnitude and significance of impacts are predicted and measured; and that alternative measures are assessed rigorously. If this is not the intent, the requirements of the environmental report must be defined.
   - The legislative requirements and administrative practice of impact assessment support:
     - an integrated approach: environmental, social and cultural;
     - an accountable and environmentally responsible decision-making process;
     - an assessment process that pursues and achieves the best solutions rather than acceptable ones;
     - the consideration of cumulative impacts;
     - specific recommendations that are enforceable with penalties;
     - a decision-making process that is perceived and is open, participatory and fair;
     - an efficient process; and
     - the linkage between property-specific decisions with decisions made at larger geographic scales.

   This comprehensive approach is quite onerous, particularly for individual farmers.
4. While there is no question that the government initiatives described in Chapter 4 will support better management of the 'natural' environment, it is unclear how well they support ESD in the context of linking environmental, economic and social considerations. This was the clear challenge that the Brundtland Commission identified when it suggested that:

   > Those responsible for managing natural resources and protecting the environment are institutionally separated from those responsible for managing the economy. The real world of interlocked economic and ecological systems will not change, the policies and institutions must (WCED, 1987: 9).

Since the 1990s, 'environmental policies' have changed dramatically but there have been relatively marginal adjustments in the administrative arrangements for sugarcane assignment. For instance, the requirement for environmental plans and Codes of Practice are being 'added on' to the existing cane assignment system. An outcome of this situation is that

locally based forums to support the ongoing and constructive dialogue between the 'sugar industry' and 'others' are not readily apparent. The system appears to be centrally controlled as reflected in the binding 2.5% annual increase in assigned area. This requirement appears to have been generated from 'the top', with little participation from 'the bottom'. However, locally based forums are required not only to support the principles of ESD, but also to work out 'routine' issues. It is unclear how the present arrangements effectively integrate economic and environmental considerations. They certainly did not provide the additional resources to government agencies that were promised by the minister.

With the proclamation of the *Sugar Industry Bill 1999*, several changes have been made to the process of assessing and assigning new cane lands. These changes provide additional requirements for environmental and sustainability issues to be considered in the horizontal expansion process and thereby provide the capacity to consider such issues prior to the allocation of land for cane production. Cane Production Boards have an important role in achieving the sustainable production of cane by making guidelines that relate to land use, the environment, and transport. These guidelines are to be considered when assessing applications for cane production areas. Production Boards are further required to consider the suitability of the land for cane production when assessing applications through consideration of land capability, appropriate agricultural practices and any relevant environmental guidelines. Additional changes include the requirement that negotiation teams assess the demand for cane expansion before Production Boards assess individual applications and the ability of cane production boards to require additional information from applicants before deciding an application. These developments address environmental issues but appear to fall short of effectively integrating environmental, economic and social considerations.

Effective responses to the changes, uncertainties, complexities and conflicts that will continue to be part of the sugar industry's future lies in administrative mechanisms, planning initiatives, and scientific research. On the one hand, government policies could be seen as a 'command-and-control' approach that seeks to regulate every aspect of the industry. This can stifle progress, be costly to monitor, and be frustrating for and confusing to individual farmers who now have a plethora of regulations before them (Figure 5.2). Not only are they concerned with the environment, but they must also make a living at the end of the day. On the other hand, government policies could be seen as identifying new standards of industry performance. How that will be done is often perceived to be primarily the industry's problem. While these views are somewhat simplified, the current policy environment does not adequately embrace the five principles of ESD. Thus, there are conceptual and practical shortcomings in present responses that suggest the need for changes to the sugar assignment process.

5.3 Application Profile in the Herbert River District: 1993-1996

As noted earlier, 525 applications for assignment, covering an approximate area of 16,000ha, were submitted to the Victoria and Macknade Local Boards for approval during the study period. It was feasible to link information from complete application forms (Appendix 1) with the spatial database for 472 applications (89.9%) of the total application pool. These applications encompassed an area of 15,013ha or about 94% of the total 15,994ha area applied for. The data that are presented in the maps and tables below will refer to those applications with spatial representation.

Table 5.1 provides a profile of the outcomes from the cane assignment process during the study period. During the study period, 472 applications were spatially represented and comprised an area of 15,013ha. From this total, 355 (75%) applicants were awarded their entire request, 92 (20%) were awarded less than their request, and 22 (5%) were denied. Of the 15,013ha applied for, 12,165ha were awarded, representing an 81% approval rate. 1,962ha were not awarded on

the basis of an applicant being granted less than 100% of their request. In addition, 887ha were denied an award. All applications that were denied occurred in 1996 and represented an area of 2,736ha. Since the 1996-application pool contains applications that were denied, the following analysis pays particular attention to it. This point is re-enforced in Figure 5.3 that identifies the location of applications during the study period. While some of the awards represent consolidation within traditional cane-growing areas, much of the development pushed new frontiers into the Upper Stone, Toobanna, and Mutarnee regions. These data and pattern of development raise concerns about how effectively the sugarcane assignment process (Figure 5.1) supported the principles of ESD. Each principle is considered in the following sections.

Table 5.1 Profile of assignment applications awards and denials, Herbert River district: 1993 - 1996.

			Spatially Represented Data							
	Total Applications Submitted		Applications Recorded		Granted 100% of Request		Granted < 100% of Request		Application Denied

Note: Area figures are in hectares.

5.4 Enhancing Ecosystem Management

The ecosystem approach is one principle of sustainable development. There are many challenges to developing and implementing an ecosystem approach. According to Mitchell (1997), one challenge of the ecosystem approach is to consider how it can be applied to solve real-world problems in a timely manner. A second issue pertains to ensuring managers are not unduly human-centred and consider the needs of non-human species with which we share this planet.

These introductory comments serve to structure the following three-part discussion of the ecosystem approach. The first focus directs attention on the perceptions of the residents in the Herbert River catchment. The second perspective considers human use and management of the environment by examining drainage issues and planning. The last focuses on non-human species, specifically land cover and landscape pattern changes, and endangered species and habitat management.

5.4.1 Community attitudes towards the environment

The views of Herbert River catchment residents towards their quality of life and their perception of regional resource management issues were surveyed in 1996 and 1998 (Butterworth *et al.*, 1997; Macreddin and Syme, 1999). In general, respondents had a fairly high level of satisfaction with living in the Herbert. The survey reported that residents found resource management issues to be generally important and that some issues required urgent action. High ratings of personal importance for the Herbert community included water quality problems, land degradation, water quantity problems, and nature conservation. Moderate importance was placed on flooding, wetlands management, vegetation on riverbanks, and the loss of biodiversity. This relatively high level of awareness of problems implies general support for some of reform of current institutional arrangements (Figure 5.1). Indeed, the community believed that they, rather than the state, Commonwealth or other outside agents had a reasonable level of control over activities in the Herbert River catchment. However, since land and water management issues were not uppermost in people's minds, any reforms should, from most local residents' perspective, not interfere with their first priority – life issues. These life issues included high unemployment, a

lack of opportunities for young people, and a lack of diversity of industry.

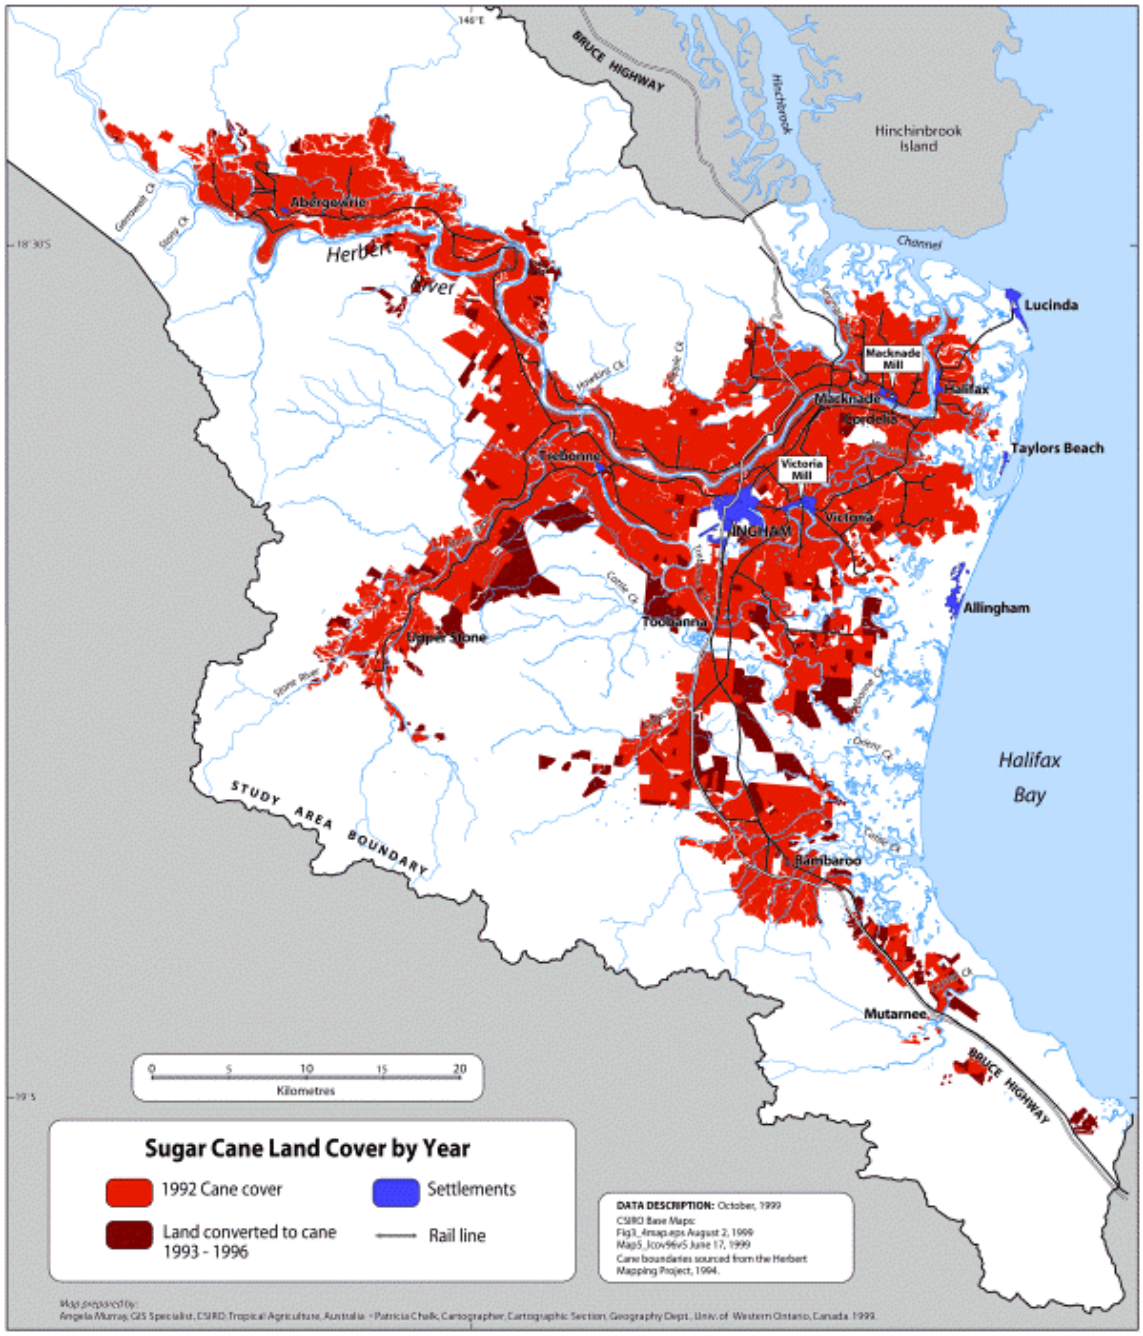

Figure 5.3 Location of assignment grants (1993-1996).

These perceptions reflect the Herbert River community's complete living experience – that mix of environment, economy and society. The next two subsections focus attention on two other aspects of ecosystem management – drainage and biodiversity.

5.4.2 Responding to drainage problems

The *Hinchinbrook Rural Drainage Study* has been consistently referred to in the Conditions of Assignment granted between 1993 and 1996 (Table 4.1). As noted earlier, that study's objectives were "to achieve a consistent standard of drainage which would increase rural production and to define required works, their location, cost and benefits to be achieved from the works, and subsequent management and operation leaving only detailed design and documentation necessary to implementation" (Cameron McNamara, 1984: 1-1).

Much of the land awarded assignment between 1993 and 1996 was not considered for detailed study in the 1984 *Hinchinbrook Rural Drainage Study* (Table 5.2 and Figure 5.4). Of the 450 spatially represented awards approved during the study period, 141 (31%) were located entirely within the Cameron-McNamara study area. However, these awards represented only about 10% of the total land area awarded (1,280ha of a total of 12,164.9ha). These data suggest that the individual drainage works for the successful applicants situated on the 10,884.9ha located outside the Cameron-McNamara study area were not guided by a strategic water management plan. In partial response to this situation, the Local Board requested that "plans for works must be in accordance with the plan submitted at the time of application" (Table 4.1). However, in the absence of an overall drainage plan, it is unclear how these proposals would be written or reviewed effectively. Individual applications, which included one proposal for development of over 1,500ha, failed to contract a professional engineer to write a drainage report.

Table 5.2 Location of applications relative to the Cameron-McNamara study area. Figures shown for applications with spatial representation.

					Cameron-McNamara Study Area Applications					
	Total Applications		Total Approved		Total Overlapping		1996 Approved		1996 Denied	
Year	Number	Area	Number	Area	Number	Area	Number	Area	Number	Area
1993	199	3979	199	3705	57	502	0	0	0	0
1994	77	2849	77	2704	33	428	0	0	0	0
1995	87	2185	87	2155	18	130	0	0	0	0
1996	109	6001	87	3602	33	221	25	221	8	138
Total	472	15013	450	12165	141	1280	25	221	8	138

Note: Area figures are in hectares.

While Property Management Plans prepared by farmers can use 'rule-of-thumb' guidelines to consider individual farm drainage problems, there is no effective plan that considers the cumulative impact of these individual land use changes. Many applicants for new cane assignment only provide sketch maps of their planting intentions, and do not seek professional assistance. This is sometimes not a problem, as some areas will require drainage works which do not connect to watercourses (and do not require a permit). Some successful applicants, such as those in the Pomona and Wharps land holding areas, required drainage permits under the *Water Resources Act 1989*. Indeed, some of the areas of Cattle Creek are perceived by the Environmental Advisory Committee as unsuitable for cane farming because of the high probability of inadequate drainage. Farmers who received assignments in this area may request major drainage projects in order that a reasonable level of productivity is achieved. This demand could be associated with a return to more 'normal' precipitation patterns and levels (Figure 3.5). Since these projects would be beyond the ability of individual landowners to finance, government cost sharing would be required.

Downstream landowners may be concerned that new farms and proposed works could significantly increase inundation of their properties. Hence, increased drainage conflicts among landowners could occur without effective management processes. If drainage works and/or permits were denied, farmers would be unable or have some difficulty in recouping financial returns from their full assignment. This situation could promote the farmers to use inappropriate agricultural practices in order to increase productivity. This potential problem could be heightened if prices for sugar retreat from recent high levels (Figure 2.1).

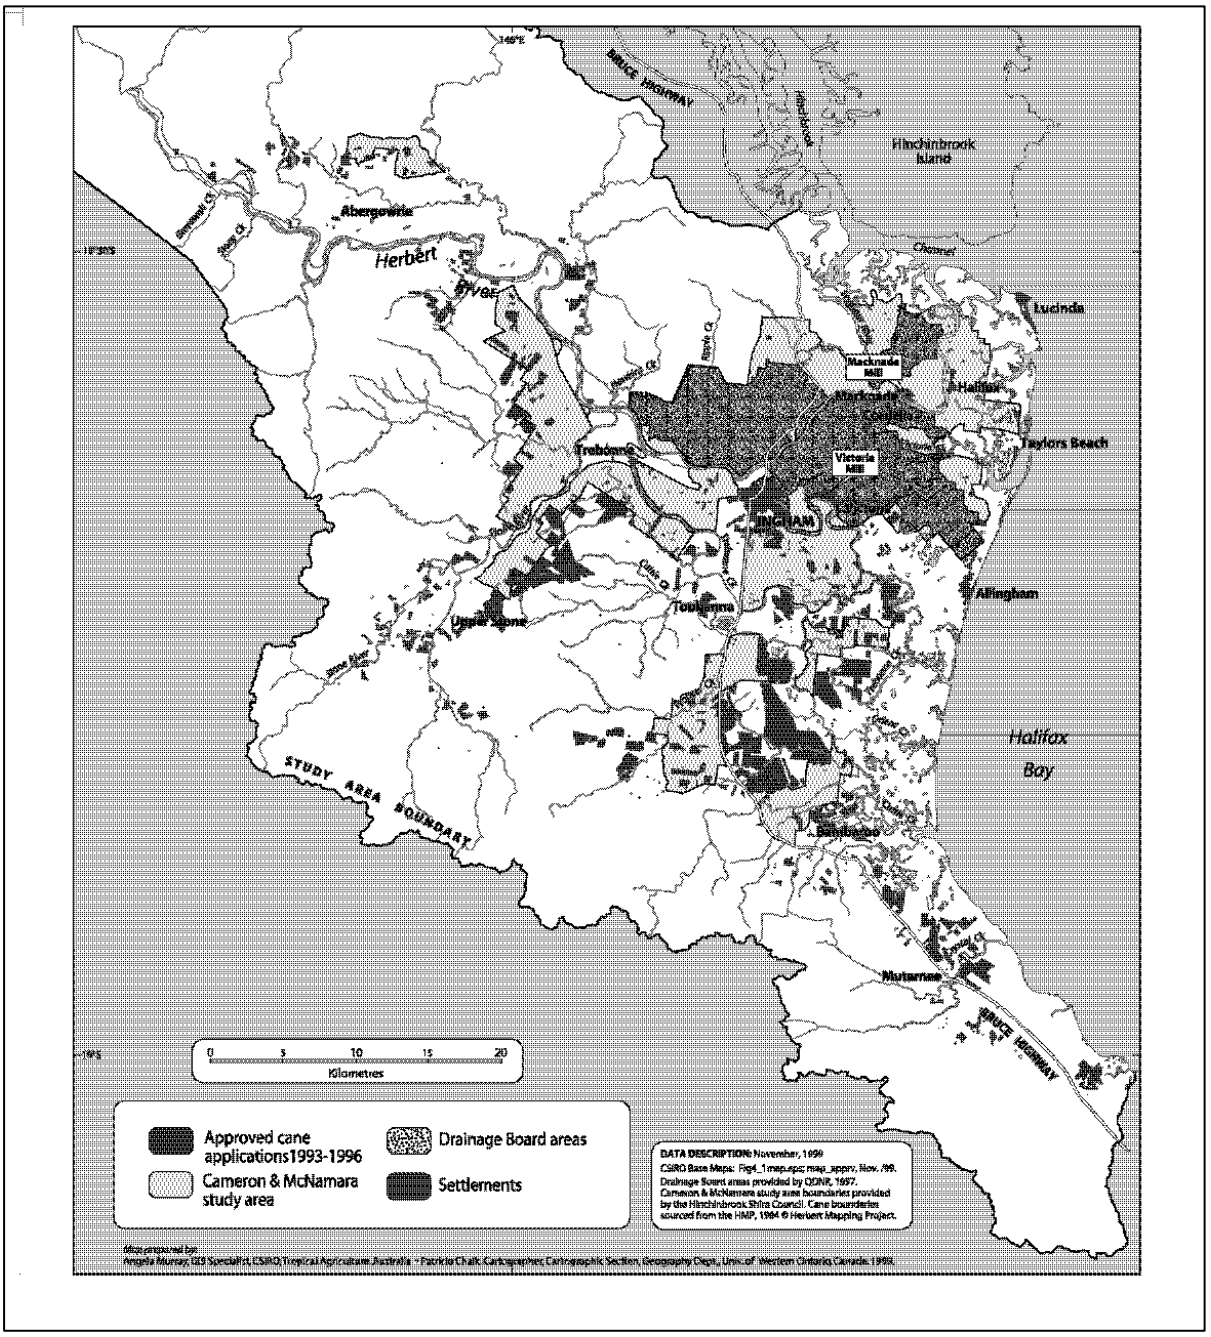

Figure 5.4 Location of assignments awarded relative to Drainage Board and Cameron-McNamara study area.

At present, a cost-sharing approach to major drainage works is being contemplated under the Sugar Industry Infrastructure Package (SIIP). Initiated in 1992, this $117 million Commonwealth-State program aims to enhance the sugar industry's economic performance by developing required infrastructure, such as major drainage works. In the Herbert River district, there are two SIIP initiatives. The first is focused on the Cameron-McNamara study area (Figure 5.4). It generally supports the structural adjustments recommended in that 1984 study. The second study is focused on the remainder of the Herbert River district. If sufficient landowner support is achieved within the lower Herbert, the desirability and feasibility of these proposed works can be considered. Although past attempts to form a single drainage board have failed to produce tangible results and there are statements in the Conditions of Assignment that refer to drainage boards (Table 4.1), the formation of a Water Management Board is a requirement of SIIP. On the one hand, the creation of a single drainage authority will be resisted by individual farmers and may be impossible to implement. On the other hand, these studies should provide for a

comprehensive drainage plan that guides individual farm-level projects.

While environmental assessments are part of the SIIP process, the following shortcomings can be identified:

- The need for the projects is unclear. They are motivated by the perceived economic needs of industry and government. The normative judgements about the need for infrastructure appear to have been made without rigorous consideration of social and environmental factors, particularly at the local level. This approach does not effectively reflect the principle of balanced management.
- Environmental assessments appear to be 'tagged on' to the end of the process, rather than the beginning. According to the Brundtland Commission, ecological factors should be considered at the same time as economic and other dimensions.
- The significance of environmental impacts has often not been well demonstrated. Part of this shortcoming is the absence of clearly defined values attached to significant ecological features.

These deficiencies suggest that the SIIP process fails to adequately consider the linkages within the natural ecosystem as well as those with the economy and society.

5.4.3 Land Cover and Landscape Pattern Changes in the lower Herbert River Catchment

According to the Commonwealth Government (1996, ES-14), land clearing and related activities are the "single largest threat to biodiversity" in Australia. The situation is deteriorating as threatening activities continue." Johnson *et al.* (1999a) described land cover change in the lower Herbert River region since European settlement. Figure 5.5 shows changes in land cover since the 1970s. The period between 1970 and 1996 saw a rapid expansion in the area of sugarcane. The consequences of this expansion have resulted in a decrease of approximately 40% in the area of Melaleuca dominated patterns (half of this area was converted between 1992 and 1996), a 13% decrease in the area of Eucalypt woodland. In contrast, there has been a 70% increase in the area of sugarcane during the same period.

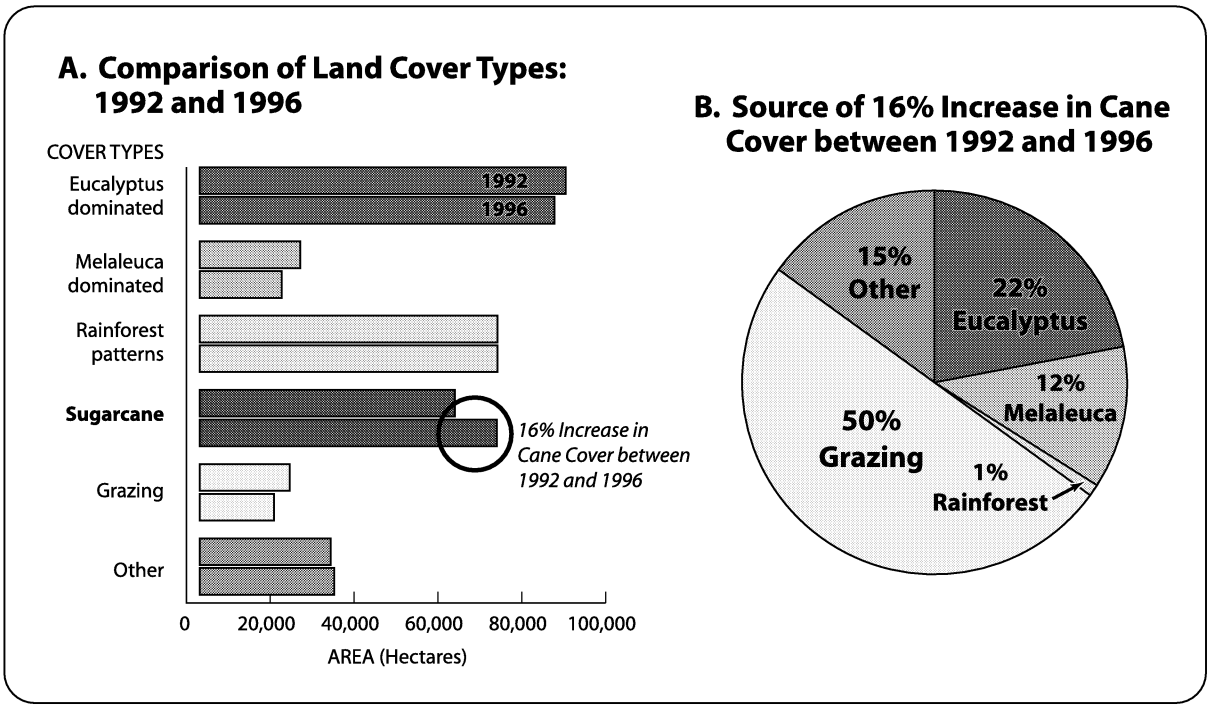

Figure 5.5 Land cover changes 1992-1996.

Johnson *et al.* (1999a) undertook an analysis of landscape pattern in the lower Herbert River region since European settlement. Figure 5.6 shows the number of Melaleuca, Eucalypt and rainforest islands has increased since European settlement. The number of sugarcane islands has remained relatively stable over the last 50 years, however island number peaked during major periods of sugar industry expansion in the 1970s and 1995-1996. Although the number of islands increased for Melaleuca, Eucalypt and rainforest land cover, mean island size for Melaleuca decreased substantially between 1992 and 1996. Mean island size for Eucalyptus patterns and for sugarcane increased during the same period.

Island distribution indices (IDI) for rainforest and Melaleuca patterns between 1977 and 1996 show contrasting island aggregation characteristics. Rainforest patterns show an increasing IDI, indicating that remnant cover is disaggregated, while IDI for Melaleuca patterns declines over time, indicating a pattern of island aggregation. It could be concluded that this contradicts results presented in Figure 5.6, although it is not unexpected given that in an ever increasing "sea" of agricultural land, remnant areas of Melaleuca tend to occur as clusters on the floodplain. However, as previously discussed, the mean size of each cluster is also decreasing.

Landscape distribution indices (DL) for rainforest patterns, Eucalyptus and sugarcane increased between 1992 and 1996, indicating that islands of these land cover classes have become longer and narrower over time. In contrast, values for Melaleuca patterns have declined slightly. These results support those obtained for IDI distributions. Measures of diversity and evenness show an increasing landscape richness and evenness in the lower catchment between 1977 and 1994, as the landscape became more evenly divided among component cover types. However both measures begin to decline post 1994, in response to the large increase in the area of sugarcane. Hence a more uniform/less diverse landscape now exists on the Herbert coastal floodplain when compared with historical patterns.

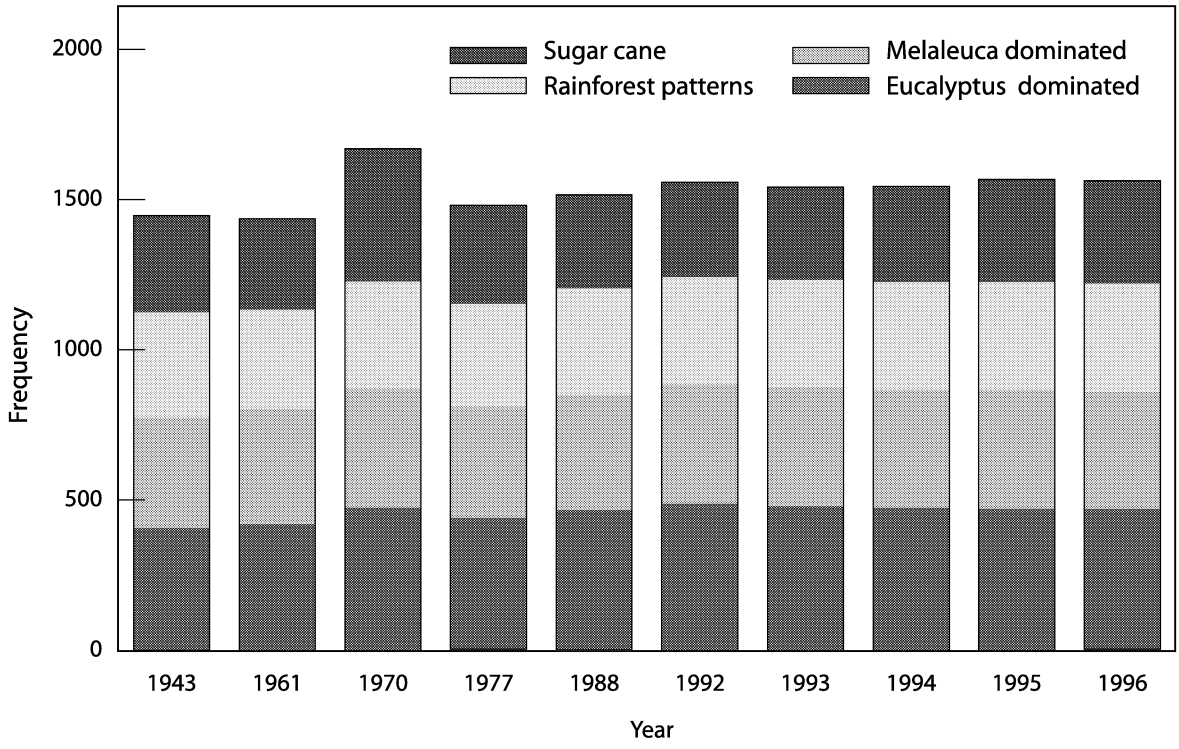

Figure 5.6 Land cover island analysis 1992-1996.

These results support those obtained in a companion study focussing on land cover changes in seasonally inundated areas of the lower Herbert River floodplain (*i.e.* areas below 13m AHD) (Johnson *et al*., 1999b). This study concluded that mean island size for rainforest islands decreased from 128ha in 1860, to 28ha in 1942 and to 24ha in 1996. Similarly, mean island size for Melaleuca forests decreased from 135ha in 1860, to 82ha in 1943, to 46ha in 1977 and to 22ha in 1996. The trends observed in the lower Herbert River catchment are not unique. Similar trends are apparent in the Tully, Murray (Tait, 1994), Johnstone (Russell and Hales, 1996), Mulgrave-Russell, Mossman, Daintree and, to a lesser extent, Burdekin and Haughton River catchments (Johnson *et al.*, 1997).

Given these results, it is clear that the ecosystem in the lower Herbert River has been altered substantially. Hence, unless a change in current land use policy, planning and management occurs, then the area of Melaleuca, Eucalypt and rainforest cover in the catchment will be reduced to a very low level. It is likely that the area of these classes on the floodplain proper are already less than is required to perform as effective and functional biological units (Johnson *et al.,* 1997). While no attempt was made to evaluate the ecological status of remaining riparian and wetland areas, a recent ecological audit of river catchments in Queensland (Moller, 1996) demonstrated that the ecological condition of remaining stands of native vegetation outside of reserves and National Parks in the Herbert River district is poor to very poor. This finding implies that improving the ecological status of native vegetation requires increased efforts to acquire public lands, and/or more effective programs that are targeted at freehold land. These results have also served to identify those land cover types requiring priority management attention.

One of the most intense issues of conflict during the study period, and one that lingers today, concerns the clearing of valued species habitat. This conflict is illustrated in the awards granted in Mahogany Glider habitat, particularly in the Wharps and Pomona areas (Figure 3.2). In 1995, an interim conservation order was issued under the *Nature Conservation Act 1992* to land clearing activities in the Pomona area. A draft Conservation Plan, issued in 1995, raised public and industry concerns about the mapping methodology and the criteria for defining critical habitat. Under the *Nature Conservation Act 1992*, critical habitat is defined as:

> Habitat that is essential for the conservation of a viable population of protected wildlife or community of wildlife, whether or not special management considerations and protection are required.

Unfortunately, two fundamental cornerstones of this definition are not readily apparent and make implementation difficult. First, the phrase "essential for the conservation of a viable population" cannot be clearly defined by "biophysical science" alone. Instead, this judgement involves both a scientific and social/political view about what is "essential". There is guidance in neither the statute nor regulation on this matter. This shortcoming requires attention in the future. The second issue concerns areas that can be mapped and relevant land use practices performed on both freehold and leasehold land. Where critical habitat is located on freehold land, the need to compensate landowners could have significant financial implications. Thus, there is a need to balance ecological ideals with financial realities in order that some effective action is taken. On leasehold land, land clearing is subject to a permit under the *Lands Act 1994*. Since permits should be refused in areas of critical habitat and there is no 'loss' to the leaseholder, no compensation is needed. The critical habitat maps should form the basis for identifying relevant areas in local Planning Schemes. At present, these maps are produced at a scale (1:50,000) that precludes their use at a property-specific level. This limitation, combined with the need for an ongoing dialogue with farmers, highlights the need for well-qualified and well-rounded field staff.

During the period of study, 143 applications were submitted to the Local Board that covered 691.9ha of Mahogany Glider habitat (Figure 5.7 and Table 5.3). Forty-one of these applications were made in 1996, after the Pomona controversy. However, a significant amount of uncertainty

remains. It is unclear that the Mahogany Glider is endangered. Since habitat maps that have been produced after 1996 have identified different habitat boundaries, the credibility of the 'science' has been questioned. The adequacy of the Condition of Assignment (Table 4.1) that indicates a 10m riparian zone of native vegetation maintained along watercourses is also questionable. Not only is it difficult to enforce, but some farmers clear land prior to their application for assignment (called pre-emptive clearing). In these cases, there were no effective laws in place during the study period to prevent this activity.

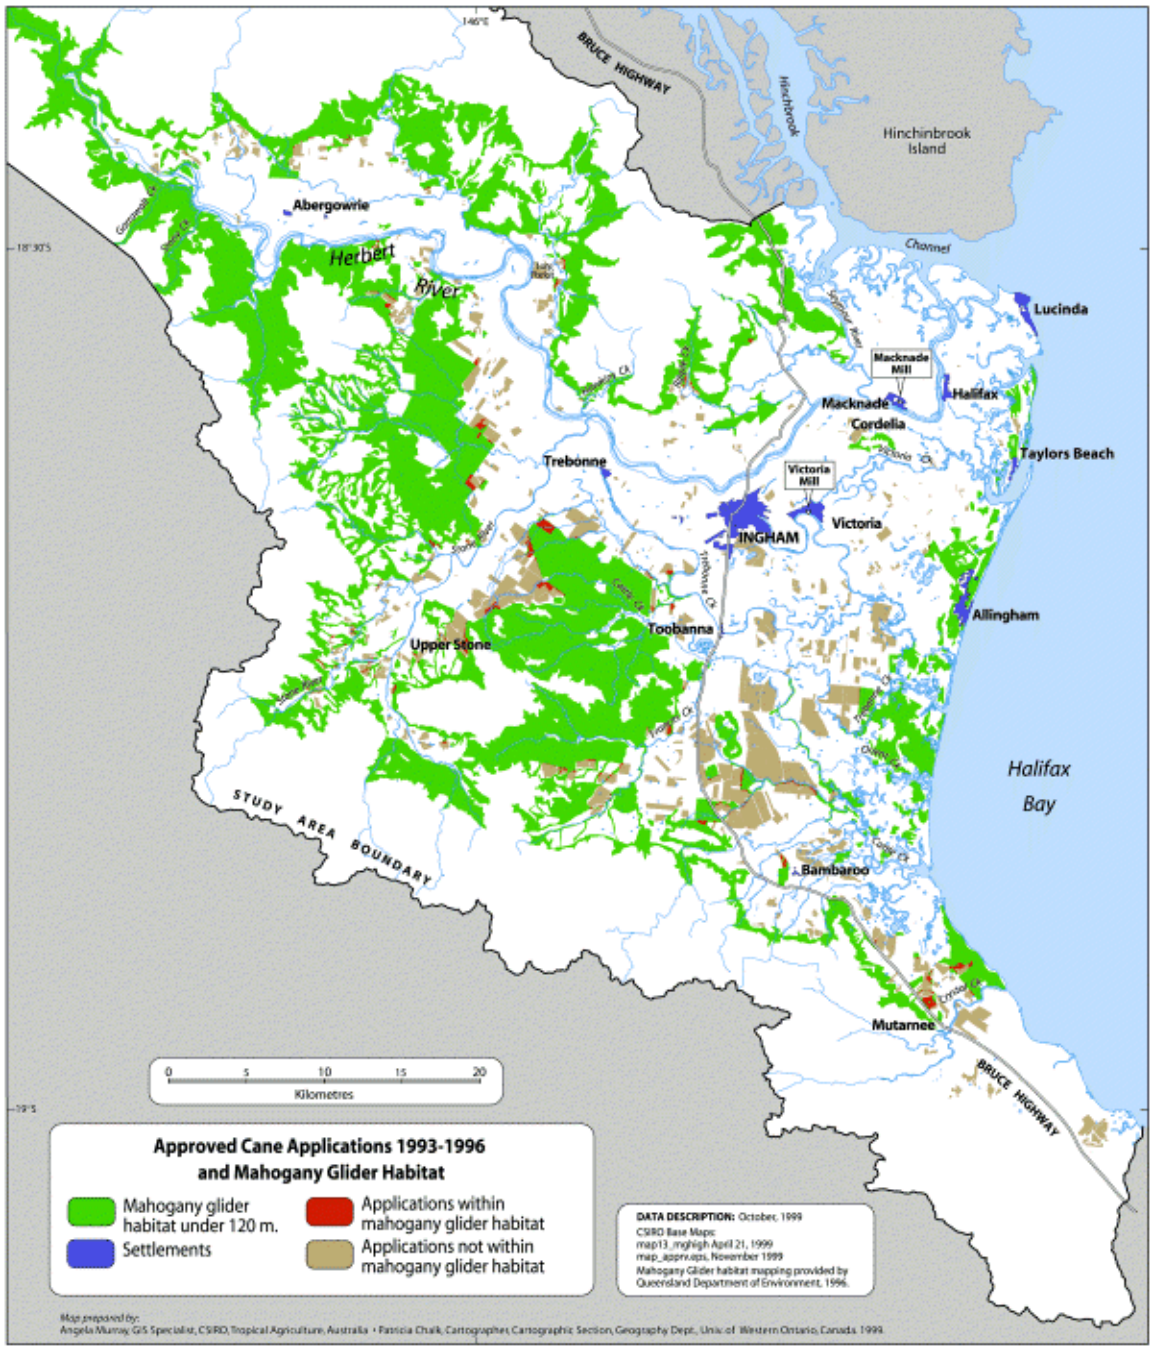

Figure 5.7 Location of assignments awarded relative to mahogany glider habitat.

Altering the timing of the call for assignment applications could reduce the perceived need for applicants to clear their land in a pre-emptive manner. At present, the timing of the decision-making process may support this activity and its negative ecological outcomes. Announcing final assignment decisions in the summer months as was done in 1995 can have such an effect. For many growers in the Herbert River district, land clearing is perceived to be most convenient, easiest and cheapest in February - March while the harvest is three months away and the ground

is moist. This period also provides sufficient time to plant a crop and harvest it in the next season. Between 1993-1996, specific announcement dates have varied. They have primarily reflected administrative requirements rather than an applicant's needs and environmental conditions. This timing, when combined with a farmer's potential need to make payments on any necessary loans and a perception that Local Boards favour applicants who can provide cane to the mill quickly, often promotes land clearing and planting before the announcement of assignment grants (*i.e.*, pre-emptive clearing). This perception is created, in part, by the application form which asks the area of land that is cleared, uncleared, partially cleared and under cane (Appendix 1).

Table 5.3 Location of applications relative to Mahogany Glider habitat as defined by QDoE (1996). Figures shown for applications with spatial representation.

					Mahogany Glider Habitat Area					
	Total Applications		Total Approved		Total Overlapping		1996 Approved		1996 Denied	
Year	Number	Area	Number	Area	Number	Area	Number	Area	Number	Area
1993	199	3980	199	3705	53	132	0	0	0	0
1994	77	2849	77	2704	16	188	0	0	0	0
1995	87	2185	87	2155	33	151	0	0	0	0
1996	109	6001	87	3602	41	222	30	167	11	56
Total	472	15013	450	12165	143	692	30	167	11	56

Note: Area figures are in hectares.

The review of applications for the 1993-1996 period suggests that many applicants have substantial areas of partially cleared or cleared land (50%+), and some applicants (10%-15%) have some cane planted at the time of application. Pre-emptive clearing can negate or reduce the applicability of subsequent conditions placed on an approved assignment. If the application were refused, it could place a farmer in some financial difficulty. One adjustment would be to impose penalties for the pre-emptive clearing of land through the assignment system. However, this approach alone would not respond to the needs of applicants. In addition, the high level of enforcement required is beyond the capacities of existing public agencies to staff and would be contrary to the partnership principle. The sugar industry seems to be unwilling to adopt this enforcement role. A more consistent approach to reduce pre-emptive clearing is by announcing assignment decisions when farmers are most likely to undertake these activities. Another option could require the granting of clearing permits from QDNR prior to receiving assignment.

It was noted earlier that 1997 applications were due 30 June 1996, and assignment awards announced in September 1996. While this adjustment could assist in reducing pre-emptive clearing, it is unclear how effective it will be in the Herbert River district. The majority of local interview respondents specified that announcements should be made in the February period. Since soil moisture, precipitation patterns and farmer practices vary throughout the state, the most effective approach may require application and announcement dates to be based on a regional or mill basis. This represents a shift from the present practice that applies the same administrative timing across the state. Its feasibility should be considered in the context of essential administrative requirements.

Recommendation: Legislative and voluntary initiatives be undertaken to reduce the clearing of valued habitats. Reduce the perceived need for pre-emptive clearing by adjusting the timing of the assignment process. In the Herbert River district, this would see the announcement of assignment awards in the February. Require applicants to obtain clearing permits from QDNR prior to receiving assignment on freehold land or leasehold land.

Action required by: Local Boards (Cane Protection Boards), Shire and QDNR.

In addition, raising the current level of grower's environmental awareness would be beneficial. The CANEGROWERS' audit found that about 23% of farmers were unaware of any industry Codes of Practice (Figure 5.8). About 37% cited Work Place Health and Safety, and 26% cited chemical codes as the most significant reasons that prompted the need farm operations to be concerned about the environment. There seems to be an extremely low level of awareness about environmentally sound procedures for, and impacts of, land clearing. While the audit indicated that a farmer would not knowingly implement farm practices that would undermine their ability to produce sugarcane, there was a general lack of understanding about long-term, broad-scale effects. This shortcoming lead some farmers to clear trees to the edge of gullies; maintain bare earth drains rather than grassed ones; and continue the use of down slope rows rather than contour ones. GHD (1996, 22) believed that a concerted education program was required "to bring to the attention of farmers the benefits of investing a small amount of effort in changing practices to maintain an environmentally sustainable farm operation."

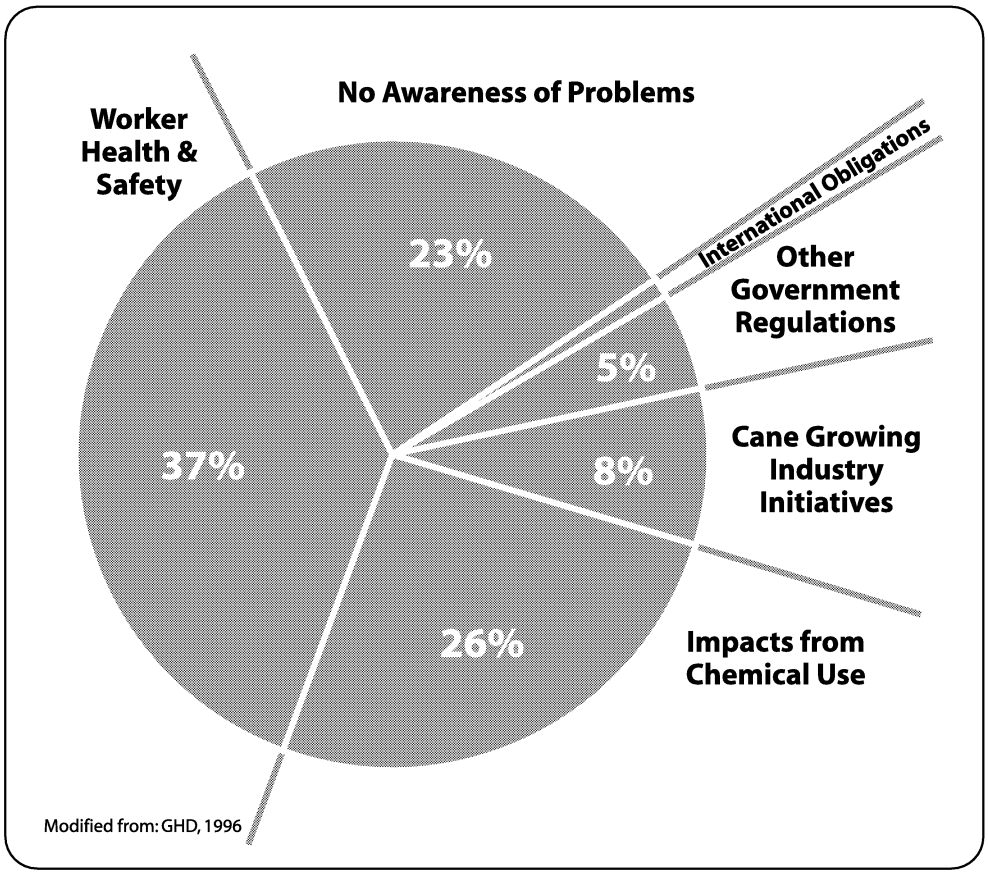

Figure 5.8 Growers level of environmental awareness.

While the audit team found that grower attitudes in the Herbert River district were more progressive than many areas of the State, in general, industry attitudes were characterised as:

> rather insular "assignment-limited" attitudes towards the environment demonstrates a lack of awareness of the wider State and national concepts such as Landcare, ICM, farm plans, revegetation and remnant protection programs, Property Management Plans (PMPs), national strategies on weeds and the management of vertebrate pests, more efficient pricing, water conservation measures, improvements in technical advice and training and ESD programs (GHD, 1996: 23).

The fact that the Herbert River district was viewed as an "isolated pocket" of a progressive attitude in a sea of ignorance and indifference has particular significance. Any shortcomings in

the Herbert River district will be even more significant in the rest of Queensland. The CANEGROWERS' leadership was challenged by the audit "to develop a performance measurement and reporting system for district offices regarding effectiveness of performance and local contact programs" (GHD, 1996: 18). Part of that performance indicator could reflect the assignment process. A preliminary approach is provided below. As noted earlier, by 1996 the Conditions of Assignment and the referral mechanism were well developed in the Herbert River district (Table 4.1). Both the Local Board and Environmental Advisory Committee agreed that no development would occur:

- below 3m ASL or slopes greater than 3%
- in soil suitability classes 4 and 5 for cane growing
- in areas prone to acid-sulphate soils, without an appropriate management plan prepared.

An initial assessment based on these measures can be conducted for the 1996 year (Table 5.4). The data suggest that only two applications were made from properties that entirely or partially contained unsuitable soil. Approval was given on condition that the areas of unsuitable soils not be farmed. Forty applications were from areas that were below 3m ASL or had slopes greater than 3%. Seventeen applications were granted approval on condition that the QDPI be consulted and/or land below 3m ASL be excluded from production; 17 were approved without these relevant conditions being applied; and six were denied. In areas identified as potentially acid sulphate prone, six applications were approved with the relevant condition (Table 4.1), one was approved without the condition applied and one was denied. Given the scale of the mapping and relatively low level of activity, these levels of approval, conditional approval and denial should not cause too much concern. The maps are unable to provide site-specific information. Since the computer-based mapping used in this present report was not available to the Local Board and EAC, these results are encouraging. Local knowledge combined with field checks seems to have served the region well although there are some isolated problems with acid sulphate soils.

Table 5.4 Profile of Conditions, Comments and Decisions for 1996 Applications according to selected locational characteristics.

	Overlapping		**Not Overlapping**		**Overlapping Area Details**							
Locational ~	**Total Applications Submitted**				**Applications Approved**		**Condition Applied**		**Condition Not Applied**		**Application Denied**	
Characteristics	**No.**	**Area**	**No.**	**Area**	**No.**	**Area**	**No.**	**Area**	**No.**	**Area**	**No.**	**Area**
3m ASL or slope > 3%	40	2047	69	1783	34	1819	17	1324	17	495	6	228
unsuitable soils	2	28	107	3581	1	21	1	21	0	0	1	7
potential acid sulphate soils	8	434	101	3310	7	292	6	285	1	7	1	142
Mahogany Glider habitat	41	2484	68	1735	30	1867	4	985	26	882	11	617

Note: Area figures are in hectares.

What is somewhat disturbing, however, is the relatively high incidence of awards located in areas of Mahogany Glider habitat that failed to have the relevant condition attached to it (Table 5.4). While 11 applications were denied in these locations, 30 were approved and only 4 required the 10m buffer of native vegetation be maintained along watercourses (Table 4.1). This reinforces the comments made in the CANEGROWERS' audit that noted the importance of education programs targeted at farmers. Indeed, this program should be extended to members of the Local Board. The data contained in Table 5.4 implies that 'functional resource issues' such as soil suitability, slope, and the potential risk of acid sulphate soil hazards are afforded more credibility than 'natural environmental issues' such as Mahogany Glider habitat. This attitude seems inconsistent with ESD and the intent of the Conditions of Assignment.

The inconsistent and relatively poor application of identifying the Mahogany Glider habitat as a Condition of Assignment on individual awards reflects, in large part, a difference in values between the Local Board and the EAC. Many of the criteria identified in the Conditions of Assignment (Table 4.1) reflect functional values; that is where is a significant risk to water quality or land degradation. These risks can affect the long-term viability of a grower's operation. The Mahogany Glider issue reflects an environmental value that is perceived to pose no significant risk to human health or farm operations. Part of the problem may also be associated with the lack of accessible information when decisions were made. Given the publicity that was associated with the land clearing in the Pomona area, there is no doubt that all participants were aware of the Mahogany Glider issue.

A more assertive stand on this type of environmental issue could demonstrate the type of leadership that GHD (1996) believed was necessary if the sugar industry was to distance itself from the "legacy of the past." In this context, the adequacy of the Conditions of Assignment must be questioned. The EAC and Local Boards could benefit from an open and public discussion about the adequacy of current Conditions of Assignment. Similarly, these issues could be better dealt with under *IPA*. However, as mentioned in Section 5.2, *IPA* has a number of deficiencies. In particular, its apparent inability to deal with cumulative impacts and variable environmental provisions in Shire Planning Schemes remains problematic.

At a broader level, a number of complementary options are available to the sugar industry to support specific provisions embedded within the assignment process:

- Legislative and voluntary initiatives could be developed and implemented to reduce the clearing of valued habitats. Motivational and voluntary incentives have already been used in some cane growing regions, and include activities such as ICM. Hence motivational incentives must be a core mechanism for improved natural resource management. Two examples of a potential application would include:
  - The identification of agreed wetland and riparian areas in cane growing catchments to underpin negotiated agreements among land holders, government and the broader community on buffer setback widths. This activity would preferably be embedded and implemented within a broader catchment planning exercise undertaken as a partnership among government, the sugar industry and the community; and
  - The establishment of voluntary conservation agreements between cane growers and government under the *Nature Conservation Act (1992).*
- Conservation covenants are particularly effective in protecting remnant vegetation or wetlands, and can be use to underpin approaches such as management agreements. The use of conservation covenants can also be linked to other incentives, for example, the local government rating systems (for rate relief purposes), to recognise the value of uncleared land.
- Although some protection for natural resources is currently afforded by planning controls embedded within a number of state laws, problems exist in areas subject to the provisions of the *Water Resources Act 1989*, or on land with freehold tenure. An increasing regulatory role for Local Government (*e.g.* through the invocation of planning controls if consent is required for subdivision, zone change and drainage development) provides some opportunity for improved natural resource management. Some of these issues are presently being addressed in the revised planning schemes of Noosa, Hinchinbrook, Cardwell and Johnstone Shires. However, for improved management to occur, greater integration among local and state government, industry and the community must be a priority.
- Opportunities also exist for the implementation of financial incentives for retention and management of high value habitat areas in cane growing regions to be dedicated as Nature Refuges or Coordinated Conservation Areas. Finally, government acquisition of riparian areas and wetlands of regional, national and international importance remains an option.

5.5 Enhancing the Principle of Balanced Decision Making

The essence of balanced decision making is to integrate economic, social and environmental considerations. Three views of balance are provided: (1) shape analysis, (2) analysis of assignment decisions, and (3) assessment of the decision-making structures.

5.5.1 Shape analysis

How concentrated or dispersed development occurs is an important issue. In order to examine this aspect, analysis as described in Section 3.5 was undertaken in order to determine the shape of the sugarcane growing area over time (Figure 5.9). The ellipses shown in Figure 5.9 contain 60% of the cane growing area. The summary analysis statistics that support the figure are provided in Appendix 2.

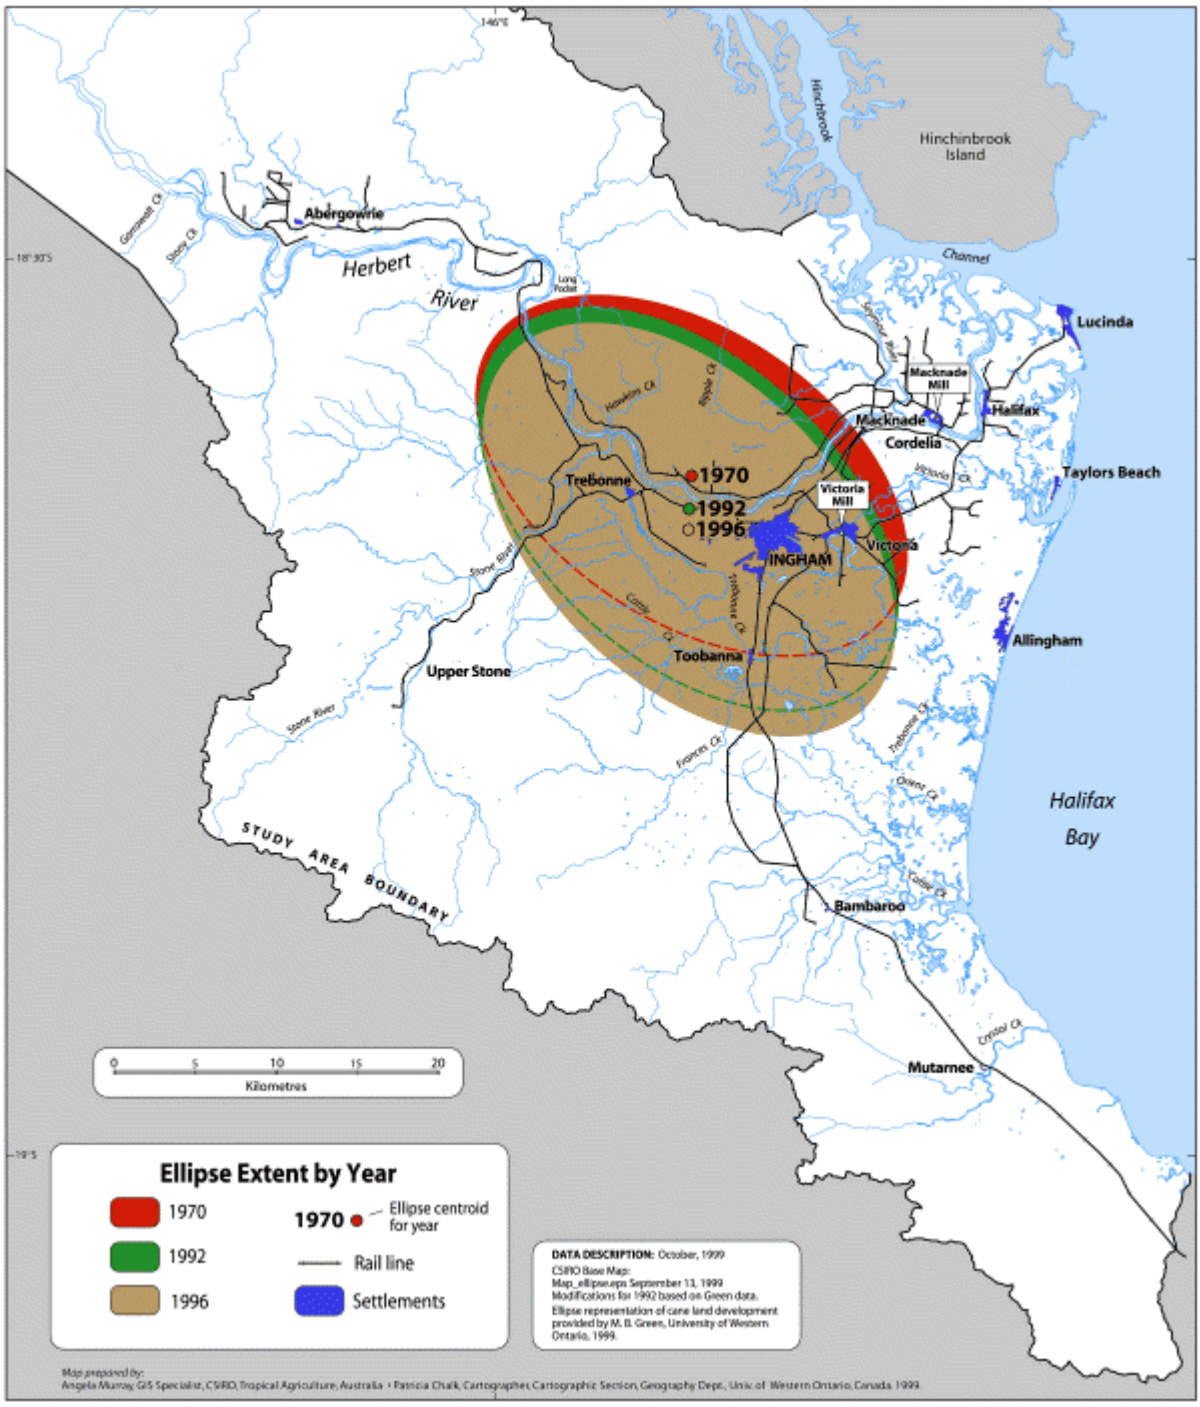

Figure 5.9 Land cover changes in the lower Herbert River district: 1970, 1992 and 1996.

The analysis suggests that development has and remains to be relatively concentrated as illustrated by the more circular rather than linear shape. Figure 5.9 suggests that the direction of development has changed over time. The first period of development was between 1970 and 1992, the period prior to the introduction of the *Sugar Industry Act 1992*, when significant changes occurred with respect to the general movement of the district. This change occurred when the rate of annual increase was relatively modest compared with more recent expansions (Figure 3.4). Between 1992 and 1996, the ellipse shape has moved further southwest. Its general shape is about the same as that which existed in 1970. This suggests that for 1970 and 1992, the cane growing area has remained at the same level of concentration. The smaller size of the area of the ellipse also implies that some infilling near the centroids has occurred. However, since the centroids have moved to a limited degree, it is difficult to comment conclusively on this issue. However, there is no doubt that concentrated development allows for efficient use of the cane tram and road network. The analysis clearly indicates that over time there have not been radical changes in the either the orientation or compactness of sugarcane cultivation. This is consistent with incremental change, which certainly seems to characteristic of the assignment process. On this basis, the pattern of expansion between 1992 and 1996 did not reflect a significant change from past practice.

It is noted that the mill locations are not near the centre of the ellipses for any of the years noted in Figure 5.9. This has implications for the transport network and may be worthy of further investigation.

5.5.2 Statistical analysis

As described in section 3.4, a statistical analysis was conducted in order to determine what variables were associated with final assignment decisions: those applicants that received 100% of their application request, those that received less than 100% of their application request, and those who were denied their request. For the years 1993 and 1994, the following five variables were studied: (i) the area of land applied for, (ii) the type of farmer (new, existing), (iii) land tenure, (iv) current assignment. None of these were positively correlated with the Approval Rate. Since the approval rate for 1995 was nearly constant at 100%, it was not analyzed. There were no significant factors in the logistic regression of the above 11 factors for Macknade Mill in 1996. The data for Victoria Mill in 1996, with all of the above 11 factors, were subjected to stepwise logistic regression (both forward and backward) and a subset of five significant factors was identified, as indicated in Table 5.5 below:

Table 5.5 Logistic parameter estimates.

Factor	Estimate	Standard Error	Chi-Square (df=1)	Pr > Chi-Square
A	-1.3292	0.5153	6.65	0.0099
Y1	2.0543	0.4977	17.041	0.0001
PY	-1.1708	0.4838	5.86	0.0155
NR	-1.3225	0.4537	8.50	0.0036
DV	1.4281	0.4787	8.90	0.0029

A table of the frequencies associated with the 2 levels of the above five factors and the 3 levels of the Approval Rate (i.e. 100%, <100%, 0) variable are given in the Table 5.6 below for Victoria Mill in 1996:

A positive sign for the estimates of the factors in Table 5.6 indicates that they contribute to increasing the Approval Rate. Consequently, we see that high percentage amount planted in year 1, and high distance to Victoria Mill are both associated with an increase the Approval Rate. Similarly, higher levels of amount Applied For, the number of years intended for planting and the Nearest Rail Distance are associated with lowering the Approval Rate.

Table 5.6 Frequencies for Victoria Mill in 1996.

	Approval	Denied	Received < 100% of request		Received 100% of request	
Level	0	1	0	1	0	1
A	14	10	16	17	48	2
Y1	21	3	26	7	18	32
PY	6	18	9	24	37	13
NR	9	15	20	13	37	13
DV	22	2	20	13	28	22

These last comments are only applicable to one year and one mill. However, they may be indicative of some of the mechanisms used in determining final sugarcane assignments. The logistic regressions have been performed on simplified codings of the predicting factors, and no interaction terms have been included in the regression equation. These interactions and other non-significant effects may be confounded with the resulting subset of important factors for Victoria Mill in 1996. A more detailed data set may provide more conclusive evidence of any strong predictors of the how approval rate is determined. However, this analysis suggests that environmental factors were not significant in determining awards for 1996. This conclusion raises questions concerning the achievement of balanced management.

5.5.3 The Environmental Advisory Committee and the Assignment Process

The formation of the Environmental Advisory Committee (EAC) and the development of the Conditions of Assignment (Table 4.1) reflect the Local Boards' primary responses to the requirement. Through these mechanisms, the Local Boards and the QSC are satisfied that assigned land is "prepared and used for the growing of sugarcane without undue damage to the environment" (*Sugar Industry (Assignment Grant) No.2) Guideline 1995*, Section 8(1)(e)). Prior to the formation of the EAC, there were few opportunities for views outside of the sugar industry to be expressed. While the Local Board and the members of the EAC should be given credit for its implementation, it provides only modest opportunities to significantly influence decision making. This shortcoming was also identified in the CANEGROWERS' environmental audit (GDH, 1996).

One way of considering balanced decision making is to return to the idea of the different levels of decision making - normative, strategic and operational (Section 4.1.1). The EAC is focused on operational level decisions and has no influence at normative and strategic levels. This situation can lead to a conclusion that suggests that this form of participation is little more than tokenism, because many important decisions are already made before the operational phase is reached. In the sugar industry, normative and strategic decisions are made through international agreements (*e.g.* GATT), corporate strategies (*e.g.* shareholder meeting, investor decisions), and regional plans (*e.g.* Continuous Crushing Agreement) (Figures 4.2 and 4.4). To enhance balance, efforts are required by both public and private managers at normative, strategic and operational levels of planning to better consider environmental, social and economic issues at all geographic scales.

The "Continuous Crushing Agreement" represents an important strategic level of decision making in the sugar industry because it reflects both producer and grower perspectives. At present, production and crushing capacities, future growth and transport planning are addressed through the "Continuous Crushing Agreement". It provides a basis for medium-term planning at the regional level. In the Herbert River district, the agreement notes that over an unspecified time period, the amount of assigned land could reach 100,000ha (Agreement, 1995). In planning for forthcoming expansions, it was agreed to work together to determine a forecast area of new land to be harvested in the following year by early July in each year. Based on this area and the cultivated area recorded for the current season, and using the five-year average rotation for

harvest (which included the estimated area for harvest for the current season), the district forecast area for harvest in the next year can be determined; and that

> ... CSR undertakes that crushing capacity will be available for the processing of the whole district crop yielding up to 83 tons per hectare over the forecast area for the harvest determined ... at CCS levels of up to 14.0 units, within the target season length.

The "Continuous Crushing Agreement" is the key strategic planning document which guides cane expansion in the Herbert River district. At present, it essentially matches projected increases in crushing and transport capacity to production capacity. It is corporate goals and the ability of the mill to crush cane that primarily influences the nature of the "Continuous Crushing Agreement". Despite the many changes that have occurred in Cane Assignment and Land Use Planning processes since 1996, none appear to have a direct influence on neither corporate goals nor the "Continuous Crushing Agreement" (Figure 5.2). This situation has implications for the nature of conflict resolution.

Presently, international agreements and the "Continuous Crushing Agreement" favour economic and corporate goals. These goals establish the context that drives the cane assignment process (Figures 4.2 and 4.4). In short, the task of the assignment process is to ensure that cane production, that does not degrade the environment, meets mill capacity. The outcome of this decision-making structure relegates the environment, as well as the concerns of local government, to an accommodative or reactive position relative to these primarily economic considerations. Environmental factors are incorporated explicitly through the referral of assignment applications to the EAC. In addition, some applicants may contact relevant government officials about the preparation of Property Management Plans or similar advice. However, at this level of decision making, the ability of environmental interests to influence the cane assignment process is limited.

When a conflict concerning assignment has occurred, "environmentalists" have sometimes questioned why the assignment was granted in the first place (*i.e.* strategic question). In contrast, the "sugar industry" has asked the EAC to identify what mitigative measures or Conditions of Assignment (Table 4.1) would adequately support sugarcane development (*i.e.* operational question). This difference illustrates the difficulties in trying to achieve balanced decision making late in planning processes. Once economic goals (*e.g.* mill capacities, corporate profit targets) are established, it becomes difficult for a person to raise other legitimate issues and be perceived as a "constructive" participant. In addition, these discussions are periodic, rather than ongoing. If decisions are to be more balanced, there is a need for the cane allocation process to effectively consider the "environment" earlier in the decision-making process, and on an ongoing basis.

In considering the principle of balance, it is also appropriate to incorporate the concerns of local government. As noted in Chapter 4, the Hinchinbrook Shire Plan (1984) was predominated by the "rural use" designation that precluded the Shire from reviewing proposals and initiating environmental assessments. It also failed to provide for a contemporary view of environment-development linkages. During the study period, the Local Boards in the Herbert River district did not refer cane land expansion within the rural zone to the Shire. Therefore, the Shire received very little information and its Strategic Plan (1984) had very little influence regarding the cane expansion process and its final decisions (Figure 5.1).

Given the Shire's responsibilities, this situation is unfortunate and perplexing. The development of sugar-related rail and road systems impact on the Shire's drainage works. The Shire is obligated to maintain these roads once they are developed. All these associated developments are treated "as a right" which precludes their formal review through the impact assessment provisions of the *Local Government (Planning and Development) Act.* This is in contrast to other statutes, such as those related to transportation that provide for the Shire's full participation. Thus, the effects that cane land expansion have on land valuation, drainage flows and road maintenance costs - all responsibilities of the Shire – are addressed through the transport planning process. However,

local government is poorly informed during the assignment process and does not participate in the discussions concerning the development of the "Continuous Crushing Agreement". Social impacts are also overlooked in the existing process. There is no representation from the Social Impact Assessment Unit (Queensland Department of Family and Community Services) or Shire on the EAC that could assist in enhancing the balance of decision making. While opportunity for these issues to be addressed under *IPA* exists, it is unclear whether this will occur in practice.

This situation could be addressed to some extent by broadening the participant base of the "Continuous Crushing Agreement". For instance, medium-term expansions could better incorporate environmental and social issues that identify both constraints and opportunities for growth. The recent establishment of the Herbert Resource Information Centre should facilitate this type of planning. In addition, through the CANEGROWERS, Shire and the Queensland Department of Families, Youth and Community Care, social issues related to the role of the family farm, as well as economic and environmental considerations could guide medium-term expansions. This mix of issues could be incorporated into mill expansion and transport planning activities and alternative assignment options assessed using tools developed by researchers in the Sugar CRC (*e.g.* Walker and Johnson, 1998). In this manner, Local Boards could better consider and communicate to potential applicants the relative weight that both the industry as a whole and existing cane growers give to specific decision criteria. It could also make an explicit statement that ensuring the viability of family farms would be given preference, or that future expansion would favour specific locations. At a corporate level, CSR could ensure that its corporate strategy effectively embraces the "green" values that it stated in Chapter 4. The common element in these initiatives is to introduce environmental and social issues earlier in the cane assignment process.

The sugar industry's rhetoric about ESD principles (Table 4.2) suggests that the ecological dimensions of policy are on a par with economic and social concerns. The evidence presented above suggests that this balance is inadequately achieved within the cane assignment process. The fact that a former 'routine process' has come under significant public scrutiny suggests that current practices are inadequate. The CANEGROWERS' audit supports this conclusion when it suggests that many non-farm respondents questioned the integrity of the assignment process and perceived that Local Boards acted "too quickly" (GHD, 1996: 6). They also noted that QDoE (now QEPA) and QDPI have had little input into the process. They believed that no mechanisms were in place to avoid and address the potential undue environmental damage. From this perspective, these are what Dovers (1997) termed non-systemic sustainability problems that can be solved, in part, be improving the information base and improving existing institutional arrangements at the margins.

However, the problems currently experienced by the sugar growing industry also reflect more deeply rooted or systemic sustainability problems. Part of the problem is related to the intractable policy problems that implementing ESD poses for resource policy makers and managers. Some of the characteristics that make the environment a difficult policy issue relative to economic and social policies, include temporal scales that exceed those determining policy and management attention, broadened spatial scales, irreversibility, complexity, ignorance and uncertainty, cumulative impacts, shifting social values and economic circumstances, and changing urgency, both perceived and real (Dovers and Lindenmayer, 1997). These difficulties are particularly evident in systemic problems such as climate change and biodiversity, rather than discrete projects or routine activities. Having corporations adopt more transparent decision-making in order that the weight applied to environmental, social and economic factors is clear and direct requires a fundamental change in current practice. It is also incumbent on the non-corporate sector to better understand the need for an adequate profit margin.

These statements as well as the evidence provided in this report suggest the need for a more

balanced decision-making process. It is beyond the scope of this study to consider the corporate adjustments required from sugar producers such as CSR. However, one step towards that principle is to recognize the different levels of planning, and to ensure that opportunities for participation at all levels are provided. At a minimum, those state and local government agencies, whose programs may be impacted by sugarcane awards, should have adequate opportunity to influence decision making. This objective can be achieved by broadening participation in the "Continuous Crushing Agreement" to the views of relevant government agencies, local government and the public. The desirability and effective management of cane expansion could be more broadly considered from economic, environmental and social perspectives. In this manner, the sugar industry would enhance the development of a balanced perspective earlier in the planning process, and ideally reduce current levels of frustration, time, and resources required to resolve conflicts.

Recommendation: Provide for the earlier consideration of environmental and social factors in the cane assignment process through existing mechanisms such as "Continuous Crushing Agreements" and corporate policies.

Action required by: Local Boards (Cane Production Boards), CANEGROWERS, and CSR.

5.6 Enhancing the Partnership Principle

Partnership was a third important principle of sustainable development. It is believed that by consulting with people living in a region who will be affected by a decision, it is possible to:

- define the problem more effectively;
- access information and understanding that fall outside an agency's technical expertise,
- identify solutions that are socially acceptable; and
- create a sense of ownership for the decision which facilitates effective implementation (Mitchell, 1997).

The extra time and energy needed to provide for effective participation can be a source of frustration and criticism for decision-makers. However, a lower level of conflict and more effective implementation should reward this effort.

The establishment of the EAC was the mechanism to provide for more formal communication between the Local Boards and those government and industry representatives who had an interest in "environmental" issues. However, the manner in which this referral has been implemented (Figure 4.4) has many of the previously described shortcomings associated with the 'Solomon Trap' (Figure 3.1). Members of the EAC can feel betrayed and frustrated when their recommendations are not acted upon because there is ineffective two-way communication. In cases where there are differences of opinion between the EAC and Local Board, the latter was under no obligation to inform the former of why it rejected an EAC recommendation. In addition, the Local Board was not required to inform the QSC that a difference of opinion existed at all. These differences of opinion can occur at two levels and pertain to: (i) areas that are suitable for cane expansion; and (ii) individual applications.

By 1995-1996, the Local Board had developed a list of Conditions of Assignment that could be placed on an award (Table 5.7). These would be supported by the provisions of the *Sugar Industry Act*. However, by that time, the EAC had also developed a list of biophysical criteria that identified unsuitable land for sugarcane expansion that differed from those established under law (Table 5.7).

Major differences of opinion between the two groups relate to two issues. The EAC viewed expansion below the 9.5m level in Cattle Creek and in Mahogany Glider habitat areas as undesirable. The Local Board did not share this view.

Based on the criteria noted in Table 5.7, Figure 5.10 identifies areas that both groups believe as desirable and undesirable for cane expansion, as well as areas of disagreement – where only the EAC believe that land is unsuitable. The location of lands that were awarded assignment in the area of disagreement is also shown. In order to provide a fair assessment of this analysis, the sequence of development should be placed in context. The Conditions of Assignment evolved over the study period (Table 4.1). In addition, the EAC commenced an initial review in 1995, and its membership was expanded in 1996. Therefore, Figure 5.10 largely provides a hindsight evaluation of expansion during the study period.

Table 5.7 Criteria for defining unsuitable land for sugarcane farming from Local Board and Environmental Advisory Committee (EAC) perspectives (1996).

Unsuitable land for sugarcane farming, according to the Environmental Advisory Committee
1. Stream buffers (40m/20m major/minor streams)
2. Water bodies, swamps and wetlands
3. Mangroves
4. Acid sulphate prone soils
5. Areas below 3m ASL
6. Soils unsuitable for sugarcane
7. Slopes of 3% or steeper
8. Mahogany Glider habitat
9. Areas below 9.5m ASL in the Cattle Creek subcatchment
Unsuitable land for sugarcane farming, according to the Local Board
1. Stream buffering (10m)
2. Water bodies, swamps and wetlands
3. Mangroves
4. Acid sulphate prone soils
5. Areas below 3m ASL
6. Soils unsuitable for sugarcane
7. Mountains or Hills (No soil suitability rating & no other constraint)

Note that tenures unavailable for sugarcane farming have also been excluded, including residential, industrial, national parks, reserves and Wet Tropics areas.

Development that occurred in the area of disagreement should not be considered as necessarily bad. However, it does highlight the need for effective site visits, strategic planning, Property Management Planning, and conflict resolution mechanisms between the EAC and Local Boards. It is the latter that is considered here.

Over 70% (8,655ha) of the awards granted during the study period occurred on land that both the Local Board and Environmental Advisory Committee were deemed suitable by both bodies (Table 5.8). About 7% (741ha) of the land was granted on land that both groups perceived as unsuitable. This last statistic is not viewed as a significant concern because scale of mapping used in the GIS is not appropriate to make site-specific comments. Field checks could better determine the appropriateness of these cane developments. Of greater concern to this report is the 2,768ha of development that occurred in the area of disagreement. This represented about 20% of development during the entire study period. More importantly, in 1996, over 1,400ha of the total assignment of 3,601.5ha (38.8%) were located in this region. In the absence of an open and transparent decision-making process and effective conflict resolution mechanisms, cane expansion in these areas may alarm government officials (and interested members of the public) who are concerned with drainage and habitat issues. It is these considerations that the Local Boards and EAC disagree on.

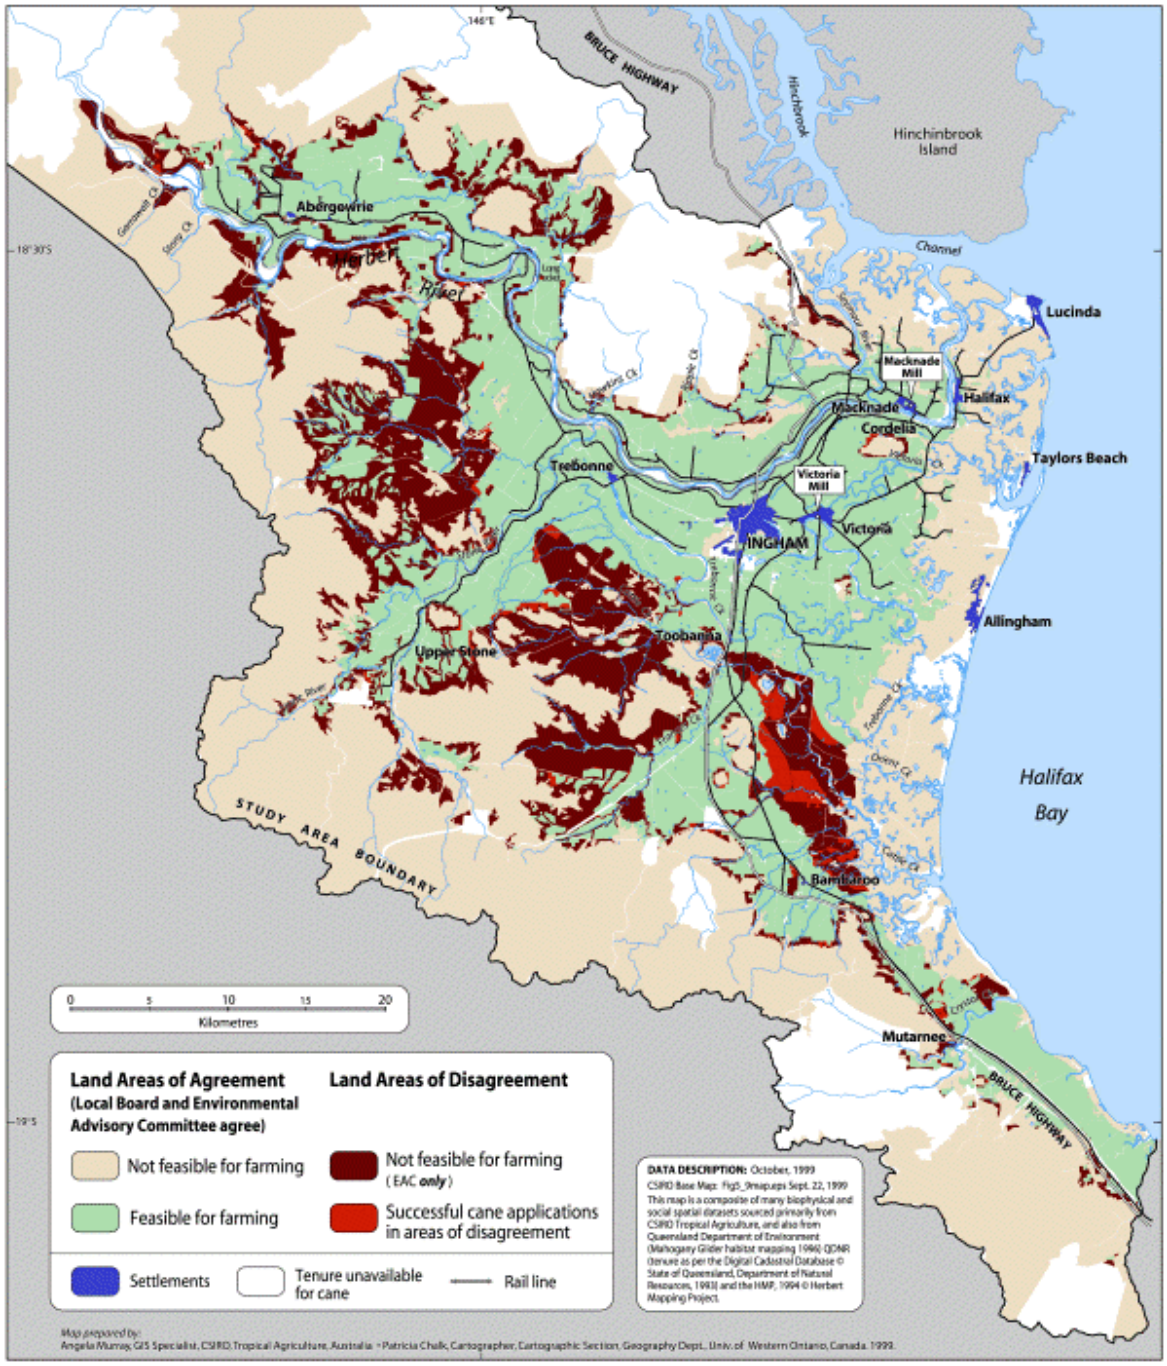

Figure 5.10 Land capability for sugarcane: Local Board and Environmental Advisory Committee perspectives (1996).

It is appropriate to note that the Hinchinbrook Shire Plan (1984) supported all the cane development that is shown in Figure 5.10 and Table 5.9. It was treated "as a right". However, the differences of opinion illustrated on Figure 5.10 reflect, in part, the evolution of values that have occurred since the writing of that document in 1984.

In the context of sugarcane assignment, this evolution re-enforces the need for continuous dialogue at strategic and normative levels of planning. Unresolved conflicts at these levels, combined with any unresolved issues concerning individual awards could result in increased levels of frustration and conflict. Since members of the EAC will likely have contact with those applicants who require a permit or seek their advice, this is potentially a very significant issue. Some members of the EAC were generally satisfied with the process, while others expressed some level of frustration. Members of the Local Board were generally pleased with the input from the EAC however, there is an absence of an unreserved and strong endorsement of the

current process. Any effort to remove some of the difficulties associated with the "Solomon Trap" would enhance the implementation process.

Table 5.8 Assignment decisions relative to Local Board and Environmental Advisory Committee (EAC) views of land suitability and tenure.

	Agreement				**Disagreement**	
	Local Board and EAC believe land is:				**EAC believes land is unsuitable:**	
	Suitable		**Unsuitable**		**Unsuitable**	
Year	**Number**	**Area**	**Number**	**Area**	**Number**	**Area**
1993	157	3255	199	171	16	279
1994	53	1787	77	70	9	847
1995	69	1734	87	180	9	240
1996 (approved)	58	1879	109	320	15	1402
Total	337	8655	472	741	49	2768
1996 (denied)	16	534	5	217	1	135

Note: Area figures are in hectares.

Differences of opinion concerning individual applications reflect operational level conflicts concerning at least three themes. First, it reflects the EAC's single focus on environmental criteria relative to the Local Board's legally required foci on economic, environmental and social factors. Second, it can indicate the greater importance given to other factors that was noted in the previous section. Third, it may imply a lack of credibility and indicate the high level of uncertainty, indeterminacy and ignorance in the technical aspects of resource management (Table 3.2). These will be discussed in greater detail in Section 5.7. In any event, the basis of final decisions is generally unclear to members of the EAC and others outside the process. A one-way exchange of information is supported through the present referral process. Even though assignments are awarded, conflicts concerning the desirability and feasibility of individual awards generally go unresolved.

In addition, the present length of time given to the EAC to review applications may be inadequate. Given that EAC members already have full-time demands from their employers and no accommodations were made to facilitate their participation, it would be appropriate to reconsider the length of time required to effectively review applications. On a positive note, the need for additional time may be reduced as a result of the establishment of the Herbert Resource Information Centre.

Current conflict resolution mechanisms are not clearly visible and effective. The two available approaches took the form of: (i) an informal "administrative pressure" that could be applied by the QSC in response to a comment/complaint by an individual applicant or EAC member; or (ii) a formal appeal to the Sugar Industry Tribunal. The QSC was likely to be unaware of differences of opinion between the Environmental Advisory Committee and Local Board on individual applications as well as feasible areas for future development (Figure 5.10). More effective dispute resolution mechanisms should be incorporated into the sugar industry legislation. While changes have been made in the *Sugar Industry Bill 1999*, resolution of disagreements relating to individual assignments remains problematic. This approach would raise awareness that a conflict exists. Based on this knowledge, appropriate responses could be determined. It would also serve as an incentive for Local Boards and the EACs to hold meaningful discussions that might resolve the conflict at the local level. At the time of writing, effective negotiations of this type are lacking. If these locally based mechanisms fail, decisions can be made through the existing mechanism – the Sugar Industry Tribunal – or through other forums that are not locally based. If the current situation is not addressed, these conflicts could prompt the need for more radical changes to the membership, responsibilities and powers of Local Boards, and their relationship with advisory

bodies. Some of these have been addressed in the *Sugar Industry Bill 1999*.

Recommendation: That the Environmental Advisory Committee and Local Boards members improve the present referral process. Industry wide, basic legislative amendments should support more effective communication between Environmental Advisory Committees and Local Boards. These should be codified in sugar industry legislation.

Action required by: Minister for Primary Industries, CANEGROWERS, Local Board (Cane Production Boards) and Environmental Advisory Committee.

Since there are many natural resource managers who are impacted by sugarcane assignment decisions, it is appropriate that their legitimate interests are raised, information shared and appropriate decisions made. Presently, environmental issues are addressed through the referral to the EAC. Miller and grower interests are very effectively considered through existing decision-making procedures. However, local government is directly impacted by decisions and is essentially excluded from the process. Expansion into new areas will often require road construction, which will eventually be maintained by local ratepayers. Roads and rail lines will affect drainage. All these items are of significance to the Hinchinbrook Shire. At present, no formal mechanism is available to provide it with information concerning the location of applications or final decisions. Unfortunately, its Strategic Plan (1984) provided little opportunity to effectively guide cane expansion (Figure 5.1).

As noted earlier, River Improvement Trusts can have notices placed on a land title when subdivision plans are approved. In the case of the Herbert River Improvement Trust, the shire is the only participating municipality. Given the concern over the maintenance of riparian corridors and the past legacy of individual and unapproved drainage works in the Herbert River catchment (Section 4.1), it is appropriate to consider similar mechanisms for the assignment process. The impact on local rates would be negligible. Possible cross-sanctions with the *Water Resources Act 1989* and the *Transport Planning and Coordination Act 1994* could also be provided. The consideration of social and economic aspects could be broadened and deepened through the Shire's participation. More timely notices concerning rate changes can be provided.

Recommendation: Better incorporate the Shire and other relevant participants into the assignment process. This could be accomplished through an effective referral process, observer status on Local Boards, full voting rights on Local Boards, or other appropriate mechanisms.

Action required by: Minister for Primary Industries, Local Board (Cane Production Boards), CANEGROWERS, CSR and Shire.

5.7 From Flexibility to Adaptability

One promising approach in environmental management is adaptive management. Pioneered by C.S. Holling and others, it emphasizes direct experimentation with policy initiatives, learning from experience and systematically adapting strategies in response to what is learned. Lee (1993) believed adaptive management begins with the premise that the complexity of ecosystems precludes sufficient understanding to base accurate predictions of cause and effect by policy makers and managers. In this instance, it is appropriate to design experiments, monitor results, and modify measures on the basis of feedback. The emphasis is on learning from the experience, rather than imposing solutions based on certain assumptions (Mitchell, 1997). Typically, when our traditional solutions fail, another one that is again based on uncertain assumptions replaces them. These are flexible solutions that are largely based on 'rules of thumb'. Adaptive management treats both natural and human systems as complex, uncertain, constantly changing, and non-linear. Learning from past experiences is a key feature.

Iles (1996) identified the five important features for adaptive management to operate effectively. First, monitoring systems must be established to track and evaluate environmental and social changes. Second, a framework needs to be established in which policy measures can be designed

and employed as hypotheses about whether specific actions are effective. Third, mechanisms need to be established that enable the constant revision of policies based on the feedback from monitoring. Fourth, mechanisms to sustain systematic and comprehensive learning need to be developed. Fifth, adaptive management needs the creation of supple and dynamically changing management structures and processes.

Institutional factors, uncertainty, lack of commitment, and reliability are obstacles confronting the widespread application of adaptive management. However, there are opportunities for both government and private participants to learn from past efforts. For instance, research questions concerning the productivity and management practices of land inside versus outside drainage board areas, or in marginal areas can be explored. The impact of varying widths of wildlife corridors can also be explored, as can be the reconstruction of native habitats. These suggestions are applicable across all sugar-producing areas of Queensland.

While the list of assignment conditions (Table 4.1) is a visible response, the effectiveness of its implementation will be unclear without effective monitoring. At present, enforcement is to be achieved primarily through the voluntary reporting of potential violations by individuals. This approach will be most effective for drainage and the maintenance of wildlife corridors that can affect adjacent landowners and are evident. However, failure to comply with elevation-based or soil-type based conditions is more difficult to detect. The recent introduction of the conditions makes it untimely in this report to consider their effective implementation. However, this question must be addressed in the future.

It is important to clarify the definitions of monitoring and auditing. While several have been offered (Tomlinson and Atkinson, 1987; Buckley, 1991) at least three are relevant to the sugar industry. *Environmental monitoring* involves the measuring and recording of biophysical, social and economic parameters associated with development impacts. This information should include traditional measures and causal factors. *Environmental impact auditing* considers how good were initial impact predictions (*e.g.* established in drainage plans or enhanced crushing agreements) or how effective were mitigative measures (*e.g* Conditions of Assignment). In contrast, *environmental management auditing* focuses attention on decision-making procedures for resource management and the associated legal obligations, risks and liabilities. Since all three forms of assessment are required and their breadth and depth of coverage is substantial, any efforts in this area must involve both the industry, public agencies, and other relevant participants. However, the Queensland Sugar Corporation must take the lead in this area and ensure that a credible process is established. Sugar mill technical staff, Cane Inspectors and the local Cane Supply Committee can also play an active monitoring role.

> **Recommendation: Immediately undertake discussions among all relevant parties that will develop an effective environmental monitoring network within the next two years. Within the next three years, conduct an environmental impact audit to examine the compliance, enforcement and effectiveness of Conditions of Assignment. Within the next five years, complete an environmental management audit. Effective and regular environmental monitoring should be an industry responsibility required under sugar industry legislation.**
>
> **Action required by: CANEGROWERS, Mills, Local Board (Cane Production Boards), QDNR, QDPI, QEPA, Shire, BSES, CSIRO and other research organisations.**

5.8 Enhancing the Precautionary Principle

It was noted earlier that applying the precautionary principle has more to do with shifting the burden of responsibility onto the proponents rather than stopping all forms of resource development. One element of the precautionary principle would support the previous recommendation to improve monitoring. However, more could be done to support the application of the precautionary principle through transferring more responsibility to proponents. Issues related to the management of Mahogany Glider habitat and acid sulphate soils demonstrate the challenges of moving the management system towards the precautionary

principle.

In the context of acid sulphate soils, government agencies have provided mapping at a scale of 1:100,000 (Figure 5.11). However, more detailed field studies are required to determine the presence and nature of on-farm problems. Little direction is currently provided regarding appropriate actions to be taken by applicants in response to this problem. However, it is reactive rather than proactive, and does not place primary responsibility clearly on the applicant.

Recommendation: Develop mechanisms that place more responsibility on applicants and the industry for determining the nature and extent of acid sulphate soils before the review of an individual application.

Action required by: CANEGROWERS, mills, and BSES to determine: (i) need for industry sponsored surveys which further the existing information base; and (ii) the need for and basis of cost-sharing arrangements which support appropriate soil tests during the application process. Relevant government agencies (e.g., QDPI, QEPA, QDNR) and research organisations (e.g., CSIRO) should participate in these discussions. This could be an important research frontier.

At present, many applications ranging in size from less than 1ha to over 1,700ha are made with little consideration of environmental issues. Without an effective water management plan for the entire lower catchment, a screening mechanism should be developed which requires the submission of a detailed Property Management Plan that addresses drainage and environmental considerations. This screening mechanism would identify those applicants who would be affected by this additional requirement, and could be based on such factors as location (*e.g.* relative to specified habitats, soil types, watercourses), area of existing assignment and/or area of assignment applied for.

As noted earlier, there were only eight applications in areas of potential acid sulphate soil (Table 5.4). However, the mapping of this soil type in the Herbert River district does not extend south of Crystal Creek. This shortcoming highlights the pressing need to fill this information void. It is unclear if appropriate field surveys were completed for new farms located in this unmapped area (Figure 5.11). If these were not, follow-up surveys may be needed to ensure appropriate remedial measures are taken. Given the areas low priority for state government funded surveys two options exist for filling this gap: (i) additional funding under the Commonwealth's NHT Program or; (ii) requiring proponents to fully fund survey costs.

Recommendation: Develop and apply an environmental impact screening mechanisms that identify applicants who must more carefully consider environmental and farm management issues with the submission of their assignment application.

Action required by: Local Board (Cane Production Boards), relevant government agencies, CANEGROWERS.

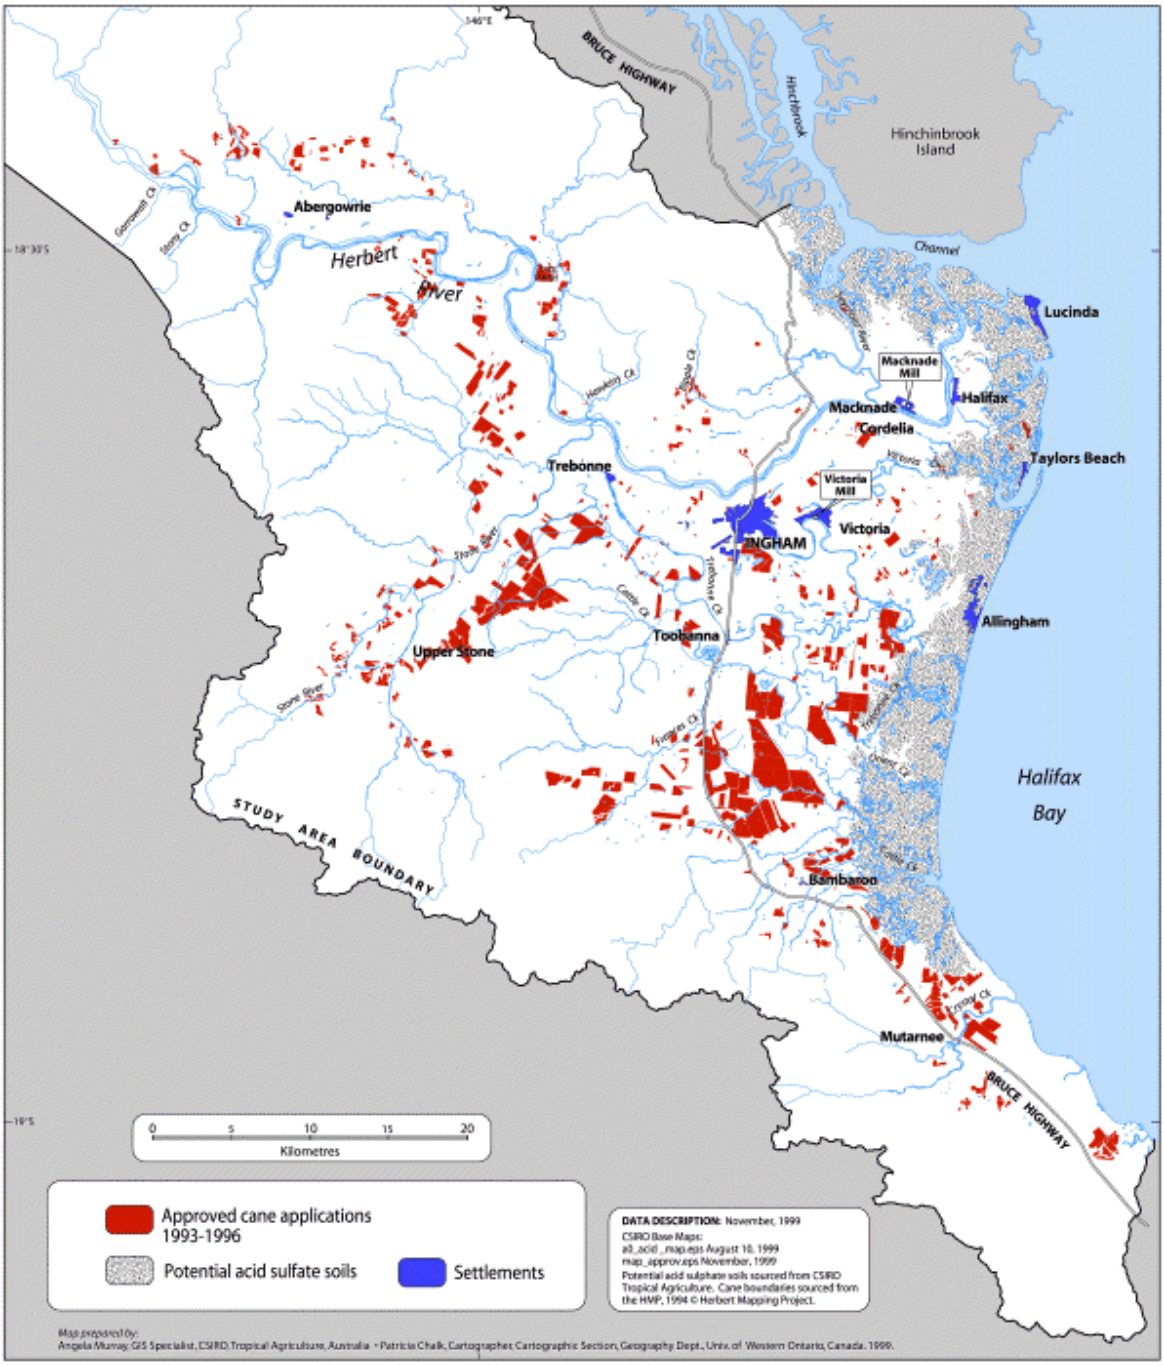

Figure 5.11 Location of awards relative to potential acid sulphate soils.

5.9 Dealing with the Future

Between 1996 and 1999, there have been significant changes to the institutional arrangements for land use planning and sugarcane assignment. A key consideration becomes the extent to which these moved the practice closer to the intent of ESD.

With respect to the ecosystem principle and the practice of drainage issues, little improvement has been made. The new institutional arrangements see the three major participants in these processes – the Hinchinbrook Shire, the Local Board and the Environmental Advisory Committee – agreeing on many criteria that define unsuitable land for sugarcane farming (Table 5.9). However, only the EAC has continued to identify the area below 9.5m ASL in the Cattle Creek subcatchment as unsuitable for sugarcane farming. The enhanced provisions of the revised *Hinchinbrook Shire Planning Scheme* continue to focus on land use issues and neglect drainage issues entirely. Past practice suggests that the difference of opinion that exists between

the Local Board and EAC on this issue will result in future awards in the area below the 9.5m ASL in the Cattle Creek subcatchment. If the SIIP process is successful in obtaining funding from senior levels of government, there are no guarantees that the associated environmental and social impacts will be given an appropriate level of consideration. On a more positive note, the completion of studies will provide a guide for future drainage works that has been lacking.

The practice of ecosystem management will be improved through the Shire and EAC's view that Mahogany Glider habitat and land abutting fish habitat areas (Table 5.9) define unsuitable cane lands. It is appropriate that the Local Board reconsider its view in order to provide unanimous support on this matter. However, the EAC will see itself wishing to maintain 20m or 40m buffers along land that abuts streams that are not designated as Mahogany Glider or fish habitat (Table 5.9). This situation suggests that more nodes might be preserved but the corridors connecting them decline. The adequacy of the size of the nodes to support viable populations in the absence of effective linkages to other nodes is unclear and deserves further scientific study.

Balanced decision making was a second principle of ESD. The previous discussion noted the manner in which "Corporate Goals" and the "Continuous Crushing Agreement" provided the fuel that drove the need for assignments but without much influence from state and local land use planning efforts. This situation had changed. As noted in Section 5.2, Production Boards are required to consider the suitability for cane farming in their planning. Presumably, this provision includes the "Continuous Crushing Agreement". However, differences of opinion among the major participants on what constitutes suitable cane land remain (Table 5.9). Thus, the need to enhance partnerships through improved conflict resolution mechanisms is essential if the assignment process is to become a model of ESD.

Table 5.9 Criteria for defining unsuitable land for sugarcane farming from Local Board, Hinchinbrook Shire Council (HSC) and Environmental Advisory Committee (EAC) perspectives (1998).

Unsuitable land for sugarcane farming, as agreed by all three groups:
1. 10m Stream buffers / wildlife corridors
2. Water bodies, swamps, lagoons and wetlands (*Water Resources Act* 1989)
3. Mangroves
4. Acid sulphate prone soils
5. Areas below 3m ASL
6. Soils unsuitable for sugarcane (DPI class 4 & 5 soils)
7. Slopes of 3% or steeper
8. Mountains or hills (no soil suitability & no other constraint)
Unsuitable land for sugarcane farming, according to the EAC and HSC:
1. 15m Stream buffers
2. Mahogany Glider habitat areas (*Nature Conservation Act* 1992)
3. Land abutting fish habitat areas (*Fisheries Act* 1994)
Unsuitable land for sugarcane farming, according to the EAC:
1. Areas below 9.5m ASL in the Cattle Creek subcatchment
2. 20m Stream buffers on minor streams and 40m stream buffers on major streams

Notes: 1. Tenures unavailable for sugarcane farming have been excluded, including residential, industrial, national parks, reserves and Wet Tropics areas.
2. Depending on the farming works to be undertaken, compliance with additional standards in the Hinchinbrook Rural Drainage Plan (Cameron & McNamara & Ass. 1984) and compliance with any other relevant State Legislation applying to the particular location or development (eg: Lands Act 1994) may become additional constraints.

Collaboration between government and cane industry participants is implied in Table 5.2. Since 1992, they have worked closely on a number of initiatives. While these interactions have a number of positive attributes - being continuous, occurring early in the statute or regulation-making processes, exchanging information and placing responsibility at the local level - there are

other areas that require improvements. Negotiations between the government and industry have not been transparent. At a local level, relevant government departments lacked the capacity to effectively guide the assignment planning and implementation processes. The recommendations of the EAC were perceived to be ignored in final decisions. The capacity of individual farmers to prepare a farm plan and adopt best management practices is varied and usually inadequate. Since the current institutional arrangements do not effectively address these shortcomings, it is possible that development will occur in areas that the only the EAC views as unsuitable (Table 5.9). This may occur because improvements to the *IPA* do not address drainage issues, no improvements to the *Water Resources Act* have been made, and inadequate conflict resolution processes between Local Boards and the EAC remain.

In the Herbert River district, the EAC maintains that 18,292ha of land are unsuitable for development (Table 5.10). If more effective conflict resolution mechanisms are not developed, members of the EAC may feel increasing levels of frustration and betrayal. In this situation, it would be appropriate to consider having the Shire and Local Board review applications, and disband the Environmental Advisory Committee. The Shire would bring increased legitimacy to the process. However, even this membership composition would continue to require the need for effective conflict resolution since differences of opinion between exist between the Local Board and Shire in defining suitable cane land (Table 5.10). While these two bodies, along with the EAC, agree that a 53,714ha of land within Hinchinbrook Shire are suitable for sugarcane farming, they disagree about the status of 23,478ha.

In the context of partnerships, it is important that all applicants in the process are treated fairly. At present, the Shire plans in Thuringowa, Cardwell and Herberton Shires identify farming "as a right". There is over 50,000ha of land in these Shires that are considered part of the Herbert River district (Table 5.10). In the spirit of fairness, the Local Board should apply the land suitability criteria that have been developed in the *Hinchinbrook Shire Planning Scheme 1999* as the minimum standard. In this way, all applicants and award holders will be meeting the same environmental standard. The application of this set of criteria to all Shires would see 3,876ha of land deemed as suitable (Table 5.10).

Another planning alternative to cane land assignment is to consider the role QDNR as the Queensland Government's land manager. Of the 41,912ha of land that either the EAC alone or with the support of the Hinchinbrook Shire's criteria deem to be not feasible for sugarcane, 13,116ha (31%) is leased land tenure (Table 5.11). Much of this land is located west of Toobanna, Upper Frances Creek and west of Trebonne (Figure 5.12). It contains Mahogany Glider habitat and several river corridors. If the Queensland Government wishes to demonstrate some visible support for the actions of its local and state resource management employees who serve on the Environmental Advisory Committee, it would ensure that applicants who are granted future leases maintain 20m and 40m buffers on minor and major streams respectively (Table 5.9). Freehold land dominates the land tenure type that the EAC perceives as not feasible for sugarcane (Table 5.11). Of the 18,292ha it alone believes is not feasible for future cane development, 16,224ha (89%) is freehold. Much of this land is located below the 9.5m ASL in the Cattle Creek subcatchment and highlights the need for effective drainage planning (Figure 5.12). In this manner, improved planning efforts in conjunction with more effective conflict resolution mechanisms can enhance the partnership principle.

Figure 5.12 also suggests that all three major participants perceive that a feasible area for future sugarcane development is located in Thuringowa Shire. However, this area has not yet been mapped for potential acid sulphate soil (Figure 5.11). Until this mapping is completed, the precautionary principle should be applied. Recent institutional innovations have not embraced adaptive management principles. These opportunities should be explored.

Table 5.10 Local Board, Hinchinbrook Shire Council (HSC) and Environmental Advisory Committee (EAC) views of future cane lands and local government jurisdiction areas.

	Overlapping Shire				
Biophysical Limitations, Agreement & Tenure	**Hinchinbrook**	**Thuringowa**	**Cardwell**	**Herberton**	**Total Area (ha)**
Biophysically potential ~ all 3 parties agreed	53714	3876	102	0	57692
Biophysically constrained ~ all 3 parties agreed	95786	5652	1129	27	102594

** Tenure unavailable for sugarcane farming includes residential, industrial, harbours & management, national park, Wet Tropics and reserves (nature, road, rail, waterbody). Tenures such as freehold would be shown here as unavailable because of overlap with Wet Tropics areas.*
 # Other tenures include mostly National Parks area along with various reserves (including nature, road, railway & waterbody)

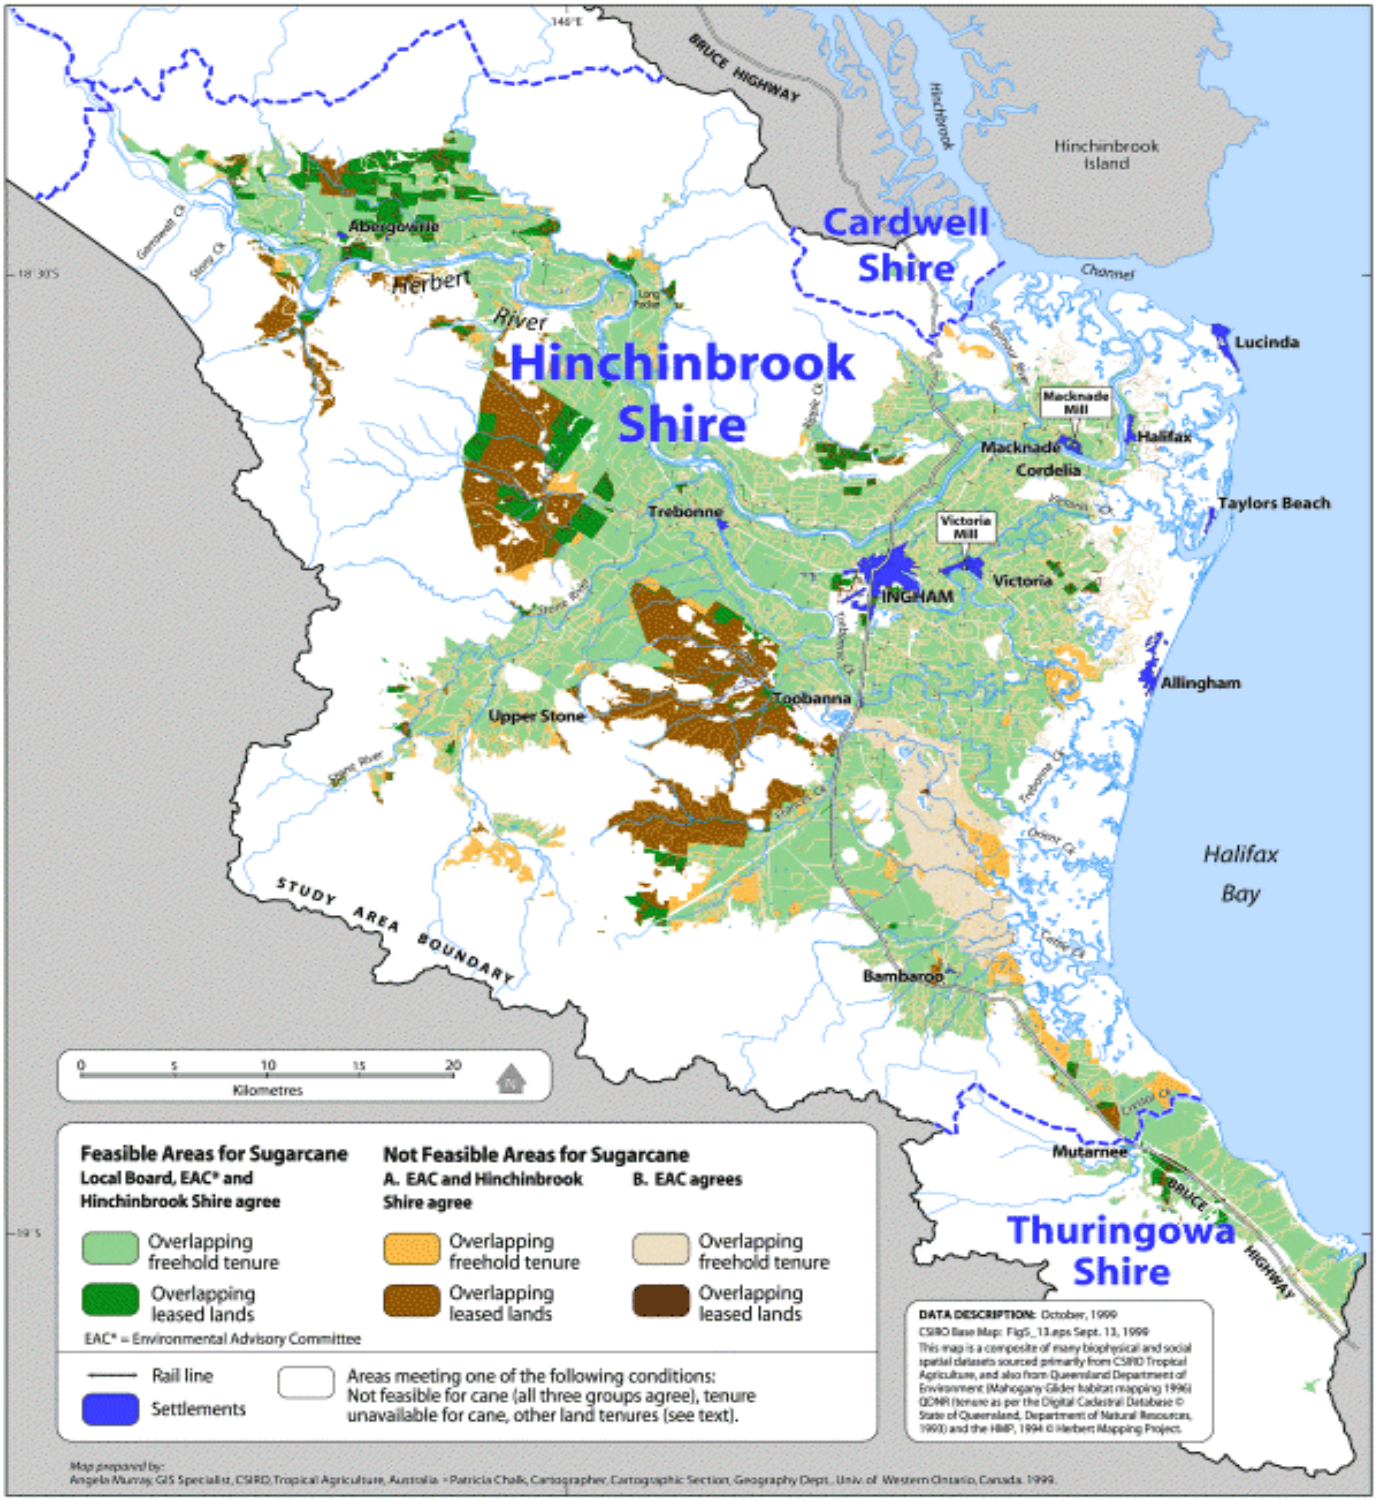

Figure 5.12 Land capability for sugarcane: Hinchinbrook Shire, Local Board and Environmental Advisory Committee perspectives relative to land tenure.

5.10 Concluding Comments: Dealing with the Legacies of the Past

ESD of natural, economic and human resources represents one of the most intractable issues confronting public and private managers. Catchment boundaries and bioregions rarely coincide with the administrative boundaries of government agencies and mill areas. Many political units claim jurisdiction over particular aspects of a resource, and landowners claim rights of use. If these multiple interests are to be accommodated effectively, it is important to legitimise a common set of principles in a clear manner. What appears to have been lacking in the past and to a lesser extent in the present, is demonstrable leadership regarding the management of natural

resources in cane growing catchments. These are elements of the WCED's challenge of reforming our institutional arrangements to achieve sustainable development.

The sugar industry must accept full responsibility to ensure that all aspects of the ESD are met. If the technological and administrative changes in the Herbert River district typify the activities of the other 23 mill areas, this will be a very formidable task. However, while the industry has a specific set of legislative objectives and developed assignment regulations, a clear vision of its commitment to sustainable resource management is lacking. This vision could enhance the credibility and legitimacy of ESD. Since the industry effectively reports to the Minister of Primary Industry (through sugar industry legislation), it is appropriate that it operationally embraces the ESD principles outlined in the 1992 *Intergovernmental Agreement on the Environment.*

The sugar industry has taken some initiatives. It has acknowledged the importance of the environment in *Caring for the Environment* and *Vision 2000.* Research has been supported as demonstrated in the establishment and co-sponsorship of the Co-operative Research Centre for Sustainable Sugar Production. An environmental audit of the cane-growing sector of the industry was completed in 1996. The industry has participated in the development of voluntary guidelines and the Code of Practice (under the *Environment Protection Act 1994*). Considering the strengths and weaknesses of these mechanisms is another area for future research.

This report outlines some of the major issues related to the cane assignment process and environmental management. The industry must take a leadership role if the importance placed on sustainable development and sustainability is to be realised. Present Conditions of Assignment suggest that failure to comply with restrictions may see the award revoked. This implies that responsibility for enforcement rests with the Local Board (Cane Production Board). These are new roles for these organisations. Leadership at the Local Board (Cane Production Board), CANEGROWERS and mills can establish an expectation that compliance is expected and required by all farmers. This also sets an example for existing growers who operate without conditions on their assignment should address relevant considerations as though they were in place. This type of widely based, voluntary action could engender very strong public support. In its absence, public support will be nurtured through compliance and enforcement. The recommended audit should provide insight into both voluntary compliance and enforcement measures. Those findings will reflect on the leadership qualities of the sugar industry, and identify the need for evolutionary and revolutionary change in its management of natural resources.

The policy environment for ESD in the context of the sugar industry will continue to respond to changing political, economic, social and environmental considerations. While the manner in which resources are managed will vary, public expectations for, and support of, effective environmental management policies will remain. In this regard, the principles for ESD will form the basis for the development of new and improved initiatives. The efficient and equitable allocation of new land for cane production must be central in these. The challenge for the sugar industry is to embrace, rather than resist, the inevitable trend toward greater public intervention in its affairs. In response, government must provide a stable environment in which locally relevant decision making can occur and in which appropriate and viable monitoring, cost-sharing and regulatory arrangements can be supported. The Australian sugar industry must continue to develop its own capacity to plan for expansion (and contraction). Such planning must be a continuous activity rather than a single exercise. Further, the industry must develop its own strategic view on where and how sugarcane will be grown – both at regional and whole of industry levels. This view will need to be based on the best available scientific information and full utilisation of the products of its substantial investment in environmental R&D.

Integrating social, economic and environmental considerations into decision making was at the

core of the WCED's view of sustainable development. To that end, consideration should be given to the role of public and corporate agencies. For instance, in considering an application for assignment, Local Boards should ensure that Property Management Plans are completed adequately. The documents should address both the biophysical and financial aspects of the operation. In that manner, farmers will be better prepared for unfavourable changes in precipitation patterns and price. Banks that finance many of the expansion activities may also wish to review an applicant's property and business plan before approving a mortgage. Senior governments can bias decision making through cost-sharing arrangements and support programs. In implementing these types of initiatives, the environmental and social consequences should be considered more systematically. The types of changes noted above reflect the difficult institutional adjustments required to address systemic problems of sustainable development.

In facing the significant challenges of balancing the dual goals of economic efficiency and environmental conservation in relation to cane expansion, the sugar industry can reflect on its own experience and that of other agricultural industries and move to a sustainable future by playing a key role in:

- *Fostering communication* across sectoral, local government and community interests;
- *Developing a structure and related processes and procedures that foster cooperation* between the industry and other industry, community groups and government organisations and paves the way for more equitable decision making and more sustainable natural resource outcomes on the ground;
- *Facilitating coordination* of effort between itself, government and community organisations; and
- *Supporting the integration* of resource management principles (including Codes of Practice for Sustainable Cane Growing) into Local Government planning schemes and broader decision-making processes. For example, the industry may wish (in partnership with lending institutions) to require a business plan to be submitted along with a PMP for an assignment application to be considered.

Many recommendations made in this report encourage and require strong leadership. Without a visible commitment to ESD, the most sophisticated institutional innovations that promote positive change will fail. Without leadership, ESD will be relegated to a thin coat of green paint masking the resource development practices of the past. If the cane assignment system is to provide effective management in the year's ahead adjustments have to be made. It is hoped this report will contribute to that end.

Acknowledgments

We are extremely grateful to all interview respondents who took time from their busy schedules to share their thoughts with the authors. We also wish to acknowledge the valuable assistance provided by the following people and agencies:

- Staff at the Ingham CANEGROWERS office - Peter Sheedy, Allan Antcliff, Wayne Thomas, Gail Alloway, Sharon Fighera, Leona Gangemi, Natalee Agostinelli and Cathy Bowrey for providing access to cane assignment records;
- Les Sullivan, Peter Allen and Joe Drovandi from CSR for their assistance in locating farms and access to cane block boundaries;
- Lois Morris and Julie Martin from the Queensland Sugar Corporation for access to the sugarcane assignment register;
- Gethen Morgan, Margaret Card, Sue Gardiner, Sharon King and Jeanette Kemp from Queensland Department of Environment Townsville for access to vegetation mapping and mahogany glider habitat mapping data;
- Mike Grundy and Donna Smith from Queensland Department of Natural Resources for providing access to data linking the sugarcane assignment register to the digital cadastral

database;
- Sonja Slatter, CSIRO Tropical Agriculture, Townsville and Clare Gambley, CSIRO Tropical Agriculture, Brisbane for assistance in the preparation of this report;
- Jenny Bellamy, Allan Dale, Stuart Cowell, Dan Walker, Stephen Tapsall and Karen Vella of CSIRO, and Geoff McDonald and Carl Smith of the University of Queensland for their constructive comments on earlier drafts.

We also wish to acknowledge the support of the CRC for Sustainable Sugar Production whose staff played a key role in both the data acquisition and analytical components of this report.

Appendix 1

QUEENSLAND SUGAR CORPORATION

Form 98(A)
Sugar Industry Act 1991

APPLICATION FORM FOR NEW OR INCREASED EXPANSION ASSIGNMENT

SECTION A FORMAL APPLICATION

Year of expansion: 19____ New ☐ or Increased ☐

Name in which assignment is/will be registered: _____

_____

Postal Address: _____

_____ P/Code: _____

Telephone number: ( ) _____

I/We (the undersigned) certify that the information contained herein has been completed to the best of my/our knowledge and will if necessary provide additional information in support of this application.

Note: This form should be signed by all the applicants named in Section A. Where the applicant is a company, the form should be executed under common seal.

Signature of applicant/s: _____ Date: _____

_____

If you are a new grower please go to Section C ➤

SECTION B APPLICATION DETAILS FOR CURRENT ASSIGNMENT HOLDERS

Home mill area: _____ Farm number: _____

Mill area in which assignment is sought: _____

Existing assignment entitlement: _____ ha

Increase sought in this application: _____ ha

The total area of available spare land
(include new land where applicable) is: _____ ha

QUEENSLAND SUGAR CORPORATION

SECTION B *Continued*

Where is the increase to be located? (Tick appropiate answer)

Present Assigned Description (PAD) ☐ or New Land ☐

If new land, refer to Section D after completing the remaining questions in Section B.

Is any PAD currently leased? YES ☐ NO ☐

If YES, the Lessor's written consent must be supplied.

Attached? YES ☐ NO ☐

Previously supplied? YES ☐ NO ☐

Did you receive assignment as a **new grower** in the past three years? YES ☐ NO ☐

What area, if any, of expansion grants since 1994 have not yet been planted? Please advise year of grant, the hectares amount and reasons.

_____

_____

_____

_____

SECTION C *APPLICATION DETAILS FOR NEW GROWERS*

Mill area in which new assignment is sought: _____

Increase sought in this application: _____ha

Do you presently hold or have you within the last five years held any legal interest in any existing cane assignment in any mill area in Queensland? YES ☐ NO ☐

Have you previously applied for a new assignment? YES ☐ NO ☐

If you answer YES to either of these questions, please provide details:

_____

_____

_____

_____

Please complete Section D

QUEENSLAND SUGAR CORPORATION

SECTION D NEW LAND (not PAD)

Refer to Section 4 of "Important Information for Applicants" before completing this section.

Please list the real property description and areas of the new land proposed for this application:

Description: _____ Area: _____ ha

Description: _____ Area: _____ ha

What is the nature of tenure of this land?

Freehold ☐ Lease ☐ Enforceable option ☐

Please attach **Formal Evidence of Title** in the same name as assignment holder. ☐ Attached

If new land is leased, attach **lessor's written consent** to the application. ☐ Attached

What area of the new land is:

Cleared? _____ ha Partly cleared? _____ ha

Uncleared? _____ ha Under cane? _____ ha

Is the new land subject to any restrictions on its use by any public authority? (e.g. land use, irrigation or drainage) YES ☐ NO ☐

If YES, what restrictions? _____

What distance is the new land from the present or possible delivery point? _____ km

Description of possible delivery point: _____

Please list real property description of all potential new cane lands held in the applicant's name and the areas of each parcel: _____

_____

SECTION E DEVELOPMENT PROGRAM

To be completed by ALL applicants

Please provide a Development Program which illustrates your capacity and willingness to plant the assignment applied for within two calendar years (inclusive) of the grant year. ☐ Attached

From your Development Program list the estimated area available to be planted in:

1st year _____ ha 2nd year _____ ha

Note: This information is sought to assist with the planning and development of industry infrastructure.

Form 96(R)

QUEENSLAND SUGAR CORPORATION

GPO Box 891, Brisbane
Queensland 4001, Australia
Telephone: (07) 3231 0199
Facsimile: (07) 3221 2906 Telex: AA41274

_____ Mill

FORMAL EVIDENCE OF TITLE

(To be returned to the Chief Executive at the above address)

I HEREBY CERTIFY that I have sighted the undermentioned document: (State type of document eg Certificate of Title, Deed of Grant, Current Title Search, Registration Confirmation Statement, Instrument of Crown Lease, Lease Document)

*(*Lease documentation will only evidence leasehold)*

_____

which evidences: ☐ Freehold ☐ *Leasehold

current title to land described as: _____

_____

_____

_____ Parish of: _____

having an area of: _____

in the name of (insert name of proprietor): _____

as: Sole proprietor ☐ Tenants in common ☐ Joint tenants ☐

If tenants in common, specify the particular interest: _____

_____

If the land is leased please supply the following:

Start date: _____ End date: _____

Name of lessor/sublessor: _____

Date: _____ Signature: _____

Full Name: _____
(Please print)

Solicitor/Bank Manager/Local Board Chairperson
(Cross out inapplicable)

QUEENSLAND SUGAR CORPORATION

IMPORTANT INFORMATION FOR APPLICANTS FOR NEW OR INCREASED EXPANSION ASSIGNMENT

1. There is only one application form for new/increased assignment. Existing growers, landlocked growers in landlocked mill areas and new growers will complete different sections of Form 98(A).

2. This application should be completed in easily readable BLOCK PRINT to facilitate the determination of your application. Where appropriate, please tick the relevant box to indicate your response.

3. Two **conditions** will apply to all new and increased grants of assignment:

   (a) the assignment being made effective

   (b) the assignment not being transferred, unless the Corporation determines otherwise

   by 30 November, in the calendar year next after the grant year (eg for assignment in grant year 1999 the date would be 30 November 2000).

4. **Formal Evidence of Title** to any new land in the name of the applicant must accompany the application. Applicants may either attach a copy of the relevant title document for example a Certificate of Title, OR attach a completed Formal Evidence of Title form. This form is reproduced on the back of this page and must be signed by either a Bank Manager, solicitor or Local Board Chairperson.

   Options to purchase or lease new land will not be considered unless they are clearly enforceable in a court of law subject only to grant of assignment on that land. These documents must be duly signed by both parties and clearly specify:

   (a) the name of both parties

   (b) the description of the new land

   (c) the term of the tenure. The term of the tenure should be at least the same as the date by which a grant must be made effective

   (d) the commencement date

   (e) the rent payable.

   Similar criteria apply to options to purchase.

5. A **Development Program** should accompany the application and clearly indicate the applicant's capacity and willingness to make the assignment sought effective within two calendar years inclusive of the grant year.

6. Applicants are required to consult with the relevant local council, Department of Transport and/or Department of Main Roads if the cane is proposed to be delivered to the mill, in whole or in part, by road.

7. **Corporation "Guidelines"** issued under Section 149 of the Sugar Industry Act 1991 define the terms of the expansion and state the matters to which a Local Board will have regard in determining an application for the grant of assignment.

8. Applications must be lodged at the office of the **CANEGROWERS Area Committee** in the mill area in which the assignment is applied for by the advertised closing date. No extensions will be granted.

QUEENSLAND SUGAR CORPORATION

For use by the Local Board in consideration of application

SECTION F LOCAL BOARD DECISION

The_____ (home) Local Board or the _____ (receiving) Local Board (if relevant) under authority delegated by the Queensland Sugar Corporation, hereby

(a) ***GRANTS***_____hectares of 19 ____ expansion assignment to the aforementioned applicant/s subject to the following conditions (if any):

_____

_____

_____

OR

(b) ***REFUSES*** the aforementioned application on the following grounds:

_____

_____

_____

Signature of Chairperson: _____ Date: _____

Home Local Board

The home local board has been consulted, and does not consider that the consultation was inadequate.

Signature of Chairperson: _____ Date: _____

Receiving Local Board

The members of the receiving local board, who were present at the meeting to determine the application, unanimously approved it.

Signature of Chairperson: _____ Date: _____

FOR USE BY LOCAL BOARD TO CATEGORISE APPLICATION TYPE

Existing grower ☐	Home mill area ☐	Refused ☐
New grower ☐	Inter-mill ☐	Approved ☐

(Eds). *Management for Sustainable Ecosystems*. Centre for Conservation Biology, The University of Queensland, Brisbane, In Press.

ABSTRACT
Management of natural resources on the basis of Ecologically Sustainable Development (ESD) principles is of inherently more complex than management premised solely on maximum productivity or conservation. More facets of the resource base need to be monitored and managed, and a more holistic view the range of potential impacts - particularly cumulative impacts - must be considered. In attempting to operationalise the goals of ESD, a number of Australian states have introduced and fostered community-based approaches to integrated resource management (IRM). Such initiatives have been broadly supported by agricultural industries, however there remains a significant gap between ESD rhetoric and actual practice. Using the Herbert River catchment as a case study, some of the key impediments to the implementation of IRM approaches are examined within the context of sugar industry activities. We argue that integrated community-based approaches to resource planning and management, in concert with a range of policy and economic instruments, can play an important role in assisting the sugar industry to achieve ESD. We also argue that operationalising the concept of ESD through integrated approaches to natural resource management poses enormous challenges and conclude by identifying some essential characteristics of an IRM process that could assist the sugar industry to adapt to, and manage change for, sustainable agriculture.

INTRODUCTION

The sugar industry is one of Australia's largest rural industries, producing in 1996/97 approximately 5.3 million tonnes of raw sugar, worth in excess of 2 billion dollars to the Australian economy. The industry supports over 6,900 cane growers and 29 sugar mills, employing some 19,000 people in total. Sugar cane is grown along 2100 kms of coastline from Grafton in northern New South Wales to Mossman in north Queensland (Figure 1). Small industries have recently commenced on the Atherton Tablelands in north Queensland and the Ord River district in Western Australia. Approximately 507 000 hectares of land are currently under cultivation and as such, the sugar industry is a major user of natural resources on the coastal zone of eastern Australia north of latitude 30^0 S.

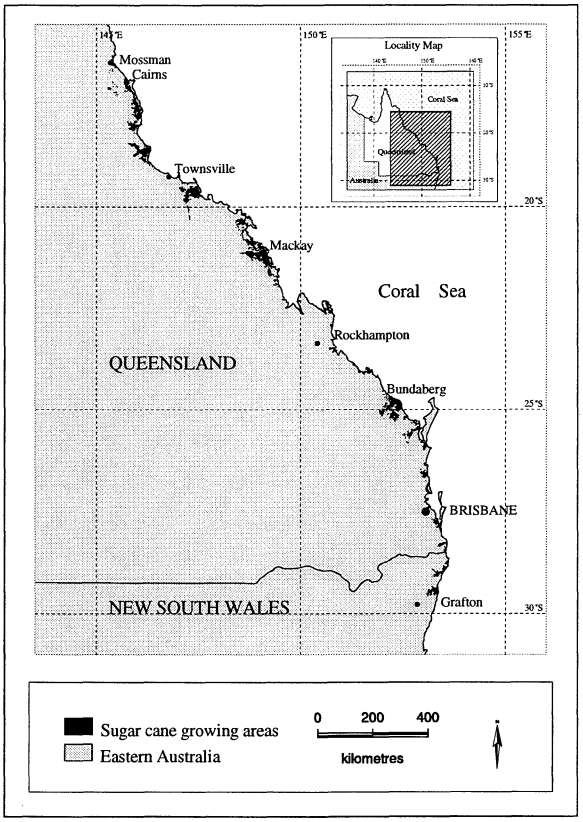

Figure 1. Location of the Australian sugar industry.

.

Significant potential exists for the Australian sugar industry to impact on the environment. In response to increasing awareness of its environmental performance, the sugar industry has made positive steps towards overcoming many existing problems. At the farm level, the use of soil conservation structures and minimum tillage techniques in conjunction with green-cane harvesting provide good examples of industry practice aimed at minimising the effects of soil erosion. A greater awareness of off-site effects has also resulted in changed management practices being adopted by many farmers, particularly in the use of inputs such as fertiliser, chemicals and water. At an industry level, the sugar industry has conducted an audit of current farming activities (Gutteridge, Haskins and Davey 1996) and endorsed an Environmental Management Strategy (CANEGROWERS, 1997) to provide a framework for addressing the audit's 156 recommendations. The Strategy contains four broad objectives and 22 desired outcomes to be achieved by 2002. Realisation of these outcomes will require a mix of on-farm initiatives, RD&E and communication activities. In response to the first listed outcome of the Strategy, the industry has developed a Code of Practice for Sustainable Cane Growing in Queensland (CANEGROWERS 1998). The Code has been endorsed by the Queensland Department of Environment and Heritage, under the provisions of the *Environment Protection Act 1994*. The industry has also been able to attract funding from the Natural Heritage Trust.

While acknowledging the improvements that have been made and the fact that the sugar industry has demonstrated a desire to implement ESD (Bonanno 1992), the magnitude of the tasks facing the industry, in terms of the way in which it manages natural resources in the future, remain substantial. As both a major "user" of natural resources and a "supplier" of environmental services, the industry is a key actor in the move toward ESD. However activities at the farm level alone are unlikely to be adequate, and achievement of ESD will require action from government as well as broader participation in sugar industry activities by the wider community.

This paper first reviews the rhetoric surrounding the achievement of ESD and then discusses some of the barriers and opportunities in translating this rhetoric into practice. We argue that planning, in concert with a range of policy and economic instruments, can play an important role attempting to achieve ESD. We conclude by proposing how such approaches may in the future contribute to more sustainable agricultural development and resource use in general in the Australian sugar industry.

THE SUGAR INDUSTRY–ECOLOGICALLY SUSTAINABLE?

The well recognised core principles of ESD are: to maintain ecological integrity, biological diversity and natural capital; to meet basic human needs; to keep options open for future generations; and to reduce injustice; and to increase self-determination (Dorcey 1991). In Australia, the Standing Committee on Agriculture and Resource Management has recommended five basic principles for assessing the level of sustainability achieved by the agricultural sector. These concern (SCARM 1998):

- the long term viability and resilience of farm economies;
- the conservation and enhancement of the natural resource base;
- the minimisation of offsite environmental impacts;
- the quality of farm level managerial skills; and
- the socio-economic viability of rural communities.

Some of the key issues relevant to these principles for the sugar industry, their possible causes and potential impacts are summarised in Table 1. In the sections that follow we briefly examine the extent to which current sugar industry practice is meeting the first three of these principles.

.

Table 1. Key ESD issues for the Australian sugar industry.

Issue	Possible causes	Potential Impacts	Sources
Maintaining the economic viability of sugarcane growing	Declining real prices paid and increasing real costs of inputs/production Declining farm equity Yield decline	Exacerbated resource degradation Increasing farm debt Greater reliance on off-farm income	ANAO (1997) Garside *et al.* (1997)
Risk to the sustainability of the natural resource base	Loss of productive capacity of soils under long term monoculture Expansion of cane farming onto marginal lands and environmentally sensitive areas Poor adoption of green cane harvesting practices in some areas High chemical (fertiliser and pesticide) usage in sugar production systems Inappropriate drainage practices Past single focus on increasing sugar productivity and improving efficiency in harvesting/processing Poor fire management and air quality impacts from smoke	Soil structural decline and compaction Declining soil fertility/organic matter Imbalance of soil micro-organisms Increased soil erosion and runoff Loss of biodiversity Increase in greenhouse gas emissions Heavy metal contamination of sugarcane soils Chemical contamination of sugar products and by-products Acid sulfate soils	Chudleigh et al. (1997) Prove and Hicks (1991) Prove *et al.* (1995) Gutteridge, Haskins and Davey (1996) Rayment and Barry (1993)
Environmental impacts of intensive sugar farming systems	Intensive use of sloping lands in areas prone to high intensive tropical rainfall High chemical (fertiliser and pesticide) usage in sugar production systems Clearing of riparian vegetation and laser levelling of coastal wetlands Inappropriate drainage development Mill emission, effluent and waste products Inefficiency of water use/irrigation scheduling Overuse of groundwater	Enhanced nutrient loads and turbidity of surface and ground waters Increased sediment delivery to estuarine and marine environments Salinisation Heavy metal pollution Acidification of drainage ways and fisheries habitats Fish kills in waterways Loss, fragmentation and degradation of habitat Inadequacy of environmental flows	Johnson *et al.* (1998a,b) Arthington *et al.* (1997) Crossland *et al.* (1997) Keating *et al.* (1995) Pailles *et al.* (1993) Pailles and Moody (1995) Gutteridge, Haskins and Davey (1996) Brunskill *et al.* (1998)
Poor integration and coordination of policy and planning across government and industry organisations	Multiple and often conflicting legislation and policy initiatives Fragmentation of responsibilities across and within all three levels of government Ad hoc decision- making on sugar infrastructure development	Gap between policy intent and outcomes Mixed or ambiguous signals to sugar growers Duplication and inefficiency in community service delivery Poor or ill-informed decision making on industry expansion and infrastructure development	Johnson *et al.* (1998a) Bellamy and Johnson (1997, 1998)
Conflict over alternative land uses	Urban expansion onto prime agricultural lands Increasing demand/opportunities for tourism and recreation Short term planning horizons of state and local governments Inadequacy of cane land allocation process	Social tensions between community interests Uncertainty for all stakeholder interests Expansion onto marginal or ecologically sensitive lands Need for industry structural readjustment	Shrubsole (1997) Johnson *et al.* (1998a)
Social problems in cane growing communities	Declining rural population and declining employment opportunities Downsizing of social infrastructure in rural communities Personal Stress Changing community values Declining government capacity to deliver services	Declining productivity Aging population of sugar farmers Threat to viability of social structures	Johnson *et al.* (1998a) Lawrence and Gray (1997) QDLGP (1998)

.

Economic Viability of Production

Deterioration in cane growers terms of trade coupled with financial inability to implement sustainable management practices (Prime Ministers Science and Engineering Council, 1995; Australian National Audit Office 1997) represents a significant threat to the capacity of the sugar industry to achieve ecological sustainability (Figure 2). In addition, the Australian sugar industry has been on a productivity (yield of sugar per harvested hectare) plateau since the early 1970s. Garside *et al.* (1997) suggest the plateau is related to both changes in farming system and the phenomenon of yield decline, that is the loss of productive capacity of sugarcane growing soils under long term monoculture.

The management of natural resources in cane growing regions will continue to be undertaken in an environment of increasing long-term demand for sugar, although the effects of the Asian financial crisis, economic uncertainty in Russia and the increase in Brazilian sugar exports are likely to have significant economic impact in the short to medium term. To survive, the sugar industry will need to expand production. However, any intensification or expansion of the industry is very likely to have environmental implications (Williams 1995; Johnson *et al.* 1998a,b), although significant R&D investment is being directed towards practices aimed at improving productivity per unit area. Australia, as an exporter of raw sugar also faces increasingly environmentally conscious international markets. Hence the industry's economic future will be inextricably linked to its environmental performance.

The Natural Resource Base and Environmental Impacts

It is clear that the sugar industry has the potential for significant environmental impacts because of its size, location along the Queensland and northern New South Wales coast and its high use of fertiliser, chemicals and irrigation water. Significant environmental impacts have already occurred in many cane growing regions and these are discussed in more detail by Johnson *et al.* (1998a,b). Four key environmental issues are discussed briefly below. These are not comprehensive and in particular do not include issues relating to soil health and fertility, air emissions, waste management, environmental flows of water or acid sulphate soils.

Soil erosion and sedimentation

Severe soil erosion has long been recognised as a potential threat to long-term productivity of sloping land growing sugar cane. Soil losses in excess of 200 t ha^{-1} have been recorded in the Mackay region (Sallaway 1979) and in excess of 500 t ha^{-1} on the wet tropical coast (Prove and Hicks, 1991). The adoption of green cane harvesting, minimum tillage practices has been shown to reduce soil erosion tenfold; from an average annual soil loss of 148t $ha^{-1}y^{-1}$ to <15t $ha^{-1}y^{-1}$ (Prove *et al,* 1995). These practices have been an important step in sustaining the productivity of cane lands and in decreasing sediment supply to the coastal zone from sugar cane lands. However to-date the practice has received only partial acceptance by the industry. Despite the fact that in many areas soil erosion remains a problem, the precise rate of sediment delivery from catchments in which sugar cane is grown to estuarine and marine environments and the environmental consequences remain poorly understood (Pailles *et al.* 1993; Pailles and Moody 1995; Wasson 1996, Crossland *et al.* 1997).

Diffuse source pollution

Given the size of the sugar industry, considerable potential exists for diffuse source pollution to generate water quality problems in both ground and surface waters. The major sources have generally increased in magnitude in recent years and have been predominantly associated with expansion in the area of land supporting sugar cane. Recent research (Bramley and Johnson 1995; Mitchell *et al.* 1995) has shown that nutrient concentrations in streams in selected sugar catchments are generally below the guidelines detailed by ANZECC (ANZECC 1992) for freshwater. Exceptions were generally associated with peak flow events associated with cyclonic

.

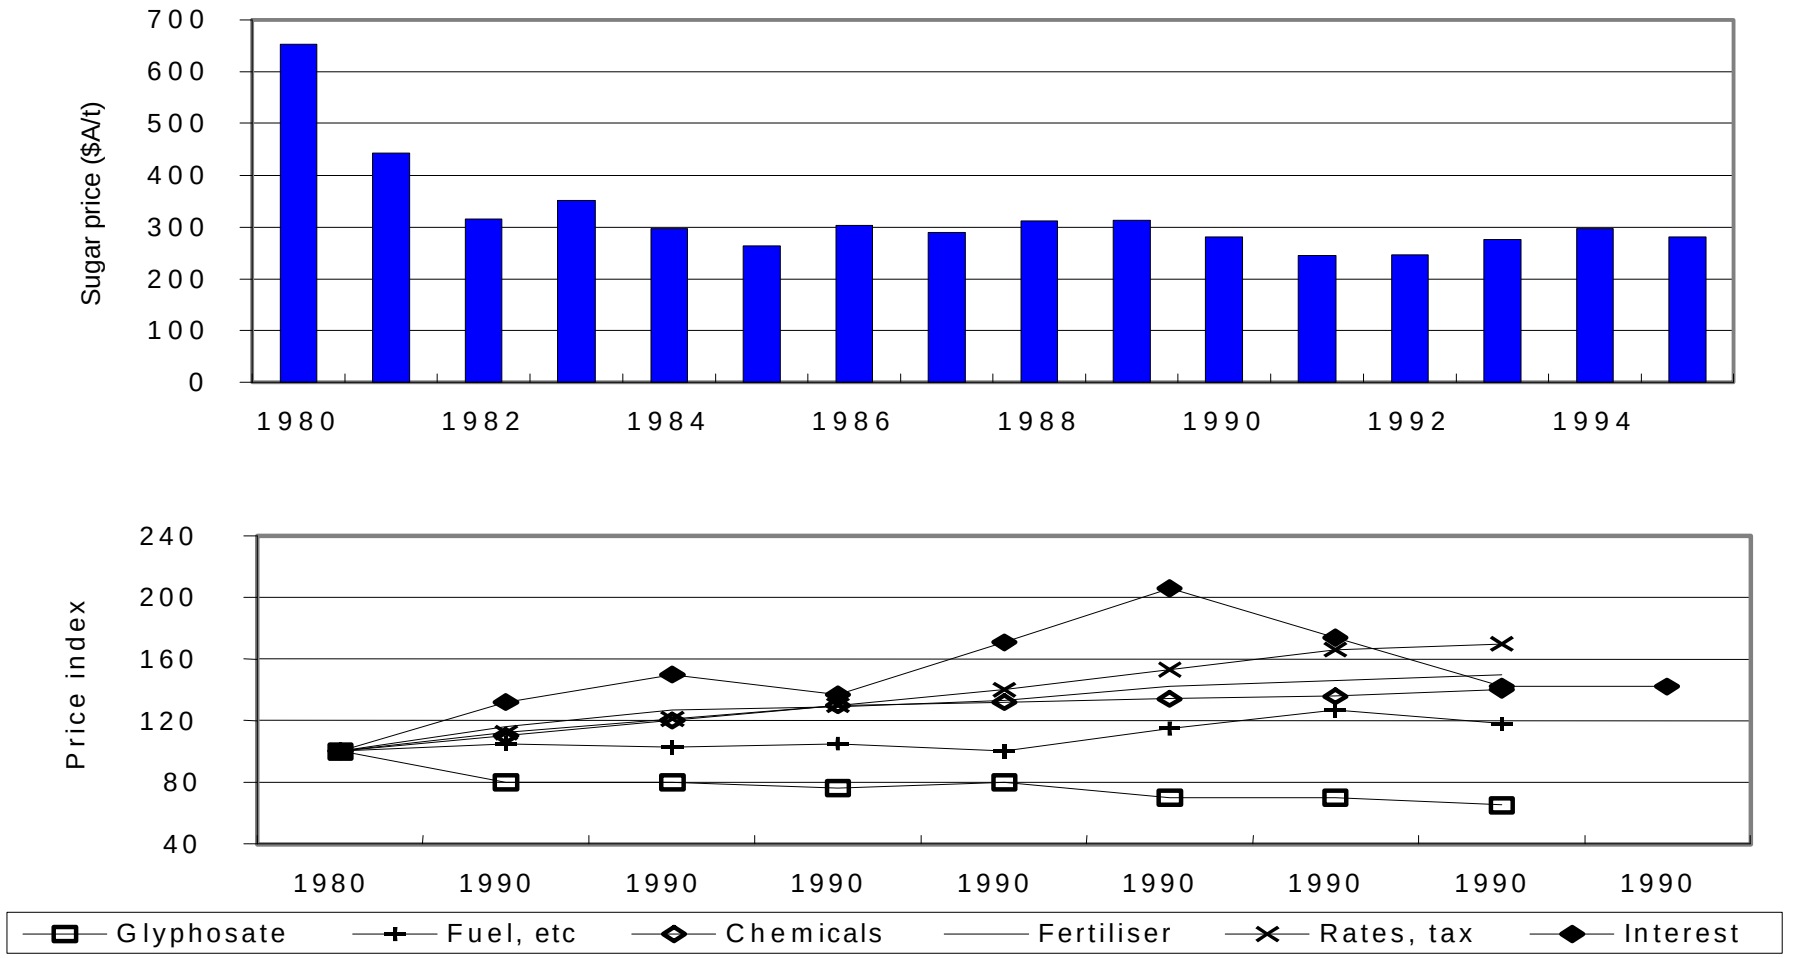

Figure 2. Queensland sugar price, 1980-95, deflated by CPI index (base 1987-88 = 100) and changing relativity in cost of farm inputs (Source: Wegener, 197)

.

or similar storm related activity. In north Queensland, nutrient concentrations in streams associated with sugar cane production were generally greater than in those associated with other land uses, but differences between these were only seen during wet season peak flow events.

In the marine environment adjacent to the Wet Tropical Coast, Furnas *et al.* (1995) have shown that direct external inputs of nitrogen (N) and phosphorus (P) through point sources are currently small relative to natural nutrient inputs. Average total riverine inputs of N and P comprise a large proportion of external inputs, but are still small relative to internal recycling fluxes. Although nutrient levels are currently low in marine waters adjacent to sugar producing regions and external inputs are small relative to natural fluxes and stocks, understanding of ecosystem behaviour is not sufficiently developed to allow the assimilative capacity of these waters to be predicted with certainty. The consequence is that pressure exists on the sugar industry to demonstrate that it is not a major contributor when there is circumstantial evidence that it might be.

Information on accession, persistence and behaviour of pesticides in cane growing and adjacent environments is sparse. While the use of organochlorine pesticides such as dieldrin and DDT has been discontinued, little is known of the persistence of organochlorine residues in existing cane growing areas. Many chemicals in this group are known to accumulate in produce suitable for human consumption. Unpublished analyses from the Mackay region (A Garside *pers comm*) have shown dieldrin levels in peanuts harvested from selected cane farms to be 25 times the acceptable level for human consumption. Mercurial compounds have been used as a fungicide continuously since the 1950's, but evidence for their current distribution is scarce. However geochemical analysis in the Hinchinbrook Channel (immediately adjacent to cane fields in the lower Herbert River floodplain) show an approximate 4 fold increase over background levels in mercury concentration since 1950 (Brunskill *et al.* 1998).

Understanding of the accession of nutrients and pesticide into groundwaters also remains limited. Evidence from the Bundaberg area (Keating *et al,* 1995) indicates that extensive nitrate accessions to the area's aquifers have occurred, although no unequivocal data are available to assess whether nitrate concentrations are continuing to rise. Similar findings have been reported in the Burdekin delta (J. Bauld, unpublished data). Likewise, evidence to support pesticide contamination has been scarce, although again, low levels of atrazine and heptachlor have been detected in the Burdekin delta aquifer system (Brodie *et al.* 1984; Keating *et al,* 1995).

In summary, current knowledge suggests that the downstream effects of agricultural production are governed to a large degree by the periodicity, volume and intensity of rainfall. Within individual catchments, climatic, spatial and temporal variability may also be significant. Recent research suggests that nutrient and pesticide loss from land under intensive agriculture is likely to exceed that from other land uses irrespective of the type of intensive agricultural production undertaken (Bramley and Johnson 1995). It is the general nature of intensive agricultural land use and the relatively high inputs that this activity involves, rather than the specific production system in operation, which results in an increased export of pollutants downstream relative to that from lower input land uses such as low intensity grazing or forestry. Minimisation of diffuse source pollution is therefore likely to depend on carefully matching actual land use to land use suitability coupled with appropriate resource management practices.

Heavy metal contamination

Heavy metals are important environmental pollutants when in sufficient quantity and can be mobilised in the environment by human activity (Rayment and Barry 1993). Little is known of the contribution of the sugar industry to heavy metal contamination. While zinc and copper have and continue to be applied in very small quantities, it is likely, given the significant use of phosphatic fertilisers in the sugar industry particularly prior to 1992, that large areas of cane growing land have elevated levels of cadmium. This is a potentially a serious problem given that

.

cadmium is extremely toxic to aquatic and marine animals (Hart 1982). In addition, given that cadmium is also known to accumulate in produce suitable for human consumption, much of the current cane growing area may be unsuitable for alternative agricultural land uses. Unpublished analyses (A. Garside *pers comm*) of peanuts from the Mackay and Tully areas have shown cadmium levels 3 times the acceptable level.

Although heavy metals may be transported offsite, environmental pollution by agricultural activities are generally considered to have little influence on heavy metal loadings in streams compared with other sources such as mine and industrial effluent (Arthington *et al.* 1997).

Riparian vegetation and wetland degradation

Considerable areas of riparian vegetation have been removed from the stream banks in sugar cane growing regions. Results from a recent environmental audit indicated that 70% of the farms surveyed had a riparian zone classed as moderate (<15m) or worse (Gutteridge, Haskins and Davey 1996). Mangrove areas have largely remained intact, although some clearing did occur in the 1960s and 1970s. Large areas of riverine rainforest with patches of eucalypts have also been cleared in many cane growing regions (Johnson *et al.* 1998b).

The wetlands, swamps, billabongs and waterholes of coastal areas play an important role in floodplain ecology (eg. providing wildlife habitats) and as an integral part of the surface and ground water hydrological regimes of floodplains (eg. providing important hydrological functions). Clearing for sugarcane has significantly reduced the area of this habitat type in most cane growing regions. For example, in the Johnstone Rivers system, there has been a 60% reduction in the area of coastal wetlands between 1951 and 1992 (Russell *et al.* 1995). On the Herbert River floodplain, Johnson *et al.* (1998b) have shown a 60% decrease in the area of *Melaleuca* dominated vegetation patterns and a 50% decrease in riparian rainforest patterns since European settlement.

What do these trends tell us?

The evidence presented in the preceding sections clearly suggests that the quality of the natural resource base on which the sugar industry depends is declining and that many key components of the surrounding terrestrial, aquatic and marine ecosystems are impacted by sugar industry activities. However, even though a substantial body of evidence exists, it is impossible to answer the question "is the sugar industry ecologically sustainable"? Answering this question in the future will remain problematic given the considerable ambiguity associated with the current understanding of the issues and the lack of a systematic approach to defining and measuring progress toward ecological sustainability.

In moving to point where the aforementioned question can be answered, there is an essential need to develop agreed concepts, definitions, objectives, benchmarks and performance indicators that are understood and "owned" by all stakeholders. Furthermore a comprehensive system of monitoring and evaluation will have to be established if the sugar industry's performance is to be adequately assessed over time. The need for such actions may be further justified if the industry aspires to become compliant with internationally accepted environmental standards (e.g. ISO14000) in the future. Implementing these monitoring and evaluation systems will take time and require a significant commitment of resources. However, they represent an important component of a suite of changes that will be required if the industry is to move towards ecological sustainability. In the sections that follow, we consider a range of other components that attempt to address existing barriers at both a conceptual and operational level.

.

ACHIEVING ESD IN THE AUSTRALIAN SUGAR INDUSTRY – NATURAL RESOURCE POLICY, PLANNING AND MANAGEMENT

In attempting to implement the goals of ESD in agricultural regions, a number of Australian states have introduced and fostered community-based approaches to IRM (Bellamy and Johnson 1997). Federal initiatives such as the National Landcare Program (ANAO, 1997) support ESD principles. At the state level Whole Catchment Management (Syme *et al.* 1994) and Property Management Planning (Commonwealth of Australia 1995) have been prominent. However, attempts to put into practice a comprehensive way of promoting ESD at the catchment and regional scale through more community-based approaches both in Canada and Australia (Dorcey 1991; Syme *et al.* 1994) are posing enormous challenges for rural communities, government and industry. Bellamy and Johnson (1998) found part of the difficulty lies in: the complexity of the problems being addressed; the failure to recognise ESD as a continuous process rather than a particular state for which to aim; flawed policy responses and ineffective program and policy implementation;, the weakness of the strategies adopted to resolve conflict;, and the frequent failure to include interests without power in the community. Any attempt to move toward ESD in the sugar industry, however, will require not only significant operational innovations, but also a conceptual shift toward adoption of an IRM paradigm.

Adopting an Integrated Resource Management Paradigm

The IRM paradigm recognises the interdependencies of natural systems, political systems, social systems, and technology in addressing "wicked" problems that are an inherent characteristic of natural resource use (Bellamy *et al.* 1999). Mason and Mitroff (1981) identified wicked problems as being interconnected, complicated, uncertain, ambiguous, conflicting and societal constraints. In recognition of these characteristics, the emerging IRM paradigm has a number of fundamental properties (Bellamy and Johnson 1997) including:

- An integrated systems approach;
- A long term perspective and broad spatial scale focus;
- The concept of 'the whole being more than the sum of the parts';
- Recognition of complexity and uncertainty in system interactions;
- Non-linear processes and connectivity between problems;
- Relevance of human and cultural context and diversity in values;
- People as part of the problem and not external to it;
- Management focus on the scale of landscapes, regions or catchments;
- Coordination of decision-making amongst stakeholders in government, industry and the community;
- Strategies for resolving conflict through negotiation; and,
- Active involvement of the whole community to encourage community ownership of the problem and its solution, and ultimately the adoption of sustainable resource use and management practices.

This new IRM paradigm has evolved from recognition of the failures of current disciplinary or sectorally based approaches based on rational planning principles, and from insights from domains other than agriculture, including the ecological, policy and social sciences (Bellamy and Johnson 1998). In response, a range of policy frameworks, institutional arrangements and implementation processes for IRM have been established around the world. Although contexts and mechanisms vary significantly, the fundamental rhetoric underlying these approaches has a number of common elements (e.g. Lang 1990; RAC 1993; Mitchell and Hollick 1993; Bellamy *et al.* 1999):

- Management of interrelated resources with regard to ecological processes and the maintenance of environmental quality;

.

- Involving multiple objectives and multiple players;
- Coordinating government, non-government and community natural resource management policies and activities; and
- Involving community participation in natural resource management.

The IRM rhetoric also supports the integration process moving beyond a purely coordination function to one that involves roles and responsibilities for both the implementation and the monitoring of integrated planning strategies and decisions on resource management at the catchment or regional level.

Responding to the Rhetoric

The 1992 Intergovernmental Agreement on the Environment commits all Australian state and territory governments, the Commonwealth Government and Local Government to the principles of ESD. Both the federal and state governments have introduced measures (e.g. modified policies, programs and institutional arrangements) to protect the environment and manage natural resources more sustainably. A key policy initiative has been the development and implementation of a number of catchment-based initiatives in all Australian States (eg. Total Catchment Management in New South Wales and Integrated Catchment Management (ICM) in Western Australia and Queensland).

The Queensland State Government released an ICM Strategy in October 1991 (Anonymous 1991). It provides a framework for fostering cooperation and coordination between landholders and other resource users, community groups and government agencies involved in the use and management of natural resources (Johnson *et al.* 1996). The Queensland Department of Natural Resources is the lead government agency for implementing the Strategy. Other state government agencies, such as the Department of Primary Industries, Department of Environment and Heritage and the Department of Communication, Information, Local Government and Planning, also play a role in promoting and supporting relevant aspects of the ICM policy initiative. The Queensland initiative is different from most other Australian experiences in that its has no legislative basis; its success will ultimately reflect the ability of relevant public and private interests to voluntarily effect required action.

To-date implementation of the ICM Strategy in Queensland has occurred in 34 catchments covering over 70% of the state. One of the first catchments in the State to initiate ICM activities was the Herbert River Catchment. The Herbert River catchment has an area of nearly 10,000 km^2 and is located on the southern end of the wet tropical coast of north Queensland. It drains directly into the Hinchinbrook Channel, part of the Great Barrier Reef Marine Park. Agriculture is the dominant land use in the catchment, consisting of mainly beef production on native pastures in the upper catchment and intensive sugarcane production on the lower coastal plain. Other significant land uses are forestry, conservation areas (ie. significant parts are within the Wet Tropics World Heritage Area), and smaller areas for horticulture and fodder cropping. The sugar industry dominates the lower Herbert both socially and economically. The sugar industry in general has been a dominant player in ICM in the lower Herbert River catchment since its inception in 1993.

The Herbert River Catchment ICM process has formed the focus of a five-year study to monitor and evaluate the implementation of ICM (Bellamy and Johnson 1997, 1998; Bellamy *et al.* 1999). The analysis of the initial stages of this implementation of ICM in the Herbert catchment by Bellamy and Johnson (1997, 1998) suggests that an ICM process may contribute to a move towards sustainable cane growing by:

- *Fostering communication* across sectoral and community interests facilitated through the establishment of an effective community based forum that reveals the diversity of

perspectives and the importance attributed to specific catchment issues;

- *Providing a structure that fosters cooperation* amongst community and sugar industry groups and government organisations that leads to more equitable decision making and more sustainable natural resource outcomes on the ground;
- *Facilitating coordination* of effort across government, sugar industry and community organisations to achieve outcomes that have benefits to a broad range of catchment stakeholders as well as the environment, and which could not be achieved by any one group alone;
- *Integrating* ICM principles into Local Government planning that provides a basis for implementing a strategic direction for the catchment; and
- *Supporting an emergent strategic ICM approach* of adaptive learning involving key and influential community actors and moves the community towards a sustainable process of integrated planning of natural resource use.

There are still very significant challenges for ICM in the Herbert River catchment. In particular it has a long way to go to achieving tangible outcomes in respect of the key natural resource management issues. However, significant progress is being made in a long term process. The Herbert River catchment is not unique, and its experiences in implementing ICM are relevant to other catchments that have a diversity of significant land and water management and biodiversity protection issues relating to sustainable sugarcane growing.

MOVING FROM RHETORIC TO PRACTICE: CHALLENGES AND OPPORTUNITIES

In responding to the rhetoric on sustainability and the new IRM paradigm, and in attempting to achieve real change, the sugar industry faces a number of significant challenges. These challenges relate to key contextual, structural and process issues influencing and controlling the sugar industry's move towards sustainable resource use (Bellamy and Johnson 1997).

Sustainable Cane Growing - A Way Forward

An ESD framework

In detailing the opportunities for moving toward ESD in the sugar industry it is instructive in the first instance to provide a broader framework for future development. We believe that it is incumbent on the industry, government and the broader community to work together towards ensuring that the following objectives are fulfilled:

1. Natural resource management in cane growing regions is undertaken as a fundamental part of, and necessary precondition for, ESD and the implementation of the precautionary and 'duty of care' principles.

2. Responsibility for natural resource management is shared between government, community and the industry in a transparent and mutually supportive manner.

3. Appropriate incentives are put in place to encourage the use of natural resources only in ways that are ecologically sustainable.

4. Appropriate mixes of incentives are developed and appropriate weighting given to motivational, voluntary, property-right, price-based, and regulatory instruments in ways which are context sensitive and responsive to local, regional and social characteristics.

5. The Australian community as a whole, as well as users and beneficiaries of natural resources contribute towards the provision of incentives to the industry, which has primary responsibility is for the on and off farm protection of the environment.

In the sections that follow we discuss a range of possible incentives, instruments and mechanisms that the sugar industry and its partners in government and the broader community could utilise in moving toward ecological sustainability.

.

Institutions

For the framework outlined above to be implemented, it is essential that governments at all levels develop the necessary supporting institutional capacity. Accordingly, governments at all levels must develop structures that empower local communities and the sugar industry to effectively manage and conserve natural resources and provide access to instruments necessary for their operation. Conversely, governments must address problems where local initiatives fail or are incomplete and, importantly, must give consistent signals to resource users and consumers about the importance of natural resources within the broader context of ESD.

Natural resource management needs to be integrated into decision making at all levels of government, community and the sugar industry. Furthermore, stakeholders must be involved in the establishment (where they do not already exist) and operation of relevant decision making and advisory bodies (eg ICM). Improved participation of local government in the cane land allocation process is also necessary. This should be done through the appointment of a local government representative(s) to Local Cane Production Boards whose role is to regulate cane growing and harvesting. Ensuring cross-compliance of cane land allocation process with Local Government planning schemes would also ensure the formal consideration of ESD principles.

Stakeholders, particularly canegrowers, also have a responsibility to ensure that their own internal processes allow real opportunities for the involvement of individual farmers at a "grassroots level". There is potential for self-interest and local needs to dominate important resource management issues. Conflict within decision-making fora represents a major potential threat to improved practice. Visible monitoring and accountability mechanisms are therefore essential pre-requisites for increased community and industry involvement, as are the development of appropriate and effective conflict resolution and facilitation processes. This is especially the case for the operation of the cane assignment system. We believe that it is more efficient to build on and adapt existing administrative and institutional structures, where possible, to address natural resource management issues rather than to create new structures. For example, suggested improvements in the cane land allocation process could include (Johnson *et al.* 1996; Shrubsole 1997):

- Reviewing the present referral process for cane land allocation by establishing and applying locally based conflict resolution mechanisms before requiring the formal involvement of the Queensland Sugar Corporation or Sugar Tribunal. These mechanisms should be codified in new sugar industry legislation;
- Local Cane Production Boards should provide for the earlier consideration of environmental factors in the cane land allocation process through existing mechanisms such as "Continuous Crushing Agreements" (ie agreements between cane growers and sugar millers on the length of the harvesting period, milling capacities, future growth and transport planning) and corporate policies. In so doing, Local Cane Production Boards could reduce the perceived need for pre-emptive clearing by adjusting the timing of the cane land allocation process.

Motivational and voluntary incentives

Incentives aimed at increasing levels of knowledge and understanding or requiring voluntary action, are premised on the belief that environmentally responsible behaviour is far more likely to result when people have a basic knowledge of the issues at stake, and/or a commitment to the principles of ESD (Young *et al.* 1996). Motivational and voluntary incentives encourage all stakeholders to share information and contribute to improved management. Motivational and voluntary incentives have already been used in some cane growing regions, and include activities such as ICM. Hence motivational incentives must be a core mechanism for improved natural resource management. Two examples of a potential application would include:

- The identification of agreed wetland and riparian areas in cane growing catchments to underpin negotiated agreements between landholders, government and the broader

community on buffer setback widths. This activity would preferably be embedded and implemented within a broader catchment planning exercise undertaken as a partnership between government, the sugar industry and the community; and

- The establishment of voluntary conservation agreements between cane growers and government under the *Nature Conservation Act 1992 (Qld).*

Property-right incentives

Two alternative types of property right incentives - covenants or management agreements have potential for application in the sugar industry. Management agreements can be used to reimburse people for the costs of resource management that can not be recovered through normal market mechanisms. An example would be to encourage canegrowers to undertake specified management activity on private land adjacent to public conservation reserves or wetlands.

Conservation covenants are particularly effective in protecting remnant vegetation or wetlands, and can be use to underpin approaches such as management agreements. The use of conservation covenants can also be linked to other incentives, for example, the local government rating systems (for rate relief purposes), to recognise the value of uncleared land. Licence and permit systems are used where there is a need to link natural resource management with an economic activity; pollution permits and land clearing for example. In the design of licence systems, there is a need to place emphasis on the dependability of the licence to protect natural resources in an efficient and equitable manner. Central to this must be the establishment of effective monitoring strategies that not only assess specific activities (eg., cane land allocation) but also general environmental performance.

Tradeable rights systems are frequently advocated by economists, but generally have a poor track record (Nelson 1977). The benefits of transferable property rights are more apparent in areas where equivalent units (eg water) can be traded than where units traded may not necessarily be equivalent (eg wetland preservation schemes). Tradeable rights have a role in the sugar industry but should not be seen as the sole solution. In virtually all cases, they need to be supported by an appropriate network of regulatory, financial and institutional measures (Young *et al.* 1996).

Regulatory incentives

Despite advocating motivational, social and market based incentives, there remains an important role for regulation, because acting alone, non-regulatory instruments are not always effective (Napier 1994). Regulations provide precautionary standards and an essential safety net to protect against the recalcitrant few not persuaded by other incentives. Each level of government needs to set such standards and no level of government should be able to undermine the standard set by another level of government, by a community or by industry itself. It is crucial that the sugar industry and the community be given the opportunity to contribute to the development of standards. As regulatory incentives provide protection against those who do not respond to other measure, they are particularly important when threats to natural resources are likely to become irreversible, for example, in the case of land clearance on coastal floodplains in which the sugar industry is a dominant land user.

Although some protection for natural resources is currently afforded by planning controls embedded within the *Nature Conservation Act 1992 (Qld)*, *Environmental Protection Act 1994 (Qld)*, *Coastal Protection and Management Act 1995(Qld)*, *Fisheries Act 1994(Qld)* and *Integrated Planning Act 1997 (Qld)*, problems exist in areas subject to the provisions of the *Water Resources Act 1989 (Qld)*, or on land with freehold tenure. An increasing regulatory role for local government (e.g. through the invocation of planning controls if consent is required for subdivision, zone change and drainage development) provides some opportunity for improved natural resource management, particularly for the management of riparian and wetland areas. Some of these issues are presently being addressed in the planning schemes of Noosa, Hinchinbrook, Cardwell and Johnstone Shires. However, for improved management to occur, greater integration between local and state

.

government, industry and the community must be a priority.

Pricing Incentives

A fundamental consideration in the development and implementation of any policy or instrument mix is the both the private and public cost implication. The cost of controlling and preventing damaging processes in cane growing regions should be borne primarily by those who cause these problems (ie. the sugar industry). However, the Australian community as a whole should take financial responsibility for protecting the natural environment when the costs of doing so cannot be recovered by the use of market mechanisms. Hence, all those who benefit from non-market dimensions of protecting the natural environment, whether directly and indirectly, should contribute to the cost of its maintenance (Young *et al.*, 1996).

The tax system is an important area for reform, particularly when taxation incentives are recognised to be the most cost effective means of encouraging altruistic investments in resource conservation by the private sector (Davenport 1995). Another method of ensuring that users pay is the imposition of levies and charges. These have the additional benefit of making users of natural resources aware of the cost of their activities (Young *et al.* 1996). This is particularly true in the case of water. Acceptance of such levies is likely to be improved if the funds raised are clearly seen to be working towards resource management and protection, preferably by being placed in resource management funds administered by the local community and the sugar industry itself. Opportunities also exist for the implementation of financial incentives for retention and management of high value habitat areas in cane growing regions to be dedicated as Nature Refuges or Coordinated Conservation Areas. Finally, direct acquisition of riparian areas and wetlands of regional, national and international importance remains an option.

Appropriate Scales

As discussed, the wide range of challenging factors facing the sugar industry means that a variety of mechanisms and arrangements are needed to address them, and that many of these solutions will be location or regionally specific. In order to overcome some of these problems, we suggest that the appropriate boundaries for government decision making on natural resource management in cane growing regions are bioregional. However, local government and the sugar industry (whose boundaries are rarely consistent with bioregional boundaries), will require close and identifiable ties with the community, and will have to provide an appropriate base for implementation. Regionally developed strategies based on and consistent with national and international ESD principles will be necessary to assist the sugar industry in increasing the sustainability of its activities. Hence it is important that common national and international agreements on the principles of ESD exist in parallel with coordinated local, regional and industry interpretations, strategy development and implementation (Geno 1996).

Science and Information

Management of resources on the basis of ESD is more complex than management premised solely on maximum productivity or conservation. Policy and planning cannot be expected to achieve societal goals in the absence of adequate data relating to biophysical, economic and social factors that impinge on resource use (Cocklin *et al.* 1987). Scientists traditionally respond to such challenges by advocating that further research is needed to fill gaps in our understanding. In response, Walker *et al.* (1996) propose that the adage that "further research is needed" provides scientists with little opportunity to have a positive impact on sustainable natural resource management. They argue that only by being prepared to invest in understanding the context of decision-making and by finding novel ways of facilitating the uptake of past and future research by decision-makers, can scientists hope to have a significant and consistent impact on practice. Johnson *et al.* (1998b) argue that the challenge for research is to address the needs of decision-makers in three key areas: problem identification; data collection, collation and analysis; and rational use of the outputs of that analysis.

.

Notwithstanding these concerns, continued research may be needed to enable more informed and appropriate management of natural resources in cane growing regions. Clearly, research is required to further understanding of the physical and socio-economic systems in which cane production occurs. However, research is also needed in the organisation of that knowledge to provide an effective basis for decision-making in relation to ESD. The integration of information technologies such as GIS, expert systems, other knowledge-based systems and simulation modelling into decision support systems may help in addressing these issues (Fedra, 1995). The role and management of such innovations also demands attention. It is hard to envisage effective ESD in the sugar industry without the use of information technology tools in some capacity (Johnson *et al.* 1998a).

CONCLUSIONS

The policy environment for ESD in the context of the sugar industry will continue to respond to changing political, economic, social and environmental considerations. While the manner in which resources are managed will vary, public expectations for, and support of, effective environmental management policies will remain. In this regard, the principles for ESD will form the basis for the development of new and improved initiatives. The general trend of shifting management responsibilities to lower levels of government will continue, although the extent will be guided by overriding state and federal government policies. There will be a continued emphasis on regional planning to establish a sound foundation for policy implementation.

The magnitude of the tasks facing the Australian sugar industry in its attempt to move toward ecological sustainability in the future remain substantial. The challenge for the sugar industry is to embrace, rather than resist, the inevitable trend toward greater public intervention in its affairs. In response, government must provide a stable environment in which locally relevant decision-making can occur and in which appropriate and viable monitoring, cost-sharing and regulatory arrangements can be supported. The Australian sugar industry must continue to develop its own policies and activities to guide its future developments within a wider context. In so doing, it must recognise that external pressures will evolve with time; hence planning must be a continuous activity rather than a single exercise. Further, the industry must develop its own strategic view on where and how sugar cane will be grown – both at regional and whole of industry levels. This view will need to be based on the best available scientific information and full utilisation of the products of its substantial investment in environmental R&D. Furthermore, for strategic planning to be successful, the sugar industry needs to be proactive in involving itself in non-sugar industry programs related to natural resource management and planning.

In facing the significant challenges of balancing the dual goals of economic efficiency and environmental conservation, the sugar industry can reflect on its own experience and that of other agricultural industries and move to a sustainable future by playing a key role in:

- *Fostering communication* across sectoral, local government and community interests;
- *Developing a structure and related processes and procedures that foster cooperation* between the industry and other industry, community groups and government organisations and paves the way for more equitable decision making and more sustainable natural resource outcomes on the ground;
- *Facilitating coordination* of effort between itself, government and community organisations; and
- *Supporting the integration* of resource management principles (including Codes of Practice for Sustainable Cane Growing) into Local Government planning schemes and decision-making processes.

Significant opportunities exist for the sugar industry to embrace a broad range of integrated resource management principles in the future. These include:

- Developing a strong culture of mutual support and information exchange with other stakeholders responsible for natural resource management in cane growing regions;

.

- Developing and refining locally-based industry regulations such as the cane land allocation system and sugar industry environmental codes of practice for cane growing which could be supported by incentive systems;
- Increasing its participation in emerging programs to operationalise the principles of ICM in Local Government planning schemes;
- Continuing to support extension, other industry networks and new opportunities in information technology to improve the capacity of the industry to address resource management issues; and
- Applying the traditional agricultural business concept of managing an asset to resource management activities, so as to establish strong market linkages for land and water resources management with farm enterprise outcomes.

If the Australian sugar industry can operate within this framework, it will be clearly able to demonstrate that environment-economy linkages can lead to positive economic, social and environmental benefits and in so doing, manage for ESD and move the sugar industry, government and community substantively along the continuum from rhetoric to practice.

Australian Journal of Environmental Management (1998), 5(2), 97-108

Abstract

The Australian sugar industry is largely confined to the narrow, high rainfall coastal zone in which competition from tourist and recreational uses, urban encroachment, public utilities and hobby farms for natural resources has increased significantly in recent years and is likely to grow in the future. This paper briefly examines the socio-political, economic and environmental context in which natural resources are currently managed in the Australian sugar industry. We argue that planning, in concert with a range of policy and economic instruments, can play an important role in the resolution of such problems. Building on the collective national and international experience of other industries, options for efficient and equitable allocation of resources between the sugar industry and its neighbours at the policy level and on-farm are outlined and discussed.

ACKNOWLEDGEMENTS

The authors wish to acknowledge the financial support of the Land and Water Resources Research and Development Corporation, which made this research possible.

The authors wish to express their extreme gratitude to all those people with have an interest or who are actively involved in the implementation of Integrated Catchment Management in Queensland and who gave time from their busy schedules to complete interviews or questionnaire survey forms that were fundamental to the success of many project activities. Of special note are the following people and agencies who willingly co-operated and provided valuable assistance to this five-year research project:

- The members of the Herbert River Catchment Coordinating Committee who actively participated and contributed their valuable time, views and knowledge.
- Dave Horsley, CSR Herbert River Mills, who was an invaluable source of information on natural resource management and related activities in the Herbert River catchment, provided substantial advice to the researchers and contributed actively to many of the research activities of this project.
- The Herbert River Catchment Coordinators, Rob Hunt and subsequently Andrew Petroeschevsky, who provided valuable comment and information as well as facilitating interactions with HRCCC members.
- Ray Quabba, Chair of the HRCCC, who gave his time, knowledge, invaluable assistance and encouragement to the researchers over the life of the project.
- Philip Rowland, Mike Merrin and Don Begbie, Department of Natural Resources, Queensland who have actively supported the project since its commencement and provided valuable assistance and access to information to the researchers involved.
- Luis Laredo, CSIRO Tropical Agriculture, Brisbane, who has provided valuable general computing assistance to the researchers involved and contributed actively to database development and management for some key research activities.
- Kathy Mitchell and Leesa Austin, CSIRO Tropical Agriculture Brisbane for invaluable assistance in the preparation of this publication.

ICM in Queensland: Response from Committee Members of Johnstone and Herbert River Catchments, 1995

Dan Shrubsole

Department of Geography, University of Western Ontario, London, Ontario NCA 5C2, Canada

Originally Published in:
Shrubsole, D. 1996: ICM in Queensland: Response from Committee Members of Johnstone and Herbert River Catchments, 1995. CSIRO Tropical Crops and Pastures, Brisbane.

Background

Eleven committee members from the Herbert River Catchment responded and six from the Johnstone River responded. These included the two Chairs, whose ratings have already been recorded in the report on Chairs and Coordinators. The Chairs responses are also included in this report.

Table 1 summarises how long each member has lived in the area, when they joined the Committee, whether they live upstream or downstream of Abergowrie (for Herbert River members) or in which shire the Johnstone River Committee members live.

Catchment	Position	Lived in area (in years)	Joined the committee	Upstream or Downstream of Abergowrie	Shire in Johnstone catchment
Herbert	Chair	65	From outset	Downstream	
Herbert	Member	36	1995	Downstream	
Herbert	Member	48	1991	Downstream	
Herbert	Member	40	1992	Downstream	
Herbert	Member	18	1993	Downstream	
Herbert	Member	20	1993	Downstream	
Herbert	Member	58	1994	Downstream	
Herbert	Member	14	1993	Downstream	
Herbert	Member	7	1994	Upstream	
Herbert	Member	46	1993	Downstream	
Herbert	Member	59	1993	Downstream	
Johnstone	Member	33	1994		Eacham Shire
Johnstone	Member	25	1991		Johnstone
Johnstone	Member		Since start		Eacham
Johnstone	Chair	34	1991		Johnstone
Johnstone	Member	40	1992		Johnstone
Johnstone	Member	45	1991		Both Johnstone and Eacham equally

The following table summarises response to question 4 on how satisfied members are with progress in the CCC. The ratings used are: 0=no response, 1=very unsatisfied, 2=unsatisfied, 3=neither satisfied nor unsatisfied, 4=satisfied,
5=very satisfied.

Rating:	1	2	3	4	5
Herbert	1	1	3	5	1
Johnstone			1	3	2

Below are comments by members on major achievements in their catchment:

Johnstone

1. Getting people together to talk rationally. Getting a lot of data. Management plan.
2. Finalisation of a strategy for our ICM and now the beginning of the implementation.
3. Raising public awareness. Bringing together diverse groups. Developing "best practices" for industries. Attracting Govt. funding for permanent staff.
4. Has developed a catchment strategy and implementation procedures which have heavily influenced ICM in other parts of the state.

5. Developing a role for the CCC and its members, provide an independent and informed and coordinated view, recognised as a useful body by some key agencies and funding bodies, it has not only "continued" ut is developing a leadership role in NRM and its implementation.

Herbert

1. Cross Section of communities viewpoints of necessary works. Trying to coordinate natural resources activity in the Herbert Catchment.
2. The level of awareness of ICM to Canegrowers has been slow. Formation of the group went well. The formation of a strategic plan has been slow. The ICM group did become involved with issues as they arose, but had no policy at that stage. This is being addressed now.
3. Too early to tell.
4. People from significant backgrounds starting to talk and share ideas. This has proven to be a slow process.
5. Works on the mining sites in the upper catchment.
6. The only achievement I see is the controlling of the mining operations in the Herberton area. This has caused major siltation in the Herbert River. This siltation has caused very dirty water for the residents of the Hinchinbrook Shire. I feel there are too many meetings. Too much talking - more positive decision making required.
7. Formulation of a management strategy. Formulation of Upper Catchment subcommittee.
8. Coordination of the mapping of Tolle catchment and drawing up of catchment management plan.
9. Bringing together different group problems and trying to solve them.

Local Issues

Below are summary tables of questions 6-8. The ratings are 0=no response, 1=very low, 2=low, 3=moderate, 4=high, 5=very high, 6=NA/don't know.

Question 6. In your opinion, what is the significance of the following issues in your catchment?

HERBERT	0	1	2	2.5	3	4	4.5	5	6

Question 9: What is the level of public awareness about these natural resource issues and associated impacts?

Catchment	No response	Very low	Low	Low to Mod.	Moderate	Mod. to High	High	Very High
Herbert River			5	1	4			1
Johnstone	1	1			3	1		

Question 10. What do you consider to be the strength of public support to solve these natural resource issues in your catchment?

Catchment	No response	Very low	Low	Moderate	High	Very High
Herbert River			6	4		
Johnstone	1		1	3	1	

Question 11: The implementation of ICM in your catchment is difficult because:

HERBERT	0	1	2	3	4	5	6
11a Resource management problems are not well understood			1		8	2	
11b Technical solutions are not feasible			7		1	1	2
11c The impacts of mismanagement are long term and incremental			1	1	7	2	
11d There is no single acute resource management issue within the catchment			5		5	1	
11e The high level of behavioural change required			1		6	4	
11f The long time frame between implementing a solution and seeing the benefits			2		5	4	
11g The high cost of known solutions			2		7	2	
11h The high level of change required from existing government agencies			1	1	6	3	
11i The absence of clear and immediate economic benefits					8	3	
JOHNSTONE	**0**	**1**	**2**	**3**	**4**	**5**	**6**
11a Resource management problems are not well understood	1		2		1	2	
11b Technical solutions are not feasible	1	1	3	1			
11c The impacts of mismanagement are long term and incremental	1	1		1	2	1	
11d There is no single acute resource management issue within the catchment	1	1			2	2	
11e The high level of behavioural change required	1		1		3		1
11f The long time frame between implementing a solution and seeing the benefits	1	1		2	1		1
11g The high cost of known solutions	1	1	1	1	2		
11h The high level of change required from existing government agencies	1		1	1	1	2	
11i The absence of clear and immediate economic benefits	1		1		3	1	

Question 12. In the last 12 months, the importance of resource management issues has:

Catchment	Increased	Stayed the Same	Decreased	No response
Herbert	8	2	1	
Johnstone		5		1

Changes that have occurred:

Herbert

- Pomono subdivision - CCC responded with inspections and some publicity. No further action taken and in hindsite a lost opportunity. Erosion control works in Herbert River at Long Pocket region and was successful in funding. Cattle Creek drainage - to be dealt with in 1996. Trebonne Creek drainage - to be dealt with in 1996.
- Mahogany glider conservation plan - response in progress
- Main issue is Mahogany Glider habitat conservation is all out clearing for cane expansion. CCC sat on fence and failed to comment (deliberately) on gross environmental vandalism in clearing creek beds and banks on Pomona Station. Even the council is now complaining about failure to observe 10m buffer on creek but still ICM holds the "must be polite" line.

- The CCC has made very broad comments condemning expansion in Pomona, the group could have been more forceful in their statements but have taken a "political approach."
- It is my opinion that the CCC is speaking too much behind closed doors and not informing the public for support etc. Too many of the members of the CCC, have affiliations to too many other organisations. Some have 6 to 8 organisation involvements. The CCC chairman is a Shire Councillor and deputy chairman of the Hinchinbrook Shire, Chairman of Works, member of the Herbert River Improvement Trust, a member of the Rural Drainage Proposed Board and he is involved in several other committees. He and several others in the CCC should not be on the CCC Board. These people should be replaced because they cannot make a decision that is good for all the organisations they represent. Fingers in too many pies. I enclose a copy of the Herbert River Express dated December 5th which outlines my views on why I oppose the decision making capacity of the Trust member, Cr. Barnes. I and the organisation I represent have been asking for this work to be done for more than 15 years. When it could be done cheaply, now we see a very high cost involved. Too much talking and very little factual work has been performed.
- Extensive land clearing due to caneland expansion. Mahogany Gliders Issue has possibly made some people more environmentally aware. Also created friction between landowners and government agencies.
- An increasing awareness of the need for water storage for agriculture in the upper catchment. ICM will be coordinating and monitoring any moves in this direction.
- Buffer zones on land clearing.

Johnstone - no comments were made in this section for Johnstone

ICM CONTEXT

Question 13. What level of public support do you believe your CCC has?

Catchment	Very low level	Low level	Low to Moderate	Moderate level	High level	Very high level
Herbert	2	2		6	1	
Johnstone		1	1	3		1

Question 14. How significant have the following items been in gaining acceptance from the public?

(0=no response, 1=very low, 2=low, 3=moderate, 4=high, 5=very high, 6=NA/don't know)

HERBERT	0	1	2	3	4	5	6
The State Government's ICM policy statement		2	2	6			1
Local government political support			4	4	3

Question 20. How effectively do you believe the news media presents your CCC's position on an issue?

Catchment	**Very ineffectively**	**Ineffectively**	**Neither**	**Effectively**	**Very Effectively**
Herbert	2	2	2	4	1
Johnstone			1	5	

Question 21. What could or should be done at state/local levels to improve the acceptance and involvement of relevant groups in the Herbert River CCC process?

Herbert River

- More public news items. School promotions. Industry promotions at grower level.

- More available funds, so that the community as a whole can see some useful work being completed instead of hearing of numerous studies being done with no effective follow-up work being obvious.
- Continue to support with financial and technical back up
- I think the CCC has to prove its credibility.
- Greater public consultation and "listening" to public opinion
- Increase public awareness of issues eg. organised articles in paper exploring issues to raise awareness. Can be difficult to manage when local "experts" get wound up.
- Recognise the role of the CCC through legislation (The Chair believes the CCC is simply an advisory group).
- The first thing that should be done is change the structure of the present CCC committee. There are members in it who do not have the confidence of the community at large. Their trust is gone and new faces and new ideas must be implemented. Many of the members have their fixed views which are not acceptable to the community. The next question has some clues.
- Greater involvement of local council - information swapping and cooperation prior to action by council. Use of CCC as database and advisory agency - high level of local knowledge on varied topics in group.
- Much more media publicity on CCC objectives and achievements. More funding for specific projects.
- Increase the public's awareness of CCC.

Johnstone

- An ongoing programme of media releases and a public information programme highlighting the achievements and pointing out the benefits to individual stakeholder groups being involved, eg. be involved in forming the strategies and decisions before some bastard does it for you.
- Appoint effective follow-on coordinators and finance the programme effectively
- Much more usage of media for publicity purposes
- Have better local media resources and have an obvious separation between the state and local view when the local view is contentious. The state view is generally seen as "Big Brother."

Question 22. The implementation of ICM in your catchment is difficult because:

HERBERT	Strongly disagree (1)	Disagree (2)	Neither (3)	Agree (4)	Strongly Agree (5)	NA/don't know (6)
22a Large size of catchment (or poor transportation links between parts of catchment)			1	10		
22b Wide variety of values and beliefs among CCC members		3		5	3	
22c Media don't report resource issues accurately		4	1	4	2	
22d Some important constituency groups are not represented on the ICM committee		9	1		1	
22e Perception that ICM has been forced on the catchment by the state government	1	5	2	1	1	1
22f Lack of an effective level of interest by CCC members	1	4	3	2	1	
22g Public's lack of trust in state/local		2	1	5	3	

govt.-sponsored initiatives					
22h Public's lack of interest in community type activities	2	1	5	3	
22i The lack of financial resources within the community	2	1	5	3	

Other/s:

- Lacks specificity and "teeth" to solve public issues - Rating 4 (Agree)
- Ecology vs. development and expansion; downstream effects ignored by upstream development - Rating 5 (Strongly agree)

JOHNSTONE	**Strongly disagree (1)**	**Disagree (2)**	**Neither (3)**	**Neither to Agree (3.5)**	**Agree (4)**	**Strongly Agree (5)**
22a Large size of catchment (or poor transportation links between parts of catchment)	3	1	2			
22b Wide variety of values and beliefs among CCC members	2	2	2			
22c Media don't report resource issues accurately	2	2	1		1	
22d Some important constituency groups are not represented on the ICM committee	2	2	2			
22e Perception that ICM has been forced on the catchment by the state government	2	2				1
22f Lack of an effective level of interest by CCC members	2	2	2			
22g Public's lack of trust in state/local govt.-sponsored initiatives	1				4	1
22h Public's lack of interest in community type activities	1				5	
22i The lack of financial resources within the community		1	3		2	

Institutional Arrangements

Question 23. Rate your level of agreement with the following statements concerning the operations of the CCC. *(1=strongly disagree, 2=disagree, 3=neither, 4=agree, 5=strongly agree, 6=NA/don't know)*

HERBERT	**1**	**2**	**3**	**4**	**5**	**6**
23a The objectives of the local ICM are very clear to all members	1	5		4	1	
23b There is a strong consensus among CCC members concerning what the CCC should do	1	6		3	1	
23c The CCC should coordinate state and local government resource management programs			2	8	1	
23d The CCC should prioritise resource management problems in the catchment		1		7	3	
23e The CCC should provide a forum for conflict resolution among resource users		1	2	6	2	
23f The local ICM process has or will resolve resource conflicts in an open manner	1	1	4	4	1	
23g The CCC should educate the public about the catchment's resource management problems and solutions			1	6	4	
23h The CCC should provide a forum for information sharing within and between public and private resource managers			1	3	7	

23I The CCC should prepare a strategic resource management plan				5	6	
23j The CCC should facilitate the implementation of resource management initiatives noted in the strategic plan				7	4	
23k The CCC should identify a common set of policies which will be implemented by relevant resource managers within the catchment				7	4	
23l The CCC should make private resource managers/owners more responsible for the impacts arising from their activities		2	1	5	3	
23m The CCC should stimulate community or regional development		3	2	4	2	
23n The CCC should be providing individuals with technical advice on solutions to natural resource issues	1	1	1	4	4	
23o The activities of our CCC have been effectively coordinated with the activities of other state and local government agencies		3	1	6	1	
23p The membership of the CCC effectively represents the interests of the catchment community		1	1	8	1	
23q At CCC meetings, all CCC members participate actively		2	2	7		
23r The local ICM process has or will resolve resource conflicts effectively		3	5	3		
23s The local ICM process has or will resolve resource conflicts efficiently	1	2	5	3		
23t The ICM process is very responsive to local needs		1	2	8		
23u The CCC is solving the priority natural resource management problems in the catchment	1	1	2	6		1

JOHNSTONE	**1**	**2**	**3**	**4**	**5**	**6**
23a The objectives of the local ICM are very clear to all members				4	2	
23b There is a strong consensus among CCC members concerning what the CCC should do		1		3	2	
23c The CCC should coordinate state and local government resource management programs		1		2	3	
23d The CCC should prioritise resource management problems in the catchment				3	3	
23e The CCC should provide a forum for conflict resolution among resource users			2	3	1	
23f The local ICM process has or will resolve resource conflicts in an open manner		1	2	1	1	1
23g The CCC should educate the public about the catchment's resource management problems and solutions			1	2	3	
23h The CCC should provide a forum for information sharing within and between public and private resource managers				2	4	
23I The CCC should prepare a strategic resource management plan			1	1	4	
23j The CCC should facilitate the implementation of resource management initiatives noted in the strategic plan		1		1	4	
23k The CCC should identify a common set of policies which will be implemented by relevant resource managers within the catchment				3	3	
23l The CCC should make private resource managers/owners more responsible for the impacts arising from their activities		2		3	1

23q At CCC meetings, all CCC members participate actively				2	4	
23r The local ICM process has or will resolve resource conflicts effectively		1	1	3	1	
23s The local ICM process has or will resolve resource conflicts efficiently		1	3			2
23t The ICM process is very responsive to local needs			1	4	1	
23u The CCC is solving the priority natural resource management problems in the catchment		1	1	4		

Question 24. Over the last 12 months, the level of financial and in kind support from QDPI has:

Catchment	No response	Decreased	Decreased - Remained the Same	Remained the Same	Increased
Herbert	2			2	3
Johnstone			1	1	4

Changes that have occurred:

Herbert

- Don't know if there has been any changes
- More DPI personnel available for advice; some increased special purpose funding; support for a student to work in the catchment.

Johnstone

- As far as I know financial support has decreased from QDPI - any increase is via NLP or other external funds. However, there are a lot of projects and we are not concerned with counting beans at our meetings
- Introduction of ICM grants
- More funding came through!

Question 25. Over the last 12 months, the level of financial and in kind support from other state and local agencies, and other external funding organisations (eg. National Landcare Program) has:

Catchment	No response	Decreased	Remained the Same	Increased
Herbert	2		6	3
Johnstone			1	5

Changes that have occurred:

Herbert

- As above - I am not aware of the detailed breakdown of contributions.
- Approval of funding for a landcare project.

Johnstone

- More funding came through.
- Significant input from Landcare for projects. Money from LWRRDC for research etc.
- As far as I know, more/additional projects have been funded

Question 26. How clear to you is the role(s) of the following groups in the local ICM process? (*Ratings are 0=no response, 1=very unclear, 2=unclear, 3=neither, 4=clear, 5=very clear, 6=NA/don't know)*

Question 27. Average hours per month devoted to ICM:

Catchment	Position	Hours/mth
Herbert	Chair	15
Herbert	Member	15
Herbert	Member	10
Herbert	Member	6
Herbert	Member	6
Herbert	Member	6
Herbert	Member	6
Herbert	Member	5
Herbert	Member	4
Herbert	Member	4
Herbert	Member	3
Johnstone	Chair	30
Johnstone	Member	20
Johnstone	Member	15
Johnstone	Member	12
Johnstone	Member	5
Johnstone	Member	4

Question 28. Identify your level of agreement with the following statements:

HERBERT	Strongly disagree (1)	Disagree (2)	Neither (3)	Agree (4)	Strongly Agree (5)
28a The amount of time I devote to ICM significantly interferes with my own business/job requirements	1	4	2	4	
28b The amount of time I devote to ICM significantly interferes with my family commitments	1	6	1	3	
28c My involvement with the CCC causes significant out-of-pocket expenses	1	4	5	1	
28d I find being a member of the CCC personally rewarding because I can contribute to the community			3	7	1
28e I find being a member of the CCC personally rewarding because I care about natural resource mgnt				8	3
28f I find being a member of the CCC personally rewarding because I can meet other members of the community who can influence resource management decision making				9	2
28g I find being a member of the CCC frustrating	1	3	2	3	2
28h I see my role in the CCC as a short-term commitment	1	6	1	3	
28i A CCC's member's role is to provide their personal views on resource management issues at CCC meetings		3	2	6	
28j A CCC member's role is to represent the resource management views of their constituency group at CCC meetings					8
28k A CCC member's role is to provide a catchment-wide perspective of natural resource management issues at CCC meetings.				3	6

JOHNSTONE	(1)	(2)	(3)	(4)	(4.5)	(5)	(6)
28a The amount of time I devote to ICM significantly interferes with my own business/job requirements	1	1	2	1			1
28b The amount of time I devote to ICM significantly interferes with my family commitments	1	1	3	1			
28c My involvement with the CCC causes significant out-of-pocket expenses		4	1	1			
28d I find being a member of the CCC personally rewarding because I can contribute to the community		1	1	3		1	
28e I find being a member of the CCC personally rewarding because I care about natural resource mgnt				3		3	
28f I find being a member of the CCC personally rewarding because I can meet other members of the community who can influence resource management decision making				2	1	3	
28g I find being a member of the CCC frustrating	2	3		1			
28h I see my role in the CCC as a short-term commitment	1	3	1	1			
28i A CCC's member's role is to provide their personal views on resource management issues at CCC meetings	1	4				1	
28j A CCC member's role is to represent the resource management views of their constituency				2		4	

JOHNSTONE	(1)	(2)	(3)	(4)	(4.5)	(5)	(6)
group at CCC meetings 28k A CCC member's role is to provide a catchment-wide perspective of natural resource management issues at CCC meetings.				3		3	

Question 29. Further comments

Herbert

- A possible problem associated with ICM in the Herbert River District is that it is virtually a single industry catchment - this gives the sugar and allied industries a fair bit of punch. My personal opinion (possibly cynical) is that certain issues - expansion, drainage, wet land reclamation, river improvement???, use of pesticides and herbicides - may not be consistent with the ideal of ecologically sustainable development. To varying degrees, these practices can be detrimental to natural flora and fauna, also downstream users of the catchment and adjacent lands and waters.
- If ICM is to succeed, I repeat that a new concept of information and advice must be found. The present views of "so called elected people" eg. Hinchinbrook Council, Canegrowers representatives, CSR and a few other organisations, must be got rid of. Unbiased people who will adopt common sense and reasoning and have a knowledge of all existing problems must be considered quickly. The above-named organisations do not know the trust of the community and I fear that if the present scenario continues, ICM will fail. People want action not to be asked to go to meetings continually. There have been millions of dollars already wasted. Let's be constructive and not destructive.
- Comments on pages 2 and 3: We are being strangled by Bureaucrats who don't know the "grass roots" of problems. Over budgeting and serious lack of communication with the public.
- The issues of Riperian Vegetation on existing cane land is a major issue with the potential of causing anxiety if not managed carefully. The issue of river management that is sand bars, instream vegetation and levies that can be rationalised has to be resolved. The level of meeting attendance is a problem and does effect continuity of the decision making process. The lack of a street frontage office I think effects our ICM public accessibility. There would be extra costs with it but it should be looked at.

Johnstone

- I am a special member with ICM and ecological and planning expertise and do not represent an interest sector as such. I became involved at the commenced of the Johnstone River CCC and am still involved.
- The role of Catchment Coordinators is vital to developing an effective strategy and bringing the diverse stakeholder groups together. He/she should be a mature person with a wide knowledge and experience of the working of government and who has very good personal communication skills. If the best and most effective representatives are to be attracted to serve on CCCs then need to be supported, resource wise, by a facility such as a Catchment Centre (for a group of catchments if necessary) to provide briefing, interpretations and back up support. An effective and ongoing media and public information programme is essential (using community media outlets with locally generated release) to effectively inform the Catchment Community on natural resource management issues.
- So called "Plot Study" is taking too long.
- Re Question on Personal Demands and Motivation [in Committee Members questionnaires only], a CCC participant's role is also to try and understand complexities and other people's points of view. I find ICM more effective as a conservationist. Before ICM any issues were

fought from the trenches or in the pages of newspapers. Now I can bring issues up at meetings and discuss them across the table - and many can be solved with very little angst. Members of Johnstone ICM are heavily involved in their respective groups - which is good in that they are knowledgable and truly representative, but it has meant a heavy commitment in time. Johnstone ICM has been effective because there was a very strong desire by groups to have their say. World Heritage was seen as being "imposed" on them.

INTRODUCTION

1.1 Survey Background

1.1.1 LWRRDC Project CTC7: Evaluation of Integrated Catchment Management in a Wet Tropical Catchment

In 1994, the Land and Water Resources Research and Development Corporation (LWRRDC) funded research staff of the CSIRO Tropical Agriculture (in Brisbane and Townsville), CSIRO Land and Water (in Perth), and the University of Queensland Department of Geographical Sciences and Planning (in Brisbane) to undertake research on Integrated Catchment Management (ICM) processes[1]. This longitudinal study over five years focuses on the community-driven ICM program in Queensland using the Herbert River Catchment process as a case study. The objectives of the investigation are.

1. Monitor and document the process of implementation of ICM in the Herbert River catchment and identify the social, economic and institutional factors that facilitate or hinder this process.
2. Evaluate key impacts of the implementation of the ICM process in terms of attitude and behaviour changes in the community and changes in the severity or tractability of the resource use conflicts for the catchment.
3. Assess the specific technical and related information needs that are relevant to an effective ICM implementation process in a wet tropical environment.
4. Develop a framework and related methods for evaluating the process of ICM implementation that will facilitate the development of more effective catchment management programs in Australia.

The complexities of catchment management are such that longitudinal studies of processes are essential if the issues of catchment management are to be better understood and appropriate lessons learned. The project acknowledges that, by its nature, ICM requires systematic evaluation (Bellamy *et al.* In Press). For example, ICM as a process needs to take many and often conflicting considerations into account. It also operates in a complex environment where uncertainty is more often the rule than the exception. Moreover, indicators of progress are not easily defined and, to date, this area of investigation has largely been neglected (Bellamy *et al.* In Press). In responding to these challenges, the project has adopted a multidisciplinary approach and draws on areas of expertise in natural resources science, social science, land use planning, resource economics, and media analysis.

1.1.2 Objectives of Survey

The LWRRDC CTC7 project seeks to find ways and means to improve the process of planning and implementing community-led ICM in Australia. Crucial to this evaluation is a better understanding of what are the problems faced by the ICM process and how they affect its implementation and ultimately its impact. By way of a longitudinal study of the ICM process in Queensland, the institutional component of the project focuses on finding out how ICM is practised in Queensland generally, and in the Herbert River catchment, in particular. This study aims to:

- provide a better understanding of the essential context in which ICM is conducted;
- provide the key baseline for the assessment of the institutional factors that hinder or foster an effective ICM process in the Herbert; and
- contribute key information for the assessment of the technical needs for effective ICM.

1 LWRRDC Project Reference: CTC7 - *Evaluation of Integrated Catchment Management in a wet tropical environment*

The first stage of the institutional component of the LWRRDC CTC7 project involved two surveys:

- a state-wide survey of ICM officials in Queensland (i.e. all Catchment Coordinators and Catchment Coordinating Committee Chairpersons) in December 1995
- a survey of the opinions of members of the Herbert River Catchment Coordinating Committee (HRCCC) in November 1995.

As part of a longitudinal study, the results of these initial two surveys provide the baseline for the institutional component of the CTC7 project. The results are reported in McDonald and Shrubsole (1996a; 1996b) and Shrubsole and McDonald (1996).

This current report presents the results of a second survey of the opinions of the HRCCC members undertaken in November 1997. The results of the second survey of ICM officials in Queensland in October 1997 are presented in a separate report (see McDonald and Bellamy 1998).

1.1.3 Background to ICM in the Herbert Catchment

Herbert River Catchment Context

The Herbert River Catchment drains an area of approximately 10000 km^2 to the Coral Sea and is the largest of the river systems located in Australia's sub-humid to humid tropical north east (Figure 1). Large areas of the catchment remain under natural vegetation, although about 40% of the coastal lowlands in the lower catchment have been cleared for crop production or improved pastures. Agricultural and pastoral activities are the largest users of land (in area) in the catchment. In terms of arable agricultural production, the sugar industry located in the lower catchment is dominant, covering nearly 65000 ha. Other important industries are forestry and small crops such as pineapples, melons and pumpkins. The middle and upper catchment have significant areas of rainforest in protected areas and State Forest Reserves. The upper catchment is, however, dominated by natural pastures for beef cattle production. Small areas of the catchment are utilised for mining and industrial activities, or alienated for urban development. The catchment population in 1993 was estimated to be approximately 18000 people (1993 National Census), of which 75% live in the lower catchment.

ICM Policy Framework

The Queensland State Government in October 1991 released an ICM Strategy for Queensland outlining the broad policy and structural arrangements (DPIQ 1991). It provides a framework for fostering cooperation and coordination between landholders and other resource users, community groups and government agencies from all levels (i.e. federal, state and local) involved in the use and management of natural resources. The strategy promotes ICM as a participative and consultative process that takes a strategic and planned approach to tackling important natural resource management issues. The Queensland Department of Natural Resources (DNR) is currently the lead government agency for implementing the Strategy. Other state government agencies, such as the Department of Primary Industries (DPI), Department of Environment (DoE) and the Department of Local Government and Planning (DLGP), also play a role in promoting and supporting relevant aspects of the ICM policy initiative.

At the catchment level, land use and resource management is influenced, managed and controlled by a complex domain of government and industry-based natural resource management programs. Of these, the most important are related to state and federal government land administration, river management, nature conservation (including World Heritage Areas and National Parks), and local government infrastructure and town planning (McDonald and Bellamy 1997) and industry arrangements (such as the sugarland allocation process, see Shrubsole 1996). The ICM policy

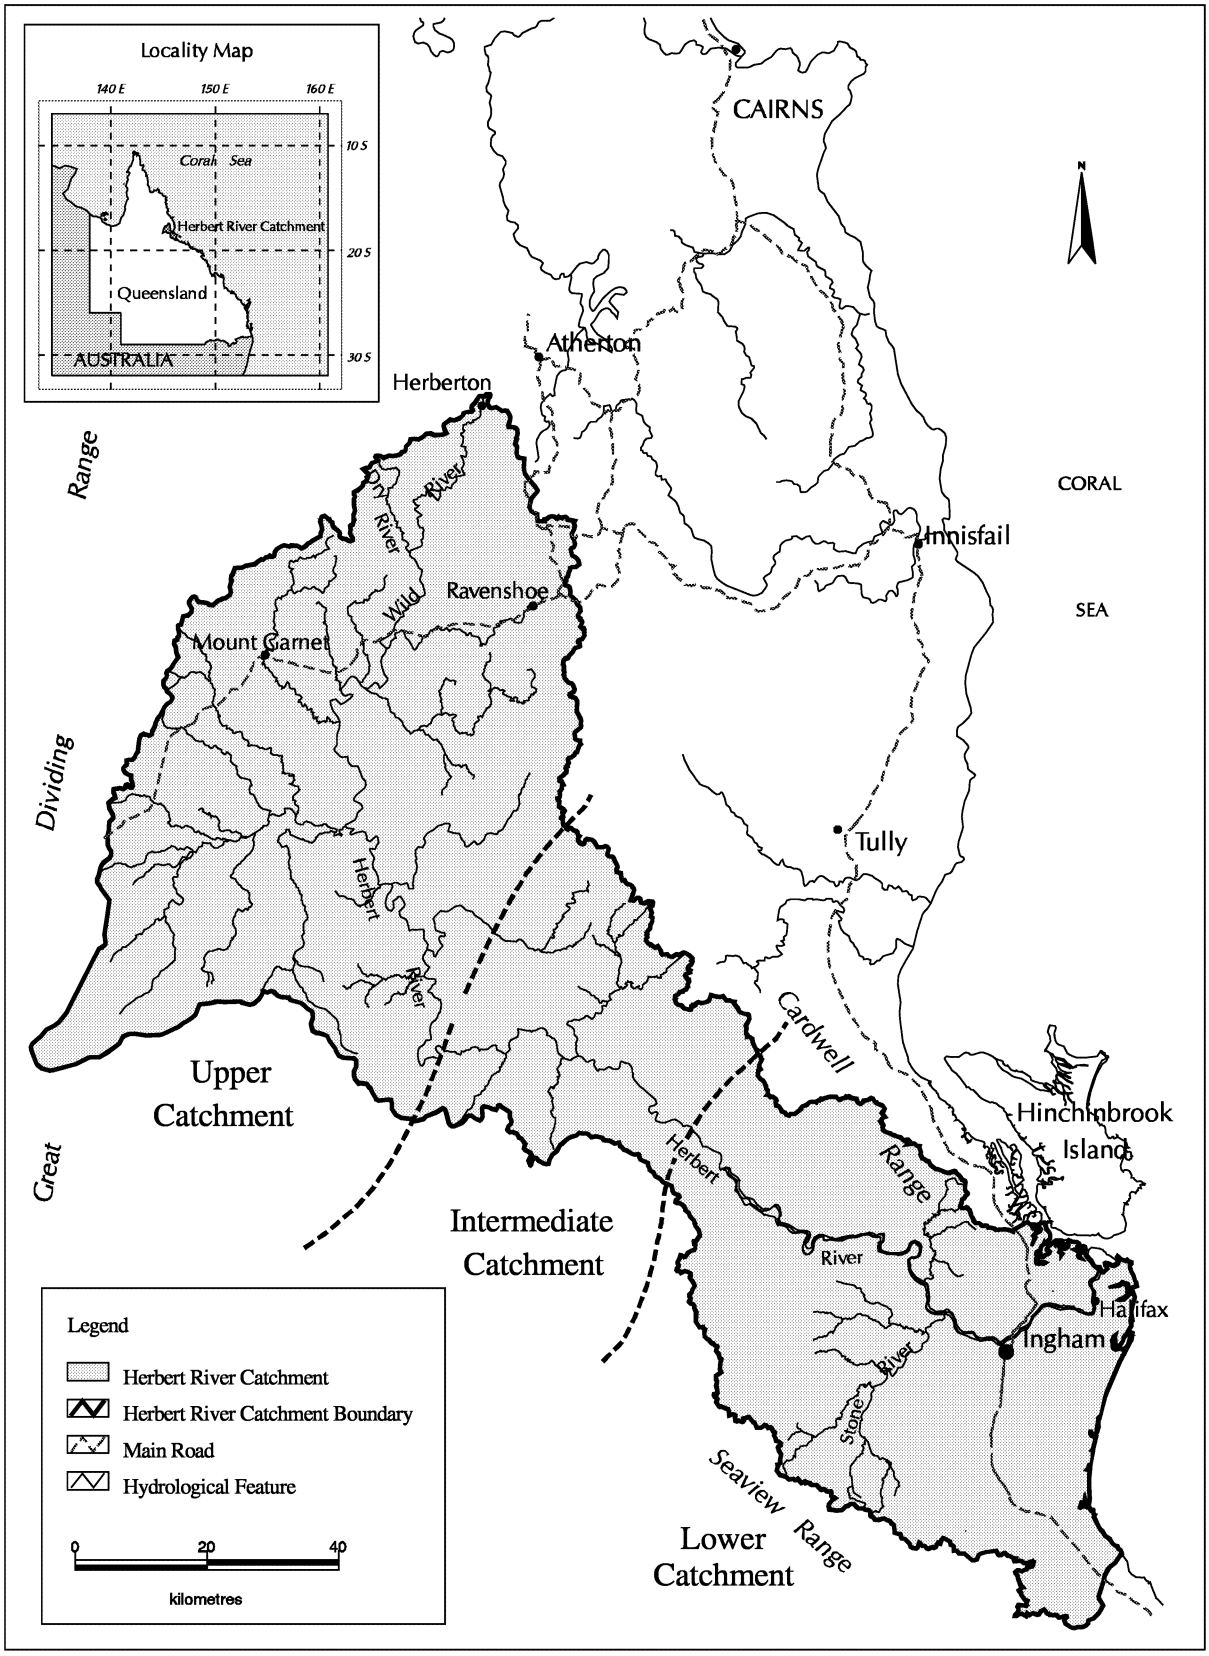

Figure 1. Herbert River Catchment.

initiative is therefore only one of a number of processes and policy initiatives all designed to influence the way natural resources are used and managed.

The implementation of ICM in Queensland is based on the establishment of Catchment Coordinating Committees (CCC). The Queensland Integrated Catchment management Strategy (QDPI 1991) identifies that:

> Catchment Coordinating Committees are established to address complex catchment management issues that involve many community groups and government agencies. Catchment Coordinating Committees comprise representatives of the major sectors of the community and government that are involved in, or influenced by the management of land and water resources in the catchment. Their major roles are to provide a forum for community input and discussion, to prioritise the issues and to develop and promote the adoption of catchment management strategies.

In December 1997, there were 29 Catchment Coordinating Committees (including 2 regional groups) formally recognised under the Queensland State Government's ICM initiative (Rowland and Begbie 1997).

Herbert River Catchment Coordinating Committee

ICM in the Herbert River catchment is a community-led and voluntary process in a formative stage. It commenced in 1992 with the formation of a Catchment Steering Committee of community leaders and government agency representatives, which established the Herbert River Catchment Coordinating Committee (HRCCC) in early 1993. A full time Catchment Coordinator was appointed to the HRCCC in April 1994. This position is funded through the federal government's National Landcare Program and based in the Department of Natural Resources, the lead government agency for ICM in Queensland. In addition, local stakeholder groups including Local Government and sugar industry bodies have provided in-kind support in terms of office accommodation, administrative support and their HRCCC member's time. State and federal government grants that are awarded through a competitive bidding process also financially support most HRCCC activities.

1.2 Methodology

1.2.1 Research Framework

Because of the evolving and holistic nature of the concept of integrated resource management, evaluations of ICM programs or processes require criteria from the environmental, social, economic and policy sciences. Bellamy *et al.* (In press) have developed a conceptual framework for evaluating integrated resource management programs that identifies a range of environmental, policy/institutional, economic, social and technological factors (Figure 2). This evaluation framework adapts the Mazmanian-Sabatier framework (Mazmanian and Sabatier 1981; Sabatier 1986) that identified a variety of legal, political and 'tractability' factors that impact on the different stages of policy implementation. The framework also includes socially significant evaluation indices such as inclusiveness, adequacy, equitableness, effectiveness, efficiency, and democratic involvement (eg. Crane 1988), and recognition of the principles of the PRIME procedural model (Syme *et al.* 1994). This latter model recognises that evaluation needs to cope with multiple parallel tasks occurring at all times. Some of these tasks will be dealing with planning; some with research monitoring and evaluation. The PRIME model also recognises that there should be appropriate areas of influence in the evaluation process by the community as well as agencies.

The framework presented in Figure 2 provides a conceptual model for identifying the causal elements impacting on ICM programs and for establishing the hypotheses to be tested. As such, it also provides a tool to structure multidisciplinary research on the effectiveness of ICM programs. The four key elements of the evaluation framework are:

- Natural resource issue characterisation
- IRM program context
- Institutional structure
- Community processes.

For each of these elements, the framework identifies variables that may potentially influence the ICM program implementation process and its outcomes. This framework has been used to structure the questionnaires for the two surveys of the HRCCC members.

1.2.2 Research Design and Approach

The second survey of HRCCC member's opinions contained selected items repeated from the first survey as well as a range of new questions focussed on HRCCC activities and ICM issues relevant to the context of a process in its fifth year of operation. Items in the survey related to:

- interviewee background information
- attitudes towards HRCCC activities and achievements
- perspectives on key natural resource management issues
- perspectives on roles and responsibilities of CCCs
- use of information sources
- attitudes on the Catchment Management Strategy development process
- perspectives on public attitudes, community support for ICM
- sector involvement in the ICM process
- perspectives on factors influencing ICM implementation
- personal demands and motivation.

The survey was administered to each of the current HRCCC members as individual face-to-face semi-structured interviews based on a pre-set questionnaire. Some questions asked were open-ended, while others required the interviewee to rate their response on a five-point scale. The questionnaire is included in this report as Appendix 1.

Interviews were conducted with 15 of the HRCCC members in November 1997, and a further 3 members not available at that time were interviewed in February 1998. An interviewer supported by a person recording responses conducted the interviews. Due to time constraints in some interviews some questions were omitted and were recorded as 'no response'.

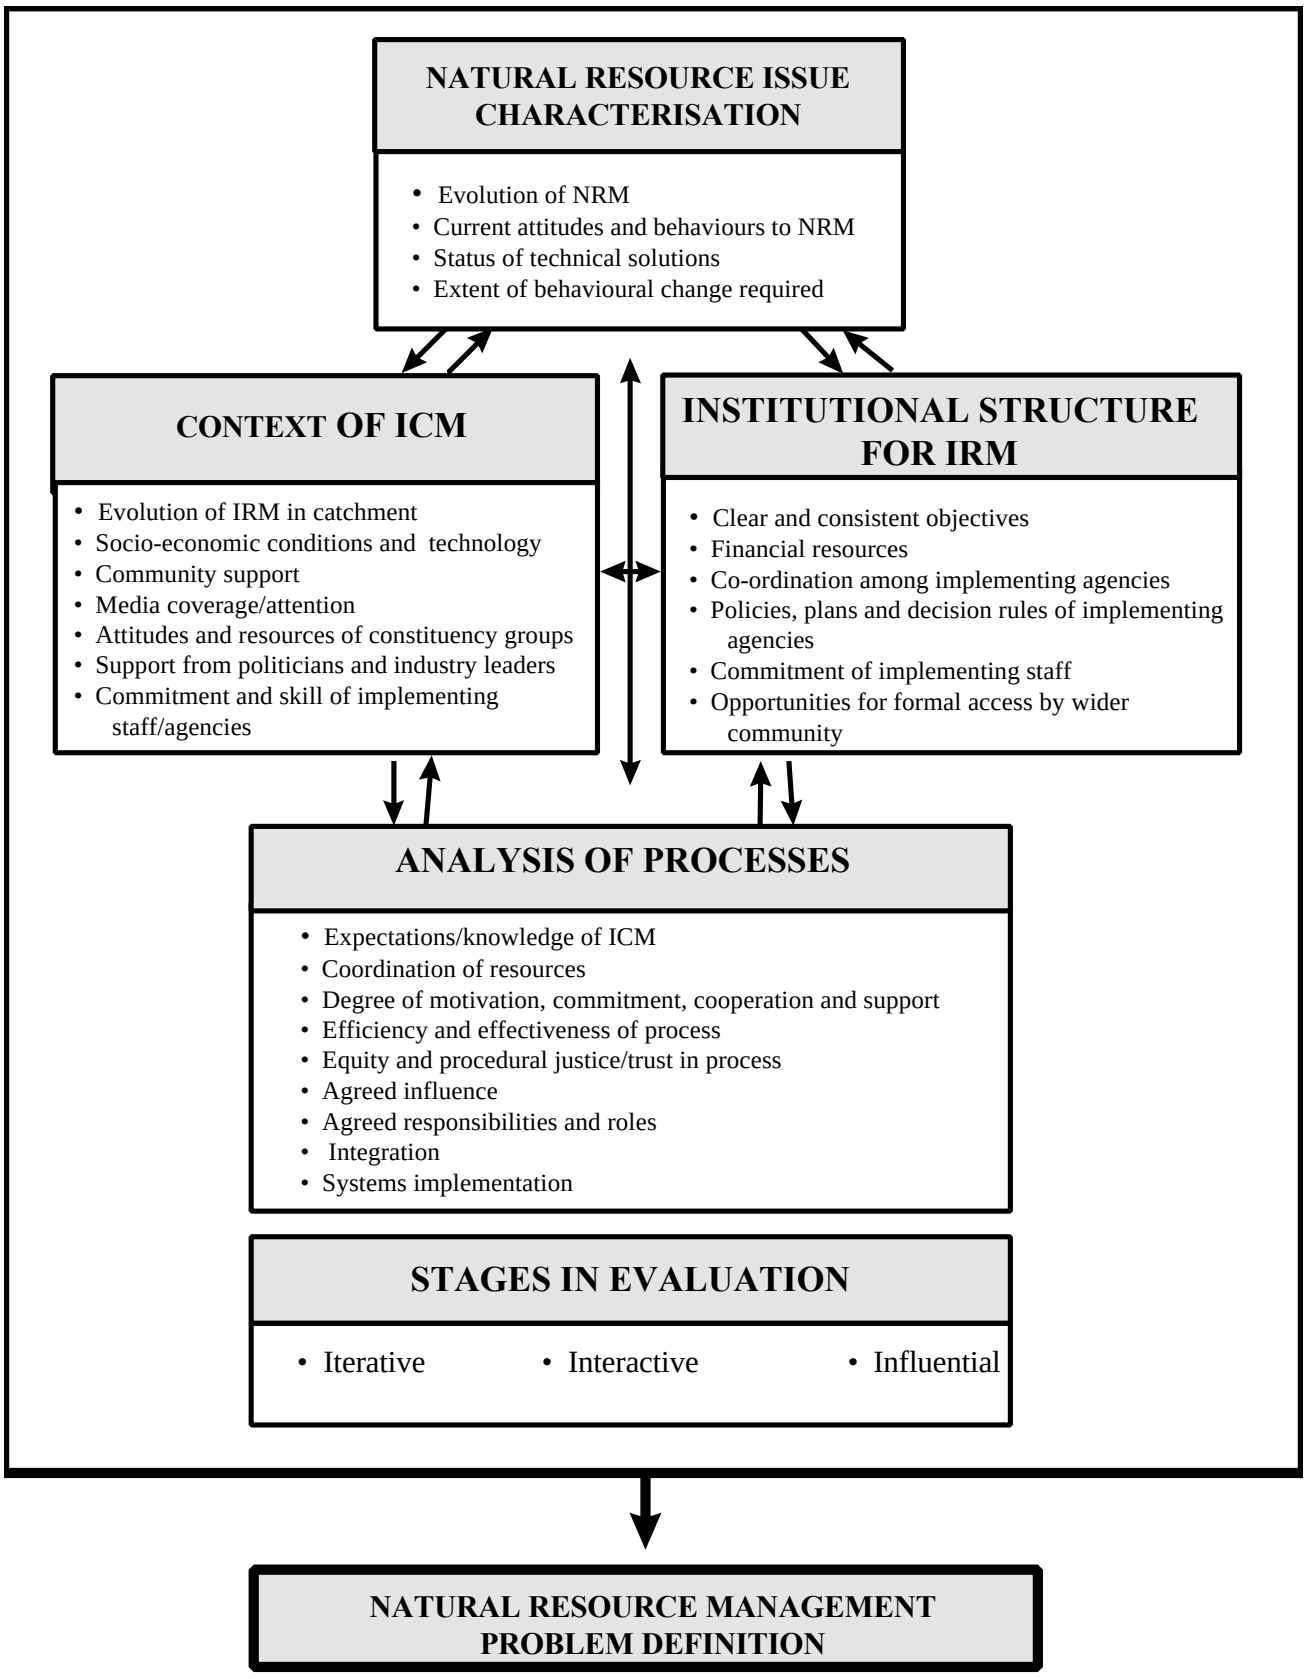

Figure 2. A conceptual framework for the evaluation of IRM programs (Bellamy et al In press)

SURVEY RESULTS

1.3 HRCCC Membership

2.1.1 Representation

In November 1997, there were 17 active voluntary sector members of the HRCCC plus a full-time Catchment Coordinator. These members were nominated to represent a range of rural industry, community and government or other statutory organisations that were considered to have an interest and/or role in natural resource management in the Herbert River catchment, as identified in Table 1.

Table 2.1: HRCCC sector group representation.

Industry	CANEGROWERS (1) CSR Herbert River Mills (1) Cattlemans Union (1) Horticulture/Rare Fruits (1) Queensland Commercial Fishing Organisation (1)
Community Group	Hinchinbrook Citizen's Association (1) Recreational/Sporting Fishing (1) Landcare (1) Wildlife Preservation Society of Queensland (1) Herberton Shire Community/Landcare (1)
Government/Statutory Body	Hinchinbrook Shire Council (3) Herberton Shire Council (1) Herbert River Improvement Trust/Drainage Boards (1) Hinchinbrook Development Bureau (1) Herbert Pest and Productivity Board (1)

The HRCCC has no state government departmental representatives. However, a Catchment Coordinator facilitates the process. This position is funded through the federal government's National Landcare Program and based in the Ingham offices of the Department of Natural Resources, the current lead government agency for ICM in Queensland.

2.1.2 Member Profiles

Table 2 summarises responses to Questions 1, 2, 3 and 4 of the survey. Two members are from the upper catchment (i.e. the Herberton Shire) and the remainder of the Committee members including the Catchment Coordinator live in the lower catchment (Hinchinbrook Shire). Ten members have lived in the catchment for over 40 years and only 3 less than 20 years. Nine of the current members have been involved with the HRCCC since its inception in March 1993 and several were on the original Steering Committee that established the ICM process in the Herbert in 1992. Most of the members are active community members with multiple allegiances and interests. For example, one of the local government representatives on the HRCCC is also a sugarcane farmer and a beef cattle producer. Similarly, the Herbert Pest and Productivity Board representative is also a member of the CANEGROWERS executive and Chairman of the Herbert River Improvement Trust (HRIT). Notably, nine members are cane farmers and two others are employed within the sugar industry. This reflects the economic, social and cultural importance of the sugar industry in the lower Herbert River community.

Table 2. Member profiles

Years lived in catchment?	Upper/Lower catchment	Member of HRCCC since?	Group representing on HRCCC	Occupation
49	Lower	1997	Commercial fishing	Fisherman,
25	Upper	1997	Herberton Shire Council	canefarmer
8	Upper	1994	Community group[1]	Retired miner
21	Lower	1993	Conservation sector	Farmer
48	Lower	1996	Grazing industry[2]	Teacher
10	Lower	1993	CANEGROWERS	Canefarmer, cattleman
22	Lower	1993	Sugar industry (CSR)	Manager
60	Lower	1993	Community group	Technical Field
61	Lower	1993	Landcare[3]	Officer
22	Lower	1993	Development Bureau	Canefarmer
43	Lower	1993	HRIT/Drainage Board[4]	Canefarmer
23	Lower	1995	Hinchinbrook Shire Council[5]	Manager
55	Lower	1997	Recreational/Sports fishing[2]	Canefarmer,
5	Lower	1994	Catchment Coordinator	contractor
49	Lower	1993	Pest &Productivity Board[3,5]	Engineer
45	Lower	1997	Hinchinbrook Shire Council	Canefarmer
43	Lower	1994	Hinchinbrook Shire Council	Extension Officer
45	Lower	1993	Horticulture/Rare fruits	Canefarmer
				Canefarmer
				Mayor/Real Estate
				Canefarmer/Rare fruits

1. Also a member of Mt. Garnet Landcare group in upper catchment
2. Also a member of Landcare group in lower catchment
3. Also member of CANEGROWERS Executive
4. Also Hinchinbrook Shire Council
5. Also member of the HRIT

2.2 HRCCC Activities and Achievements

2.2.1 What has been the major achievements to-date of the HRCCC?

HRCCC members overall considered the HRCCC had made a number of worthwhile achievements including:

(a) *the preparation of the Herbert River Catchment Strategy*:

"creating and sharing a vision (e.g. riparian vegetation to be maintained and restored)"

(b) *HRCCC meetings providing a forum that brings people together in the catchment with very different views*:

".. bring people together who would not normally be together, on ESD, (e.g. Council, CANEGROWERS, conservation, cattlemen) and bringing that relationship out into the open. There is no other forum like it."

"Providing a forum for different views"

"Linked Herbert and Hinchinbrook Shire communities. Decisions made in the Upper Catchment impact on the lower catchment. ICM has bought diverse groups together with a common focus."

(c) *Raising awareness of catchment problems amongst members and within the community*:

" Awareness that the community has a group that is looking at problems and trying to address them. Bringing people together at catchment level, and getting some cooperation over e.g. tin mines. Raising awareness at whole catchment level."

"Bringing awareness of riparian/wetlands on board (e.g. riparian forum)."

"Improved the awareness of landowners and land users"

(d) *Getting funding for a range of projects*:

"Making the community more aware through demonstration projects."

"Projects were needed and would not have been done otherwise."

(e) *Taking on a coordinative and integrative role in the region*:

"ICM is trying to co-ordinate community group projects and facilitate development of project proposals (across local community, shires, regional groups) and are using workshops to do this that involves all 3 levels as well as to identify project leaders. Stopping duplication and competition."

" taking on a coordinative role - integration with HRIT and Pest and Productivity Board work"

"Combined with HRIT to fix the Long Pocket channel."

(f) *Recognition as a source of advice on natural resource issues in the catchment*:

"Council seeking our advice - seen as a consulting body."

"People turn to them for advice"

"Able to get all different groups together and talk, and although no teeth, can give advice. Consultation process allowed this. Getting more recognition as a source of advice to do with the shire. "

Most members were positive about the HRCCC achievements. However, some members expressed some frustration with the perceived mediocrity of the group's achievements. One member could not identify any particular achievements worth noting, and another felt that "not a lot of things have been done". This latter comment however was qualified as reflecting more on the slow rate of progress than the direction the HRCCC was taking. A third member, while noting some "Landcare activities, such as owl boxes", and the HRCCC raising awareness of riparian/wetland issues in the catchment (e.g. through the riparian forum), commented that the HRCCC had "started the ball rolling but had not gone though with it". Several of the newest members were not aware of any specific achievements.

2.2.2 What are some of the most significant projects?

Members were asked to identify a significant of projects or activities undertaken by the HRCCC. The most commonly identified were**:**

- Project with HRIT at Long Pocket wash away.
- Several Owl nesting box program
- Joint restoration and revegetation projects (e.g. Wharps area, riparian area management, artificial wetland development, tree planting).
- Riparian vegetation mapping study
- Riparian "community" forum.
- Acid sulphate soils awareness.

2.2.3 Satisfaction with HRCCC progress?

Members were asked to rate their satisfaction with the progress of the HRCCC on a five-point scale from very satisfied to very unsatisfied. The results are summarised in Table 2.3. 14 members rated their satisfaction with the HRCCC's progress as either 'very satisfied' or 'satisfied', one was 'neither satisfied or dissatisfied', three were 'unsatisfied' with progress and there were no ratings of 'very unsatisfied'.

Table 2.3. Satisfaction rating with HRCCC progress.

	Satisfaction
Very satisfied	1
Satisfied	13
Neither	1
Unsatisfied	3
Very Unsatisfied	0
No Response	0

The reasons identified for a 'satisfied' or 'very satisfied' rating on progress related to the difficulty of the issues, long term nature of process, and community awareness/acceptance issues. Comments included:

"Process is working (not being held up)."
"The issues are difficult - useful forum that's doing well under the circumstance."
"Going as fast as it can proceed - on a learning curve for members including their role. Also in terms of community awareness."
"Better understanding across community and amongst local government, industry and community to coordinate and maintain drainage works. Now opportunities to address soil erosion or water quality at community level."
"Are meeting, getting projects and chasing up on issues and submissions."
"Like it to go a lot faster but not able to do this as it is a slow process getting public acceptance. Also important aspect is the large size and have involvement of lower and upper catchment - which is important to get both (critical difference, from HRIT which is only concerned with lower catchment)."
"Committee doing relatively OK - going 5.5 years - just slow process - because of need for structural change, it takes time."
"Sometimes can be bogged down, but establishing foundations for the future."
"HRCCC has done well but could have gone further."
"Frustrated at speed of implementation of ideas for which there seem to be consensus."

The reasons for either an 'unsatisfied' or a 'neither satisfied or dissatisfied' rating related to the rate of progress, community awareness of ICM, vested interests, and lack of legislative base. Specific comments were:

"Coordination of riparian [issue] is happening but ICM could have made it happen rather than individual farmers. Slightly dissatisfied with the rate of progress rather then the direction."

"Not really working for the real fundamentals of district needs. Lack of public awareness of ICM. Too much interference behind the scenes is hampering it. Taking much too much time."

"Too many vested interests protecting their castles/interests."

"Community does not have power - specifically legislative power."

2.2.4 Improving Performance

Suggestions on improving performance from those members who were 'satisfied' and 'very satisfied' with progress included better publicisation of ICM and the HRCCC in the community, ensuring ICM's legitimacy, better coordination and cooperation amongst state government agencies, support of legislative powers, and adequacy and security of funding. Some specific comments were:

"More exposure in the media to get a name (e.g. Long Pocket process only in the media once it was completed)"

"Catchment group not necessarily seen as representative of the community. Many have an interest but do not bother to get involved. Often not fully aware of the concept and yell when hits them directly. "

"Catchment committee needs to be better known in the community. Needs a bit of strength behind it."

"Issue of who is responsible for resource management needs to be clarified. Catchment Coordinator cannot do it all. Problem of responsibilities across agencies and effective and real coordination of all agencies. Better if agencies were coordinated. Lack of talk between state government agencies is an issue."

"Industry, local government, state government and federal government need to all work together effectively to address drainage issue. ICM is promoting good things to be done in the community and it should avoid ear bashing from extreme views."

"Give it legislative backing - this is essential. (Not because of the powers that are potential - there are so many agencies with powers). Also needs adequate funding, e.g. seed funding for infrastructure."

"Need to improve the legitimacy of ICM. State Government needs to facilitate projects, etc. which would speed up implementation."

"If the HRCCC had more money it could do more. For one thing, the CCC is a big job."

"Coordinator requires additional/financial support and a more secure position."

While suggestions on improving performance from those members who were 'unsatisfied' and 'neither satisfied nor dissatisfied" with progress related to the HRCCC being more proactive (versus opportunistic), communicating better with the community and having support of regulatory powers. Comments included:

"More progress on the ground needed. ICM could be more proactive rather then opportunistic (not touching the big issues such as levee banks)."

"Public communication - e.g. Public meetings, industry branch meeting, etc. Lack of public awareness of ICM needs to be addressed. Need heavy penalties on people not doing the right thing."

"Need to be more proactive and up front, involved with the media, and talking to people (e.g. recent land clearing of riparian areas)"

"ICM needs regulatory power. Consultation process can slow implementation."

2.3 Problem Characterisation and CCC Role

2.3.1 Key Resource Management Issues.

The key resource management issues identified by members fall into a number of categories (not in priority order):

(a) *river water quality* (e.g. impacts of mill waste discharge, fish kills, acid sulphate soils impact, waste water from septics, sedimentation from upper catchment from soil erosion due to either overgrazing or tin mines and tailing dams).
(b) *river management* (e.g. environmental flows, new dams for irrigation, stabilisation of river banks)
(c) *rural drainage* (e.g. rationalisation of river bank levees, infrastructure works).
(d) *riparian zone management* (e.g. revegetation of river banks, buffer zones, exclusion of cattle, weed management)
(e) *wetland degradation* (e.g. preservation and restoration within agricultural lands, fish and wildlife preservation).
(f) *caneland expansion* (e.g. need for land use planning, impacts on remnant vegetation, wildlife corridors, destruction of habitats, drainage works).
(g) *pest and weed management* (e.g. rubber vine, hymenachne, owl boxes/rat control).
(h) *coordinated extension approach* (e.g. avoidance of fragmented approach and often mixed messages, need to push sustainability issues).
(i) *catchment planning* (e.g. land use, coastal management, flood protection/management, catchment rehabilitation).

2.3.2 HRCCC Role in Natural Resource Management

Members rated their agreement/disagreement on four statements relating to the HRCCC's role in natural resource management on a five-point scale from strongly agree to strongly disagree. In general there was reasonable concurrence amongst HRCCC members in respect of these statements. The results are summarised in Table 2.4 and briefly discussed below.

a. The HRCCC helped negotiation among resource stakeholders to accommodate a wide range of resource uses?

Most members agreed with this statement, with 1 member giving a 'strongly agree' rating and 14 others an 'agree' rating in respect of the HRCCC's role. Two members disagreed with the statement but there were no 'strongly disagree' ratings. Specific comments included:

> "Agree - In some small areas"
>
> "Agree - have brought people around the table"

Two members agreed that the HRCCC is helping define the source of resource problems, but disagreed that it was identifying solutions to them.

b. The HRCCC helped stakeholders in defining the source of resource problems and solutions to them?

Most members agreed with this statement, with one member giving a 'strongly agree' rating and 13 others an 'agree' rating in respect of the HRCCC's role. One member disagreed with the statement, two others gave a 'neither agree or disagree' rating, but there were no 'strongly disagree' ratings.

> "Neither agree or disagree - beginning to happen now."
>
> "Agree - For example, riparian vegetation mapping"
>
> "Disagree - not yet helping define the source of problems – doesn't fully

understand the problems."

c. The HRCCC helped stakeholders in ensuring their resource management practices are effective, efficient, equitable, accountable?

Most members agreed with this statement, with 1 member giving a 'strongly agree' rating and 14 others an 'agree' rating in respect of the HRCCC's role. Two members disagreed with the statement but there were no 'strongly disagree' ratings.

"Agree - Just beginning in upper catchment"

"Agree - but only starting"

"Agree - HRCCC starting to get a mediation role with Landcare (e.g. weed management)"

"Agree - Cooperating with BSES to get better advice out to farmers. Also starting to get extension officers."

"Neither - Have not achieved this but Committee likes to think it has"

d. The HRCCC encouraged research and data gathering and analysis in order that solutions to resource problems can be better understood?

Most members agreed or strongly agreed with this statement, with 5 member giving a 'strongly agree' rating and 10 others an 'agree' rating in respect of the HRCCC's role. One member disagreed with the statement, another gave a 'neither agree or disagree' rating, but there were no 'strongly disagree' ratings.

"Agree - what HRCCC is doing is a starting point - and others do the research"

"Agree - e.g. relationship to CSIRO and NLP/NHT"

"Disagree - HRCCC has been a partner but not encouraging it"

Table 2.4. Agreement/disagreement ratings with statements on the HRCCC's role.

	Strongly Agree	Agree	Neither	Disagree	Strongly Disagree	Don't Know	No Response
a. Helped negotiation among resource stakeholders to accommodate a wide range of resource uses	1	14	1	2	0	0	0
b. Helped stakeholders in defining the source of resource problems and solutions to them	1	13	2	1	0	1	0
c. Helped stakeholders in ensuring their resource management practices are effective, efficient, equitable, accountable	1	14	1	2	0	0	0
d. Encouraged research and data gathering and analysis in order that solutions to resource problems can be better understood	5	10	1	1	0	0	1

2.3.3 HRCCC Role in regional resource management

Members identified a number of roles that the HRCCC has played in regional resource management, which can be summarised under four broad themes:

- contributing to the improvement of the overall information base that is available to underpin decision making on natural resource issues in the catchment (e.g. riparian vegetation mapping)
- bringing together catchment stakeholders and developing better understanding as well as raising awareness of natural resource issues.
- facilitating cooperation across stakeholder groups to get things achieved that one alone could not.
- having an advisory and influencing role on planning processes in the catchment, in particular through working in partnership with Local Government and the HRIT.

However there was a divergence of views amongst HRCCC members, with some concerns being expressed by several members on the perceived limited influence the HRCCC has had at the regional level. Comments included:

> "Bringing together stakeholders. This results in a broader definition of stakeholders. Facilitative role. However, only small input."
>
> "Trying to do something but getting diffused because of conflicts of interest amongst members, i.e. lack of real support. Very modest role to date"
>
> "It's a social "structure" without backing, it has no teeth. They go in begging to be heard. They are mainly involved in smallish issues that they could handle and not the bigger mainline issues like the land allocation process."
>
> "Where problems - they have addressed them. Tailings dam in upper; sedimentation in the lower. Currently pretty fragmented but as time goes along it will get better."
>
> "Not sure how ICM is feeding into regional managers because of structures not facilitating the process."
>
> "Once get strategy up need to follow that. ICM at present a little tied up in what it can do - we are not really doing anything - never get consensus; 7/8 of committee more on protecting the environment - people coming around.. Because it is voluntary there is no real power only through the Council who are looking to HRCCC for guidance (e.g. Riparian issue). Voluntary process - limited what it can do but working with Councils is OK, but also getting involved as adviser to other activities."
>
> "ICM has not had legitimacy to have had a significant impact."

2.3.4 How well suited is ICM in Queensland to address resource use and management issues?

HRCCC members were asked to express their opinion on how well ICM in Queensland was suited to addressing resource use and management issues within the Herbert River catchment. Most members (i.e. 14) in general considered that ICM was well suited to addressing natural resource issues in the Herbert. Responses are summarised in Table 2.5.

Table 2.5. Perspectives on the suitability of ICM to addressing natural resource issues in the Herbert

Well suited/ideal	Not sure	Not suited	No response
14	2	1	1

The most common comments made in support of ICM's suitability in the Herbert River catchment context related to ICM's strength in its community basis, its inclusiveness of catchment stakeholders and its linkages to local authoritative bodies. For example:

> "Yes, cannot think of anything that would be better. ….Its strength is in its community based approach. Dominance of community members is good."
>
> "All the views are in the HRCCC and listened to."
>
> "Good model for participation."
>
> "Yes, from the grass roots perspective its working."
>
> "Yes it is the first time the whole river top to bottom has had dialogue focused on the whole catchment and people are keen to come to meetings. A community based program. All stakeholders allowed a seat around the table."
>
> Yes, from the grass roots perspective it's working. Little input from the [State] Government. Important for it to amalgamate with HRIT - as CCC gives ideas, HRIT does the doing - so does not really need legislation.
>
> Ideal. Certainly establishing itself. Got to be community driven and include Local Government.
>
> "Well suited. Membership of ICM has been selected so that all relevant user groups have been involved."
>
> "Well suited. Existing advisory bodies (BSES) are biased. ICM represents more than vested interests."

However these comments were qualified by a range of concerns raised by members. These concerns, in particular, related to ICM's lack of enforcing power, its limited resources (e.g. financial, extension staff) and the limitations imposed by the lack of coordination across State Government agencies. Members' comments for example included:

> "I am worried that ICM might not have any teeth, but I support the community basis."
>
> "Sometimes I think it should have more teeth. It exists as a voluntary group but has no enforcing power, it can only make a recommendation. I do not see that a model for ICM that has a big stick approach would work. "
>
> "Good in proceeding as fast as the local authorities will allow it to proceed. There are also limitations imposed by state government bureaucracies (e.g. lack of a generic set of rules that are locally established) and lack of coordination across state government agencies."
>
> "Not only do government departments fight between each other but agencies also

within one department fight with each other."

"I find the conflict between government departments unbelievable."

"ICM is limited by the financial situation. It also allows for a lot of local political intervention. There is a lack of co-ordination amongst stakeholder groups. The local committee lacks the clout to implement things - it needs power to influence state government. We do not want appointed officials on it, rather it needs rank and file representatives."

"Not sure ICM is the vehicle without the statutory backing. It needs to have a good link to local government and the River Improvement Trust process. …. Sees problem in ICM or Landcare groups having the right to actually stop people doing things on the ground - rather it should be an independent body / government responsibility."

2.4 Information Use and Access

2.4.1 Types of information

HRCCC members were asked their opinion on whether specified types of information had been useful in supporting the Herbert ICM program and its activities. Of those members for which a response was recorded, the types of information perceived to be most useful were:

- catchment natural resources
- land use
- options for funding of ICM and other community activities
- government policies and regulations on natural resources and related issues
- government institutional arrangements for ICM, Landcare, natural resource management and related issues.

Importantly, it was also noted by several members that 'local input' or 'knowledge of committee members' was a key source of information to the Herbert ICM process. Details of the responses recorded for this question are summarised in Table 2.6.

Table 2.6. Types of information and its usefulness to the Herbert ICM process.

	Very Useful	Useful	Neither	Not Useful	No Response
a. Catchment natural resources	10	2	0	0	6
b. Population and land use in your catchment?	7	5	0	0	6
c. Local organisations, industry and community groups in your catchment?	1	6	2	0	9
d. Government institutional arrangements for ICM, Landcare, natural resources, and related issues?	4	3	1	0	10
e. Government policies and regulations on natural resources and related issues?	4	4	0	0	10
f. Options for funding of ICM and other community activities?	5	4	0	0	9
g. Group management and administration?	2	3	2	0	11

2.4.2 Herbert River Catchment Atlas

Nearly all members were aware of the existence of the Herbert River Catchment Atlas (Johnson and Murray 1997) which was launched at a HRCCC meeting in June 1997 (see Table 2.7).

Table 2.7. HRCCC member awareness of the Catchment Atlas.

Awareness	Responses
Aware	15
Not aware	1
No response	2

Only one member identified having personally used the Atlas. However, it was noted that the Atlas particularly in its CD-form was being used widely by local schools. Most members were impressed with its potential usefulness, particularly for children and as a general reference for raising awareness of the Herbert catchment and its resources.

2.4.3 Herbert Resources Information Centre

Members were asked if they had used the Herbert Resources Information Centre (HRIC). Nine members had made use of it for a range of purposes (e.g. retrieval of natural resource and land use information for cane growers, industry planning, cane assignment issues, planning transport routes, and local government decision making needs). In general, the HRIC was perceived as a valuable resource for ICM, in particular in a planning context and for interpretative analysis to underpin catchment management decision-making. Several members expressed an interest in visiting the Centre and finding out more about what it is doing and its potential use within the Herbert community.

2.5 Catchment Strategy

2.5.1 Purpose of the Catchment Strategy

Members were asked for what purpose did the HRCCC prepare the Herbert River Catchment Strategy in 1996. Five members identified that they had not been involved in the strategy preparation and were not aware or could not comment on its purpose. For the members who were involved in the strategy preparation or were familiar with the strategy, there was in general concurrence amongst HRCCC members on its key purposes:

- to provide a future direction to the group and guide future actions (e.g. identified issues, prioritised needs, identified stakeholders and their roles, provided a reference point to start from); and
- to get resources and support for ICM in the Herbert (e.g. get funding for Catchment Coordinator and natural resource projects; get commitment of State Government to undertake projects).

2.5.2 Usefulness of the Strategy Development Process.

Similarly, five members who had not been involved in the strategy development did not offer a response on its usefulness. Of the 13 members who were involved in the preparation of the Catchment Strategy, 12 found the process useful, while one member rated it as not being really useful.

A range of reasons were given for the perceived usefulness of the process:

- *inclusiveness and transparency*: bringing all viewpoints on issues together and out into the open
- *establishing direction*: helped focus the group and provided some direction
- *raising awareness*: improving Committee member's awareness of issues and other stakeholder viewpoints
- *identifying areas of agreement*: leading to agreement on some issues and the development of better projects.

However some concerns were expressed regarding the lack of resolution on some key issues, and the failure for the strategy to have a significant impact on what the Committee was currently doing. While the member who did not find the process useful felt that the process had only "identified problems we already knew about".

2.5.3 Approach to Strategy Development

The Catchment Coordinator conducted an initial workshop with committee members to discuss the strategy process and to agree on a list of priority issues to be developed further through small working groups. Each member then identified their area(s) of particular interest to form five working groups. The working groups scoped the issues further and the outcomes were then reviewed by all interested Committee members. The Catchment Coordinator then incorporated all the information and comments from members into a final draft strategy document which was sent for approval by DNR Head Office.

The Draft Catchment Strategy was "launched' by the HRCCC in June 1997 for public comment but so far no real feedback or official comment has been received.

2.5.4 Improving the Process

Members were also asked whether anything should or could have been done to improve the strategy development process. The majority of members did not perceive that in general much else could have been done and were reasonably satisfied with what had been done at the time. For example, comments included:

> "No glaring mistakes."
>
> "Not really, reasonable job at the time."
>
> "No- happy the way it was - gave a good base to start and can only be improved upon."
>
> "No - do not know what else could be done"

However, one member felt the process could have been improved but was not sure in what way:

> "The strategy is a bit "dreamy". It has a tendency to overlook the economic side of things - more balance is needed in looking at whether the strategies are viable for stakeholders, and there is a need to look at the reality of individuals in the catchment context."

Two other members felt that the development process for the Draft Strategy should have included more people beyond just the HRCCC members:

> "There is an issue of the wrong people involved in its development - more community/landholder involvement was needed. It did not make good use of local knowledge in the community."
>
> "Could not have been improved internally, but externally it could have gone a lot wider."

Similarly, one other member expressed dissatisfaction with the DNR approval process:

> "There was a problem with the government approving the strategy - it went into the system and just sat there. The HRCCC could not do anything."

2.6 Public Attitudes, Support and Involvement

2.6.1 Level of Public Awareness on Natural Resource Issues

Members perspectives were sought on the level of public awareness on natural resource issues within the Herbert catchment community on a five point scale from 'very low' to 'very high'. In general, HRCCC members perceived that the rural community's awareness was overall substantially higher than the urban community's awareness. The results are summarised in Table 2.8.

Table 2.8. Perspectives on public awareness of natural resource issues in the Herbert catchment.

Rating	Rural	Urban
Very high	3	1
High	7	2
Moderate	3	6
Low	3	1
Very low	2	7
Don't know	0	1

Members perspectives were also sought on whether public awareness had changed over the last year, and if so, in what way. 15 members felt awareness had changed, while 3 felt there had been no change. Of those members that perceived a change, all considered that the trend was "improving" or "increasing". This improvement was seen by some as being only "slowly" but others felt a more marked change was occurring. The reasons for the improvement were not necessarily seen to be related to the Herbert ICM process, although the HRCCC was perceived as the body taking the issues on. The most common reasons given for change related to specific well publicised or controversial issues such as cattle-to-cane land conversion, land clearing for caneland expansion, owl boxes, fish kills in the river, damming of streams and acid sulphate soils.

There was some divergence of opinion on whether the increase in awareness had been greater for the urban or rural populations.

2.6.2 Level of Public Support for the HRCCC

HRCCC members were asked to rate their opinion on a five-point scale (from very high to very low) of the level of public support for the HRCCC. There was a divergence of opinion on this question amongst HRCCC members as shown in Table 2.9.

Table 2.9 Opinions on the level of public support for the HRCCC.

Rating	No. of Responses
Very high	1
High	3
Moderate	6
Low	6
Very Low	1
Don't know	1

Of those 12 members rating public support as low or moderate, six considered that support was definitely growing. This was in part attributed to HRCCC's on-ground projects and to high profile events in the catchment bringing attention to the HRCCC. However it was also suggested that many people did not really understand what the HRCCC does and that this needed attention.

2.6.3 Effectiveness of Stakeholder Involvement

The HRCCC members were asked to rate on a five point scale (from very effective to very ineffective) the involvement in the Herbert ICM process of a range of stakeholder groups. The results are presented in Table 2.10.

Table 2.10. Opinions on the effectiveness of stakeholder group involvement.

	Very Effective	Effective	Neither	Ineffective	Very Ineffective	Not Applicable	No Response
a. Rural producers	7	7	1	2	0	0	1
b. Local government politicians	3	11	0	3	0	0	1
c. Local government administrators	5	8	1	3	0	0	1
d. State government politicians	1	5	5	5	0	0	2
State Government agencies: e. DPI	1	5	2	7	1	0	2
f. DNR Forestry	1	5	5	4	0	2	1
g. DNR Land Management	0	9	3	3	0	1	2
h. DNR Lands Administration	0	5	6	4	1	1	1
i. DNR Water Resources	1	8	5	2	0	0	2
j. Department of Environment	1	6	6	1	1	1	2
k. Local Government and Planning	0	7	6	2	0	1	2
l. River Improvement Trust	5	12	0	0	0	0	1
m. Drainage Board(s)	4	8	2	1	0	2	1
n. Rural Industry Organisations	3	10	0	0	0	1	4
o. Environmental Organisations	4	5	3	2	1	1	2
p. The Media	2	8	1	5	0	0	2
q. Landcare Groups	3	9	1	2	1	0	2

Overall effective or very effective involvement was attributed most commonly to rural producers, local government politicians and administrators, the Herbert River Improvement Trust, the Drainage Boards, rural industry organisations and Landcare groups. Ineffective or very ineffective involvement was attributed most commonly to Queensland State Government agencies (that is DPI (particularly Fisheries group), DNR Lands Administration group, and DoE), as well as State Government politicians.

2.6.4 Improving Stakeholder Involvement

HRCCC members were asked what could be done at state and local levels to improve the acceptance and involvement of relevant groups and the general public in the HRCCC process. A diversity of opinions were expressed including:

- improve representativeness of HRCCC as for example some stakeholder groups were not involved in the HRCCC (e.g. mirade of conservation groups in the catchment, bee keepers, and Caneland Assignment group)
- need for more effective government agency involvement (e.g. DNR Water Resources, DPI Fisheries, DoE, DoT, DLGP and GBRMPA)
- greater publicisation and promotion of the HRCCC and its activities (e.g. lift the profile in the media)
- government agencies be required to consult with the HRCCC on all their programs in the catchment (not just the other way around)
- ICM given a legislative base.

2.6.5 Satisfaction with Local Government Involvement

The majority of members (i.e. 14) were satisfied with the involvement of local government in ICM in the Herbert catchment. The reasons given were diverse and related to Local Government:

- having active involvement in the ICM Committee since its inception
- providing an important information source
- recognising the HRCCC as a legitimate referral and advisory group, and seeking their advice on issues
- providing ICM with "teeth for implementation".

Comments on local government involvement in the Herbert ICM process included:

> "Local Government is doing a really good job. Always reports well when asked. They've got access to facts/figures and they bring them along"
>
> "Involvement of CCC in their projects (eg. Strategic Plan, Local Government and ICM Project)."
>
> "Bringing a lot of knowledge about the catchment."
>
> "In Hinchinbrook Shire Yes, but No in Herberton Shire which is not involving ICM in anything. ICM/local government project with the Hinchinbrook Shire is helping heaps"
>
> "Councillors see the need to come to the HRCCC for advice. Mayor is now Deputy Chairman of the HRCCC. Also involvement through Hinchinbrook Shire's Strategic Planning Process. This is a change in the practice from last year. Before HRCCC seen just as a reference group, but now it seems to be changing. HRCCC getting more credit. Government putting more pressure on Councils over land use issues."
>
> "Close involvement since inception. No issues local government espouses which ICM opposes. ICM has teeth through local government and if this is to remain then ICM will remain advisory and local government the implementing agency."
>
> "Local Government and ICM supportive of each other in addressing issues. Local government is a regulating authority which can support ICM programs. Local government implements programs for ICM."

HRCCC member opinions on what more Local Government could do to help were varied but with most seeing its past involvement as effective. Comments included:

> "Making the developer much more responsible about what they do"
>
> "Would like to see more teeth in stopping people doing things. (e.g. riparian zone and tree clearing etc. are not only subject to voluntary action)."
>
> "Could do more through the regulatory side."
>
> "Full participation in process; perhaps support administrative aspects of ICM in turn with cane growers."
>
> "Yes would like it to help ICM a lot more, especially at getting things done"
>
> "Not sure it could do much more except be a bit more active in part of the committee. Key for ICM to work as they are the key implementers."
>
> "Level of involvement is satisfactory. Local government provides a broad community

view into ICM rather than the view of a specific vested interest group. Role of local government is advisory to ICM - providing information"

2.6.6 Shire Proposal on Development of New Rural Lands

HRCCC members were asked their opinion on the proposal that farmers opening up new areas of intensive agriculture will require Hinchinbrook Shire Council approval (for conditions) under the new Hinchinbrook Shire Plan. The 13 members for which a response was recorded to this question were all aware of this proposal and supported the Shire Council in principle in having these powers. However, HRCCC member's comments most commonly related to the State Government's failure to effectively use their powers in this area, the Council's capacity or political will to implement them, and technical and interpretative issues. Comments included:

"Applies only to subdivision and land use change. Nothing to stop cattleman clearing/draining and then converting."

"The difficulties are how vigorous the council pursues this. How is it going to work. What are the sanctions and what are the resources to monitor."

"Used to have conditions there (i.e. in 1960's re: viable cane) - but then non-compliance no longer there. Very keen to have conditions on assignments."

"Local government lacks capacity to make decision on land allocation (e.g. Sugarcane). Local Government has been lumbered with a big job because DoE and DPI Fisheries are ineffective and have passed down to local government."

"Good opportunity to really coordinate all agency input into intensification of land use / new developments issues, especially inputs of DNR, DOE, DPI Fisheries, etc.."

"Big step - not sure how council can implement it. Do not have the people to do it. Need CSIRO planner to provide the capability to be proactive."

"Good influence on regulating land management."

"Support new conditions to prevent minority who aren't conscious of the impact of management."

2.7 Factors Influencing the ICM Process

2.7.1 Recent Changes Influencing the HRCCC's Efforts

Ten HRCCC members gave varied responses to this question. Opinions related to project funding successes (e.g. NHT), appointment of a new Chairman of the HRCCC, increased linkages to Local Government, improvement in the cooperation amongst collaborating agencies, and the appointment of new DNR extension staff. Specific comments included:

"The new chairman is very active and 'with it' on ICM. NHT process made us look at priorities more closely. Made us focus more on the confronting issues and ones that have a chance of doing something about - likely to get some outcomes and this will enhance ICM."

"Degree of co-operation shown by collaborating agencies much improved"

"Success in getting project funding (NLP/NHT) and the appointment of DNR staff."

"Greater emphasis on wetlands by the community; dam building may have an influence soon. NHT has led to a lot more time spent on developing funding applications."

"ICM has developed policies which need to be implemented by local government. Hinchinbrook local government is hindered by state government agencies."

"ICM has had an impact on change, rather than the other way around"

2.7.2 Difficulties of ICM Implementation

HRCCC members were asked to rate their opinion on a five point scale (strongly agree to strongly disagree) on a series of statements relating to difficulties in ICM implementation. The statements and responses are presented in Table 2.11 and discussed below.

Table 2.11. Difficulties of ICM Implementation.

	Strongly Agree	Agree	Neither	Disagree	Strongly Disagree	Don't Know	No Response
The implementation of ICM in the catchment is difficult because:							
a. The large size of the catchment (or poor transportation links between parts of catchment)	4	9	0	4	0	0	1
b. The wide variety of values and beliefs among HRCCC members seriously detracts from an effective level of cooperation developing among them	1	6	0	8	2	0	1
c. Some important constituency groups are not represented in the ICM process	0	3	0	9	5	0	1
d. The perception that ICM has been forced on the catchment by the state government	0	0	0	10	6	1	1
e. The lack of an effective level of interest by HRCCC members	1	3	1	7	5	0	1
f. The public's lack of trust in state/local government-sponsored initiatives	1	8	0	4	3	1	1
g. The public's lack of interest in community type activities	1	7	2	7	0	0	1
h. The lack of financial resources within the community	3	3	2	8	0	0	2
i. The lack of agreement among HRCCC members concerning its objectives	0	0	0	14	3	0	1
j. The lack of agreement on feasible solutions	0	5	2	8	2	0	1
k. There is no single acute resource management problems within the catchment	0	8	0	5	1	0	4

a. The large size of the catchment (or poor transportation links between parts of catchment). The majority of members (13) agreed or strongly agreed that ICM implementation in the Herbert River catchment was difficult because of the large size of the catchment. However 4 members disagreed with this statement.

b. *The wide variety of values and beliefs among HRCCC members seriously detracts from an effective level of cooperation developing among them.* Members had divergent views on this statement with 10 members disagreeing or strongly disagreeing, and 7 members agreeing or strongly agreeing.

c. Some important constituency groups are not represented in the ICM process. Members in general disagreed with this statement with 5 members strongly disagreeing and 9 members disagreeing and only 3 members giving an 'agree' rating.

d. The perception that ICM has been forced on the catchment by the state government. Members overall of disagreed with the statement that ICM was difficult because it had been forced on the catchment by the state government with 6 members giving a 'strongly disagree' rating and 10 members giving a 'disagree' rating, and no members agreeing with it.

e. The lack of an effective level of interest by HRCCC members. There was some difference of opinion amongst HRCCC members whether the lack of effective interest by HRCCC members made

ICM difficult but most disagreed. Five members strongly disagreed/disagreed, 1 member neither agreed or disagreed, and 4 agreed/strongly agreed with the statement.

f. *The public's lack of trust in state/local government-sponsored initiatives.* There was a divergence of opinion amongst HRCCC members regarding the statement that the public's lack of trust in state/local government-sponsored initiatives made ICM implementation difficult. Nine members agreed/strongly agreed and 7 members disagreed/strongly disagreed with the statement.

g. *The public's lack of interest in community type activities.* There again was a strong divergence of opinion on whether the public's lack of interest in community type activities made ICM implementation difficult. 8 members strongly agreed/agreed, 2 neither agreed or disagreed, and 7 members disagreed with the statement.

h. *The lack of financial resources within the community.* There was a divergence of opinion on whether the lack of financial resources within the community made ICM implementation difficult or not. 6 members strongly agreed/agreed with the statement, 2 neither agreed or disagreed, and 8 members disagreed with the statement.

i. *The lack of agreement among HRCCC members concerning its objectives.* Members predominantly disagreed with the statement that lack of agreement among members concerning its objectives made ICM difficult. No members agreed or strongly agreed, and 14 members disagreed and 3 strongly disagreed.

j. *The lack of agreement on feasible solutions.* There was a difference of opinion on whether the lack of agreement on feasible solutions made ICM implementation difficult. Most members disagreed with 2 giving a 'strongly disagree' rating and 8 a 'disagree' rating. 2 other members neither agreed or disagreed, while five agreed with the statement.

k. *There is no single acute resource management problems within the catchment.* There was a divergence of opinion on whether the lack of a single acute resource management problem in the Herbert catchment made ICM implementation difficult or not. 8 members agreed with the statement, 5 members disagreed and 1 member strongly disagreed with the statement.

2.7.3 ICM Process Issues

HRCCC members were asked to rate their opinion on a five point scale (from strongly agree to strongly disagree) on five statements relating to the ICM implementation process. The results are presented in Table 2.12 and discussed below.

a. *There is a strong consensus among HRCCC members concerning HRCCC functions.* There was overall general agreement that there was a strong consensus of opinion among HRCCC members concerning HRCCC functions with 11 members strongly agreeing/agreeing, 2 neither agreeing or disagreeing and only one member disagreeing with this statement.

b. *At HRCCC meetings, all HRCCC members participate actively.* Again there was in general a consensus of opinion that all HRCCC members participated actively in meetings with 14 agreeing/strongly agreeing, and only 2 giving a 'disagree' rating.

c. *The local ICM process effectively resolves resource conflicts.* There was a divergence of opinion on whether the local Herbert ICM process was effectively resolving resource conflicts in the catchment. 6 members gave a 'strongly agree' or 'agree ' rating, 4 neither agreed or disagreed, and 4 gave a 'disagree' or 'strongly disagree' rating.

d. *The ICM process is responsive to local needs.* There was a concurrence of opinion amongst HRCCC members that the ICM process was responsive to local needs with 3 members strongly agreeing, 11 members agreeing, and only one member giving a 'disagree' rating.

e. *The HRCCC is solving the priority natural resource management problems in the catchment.* Although there was a difference of opinion amongst HRCCC members on whether the HRCCC was solving the priority natural resource management problems in the catchment, the majority of members were in agreement with this statement. 10 members agreed/strongly agreed, 3 neither agreed or disagreed while 3 members gave a 'disagree' rating to this statement.

Table 2.12. Opinions on the ICM Implementation Process.

	Strongly Agree	Agree	Neither	Disagree	Strongly Disagree	Don't Know	No Response
a. There is a strong consensus among HRCCC members concerning HRCCC functions	2	9	2	1	0	0	4
b. At HRCCC meetings, all HRCCC members participate actively	1	13	0	2	0	0	2
c. The local ICM process effectively resolves resource conflicts	2	4	4	3	1	1	3
d. The ICM process is responsive to local needs	3	11	0	1	0	0	3
e. The HRCCC is solving the priority natural resource management problems in the catchment	1	9	3	3	0	0	2

2.8 Personal Demands and Motivation

2.8.1 Time Devoted to ICM

HRCCC members were asked on average what number of hours per month did they devote to ICM. The majority of members devoted between 5 and 8 hours per month with 3 members spending less than 4 hours per month on ICM matters. However 3 members estimated they spent between 11 and 15 hours per month while the Committee Chairman and Catchment Coordinator devoted more than 16 hours per month (up to 18 hours and up to 180 hours respectively). The distribution of responses on time spent on ICM by HRCCC members is presented in Figure 2.

2.8.2 Demands on Members of ICM Involvement

HRCCC members were asked to rate their agreement/disagreement with three statements relating to the personal demands of ICM involvement on a six point scale (from completely agree to completely disagree). The responses are presented in Table 2.13 and discussed below.

Figure 2. Frequency distribution of time spent on ICM.

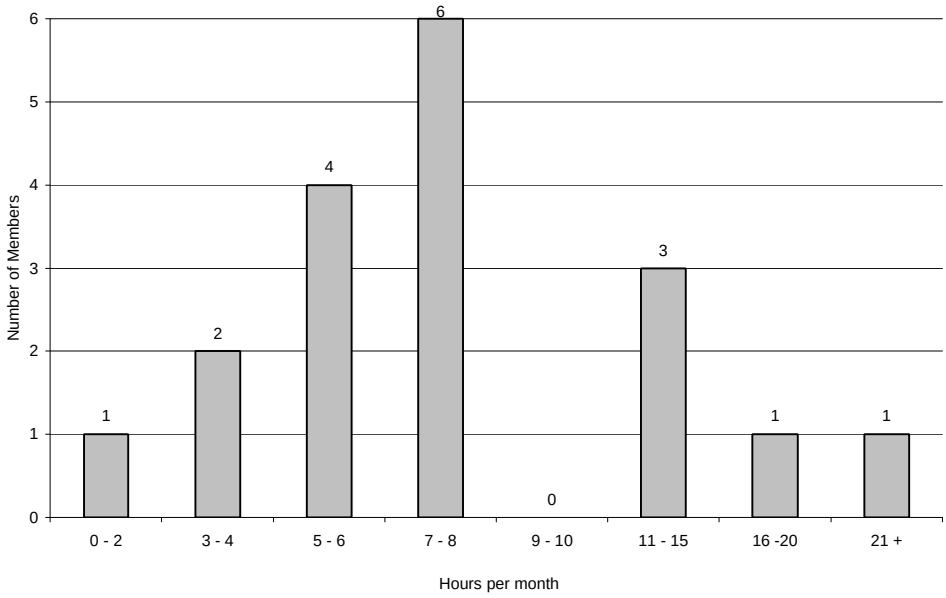

Table 2.13. Personal demands and motivation for ICM involvement.

	Completely Agree	Agree	Moderately Agree	Neither	Disagree	Completely Disagree	N/A	No Response
a. The amount of time I devote to ICM significantly interferes with my own business/job requirements	1	5	1	0	5	4	2	0
b. The amount of time I devote to ICM significantly interferes with my family commitments	1	2	1	0	8	4	2	0
c. My involvement with the HRCCC causes significant out-of-pocket expenses	0	3	0	1	6	6	2	0
d. I find being a member of the HRCCC personally rewarding because I can contribute to the community	9	7	1	0	0	0	1	0
e. I find being a member of the HRCCC rewarding because I care about natural resource management	10	7	0	0	0	0	1	0
f. I find being a member of the HRCCC rewarding because I can meet other members of the community who can influence resource management decision making	7	7	2	0	1	0	1	0
g. A HRCCC member's role is to provide their personal views on resource management issues at CCC meetings	2	8	0	0	5	2	1	0
h. A HRCCC member's role is to represent the resource management views of their constituency group at CCC meetings	2	12	2	0	0	1	1	0
i. A HRCCC member's role is to provide a catchment-wide perspective of natural resource management issues at CCC meetings	5	8	0	0	3	0	0	1

a. The amount of time I devote to ICM significantly interferes with my own business/job requirements. There were wide differences in experience amongst HRCCC members on whether ICM interfered with their own business or job requirements. 4 members 'significantly disagreed', 5 'disagreed', 6 'agreed', one member 'moderately agreed' and 1 'completely agreed' with this statement.

b. The amount of time I devote to ICM significantly interferes with my family commitments. The majority of HRCCC members disagreed with the statement that ICM interfered with their family commitments with 12 members 'completely disagreeing' or 'disagreeing', and only 4 members either 'agreeing', 'moderately agreeing' or 'strongly agreeing'.

c. My involvement with the HRCCC causes significant out-of-pocket expenses. The majority of HRCCC members disagreed with the statement that ICM involvement caused significant out-of-pocket expenses with 12 members 'completely disagreeing' or 'disagreeing', 1 'neither agreeing or disagreeing' and only 3 members 'agreeing'.

2.8.3 Motivation for ICM Involvement

HRCCC members were asked to rate their agreement/disagreement with three statements relating to their motivation to be a member of the Herbert ICM process on a six point scale

(from completely agree to completely disagree). Their responses are presented in Table 2.13 and discussed below.

d. *I find being a member of the HRCCC personally rewarding because I can contribute to the community.* Members were in strong agreement that part of their motivation for involvement in the HRCCC was that they could contribute to the community. 9 members gave a 'completely agree' rating, 1 member a 'moderately agree' rating and 7 members an 'agree' rating for this statement.
e. *I find being a member of the HRCCC personally rewarding because I care about natural resource management.* Again there was a strong concurrence of agreement amongst HRCCC members that they found involvement in the HRCCC personally rewarding because they cared about the environment with 10 members 'completely agreeing' and 7 members 'agreeing'.
f. *I find being a member of the HRCCC personally rewarding because I can meet other members of the community who can influence resource management decision-making.* Overall there was strong concurrence of agreement amongst HRCCC members with this statement with 7 members giving a 'completely agree' rating, 1 member a 'moderately agree' rating, 7 an 'agree' rating and only one member disagreeing with this statement.

2.8.4 Opinions on Catchment Committee Member's Role

HRCCC members were asked to rate their agreement/disagreement with three statements relating to their role as a member of the Herbert River Catchment Coordinating Committee on a six point scale (from completely agree to completely disagree). Their responses are presented in Table 2.13 and discussed below.

g. *An HRCCC member's role is to provide their personal views on resource management issues at CCC meetings.* There was a marked divergence of opinion amongst members on this statement with 7 members giving either a 'completely disagree' or 'disagree' rating and 10 members giving either an 'agree' or a 'completely agree' rating.
h. *An HRCCC member's role is to represent the resource management views of their constituent group at CCC meetings.* There was a strong concurrence of agreement amongst HRCCC members with this statement with 14 members giving a 'completely agree', 'moderately agree' or 'agree' rating and only one member giving a 'completely disagree' rating.
i. *An HRCCC member's role is to provide a catchment-wide perspective of natural resource management issues at CCC meetings.* There was a difference of opinion amongst HRCCC members on this statement, although the majority was in agreement with it. 13 members either gave a 'completely agree' or 'agree' rating, while 3 members gave a 'disagree' rating.

2.9 Other Comments

Members were asked if they would like to add any additional comments. A diverse range of comments were made including:

- *Issue - upper catchment involvement:* it was felt by several members that there was a need to get more happening in the upper catchment, more representation and even the possibility of a more formal sub-group being formed in the upper catchment was proposed on two grounds: (i) logistics of attendance at meetings (as it takes 4-5 hour drive each way from the upper to the lower catchment; (ii) differences in issues and context between the upper and lower parts of the catchment make ICM difficult.
- *Issue - progress:* The need to "keep the momentum up" was flagged with some concern being expressed at the slow rate of progress (rather than its direction) and the tendency to "move ahead in fits and starts". Even when there was good consensus in the Committee on an issue, it was suggested that often the HRCCC did not take it further.
- *Issue - awareness:* The point was made that although awareness of natural resource issues may be high amongst both CCC members and the community, understanding of issues varied significantly. A significant difference in awareness was perceived by some between

urban and rural stakeholders, with the rural community being attributed with higher awareness.

- *Importance of local and active ICM champions:* The importance of an effective Catchment Coordinator was seen by several members to be fundamental to the HRCCC's current and future success. Moreover the input of an active and committed Chairman was also raised as an important ingredient.
- *Linkages with other local statutory bodies:* Effective and strong linkages of ICM to Local Government and the Herbert River Improvement Trust were seen by several members as fundamental to the successful implementation of ICM. The current Hinchinbrook Shire planning process and the close linkages with ICM (including the involvement of HRCCC members) was providing a real opportunity to address the priority natural resource management issues in the catchment.
- *Funding:* The inadequacy and uncertainty of funding for ICM (both the Catchment Coordinator position and on-ground projects) was seen by several members as a major issue.
- *Issue - vested interest:* Concern was expressed regarding the number of members with multiple and conflicting interests and that too few people had too much power within the HRCCC. In particular, there was some concern expressed at the dominance of sugar industry representation on the CCC.

3. COMPARATIVE ANALYSIS OF 1995 AND 1997 SURVEY FINDINGS

3.1 Introduction

This section of the report provides an initial comparative analysis of the opinions of HRCCC members on aspects of ICM from the first HRCCC survey in November 1995 (Shrubsole and McDonald 1996) with those of the second HRCCC survey in December 1997. In the first survey, a mail-out questionnaire, responses from only 12 of the 15 current HRCCC members were received. However, in the second survey responses were recorded for all current HRCCC members in 18 face-to-face interviews.

3.2 HRCCC Membership

The number of members on the HRCCC over the period November 1995 to December 1997 increased from 15 to 18. The additional members on the HRCCC in 1997 are sector representatives for recreational/sporting fishing, the upper catchment community/Landcare, and an additional Hinchinbrook Shire Councillor. The sector groups represented on the HRCCC for both 1995 and 1997 are compared in Table 3.1.

Table 3.1. HRCCC membership in 1995 and 1997.

Stakeholder Group	Representatives in 1995	Representatives in 1997
INDUSTRY:		
CANEGROWERS	1	1
CSR Herbert River Mills	1	1
Cattlemans Union	1	1
Horticulture/Rare Fruits	1	1
Queensland Commercial Fishing Organisation	1	1
COMMUNITY GROUP:		
Hinchinbrook Citizen's Association	1	1
Recreational/Sporting Fishing	-	1
Landcare - lower catchment	1[1]	1[1]
Wildlife Preservation Society of Queensland	1	1
Herberton Shire Community/Landcare - upper	-	1

GOVERNMENT/STATUTORY BODIES		
Catchment Coordinator (DNR)	1	1
Hinchinbrook Shire Council	1	3
Herberton Shire Council	1	1
Herbert River Improvement Trust	1[2]	0.5[2]
Drainage Boards	1	0.5[2]
Hinchinbrook Development Bureau	1	1
Herbert Pest and Productivity Board	1[1]	1[1,3]
TOTAL	15	18

1. Also a member of CANEGROWERS Executive
2. Also a Councillor of Hinchinbrook Shire
3. Also a member of the Herbert River Improvement Trust

3.3 HRCCC Progress and Achievements

3.3.1 Major Achievements of the HRCCC

The major achievements of the HRCCC identified by members in the 1995 and 1997 surveys have been summarised into key points and these are presented in Table 3.2. There is strong similarity in the first three achievements for both surveys. These relate to group formation and some initial products (i.e. strategy development and on-ground activities). However, three additional achievements were identified in the 1997 survey. These additional achievements relate to process (i.e. awareness raising) and CCC function (i.e. coordination and referral/advisory role). Moreover the range of projects identified had broadened substantially from tin mines and tailing dam inventory in the upper catchment in 1995 to include in 1997: a joint project with HRIT at Long Pocket on bank stabilisation, the owl nesting box program, several restoration and revegetation projects (e.g. Wharps area, riparian area management, artificial wetland development, community tree planting), riparian vegetation mapping study, riparian "community" forum, and acid sulphate soils awareness.

Table 3.2. Members opinions of HRCCC achievements.

1995 Achievements	1997 Achievements
• Establishing a group that is bringing key catchment group representatives together to talk and share ideas. • Preparation of an initial draft catchment strategy. • Assisting community groups and agencies to undertake projects (e.g. tin mining sites in upper catchment).	• HRCCC meetings providing a forum that brings people together in the catchment with very different views. • The preparation and launching for public review of the Draft Herbert River Catchment Strategy. • Getting funding and undertaking a range of projects. • Raising awareness of catchment problems amongst HRCCC members and within the community • Taking on a coordinative and integrative role on natural resource issues in region • Recognition as a source of advice on natural resource issues in the catchment.

3.3.2 Satisfaction with Progress

Members were asked in both 1995 and 1997 about their level of satisfaction with progress in the HRCCC on a five point scale from very satisfied to very unsatisfied. Over the period 1995 to 1997, there appears to be a general improvement in satisfaction with progress. In 1995, 55% of members gave a rating of 'satisfied' or 'very satisfied' but in 1997 this had increased to 78% of members. A comparison of the results is presented in Table 3.3.

Table 3.3. Comparison of level of satisfaction on progress in the HRCCC for 1995 and 1997.

Satisfaction Rating	No. (%) of members 1995	No. (%) of members 1997
Very satisfied	1 (8)	1 (6)
Satisfied	5 (42)	13 (72)
Neither	3 (25)	1 (6)
Unsatisfied	1 (8)	3 (16)
Very Unsatisfied	1 (8)	0 (0)
No response	1 (8)	0 (0)

3.4 Problem Characterisation and HRCCC Role

3.4.1 Key Resource Management Issues

The most important resource management issues in the catchment identified by HRCCC members in 1995 and 1997 are compared in Table 3.4. In 1997, members' perspectives on these issues had broadened and become more strategic in scope.

Table 3.4. Comparison of Perceived Key Resource Management Issues in 1995 and 1997.

1995	1997
Rural drainage	Rural drainage
Allocation of sugar caneland	Caneland expansion
Stream bed and bank erosion	River management
Urban flooding	Water quality
Land clearing	Riparian management
	Wetland degradation
	Pest and weed management
	Coordinated extension approach
	Catchment planning

3.5 Public Attitudes, Support and Involvement

3.5.1 Level of Public Awareness on Natural Resource Use Issues

In both surveys members' perspectives were sought on the level of public awareness on natural resource issues within the Herbert River catchment. In 1995, responses were given for the Herbert community as a whole. In 1997, members considered that differentiation between rural and urban communities was appropriate. Table 3.5 compares the results from the two surveys. Overall members considered that public awareness was higher in 1997 than in 1995. For example, 42% of those responding in 1995 gave a moderate to very high rating, while in contrast, in 1997, 72% of members considered rural awareness to be moderate or higher, and 53% of members considered urban awareness to be moderate or higher.

Table 3.5. HRCCC Perspectives on the Level of Public Awareness on natural Resource Issues for 1995 and 1997.

Rating	1995	1997 - Rural	1997 - Urban
Very high	1	3	1
High	0	7	2
Moderate	4	3	6
Low to moderate	1	o	0
Low	6	3	1
Very low	o	2	7
No response	3	0	1

3.5.2 Public Support for the HRCCC

In both 1995 and 1997, HRCCC members were asked to rate their perception of the level of public support for the HRCCC on a five-point scale (from very high to very low). The results are presented in Table 3.6. In both surveys there was a divergence of opinion amongst HRCCC members on this question. However overall members rated support for the HRCCC as low to moderate.

Table 3.6. Comparison of members opinions of public support for the HRCCC for 1995 and 1997.

Rating	1995	1997
Very High	0	1
High	1	3
Moderate	6	6
Low	3	6
Very Low	2	1
Don't know	0	1

3.5.3 Effectiveness of Stakeholder Involvement

In both 1995 and 1997, HRCCC members were asked to rate on a five point scale (from very effective to very ineffective) the involvement in the Herbert ICM process of a range of stakeholder groups. Due to structural changes at State Government level, there have been some title changes to departments. However, functional groups with an interest or role in natural resource management can still be clearly matched. The results are presented in Table 3.7.

In both 1995 and 1997, there was considerable divergence of opinion on the effectiveness of different sector or stakeholder groups in the Herbert ICM process. However some general observations can be made. Rural producers, the HRIT and Drainage Boards were seen to be effectively or very effectively involved in the Herbert ICM process, while State Government politicians and the Department of Lands/DNR Lands Administration were seen by most members to be less effective in the ICM process. In 1995, the DPI (which then included the roles of the current DNR) and the Department of Environment and Heritage (now DoE) also were seen as having an effective involvement in the Herbert ICM process. However in 1997, there was a lowering of perceptions of the effectiveness of these two groups by HRCCC members, with the DPI (particularly the Fisheries group) been seen as in general to be much less effective in the ICM process. In contrast, Local Government administrators and politicians were perceived to have become much more effective in the ICM process in 1997 than in 1995.

Table 3.7. Most common ratings on the effectiveness of different stakeholders in the Herbert ICM.

Effectiveness Rating	Stakeholder Groups 1995	Stakeholder Groups 1997
Effective/very effective	Rural producers DPI (included DNR) Dept. Environment & Heritage HRIT Drainage Boards	Rural producers Local Government Politicians Local Government Administrators HRIT Drainage Boards
Neither/ineffective/very ineffective	State Government politicians Dept. Housing, Local Govt & Planning Dept. Lands Local Government administrators Local Government politicians	State Government politicians DPI (particularly Fisheries) DNR - Land Administration

3.5.4 Improving Stakeholder Involvement

In both the 1995 and 1997 surveys, HRCCC members were asked what could be done at state and local levels to improve the acceptance and involvement of relevant groups and the general public in the HRCCC process. A diversity of opinions were expressed in both surveys, however, there are common elements in both. The members' suggestions are summarised under key points in Table 3.8. The first two points are very similar for both years. In 1995, members also identified the need to get better involvement of local government, funding for projects, and raising public awareness. All of these have been addressed/achieved by 1997 to the satisfaction of HRCCC members (see Table 3.2 and Table 3.7 above). In 1997, however members also identified improving representativeness of the CCC and effectiveness of State Government agency involvement as key issues of concern.

Table 3.8. Member suggestions on ways stakeholder involvement could be improved

1995	1997
• greater publicisation and promotion of the HRCCC and its activities (particularly in the media) • recognising the role of the CCC through legislation • greater involvement of local government • getting funding for on-ground works/projects • raising community/public awareness of natural resource issues. • greater public consultation	• greater publicisation and promotion of the HRCCC and its activities (particularly in the media) • ICM to be given legislative power/base • improve representativeness of the CCC (e.g. some stakeholder groups were not involved in the HRCCC) • more effective government agency involvement • government agencies to consult with the HRCCC on all their programs in the Herbert catchment.

3.6 Factors Influencing ICM Process

3.6.1 Difficulties of ICM Implementation

In both 1995 and 1997, HRCCC members were asked to rate their opinion on a five point scale (strongly agree to strongly disagree) on a series of statements relating to difficulties in ICM implementation. The statements and responses are compared below for both surveys.

a. The large size of the catchment (or poor transportation links between parts of catchment).

In both the 1995 and 1997 surveys, the majority of HRCCC members 'strongly agreed' or 'agreed' that the large size of the catchment made ICM implementation difficult. However 4 members in 1997 disagreed with this statement.

	Strongly Agree	Agree	Neither	Disagree	Strongly Disagree	No Response
1995	0	11	1	0	0	0
1997	4	9	0	4	0	1

b. The wide variety of values and beliefs among HRCCC members seriously detracts from an effective level of cooperation developing among them.

In 1995, the majority of members (75%) 'strongly agreed' or 'agreed' that the wide variety of values and beliefs among HRCCC members seriously detracted from an effective level of cooperation developing, and only 25% disagreed. However in 1997 opinions had shifted and this was not perceived as such an issue with 55% giving a 'disagree' or strongly disagree' rating. This shift suggests a greater acceptance/tolerance of the diversity of views amongst members.

	Strongly Agree	Agree	Neither	Disagree	Strongly Disagree	No Response
1995	3	6	0	3	0	0
1997	1	6	0	8	2	0

c. Some important constituency groups are not represented in the ICM process.

Opinions overall have not changed with the majority of members (approx. 80%) 'disagreeing' or 'strongly disagreeing' that ICM was difficult because important constituent groups were not represented. However 3 members in 1997 'agreed' with this statement and 1 member in 1995 'strongly agreed'.

	Strongly Agree	Agree	Neither	Disagree	Strongly Disagree	No Response
1995	1	0	1	10	0	0
1997	0	3	0	9	5	1

d. The perception that ICM has been forced on the catchment by the state government.

In 1995, there was a divergence of opinion amongst HRCCC members on the statement that ICM implementation was difficult because there was a perception that State Government had forced ICM on the catchment. However the majority of HRCCC members 'disagreed' or 'strongly disagreed' with this statement. In 1997, all respondents 'disagreed' or 'strongly disagreed' that this was an issue.

	Strongly Agree	Agree	Neither	Disagree	Strongly Disagree	No Response
1995	1	1	2	5	2	0
1997	0	0	0	10	6	2

e. The lack of an effective level of interest by HRCCC members.

In both surveys there was a divergence of opinion amongst members on whether ICM in the Herbert was difficult because of the lack of an effective level of interest by HRCCC members. However in 1997 the majority of members (67%) 'disagreed' or 'strongly disagreed' that this was an issue indicating a slight shift in opinion from 1995 to 1997.

	Strongly Agree	Agree	Neither	Disagree	Strongly Disagree	No Response
1995	1	2	3	5	1	0
1997	1	3	1	7	5	1

f. The public's lack of trust in state/local government-sponsored initiatives.

In 1995, the majority of members (67%) were in general agreement with the statement that the public's lack of trust in state/local government-sponsored initiatives made ICM implementation difficult. In 1997, there was a stronger divergence of opinion on this statement. However a greater number of members 'disagreed' or 'strongly disagreed' in 1997 (i.e. 39%) than in 1995 (i.e. 17%).

	Strongly Agree	Agree	Neither	Disagree	Strongly Disagree	No Response
1995	3	5	1	2	0	1
1997	1	8	0	4	3	2

g. The public's lack of interest in community type activities.

In 1995, the majority of members (67%) were in general agreement with the statement that the public's lack of interest in community type activities made ICM implementation difficult. In 1997, there was a stronger divergence of opinion on this statement. However a greater number of members 'disagreed' in 1997 (i.e. 39%) than in 1995 (i.e. 17%).

	Strongly Agree	Agree	Neither	Disagree	Strongly Disagree	No Response
1995	3	5	2	2	0	0
1997	1	7	2	7	0	1

h. The lack of financial resources within the community.

In 1995, the majority of members (67%) were in general agreement with the statement that the lack of financial resources within the community made ICM implementation difficult. In 1997, there was a stronger divergence of opinion on this statement. However a greater number of members 'disagreed' or 'strongly disagreed' in 1997 (i.e. 44%) than in 1995 (i.e. 25 %).

	Strongly Agree	Agree	Neither	Disagree	Strongly Disagree	No Response
1995	3	5	1	2	1	0
1997	3	3	2	8	0	2

i. There is no single acute resource management problems within the catchment.

There is a strong divergence of opinion amongst members on whether ICM is difficult because there are no single acute problems within the catchment, and overall opinions have not really changed over the period 1995 to 1997.

	Strongly Agree	Agree	Neither	Disagree	Strongly Disagree	No Response
1995	1	5	1	5	0	2
1997	0	8	0	5	1	4

3.6.2 ICM Process Issues

In both the 1995 and 1997 surveys, HRCCC members were asked to rate their opinion on a five point scale (from strongly agree to strongly disagree) on five statements relating to the ICM implementation process. The overall responses are compared below.

a. There is a strong consensus among HRCCC members concerning HRCCC functions.

There has been a shift on the overall opinion of the HRCC members on this statement. In 1995, 68% of members 'disagreed' or 'strongly disagreed' that there was a strong consensus among HRCCC members concerning HRCCC functions. While in 1997, 61% of members expressed agreement or strong agreement with this statement.

	Strongly Agree	Agree	Neither	Disagree	Strongly Disagree	No Response
1995	1	3	0	7	1	0
1997	2	9	2	1	0	4

b. At HRCCC meetings, all HRCCC members participate actively.

There was overall agreement in both the 1995 and 1997 surveys by HRCCC members that at HRCCC meetings all members participated actively. However this opinion was more widely held in 1997 with 78% of members 'agreeing' or 'strongly agreeing' compared with 58% in 1995.

	Strongly Agree	Agree	Neither	Disagree	Strongly Disagree	No Response
1995	0	7	3	2	0	0
1997	1	13	0	2	0	2

c. The local ICM process effectively resolves resource conflicts.

In both the 1995 and 1997 surveys, there was a divergence of opinion amongst HRCCC members on whether the local ICM process is effectively resolving resource conflicts in the catchment.

	Strongly Agree	Agree	Neither	Disagree	Strongly Disagree	No Response
1995	0	3	6	3	0	0
1997	2	4	4	3	1	4

d. The ICM process is responsive to local needs.

In the 1995 survey there was a strong divergence of opinion amongst members from 'strongly disagree' to 'agree' on whether the ICM process was responsive to local needs. However in 1997, 78% of HRCCC members either 'agreed' or 'strongly agreed' with this statement. This possibly reflects the overall greater confidence being expressed by members in general in the Herbert ICM process.

	Strongly Agree	Agree	Neither	Disagree	Strongly Disagree	No Response
1995	0	4	5	2	1	0
1997	3	11	0	1	0	3

e. The HRCCC is solving the priority natural resource management problems in the catchment.

There is a divergence of opinion in both the 1995 and 1997 surveys on whether the HRCCC is solving the priority natural resource problems in the catchment. However the results for both surveys suggest there is stronger agreement rather than disagreement amongst members.

	Strongly Agree	Agree	Neither	Disagree	Strongly Disagree	No Response
1995	0	6	2	2	1	1
1997	1	9	3	3	0	2

3.6.3 Demands on Members of ICM Involvement

HRCCC members were asked on average what number of hours per month did they devote to ICM. A similar range of hours spent on ICM was identified in both surveys. The Chairman and Catchment Coordinator spending the most time in both cases.

Hours/month	1995	1997
0-2	0	1
3-4	3	2
5-6	5	4
7-8	0	6
9-10	1	0
11-15	2	3
16-20	0	1
21+	1	1

In both 1995 and 1997 surveys, HRCCC members were asked to rate their agreement/ disagreement with three statements relating to the personal demands of ICM involvement on a six point scale (from completely agree to completely disagree). The responses are compared below.

a. The amount of time I devote to ICM significantly interferes with my own business/job requirements.

Both surveys indicate a difference in experience amongst HRCCC members on whether the time devoted to ICM interfered with their business/job requirements. However overall the distribution of responses was similar in both surveys.

	Strongly/ Completely Agree	**Agree/ Moderately Agree**	**Neither**	**Disagree**	**Strongly/ Completely Disagree**	**No Response**
1995	0	4	2	4	1	0
1997	1	6	0	5	4	2

b. The amount of time I devote to ICM significantly interferes with my family commitments.

Both surveys indicate a difference in experience amongst HRCCC members on whether the time devoted to ICM significantly interfered with family commitments. However the majority of members on both occasions 'disagreed' or 'strongly disagreed' with this statement.

	Strongly/ Completely Agree	**Agree/ Moderately Agree**	**Neither**	**Disagree**	**Strongly/ Completely Disagree**	**No Response**
1995	0	3	1	6	1	0
1997	1	3	0	8	4	2

c. My involvement with the HRCCC causes significant out-of-pocket expenses.

The majority of members in both surveys 'disagreed' or strongly disagreed' that involvement in the HRCCC caused significant out-of-pocket expenses.

	Strongly/ Completely Agree	**Agree/ Moderately Agree**	**Neither**	**Disagree**	**Strongly/ Completely Disagree**	**No Response**
1995	0	1	5	4	1	0
1997	0	3	1	6	6	2

3.6.4 Motivation for ICM Involvement

In both the 1995 and 1997 surveys, HRCCC members were asked to rate their agreement/disagreement with three statements relating to their motivation to be a member of the Herbert ICM process on a six point scale (from completely agree to completely disagree). Their responses are compared below for both surveys below.

d. I find being a member of the HRCCC personally rewarding because I can contribute to the community.

In both the 1995 and 1997 surveys, members were in strong agreement that part of their motivation for involvement in the HRCCC was that they could contribute to the community.

	Strongly/ Completely Agree	Agree/ Moderately Agree	Neither	Disagree	Strongly/ Completely Disagree	No Response
1995	1	7	3	0	0	0
1997	9	8	0	0	0	1

e. I find being a member of the HRCCC personally rewarding because I care about natural resource management.

In both the 1995 and 1997 surveys, members were in strong agreement that being a member of the HRCCC was personally rewarding because they cared about natural resource management.

	Strongly/ Completely Agree	Agree/ Moderately Agree	Neither	Disagree	Strongly/ Completely Disagree	No Response
1995	3	8	0	0	0	0
1997	10	7	0	0	0	1

f. I find being a member of the HRCCC personally rewarding because I can meet other members of the community who can influence resource management decision-making.

In both the 1995 and 1997 surveys, members were in strong agreement that being a member of the HRCCC was personally rewarding because they could can meet other members of the community who can influence resource management decision-making.

1995	2	9	0	0	0	0
1997	7	9	0	1	0	1

3.6.5 Opinions on Catchment Committee Member's Role

In both the 1995 and 1997 surveys, HRCCC members were asked to rate their agreement/disagreement with three statements relating to their role as a member of the Herbert River Catchment Coordinating Committee on a six point scale (from completely agree to completely disagree). Their responses are compared below.

g. An HRCCC member's role is to provide their personal views on resource management issues at CCC meetings.

There was a marked divergence of opinion amongst members in both surveys on whether a member's role is to provide their personal views on resource management issues at CCC meetings.

	Strongly/ Completely Agree	Agree/ Moderately Agree	Neither	Disagree	Strongly/ Completely Disagree	No Response
1995	0	6	3	3	0	0
1997	2	8	0	5	2	1

h. An HRCCC member's role is to represent the resource management views of their constituent group at CCC meetings.

There was strong agreement amongst members in both surveys that a member's role is to represent the resource management views of their constituent group at CCC meetings.

	Strongly/ Completely Agree	Agree/ Moderately Agree	Neither	Disagree	Strongly/ Completely Disagree	No Response
1995	9	0	0	0	0	3
1997	2	14	0	0	1	1

i. An HRCCC member's role is to provide a catchment-wide perspective of natural resource management issues at CCC meetings.

There was in general agreement amongst members in both surveys that a member's role is to provide a catchment-wide perspective of natural resource management issues at CCC meetings.

	Strongly/ Completely Agree	Agree/ Moderately Agree	Neither	Disagree	Strongly/ Completely Disagree	No Response
1995	6	3	1	0	0	2
1997	5	8	0	3	0	1

4. OVERALL DISCUSSION OF THE 1995 AND 1997 HRCCC MEMBER SURVEY FINDINGS

4.1. The HRCCC

In November 1997, the Herbert River Catchment Coordinating Committee (HRCCC) had a local Chairman and 16 members representing community, industry and local government and statutory bodies in the catchment as well as a full-time Catchment Coordinator. Nine of the current members (50%) have been involved with the HRCCC since its inception in March 1993. Two members are from the upper catchment and the remainder lives in the lower catchment. The HRCCC had no State Government agency representatives. Most of the members are active community members with multiple sectoral interests. Eleven of the members are either cane farmers or employed within the sugar industry reflecting the economic and social importance of the sugar industry in the lower Herbert catchment community.

4.2. Key Resource Management Issues

In 1995, the HRCCC members identified the key resource management issues in the Herbert River catchment as rural drainage, allocation of sugar caneland, stream bed and bank erosion, urban flooding and land clearing. In 1997, members' perspectives on these issues had broadened and become more strategic in scope to also include water quality, riparian management, wetland degradation, pest and weed management, a coordinated extension approach, and catchment planning.

4.3. HRCCC Activities and Achievements

In both the 1995 and 1997 surveys, members identified several achievements of the HRCCC relating to group formation and some initial products. These included the HRCCC providing a forum that brings people together in the catchment with very different views, the preparation of the Herbert River Catchment Strategy and getting funding for on-ground projects. However, in 1997 some important additional achievements relating to the ICM process were identified. These included: raising awareness of catchment issues amongst members and the community, the HRCCC being recognised as a source of advice on natural resource issues, and the HRCCC

starting to take on a coordinative and integrative role on natural resource issues in the catchment. In addition, the range of projects identified had broadened substantially from a tin mine and tailing dam inventory in the upper catchment in 1995 to include in 1997: a joint project with HRIT at Long Pocket on bank stabilisation, the owl nesting box program, several restoration and revegetation projects (e.g. Wharps area, riparian area management, artificial wetland development, community tree planting), riparian vegetation mapping study, riparian "community" forum, and acid sulphate soils awareness.

In 1997, most members were positive about these achievements and the group's overall direction, however, some frustration was expressed with the slowness of the overall process. Significantly there is a general improvement in satisfaction amongst members with progress since the 1995 survey. Most members rated the progress of the HRCCC in 1997 as satisfactory due to the difficulty of the issues being addressed, the long term nature of the ICM process, and the slowness of the process of raising community awareness of issues and gaining public acceptance. Three members however rated progress as unsatisfactory, which was attributed largely to the slow rate of progress, the low community awareness of ICM, and the lack of enforcing power on natural resource issues.

Members also made a number of suggestions on ways to improve performance. These included: better publicisation of ICM and the HRCCC within the community, being more proactive (versus opportunistic), improving ICM's legitimacy, better coordination and cooperation amongst state government agencies, having the support of enforcing powers, and ensuring the security of tenure for a Catchment Coordinator and the adequacy of funding for HRCCC activities.

4.4 The HRCCC'S Role

Most members agreed that ICM was well suited to addressing natural resource issues in the Herbert because of ICM's strength in its community base, its inclusiveness of a broad range of catchment stakeholders and its good linkages with local authoritative bodies.

A number of roles that the HRCCC was taking in natural resource management in the catchment were identified. These included bringing together catchment stakeholders, raising awareness of natural resource issues and developing a better understanding of their causes. The HRCCC was seen to be facilitating cooperation across stakeholder groups that was getting things achieved that one group could not have done alone. An important development is that the HRCCC was providing an advisory and influencing role on natural resource issues and planning processes in the catchment, in particular through working in partnership with Local Government and the Herbert River Improvement (HRIT). In addition, the HRCCC had contributed to the improvement of the overall information base on natural resource issues that is available to underpin decision making in the catchment (e.g. riparian vegetation mapping).

There was a divergence of views amongst HRCCC members however on the HRCCC's role in the Herbert River community. Concerns were expressed by several members on the overall limited role the HRCCC had played to-date at the catchment and regional level, in particular, in relation to the identification of solutions to the major resource use problems of the catchment. Moreover members identified ICM's lack of enforcing power, its limited resources (e.g. financial, extension staff) and the limitations imposed by the lack of coordination across State Government agencies as important issues influencing the HRCCC's role in natural resource management.

4.5. The Catchment Management Strategy

The HRCCC released a draft Herbert River Catchment Management Strategy in May 1996 for

public comment. HRCCC members agreed in general that this strategy, firstly, provided a future direction to the group and a guide for future actions (e.g. identified issues, prioritised needs, identified stakeholders and their roles, provided a reference point to start from), and, secondly, helped to get resources and support for ICM in the Herbert (e.g. funding for Catchment Coordinator and natural resource projects, and ensuring the commitment of State Government to undertake projects).

A majority of members rated the Catchment Management Strategy development process as useful because the process was seen to be inclusive and transparent within the Committee. It also raised awareness of issues and others viewpoints within the HRCCC membership, it identified areas of agreement, and helped to focus the HRCCC and establish an overall direction. Some concerns however were expressed regarding the lack of resolution on some key issues, and the failure of the strategy to have a significant impact on what the Committee was currently doing. Most members did not feel that the strategy development process could have been improved with the exception that two members felt that it should have included more people beyond just the HRCCC members.

4.6. Public Attitudes and Support

HRCCC members perceived that the rural community's *awareness* on natural resource issues was overall substantially higher than the urban community's awareness, and that it had increased since 1995; although only slowly. Several members felt that this improvement was related to specific well publicised or controversial issues (such as cattle-to-caneland conversion, land clearing for caneland expansion, owl boxes, fish kills in the river, damming of streams and acid sulphate soils).

Members diverged in their opinion on the level of public support for the HRCCC with 12 members rating public support as low or moderate, whereas 4 rated it as high to very high. The reasons given were HRCCC's on-ground projects and a number of high profile events in the catchment bringing attention to the HRCCC. However it was also suggested that many people did not really understand the HRCCC's objectives and role.

4.7. Stakeholder Involvement

In both the 1995 and 1997 surveys, there was considerable divergence of opinion amongst members on the effectiveness of different sector or stakeholder groups in the Herbert ICM process. However some general observations can be made. Rural producers, the HRIT and Drainage Boards were seen to be effectively or very effectively involved in the Herbert ICM process, while State Government politicians and the Department of Lands/DNR Lands Administration were seen to be less effective in the ICM process. In 1995, the DPI (which then included the roles of the current DNR) and the Department of Environment and Heritage (now DoE) also were seen as having a largely effective involvement in the Herbert ICM process. However in 1997, there was a lowering of perceptions of the effectiveness of these two groups, with the DPI (particularly the Fisheries group) been seen as in general to be much less effective in the ICM process. In contrast, Local Government administrators and politicians were perceived to have become much more effective in the ICM process in 1997 than in 1995.

To improve stakeholder involvement in the Herbert ICM process, members in 1995 made several suggestions. First, there was a need for greater publicisation and promotion of the HRCCC and its activities (particularly in the media). Second, the role of the CCC should be recognised through legislation. Thirdly, the HRCCC needed greater involvement of local government. Fourth, access to greater funding was required for on-ground works/projects. Finally the HRCCC needed to focus on raising the Herbert community's awareness on natural resource issues, and to improve the public consultation process. By 1997, some of these

suggestions had been achieved, that is, local government involvement had increased significantly and the Committee had improved their funding for on-ground works/projects. However members made a number of other important suggestions on how stakeholder involvement could now be improved. These were that the representativeness of the HRCCC needed improvement, there was a need for more effective government agency involvement in the ICM process and this included government agencies being required to consult with the HRCCC on all their programs in the catchment, and finally greater publicisation and promotion within the catchment of the HRCCC and its activities.

4.8. Local Government Involvement

In 1997, most members were now satisfied with the involvement of local government because it had been actively involved in the ICM Committee since its inception, it was proving to be an important information source, it was now recognising the HRCCC as a legitimate referral and advisory group and seeking their advice on issues, and it could provide ICM with "teeth for implementation".

Members were aware of an emerging and positive development in the proposal that farmers opening up new areas of intensive agriculture will require Hinchinbrook Shire Council approval (for conditions) under the new Hinchinbrook Shire Plan. Most members in principle supported the Shire Council in having these powers. However, HRCCC member's expressed concern over the State Government's failure to effectively use their powers in this area, and whether the Council had the capacity or political will to implement them.

4.9. Factors Influencing the ICM Process

In 1997, members identified project funding successes (e.g. NLP/NHT), the appointment of a new Chairman of the HRCCC, increased linkages to Local Government, the improvement in the cooperation amongst collaborating agencies, and the appointment of additional DNR extension staff as key factors having a positive influence on the HRCCC's progress particularly since 1995.

In both 1995 and 1997, the majority of members were in agreement that ICM implementation in the Herbert River catchment was difficult because of the large size of the catchment. Significantly, most members did not support the views that ICM was difficult because some important constituency groups were not represented in the ICM process, or because of the lack of agreement among members concerning its objectives. There was however agreement in both surveys that all HRCCC members participated actively in meetings, and that the ICM process was responsive to local needs. Importantly these opinions appear to be more strongly and widely held in 1997 than in 1995.

The main areas where there was a divergence of opinion among members on key factors influencing the ICM process related to whether ICM was difficult because of the lack of effective interest by HRCCC members, the public's lack of trust in state/local government-sponsored initiatives, the public's lack of interest in community type activities, the lack of financial resources within the community, the lack of agreement on feasible solutions and the lack of a single acute resource management problem in the Herbert catchment. There was also a divergence of opinion amongst members in both surveys on whether the local Herbert ICM process was effectively resolving resource conflicts, and whether the HRCCC was solving the priority natural resource management problems in the catchment

Of importance is a shift in opinion from 1995 to 1997 on several factors perceived to be influencing the ICM process. In 1995, the majority of members agreed that the wide variety of values and beliefs among HRCCC members seriously detracted from an effective level of cooperation developing but in 1997 this was not seen to be an issue. Moreover in 1995,

members were in agreement that ICM implementation in the Herbert River catchment was difficult because of the public's lack of interest in community type activities as well as in state/local government-sponsored initiatives, and because of the lack of financial resources within the community. However in 1997, there was a clear divergence of opinion regarding these factors, with a shift to more members disagreeing than in 1995.

There were three other apparent shifts in the opinion of the majority of HRCCC members on factors influencing the ICM process. In 1995, there was a divergence of opinion amongst members on whether ICM implementation was difficult because it had been forced on the catchment by State Government, but in 1997 members largely disagreed with this view. In 1995, most members disagreed that there was a strong consensus among HRCCC members concerning HRCCC functions, however by 1997, the majority of members now agreed with this statement. In addition, in the 1995 survey there was a strong divergence of opinion amongst members on whether the ICM process was responsive to local needs but, in 1997, most agreed with this statement.

In sum, these views indicate that overall the Committee appears to be working well with overall agreement on their role and function, but some divergence of opinion on how well they are progressing.

4.10 Personal Demands and Motivation

Members were in strong agreement that they found involvement in the HRCCC personally rewarding because they could contribute to the community, they cared about the environment, and that they could meet other members of the community who could influence resource management decision-making.

In both the 1995 and 1997 surveys, members diverged in their experience on whether the time they devoted to ICM interfered with their business/job requirements and whether it significantly interfered with family commitments. However, members in both surveys were in strong agreement on a number of issues: involvement in the HRCCC did not cause significant out-of-pocket expenses; their motivation for involvement in the HRCCC related to the contribution they could make to the community; and that involvement was personally rewarding because they cared about natural resource management and because they could can meet other members of the community who can influence resource management decision-making.

The majority of members agreed that an HRCCC member's role is to represent the resource management views of their constituent group at CCC meetings. However, there was a divergence of opinion on whether an HRCCC member's role is to provide either their personal views on resource management issues or a catchment-wide perspective of natural resource management issues at CCC meetings.

4.11 Other General Comments

There were several additional issues raised by HRCCC members, as general comments. Concern was expressed for better linkages with the upper Herbert catchment, including better representation on the HRCCC and the possibility of the formation of an ICM sub-group in the upper catchment. There was a need to not only raise the Herbert community's awareness of ICM but also to develop a better understanding in the community of the HRCCC's objectives and role as well as the cause-and-effect relationships of catchment resource management issues. The importance of an effective Catchment Coordinator and active committed Chairman were seen to be essential ingredients of an effective ICM process. Closely related to this was the need for both adequacy and certainty of government funding for the Catchment Coordinator position. Moreover strong linkages between ICM and local government and other local

statutory agencies (e.g. RIT) was seen as fundamental for the ICM process being able to effectively address the priority natural resource issues in the catchment

APPENDIX 1.

1997 QUESTIONNAIRE FOR HRCCC MEMBERS

HERBERT RIVER CATCHMENT

COORDINATING COMMITTEE OPINIONS

HRCCC Members Name: …….

BACKGROUND

1. How long have you lived in this catchment? ……Years

2. What year did you become a member of the HRCCC? ……Years

3. Which of the following groups do you represent on the HRCCC? (please tick)

? Local government
? State government agency
? Sugar industry
? Grazing industry
? Fishing industry
? Horticulture/Rare Fruits
? Conservation
? Tourism
? Community group
? Other (please specify)

……
……
……
……

4a. Do you live upstream or downstream from Abergowrie? (please tick)

? Upstream (not including Abergowrie)
? Downstream (includes Abergowrie)

4b. What is your occupation? ……

5a. What have been the major achievements of the HRCCC? (tick)

- ☐ prepared a catchment strategy or plan
- ☐ offered advice to landowners
- ☐ conducted projects
- ☐ Other (please specify)

……

……

……

What are some of the most significant projects or achievements?:

……

……

……

……

……

5b. Since assuming your current responsibilities, how satisfied are you with progress in the HRCCC? (tick)

- ☐ very satisfied
- ☐ satisfied
- ☐ neither satisfied nor unsatisfied
- ☐ unsatisfied
- ☐ very unsatisfied

15c. Why? What are some of your reasons:

……

……

……

……

……

……

15d. Is there anything that should be done to improve performance?

……

……

……

……

6. From your perspective what currently are some of the key catchment resource management issues?

……

……

……

……

……

……

……

7. In respect of the following statements about the role that the HRCCC has played in resource management, can you rate your agreement on a five point scale from:

	Strongly agree	Agree	Neither agree nor disagree	Disagree	Strongly disagree	Don't know
The HRCCC has:						
a. Helped negotiation among resource stakeholders to accommodate a wide range of resource uses.	?	?	?	?	?	?
b. Helped stakeholders in defining the source of resource problems and solutions to them	?	?	?	?	?	?
c. Helped stakeholders in ensuring their resource management practices are effective, efficient, equitable, accountable.	?	?	?	?	?	?
d. Encouraged research and data gathering and analysis in order that solutions to resource problems can be better understood	?	?	?	?	?	?
e. How well suited is the ICM program in Queensland suited to address complex resource issues within your catchment?	?	?	?	?	?	?

8. From your perspective describe the role that the HRCCC has played in regional resource
management.

.....
.....
.....
.....
.....
.....
.....
.....
.....
.....
.....
.....
.....
.....
.....

9. From your perspective how well suited is the ICM program in Queensland suited to address resource use and management issues within the Herbert catchment?

.....
.....
.....
.....
.....
.....
.....
.....
.....
.....
.....
.....
.....
.....
.....

10. We are interested in understanding the types of information needed to support all aspects of an ICM program and its activities. Such information may be available in a number of forms (eg., databases, reports, pamphlets, maps, or through a catchment resource centre).

	Yes/No	Very Useful	Useful	Neither	Not useful
10A. In your involvement in the HRCCC have you used information or data on:					
If yes, how useful was it on a four point scale:					
a. Catchment natural resources.	?	?	?	?	?
b. Population and land use in your catchment?.....	?	?	?	?	?
c. Local organisations, industry and community groups in your catchment?.....	?	?	?	?	?
d. Government institutional arrangements for ICM, Landcare, natural resources, and related issues?	?	?	?	?	?
e. Government policies and regulations on natural resources and related issues?	?	?	?	?	?
f. Options for funding of ICM and other community activities?....	?	?	?	?	?
g. Group management and administration?.....	?	?	?	?	?
h. Other - please specify:					
....	?	?	?	?	?
....	?	?	?	?	?

10B. What types of information would have been useful/of value, if it had been available and why? (identify a to h)

……
……
……
……
……
……
……
……
……
……
……
……
……
……
……

10C. Are you aware of the Catchment Atlas?..... **Yes/No**

Have you made use of it in any way?

……
……
……
……
……
……
……
……
……
……
……

10D Have you used the Herbert Resources Information Centre (HRIC)? **Yes/No**
If yes, for what purposes?

.....
.....
.....
.....
.....
.....
.....
.....
.....
.....
.....
.....
.....
.....
.....

THE HERBERT RIVER CATCHMENT MANAGEMENT STRATEGY

11a. For what purpose did the HRCCC prepare a catchment strategy/plan?

.....
.....
.....
.....
.....
.....
.....
.....
.....
.....

11b Was the process of development of a catchment strategy/plan useful? Yes/No

If so, in what ways was it useful?

.....
.....
.....
.....
.....
.....
.....
.....

12. Please indicate your level of agreement with the following statements:

		Strongly agree	Agree	Neither	Disagree	Strongly disagree	Don't know
12a	The catchment strategy will contribute to effective resource management	?	?	?	?	?	?
12b	The catchment strategy will assist in resolving resource management conflicts.....	?	?	?	?	?	?
12c	I was effectively involved in the writing of the catchment strategy	?	?	?	?	?	?
12d	My constituency group supports the implementation of the strategy.....	?	?	?	?	?	?

12 e. What was the process the HRCCC used to develop the strategy?:

……

……

……

……

……

……

……

……

……

12 f. In retrospect, was there anything that should/could have been done to improve the process?

……

……

……

……

……

……

……

……

PUBLIC ATTITUDES AND RECENT DEVELOPMENTS

13a. In your opinion, what is the level of public awareness about natural resource issues in the Herbert catchment? (tick)

? very high
? high
? moderate
? low
? very low
? don't know

13b. Has public awareness changed over the last year?…….……Yes/No

13c. If so, how or in what way?……

……
……
……
……
……
……

14a. What level of public support do you believe the HRCCC has? (tick)

? very high
? high
? moderate
? low
? very low
? don't know

14b. How has public support for the HRCCC changed over the past year?

……
……
……
……
……
……
……
……

15. How effective has the involvement of the following groups been to the HRCCC?

	Very effective	Effective	Neither	Ineffective	Very ineffective	Not applicable
a. Rural producers (specify)	?	?	?	?	?	?
b. Local government politicians.....	?	?	?	?	?	?
c. Local government administrators.....	?	?	?	?	?	?
d. State government politicians.....	?	?	?	?	?	?
State government agencies:

16. What could or should be done at state/local levels to improve the acceptance and involvement of relevant groups and the general public in the HRCCC process?

……
……
……
……
……
……
……
……

17. a. Are you satisfied with the involvement of local government in ICM in the Herbert?

(Yes/No)

17b. Why?

……
……
……
……
……
……
..... ……
…

17c. What more could local government do to help ICM? ..

……
..... ……
…
……
……
……

17d. Do you know of the proposal that farmers opening up new areas of intensive agriculture will require Hinchinbrook Shire Council (HSC) approval (for conditions) under the new HSC Plan?

.... **Yes/No**

17e. What is your opinion about the proposal?

……
..... ……
……
……
……
……
..... ……
…

18. What have been some of the recent major changes (political, financial, economic, or environmental issues at local, regional or national scales) that have significantly influenced the HRCCC's efforts?

……
……
……
……
……
……

19. The implementation of ICM in this catchment is difficult because:

		Strongly agree	Agree	Neither	Disagree	Strongly disagree	Don't know
19a	The large size of the catchment (or poor transporation links between parts of catchment).....	?	?	?	?	?	?
19b	The wide variety of values and beliefs among HRCCC members seriously detracts from an effective level of cooperation developing among them.....	?	?	?	?	?	?
19c	Some important constituency groups are not represented in the ICM process.....	?	?	?	?	?	?
19d	The perception that ICM has been forced on the catchment by the state government	?	?	?	?	?	?
19e	The lack of an effective level of interest by HRCCC members	?	?	?	?	?	?
19f	The public's lack of trust in state/local government-sponsored initiatives.....	?	?	?	?	?	?
19g	The public's lack of interest in community type activities	?	?	?	?	?	?
19h	The lack of financial resources within the community	?	?	?	?	?	?
19i	The lack of agreement among HRCCC members concerning its objectives	?	?	?	?	?	?
19j	The lack of agreement on feasible solutions.....	?	?	?	?	?	?
19k	There is no single acute resource management problems within the catchment.....	?	?	?	?	?	?

20. Rate your level of agreement with the following statements:

		Strongly agree	Agree	Neither	Disagree	Strongly disagree	Don't know
20a	There is a strong consensus among HRCCC members concerning HRCCC functions	?	?	?	?	?	?
20b	At HRCCC meetings, all HRCCC members participate actively	?	?	?	?	?	?
20c	The local ICM process effectively resolves resource conflicts.....	?	?	?	?	?	?
20d	The ICM process is responsive to local needs.....	?	?	?	?	?	?
20e	The HRCCC is solving the priority natural resource management problems in the catchment	?	?	?	?	?	?

PERSONAL DEMANDS AND MOTIVATIONS

21. On average, how many hours per month do you devote to ICM? ……Hours/months

21. Identify your level of agreement with the following statements according to the following scale:

		Completely agree	Agree	Moderately agree	Disagree	Completely disagree	Not applicable
22a	The amount of time I devote to ICM significantly interferes with my own business/job requirements	?	?	?	?	?	?
22b	The amount of time I devote to ICM significantly interferes with my family commitments	?	?	?	?	?	?
22c	My involvement with the HRCCC causes significant out-of-pocket expenses	?	?	?	?	?	?
22d	I find being a member of the HRCCC personally rewarding because I can contribute to the community	?	?	?	?	?	?
22e	I find being a member of the HRCCC rewarding because I care about natural resource management	?	?	?	?	?	?
22f	I find being a member of the HRCCC rewarding because I can meet other members of the community who can influence resource management decision making	?	?	?	?	?	?
22g	A HRCCC's member's role is to provide their personal views on resource management issues at CCC meetings	?	?	?	?	?	?
22h	A HRCCC member's role is to represent the resource management views of their constituency group at CCC meetings	?	?	?	?	?	?
22i	A HRCCC member's role is to provide a catchment-wide perspective of natural resource management issues at HrCCC meetings	?	?	?	?	?	?

OTHER COMMENTS

20. If there are any further comments you wish to make about ICM, please feel free to do so.

Chapter 3

An Analysis of the Views of the Herbert River Catchment Coordinating Committee Members: November 1998 with Cross Comparisons from 1995 to 1998

APPENDIX 1: 1998 Questionnaire for HRCCC Members 133

1.0 INTRODUCTION

1.1 Background to the LWRRDC CTC7 R&D Project

In 1994, the Land and Water Resources Research and Development Corporation (LWRRDC) funded research staff of the CSIRO Tropical Agriculture (in Brisbane and Townsville), CSIRO Land and Water (in Perth), and the University of Queensland Department of Geographical Sciences and Planning (in Brisbane) to undertake research on Integrated Catchment Management (ICM) processes[1]. This longitudinal study over five years focuses on the community-driven ICM program in Queensland using the Herbert River Catchment process as a case study. The objectives of the investigation are.

1. Monitor and document the process of implementation of ICM in the Herbert River catchment and identify the social, economic and institutional factors that facilitate or hinder this process.
2. Evaluate key impacts of the implementation of the ICM process in terms of attitude and behaviour changes in the community and changes in the severity or tractability of the resource use conflicts for the catchment.
3. Assess the specific technical and related information needs that are relevant to an effective ICM implementation process in a wet tropical environment.
4. Develop a framework and related methods for evaluating the process of ICM implementation that will facilitate the development of more effective catchment management programs in Australia.

The complexities of catchment management are such that longitudinal studies of processes are essential if the issues of catchment management are to be better understood and appropriate lessons learned. The project acknowledges that, by its nature, ICM requires systematic evaluation (Bellamy *et al.*1999). For example, ICM as a process needs to take many and often conflicting considerations into account. It also operates in a complex environment where uncertainty is more often the rule than the exception. Moreover, indicators of progress are not easily defined and, to date, this area of investigation has largely been neglected (Bellamy *et al.*1999). In responding to these challenges, the project has adopted a multidisciplinary approach and draws on areas of expertise in natural resources science, social science, land use planning, resource economics, and media analysis.

1.2 Objectives of Survey

The LWRRDC CTC7 project seeks to find ways and means to improve the process of planning and implementing community-led ICM in Australia. Crucial to this evaluation is a better understanding of what are the problems faced by the ICM process and how they affect its implementation and ultimately its impact or influence on the management of land and water resources. By way of a longitudinal study of the ICM process in Queensland, the institutional component of the project focuses on finding out how ICM is practised in Queensland generally, and in the Herbert River catchment, in particular.

1 LWRRDC Project Reference: CTC7 - *Evaluation of Integrated Catchment Management in a wet tropical environment*

The institutional component of this R&D project aims to:

- provide a better understanding of the institutional or policy context in which ICM is conducted;
- provide the key baseline for the assessment of the institutional factors that hinder or foster an effective ICM process in the Herbert; and
- contribute key information for the assessment of the technical needs for effective ICM.

As part of a longitudinal study, the first stage of the institutional component of the LWRRDC CTC7 R&D project involved two separate surveys. The first was a state-wide survey of ICM officials in Queensland (i.e. all Catchment Coordinators and Catchment Coordinating Committee Chairpersons) in December 1995. The findings were reported in McDonald and Shrubsole (1996a; 1996b). The other involved surveying the opinions of members of the Herbert River Catchment Coordinating Committee (HRCCC) in November 1995 as reported in Shrubsole and McDonald (1996). A second set of surveys were undertaken covering both ICM officials across the state in October/November 1997 (see McDonald and Bellamy 1998) and the opinions of the HRCCC members in November 1997/February 1998 (see Bellamy *et al.* 1998). This current report presents the results of a third and final survey of the opinions of the HRCCC members undertaken in December 1998.

1.3 Survey Design and Approach

The third survey of HRCCC member's opinions repeated selected items from the previous two surveys as well as a range of new questions focussed on HRCCC activities and ICM issues. The questionnaire is included in this report as Appendix 1. Items in the survey related to members' views on:

(i) Nature and tractability of catchment management issues (Q8-11)
(ii) HRCCC achievements and role (Q12-19)
(iii) Herbert River Catchment Management Strategy – progress and influence (Q20-24)
(iv) The ICM program in Queensland suitability and needs (Q25-28)
(v) Public awareness, community support and involvement in ICM (Q29-35)
(vi) State Government involvement and influence in the ICM process (Q36-42)
(vii) Local government involvement and influence in the ICM process (Q43-48)
(viii) Factors influencing ICM implementation (Q49-56)
(ix) Personal background information, group/organisational involvement and time commitment to ICM (Q1-7, Q57).

The survey was administered to 15 of the current HRCCC members as individual face-to-face interviews based on a pre-set questionnaire. Two other members were unavailable for interview. Some questions asked were open-ended, while others required the interviewee to rate their response on a five-point scale. Interviews were conducted in December 1998 and involved an interviewer supported by a person recording responses. Due to time constraints of some members, selected questions were omitted from some interviews and are recorded as 'no response'.

2.0 1998 HRCCC SURVEY RESULTS

2.1 HRCCC Membership

2.1.1 Representation

In December 1998, there were 15 voluntary local community/sector members of the HRCCC. These members were nominated to represent a range of rural industry, community and

government or other statutory organisations that were considered to have an interest and/or role in natural resource management in the Herbert River catchment, as identified in Table 2.1.

Table 2.1: HRCCC sector group representation.

Industry Organisations	CANEGROWERS (1) CSR Herbert River Mills (1) Cattlemans Union (1) Fruit and Vegetable Grower Association (1) Queensland Commercial Fisherman's Organisation (1)
Community Organisations	SUNFish - Recreational/Sporting Fishing (1) Hinchinbrook Landcare (1) Wildlife Preservation Society of Queensland (1)
Government/Statutory Body	Hinchinbrook Shire Council (3) Herberton Shire Council/Landcare (1) Drainage Boards (1) Hinchinbrook Development Bureau (1) Herbert River Improvement Trust (0.5) Herbert Pest and Productivity Board (0.5)

In addition, a Catchment Coordinator facilitates the process. This position is funded through the federal government's National Landcare Program and based in the Ingham offices of the Department of Natural Resources, the current lead government agency for ICM in Queensland. A representative of the Department of Natural Resources Queensland (ie. the Wet Tropics Region ICM Project Officer) based in Innisfail has also frequently participates in HRCCC meetings in the past year.

2.1.2 Member Profiles

All local community/sector members live in the catchment with one member living in the upper catchment and the other 14 members as well as the Catchment Coordinator living in the lower catchment. The HRCCC membership has been remarkably stable since the HRCCC was first established in 1993 with 9 of the current members (nearly 60%) being the original foundation HRCCC members.

In addition to involvement on the HRCCC, all the members are active community leaders who belong to a wide range of different organisations in the catchment holding executive and other leadership positions. They therefore have multiple allegiances and interests. For example, there is a formal Landcare representative on the HRCCC but in addition six other members are active in one of the catchment's two Landcare groups. The representatives for commercial fishing, recreational/sporting fishing, the fruit and vegetable growers, the Drainage Boards, the Herbert River Improvement Trust, the cattle industry and one of the local government member are also cane producers. In summary, nine of the current HRCCC members are cane farmers (full or part time) and two others are employed within the sugar industry. Each of these members is involved in a range of sugar industry working groups, mill boards, assignment committees, and sugar productivity and pest management and productivity boards. The predominance of sugar industry interests on the HRCCC therefore to a large extent reflects the economic, social and cultural importance of the sugar industry in the lower Herbert River community.

2.2 Catchment Issues

2.2.1 Key Resource Management Issues and their Tractability.

Members were asked to identify what they perceived as the three key catchment land and water management issues facing people in the Herbert. For each issue that a member identified, they

were then asked to rate the tractability of each issue on a 5-point scale (from very low to very high) in terms of:

(i) the degree of technical complexity involved in dealing with the issue.
(ii) the level/intensity of community conflict that influences its resolution.

The issues identified by members are ranked in Table 2.2 and the mean ratings on tractability variables are identified.

Table 2.2. Tractability of key resource management issues.

Issue	Number of responses	Technical Complexity Mean Rating	Intensity of Conflict Mean Rating
Drainage coordination/management on floodplains (eg. levee banks, laser levelling, road and rail infrastructure)	9	3.7	4.1
Water quality (eg. fish kills, sedimentation)	6	4.3	4.2
Riparian vegetation degradation/management	5	2.4	3.2
Wetland degradation/management	5	3.0	3.4
Land use planning, catchment/floodplain systems management	5	3.4	3.8
Waterways management (free flow and river outlets) and flooding (lower catchment)	5	4.6	3.2
Land or remnant vegetation clearing/industry expansion (lower catchment)	4	3.3	4.0
Grazing land degradation/erosion (upper catchment)	1	3	3
Weed management	1	4	3
Water quantity/availability (upper catchment)	1	5	5

Repeat questions from the first survey in1995 on catchment issues and their tractability were included. Several equivalent questions were also included in the 1998 survey of community views on land and water management in the Herbert River catchment. Members were asked to rate in their opinion *how significant* a range of specified natural resource management issues were to the people in the Herbert generally on a five point scale (from very low to very high). The results are shown in Table 2.3

Although there is a diversity of views amongst HRCCC members, the most significant issues (ie. with a mean rating of moderate to very high) identified are rural drainage, rural flooding, water quality problems and wetlands degradation. While water quantity problems, loss of biodiversity, vegetation on river banks were viewed by most members of low to moderate significance.

Table 2.3. Significance of natural resource management issues.

Issue	5. Very high	4. High	3. Moderate	2. Low	1. Very low	Mean Rating	Rank
Land degradation	0	3	4	6	1	2.6	5
Grazing land degradation	1	2	3	6	2	2.6	5
Water quality problems	2	5	4	3	0	3.4	3
Water quantity problems (eg. insufficient water)	1	1	1	5	6	1.9	8
Rural flooding	5	7	1	1	0	4.1	2
Rural drainage	8	5	1	0	0	4.5	1
Vegetation on river banks	0	1	5	6	1	2.5	6
Wetlands degradation	3	2	6	2	1	3.3	4
Loss of biodiversity	1	0	4	6	3	2.3	7

Secondly, members were asked to rate in their opinion, how much a range of specified issues *impacted* on people in the Herbert generally, on a five point scale from very low to very high. The results are presented in Table 2.4.

Table 2.4. Impacts of specified issues on Herbert community.

Issue	5. Very high	4. High	3. Moderate	2. Low	1. Very low	Mean Rating	Rank
High cost of water	0	0	0	8	5	1.6	8
Loss of farm productivity	6	3	3	1	0	4.1	1
Higher production costs	4	3	5	1	0	3.8	2
Poor drinking water	0	1	4	4	4	2.2	7
Emotional stress	1	2	6	4	0	3.0	4
Higher taxes	2	5	3	1	0	3.7	3
Lower fish numbers/fish kills	3	5	3	2	0	3.7	3
Loss of access to recreation	1	3	1	3	5	2.4	5
Loss of confidence in government's ability to manage land and water resources	1	8	3	1	0	3.7	3
Loss of environmental uses or benefits (eg. wildlife habitat)	1	0	4	4	3	2.3	6

Issues identified by members overall as having a significant impact on people in the Herbert (ie. with a mean rating of moderate to high) were loss of farm productivity, higher production costs, higher taxes, lower fish numbers/fish kills, loss of confidence in government's ability to manage land and water resources and emotional stress. While the high cost of water, poor drinking water quality, loss of access to recreation, loss of environmental uses or benefits were viewed by most members to have a low impact.

HRCCC members were also asked to rate their level of agreement or disagreement with a number of statements relating to the difficulties in managing land and water resources in the Herbert. The results are presented in Table 2.5. When greater than 80% of respondents agreed (ie. a rating of either 'agree' or 'strongly agree') or disagreed (ie. a rating of either 'disagree' or 'strongly disagree') with the statement, this was given an overall rating of 'high agreement' or 'high disagreement' respectively. When 60 to 80% of respondents agreed or disagreed with the statement, this was given an overall rating of 'general agreement' or 'general disagreement'. Where there was a clear divergence of opinions amongst members with a spread of responses from disagree to agree (and a mean rating of 2.5 to 3.5), this was given an overall rating of 'split opinion'.

In summary, although there was a diversity of views amongst HRCCC members, most agreed or strongly agreed that managing land and water resources in the Herbert was difficult because of:

(a) 'institutional failure':
- Government strategies are too slow
- Government departments and other agencies are too slow to react to new issues
- The government doesn't want to spend money on solutions

(b) economic issues – that is high costs and low financial capacity in the community:
- Solutions are expensive
- Local people lack the money to spend on solutions.

Table 2.5 HRCCC views on the difficulties in managing land and water resources in the Herbert.

Managing land and water in the Herbert is difficult because:	5. Strongly agree	4. Agree	3. Neither	2. Disagree	1. Strongly disagree	Mean Rating	Overall Rating
Problems aren't well understood	2	3	1	4	0	3.3	Split opinion
Local people lack the money to spend on solutions	1	6	1	2	0	3.6	General agreement
Government strategies are too slow	5	4	0	1	0	4.3	High agreement
Solutions are expensive	3	7	0	0	0	4.3	High agreement
There are few benefits and many costs	2	2	1	4	0	3.2	Split opinion
Local people don't want to spend money on solutions	1	2	4	2	0	3.2	Split opinion
The Herbert catchment covers a large area	0	6	0	4	0	3.2	Split opinion
Local people don't trust government programs	1	2	4	2	0	3.2	Split opinion
Local people aren't that interested in community type activities	3	2	0	4	1	3.2	Split opinion
The government doesn't want to spend money on solutions	1	8	0	1	0	3.9	High agreement
Government departments and other agencies are too slow to react to new issues	5	4	0	1	0	4.3	High agreement
People on the catchment lack access to information needed to respond to/deal with new catchment issues or problems	0	1	1	8	0	2.3	High disagreement

However, most members disagreed with the statement that managing land and water resources in the Herbert was difficult because:

- People on the catchment lack access to information needed to respond to/deal with new catchment issues or problems.

Clearly members perceived that lack of relevant information was not the real problem or constraint for ICM in the Herbert.

Significantly there was a clear divergence of opinion amongst members on whether managing land and water resources in the Herbert was difficult because:

(a) tractability issues:

- Problems aren't well understood
- There are few benefits and many costs
- The Herbert catchment covers a large area

(b) community attitudes, including trust and willingness to be involved:

- Local people don't want to spend money on solutions
- Local people don't trust government programs
- Local people aren't that interested in community type activities.

2.3 The HRCCC: Achievements and Role

2.3.1 What have been the major achievements of the HRCCC to-date?

Members overall considered the HRCCC had made a number of significant achievements including:

(i) *Providing a forum that brings very different people in the catchment together to exchange ideas and providing a catalyst for change*:

"Raising public awareness of the issues. Creating a focal point for change - as a catalyst or idea"

"Provided a forum to give greater exchange of ideas and solutions."

"Forcing broad discussion on issues (eg clearing waterways)"

"Getting all different people together to work things out, Including CSR and the Shire Council. Importantly these are voluntary people rather than appointed people working things out"

"Facilitated bringing together of people on conflict issues - Sitting around the table [at HRCCC meetings] is the important forum"

"Good discussion/relations between the groups (CSR, CG, HSC, RIT, ICM)" - Good effort being made in the HRCCC to work with the different groups."

(ii) *Supporting a range of projects on natural resource management*:

"Getting seed funding for projects"

"Re: Long Pocket project - ICM sourced funds which would not have happened otherwise. It resolved the issue in minimising risk of a catastrophic change in course of river (high flows)"

"Helped Long Pocket project to actually happen and achieved result intended –end result was that the local community was happy"

"Through projects have achieved a much greater involvement in a whole range of environmental issues"

"The HRIC/GIS thing, the survey of mine tailings dams established, and riparian survey, etc - engaged people to collect information for use in the future,"

"The Atlas, tin-mining dam project, vegetation mapping, etc. will help with the implementation of the HRCCC Catchment Strategy"

"Gives people and organisations access to lot more information that was not previously available"

"The Atlas gives people information on the catchment, and people involved use it"

"ICM had a big input into the establishment of the Herbert Resources Information Centre (HRIC)"

"Owl nesting box project received high publicity as well as real ecological benefits."

(iii) *Raising community awareness of catchment NRM issues:*

"Raised awareness of NRM issues in the catchment - public knows who they are."

"Brought awareness of ICM issues to the fore to the public"

"Awareness in the community that there's a group there over-looking what's going on – especially through presentations and representations on issues"

"Raising community awareness of problems & possible solutions"

"Owl boxes - raising community awareness"

"Owl boxes raised public awareness of need for the control of rats."

(iv) *As an influential group on NRM in the catchment:*

a. ICM and Local Government Linkages:

"Influence on ICM local government planning - they jumped straight into it. Created good relation with Hinchinbrook Shire Council."

"ICM gave direction to local government planning"

"Getting direct input into local government planning."

"Influence on strategic plan with local shire (Hinchinbrook Shire Plan),"

b. ICM and Herbert River Improvement Trust linkages:

"Created good relation with the Trust (HRIT)."

"Developed important linkage with the River Improvement Trust – eg though the Long Pocket project"

"Fostering of soft engineering solutions to achieving bank stability had an impact on River Improvement Trust. Trust members are now thinking about other alternatives than rocks"

c. NRM planning and related development in the catchment:

"A major achievement has been the preparation by HRCCC of the Herbert River Catchment Management Strategy:"

"Owl box program - win/win outcome - increased awareness of impacts on wildlife as well as providing Input into Hinchinbrook Pest Management Plan."

"HRCCC as a sounding board for SIIP projects."

"ICM has had a key input into the Coastal Management Plan"

"HRCCC now seen as a source of good technical advice on NRM for the catchment"

Overall most members were fairly positive about the HRCCC achievements. However, two members expressed some concerns regarding some of the high priority catchment issues. One member commented that:

"It hasn't solved anything in the last 12 months."

Although recognising a number of important achievements, another member reflected that

"the HRCCC had continued to avoid dealing with levee bank rationalisation due to potential conflict of interests within the Committee".

2.3.2 The most significant projects undertaken by the HRCCC?

The most significant projects undertaken by the HRCCC that members identified were broad ranging and are identified in Table 2.6.

Table 2.6. Members views on the most significant HRCCC projects.

Project	Number of responses
Owl nesting boxes	10
Getting community involved in Landcare projects (eg. Wharps Estate, creek restoration, tree planting, Waterwatch)	7
Joint project with HRIT at Long Pocket on riverbank rehabilitation	6
Riparian vegetation mapping	4
Herbert River Catchment Management Strategy	4
Mine tailing dam survey	3
Catchment Atlas	2
Support for Herbert Mapping Project which led to the establishment of the Herbert Resources Information Centre (HRIC)	2
Weed control/clearing of waterways	2
Acid sulfate soils awareness	1
ICM/Local Government wetlands study	1

2.3.3. Satisfaction with HRCCC progress?

Members were asked to rate their satisfaction with the progress of the HRCCC on a five-point scale from very satisfied to very unsatisfied. The results are summarised in Table 2.7. HRCCC

members were predominantly satisfied to very satisfied with the rate of progress of the HRCCC, 13 members rated their level of satisfaction as either 'very satisfied' or 'satisfied', one as 'neither satisfied or dissatisfied', one as 'unsatisfied' with progress and there were no ratings of 'very unsatisfied'.

Table 2.7. Satisfaction rating with HRCCC progress.

Satisfaction Level	No. (%)
5. Very satisfied	3 (20)
4. Satisfied	10 (66)
3. Neither	1 (7)
2. Unsatisfied	1 (7)
1. Very Unsatisfied	0 (0)
Mean rating	4.0

The reasons identified for a 'satisfied' or 'very satisfied' rating on progress in 1998 related to:

> "The HRCCC has achieved a lot. Its done very well but we are not perfect - there's more we can do. We need to get everyone onside. We've been the leaders in NRM."
>
> "We've done as much as we could have."
>
> "Lot of enthusiasm and people work together to get things done. Forum for discussing those issues that was not there before."
>
> "HRCCC has a good chairman. Committee has representatives of all sections of the community and all can have a say - all different interests, land uses, and local government. All with a say and having some ownership of decisions being made."
>
> "Starting to make some headway. Only forum like it. Brings all different groups together."
>
> "I originally started thinking it was just another talk show. But ICM has done more than I expected. It has pulled diverse groups together."
>
> "Pulled upper and lower catchment together. Developed own strategy and linked with River management strategy. In general it has been worthwhile."
>
> "Because of the major involvement of ICM in decision making in catchment (eg with local government)."
>
> "There's a group there to deal with issues now (eg water needs)."
>
> "Achieved a fair bit, and seem to be working alright. People get involved and come to meetings."
>
> "Achieving some of the things it was set up for. Achieved reasonable profile in the community."
>
> "Has a reasonable track record at implementing projects and credibility in the eyes of local government."

The member who was neither satisfied nor dissatisfied with progress considered that the HRCCC had "Got some luck on our side that could go either way". The one member who expressed dissatisfaction with progress was concerned that the HRCCC tended to "go over old ground" and was "slow to react to obvious issues/problems".

2.3.4. What should be done to improve the HRCCC's performance?

Suggestions on improving performance from those members who were 'satisfied' and 'very satisfied' with progress included:

(i) More resources/funding to undertake community or general awareness raising projects.

(ii) Broaden representation of views on the HRCCC (eg. direct involvement of local business through the Chamber of Commerce; active involvement of environment interests; representation of government technical expertise).

(iii) Improve input from technical expertise to move the process forward more quickly and effectively (eg. presentations from DEH and DNR).

(iv) More publicity to raise the profile of ICM/HRCCC in the community.

Suggestions on improving performance from the two members who were either 'unsatisfied' or 'neither satisfied nor dissatisfied' with progress related to getting some real "runs on the board" or "more concrete action" (eg. by being more proactive on some of the tougher issues in the catchment such as establishment of structures for drainage management, codes of practice, managing mill mud, etc).

2.3.5. Is the HRCCC heading in the right direction?

Members were also asked whether they considered that the HRCCC was heading in the right direction. The 15 respondents were unanimous in feeling that on the whole the HRCCC was heading in the right direction. Reasons given included:

> "I think so-for it's age, yes. It may need a new direction after it passes its infancy stage - to become more intrusive into conflicting issues like levees."
>
> "All the parties are working together on the problems."
>
> "It has built a lot of credibility, got some runs on the board."
>
> "People say what they think and then work it out."
>
> "As long as we keep representing local community interests."
>
> "Yes, the only thing disappointing is the messing around with the Catchment Management plan - ie its endorsement by State Government. The HRCCC should be picking up and running with it – ie. more structured implementation."
>
> "Do not want it to become the policeman in the district. Getting the balance right is most important."

2.3.6 HRCCC Role in Natural Resource Management

Members rated their agreement/disagreement on seven statements relating to the HRCCC's role in natural resource management on a five-point scale (from strongly agree to strongly disagree). In general there was reasonable concurrence amongst HRCCC members in respect of agreement or disagreement with these statements. The results are summarised in Table 2.8 and briefly discussed below.

a. The HRCCC helped negotiation among resource stakeholders to accommodate a wide range of resource uses?
In aggregate ,members agreed with this statement (mean rating of 4.0). Ten members (77% of respondents) either strongly agreed or agreed with this statement, one neither agreed nor disagreed, and one member disagreed.

b. The HRCCC initiated key collaborative linkages/ arrangements with other organisations to actively address key land and water use issues in the catchment
In aggregate, members agree that the HRCCC is helping initiate key collaborative linkages/ arrangements with other organisations to actively address key land and water use issues in the catchment (mean rating of 4.1). With eleven members (92% of respondents) either 'strongly agreeing' or 'agreeing' with this statement. However one member neither agreed nor disagreed because they felt that although the HRCCC has "working relationships it is not always active in identifying solutions".

c. The HRCCC helped stakeholders in defining the source of resource problems?
In aggregate, members agree that the HRCCC is helping stakeholders define the source of resource problems and solutions to them (mean rating of 3.8). Ten members (83% of respondents) either strongly agreed or agreed with this statement, one neither agreed nor disagreed, and one member disagreed.

d. The HRCCC helped stakeholders in identifying solutions to resource problems? Most members (67% of respondents) 'agreed' or 'strongly agreed' that the HRCCC was helping stakeholders to identify solutions to resource problems. However, there was a significant amount of disagreement amongst members regarding this role with a third 'neither agreeing or disagreeing' or 'disagreeing' that the HRCCC was helping stakeholders in identifying solutions to resource problems (mean rating of 3.6).

e. The HRCCC helped stakeholders in ensuring their resource management practices are equitable and accountable? Overall members were not in agreement with this statement (mean rating of only 3.1). The majority of members (64% of respondents) either 'disagreed' or 'neither agreed or disagreed' with it. Significantly only 4 members (36% of respondents) 'agreed' that the HRCCC was helping stakeholders to ensure that their resource management practices were equitable and accountable.

f. *The HRCCC has encouraged research and data gathering and analysis in order that solutions to resource problems can be better understood?* In aggregate members agreed that the HRCC has encouraged research and data gathering and analysis (mean rating of 4.2). Eleven members (92% of respondents) either 'strongly agreed' or 'agreed' with this statement, with only one 'neither agreeing nor disagreeing'.

g. The HRCCC has helped ensure that the catchment land use planning decision-making process is fair and accountable to all interests? Although the majority of members (64% of respondents) 'agreed' or strongly agreed' that the HRCCC was helping ensure that the catchment land use planning decision-making process is fair and accountable to all interests, there was a clear divergence of opinion amongst members (mean rating of 3.6). Three members (27% of respondents) 'disagreed' and one member 'neither agreed or disagreed' with this statement.

Table 2.8. Level of agreement/disagreement with statements on the HRCCC's role.

Statement	5. Strongly Agree	4. Agree	3. Neither	2. Disagree	1. Strongly Disagree	Mean Rating	Overall rating
a. Helped negotiation among resource stakeholders to accommodate a wide range of resource uses	3	7	1	1	0	4.0	High agreement
b. Initiated key collaborative linkages/ arrangements with other organisations to actively address key land and water use issues in the catchment	2	9	1	0	0	4.1	High agreement
c. Helped stakeholders in defining the source of resource problems	1	9	1	1	0	3.8	High agreement
d. Helped stakeholders in identifying solutions to resource problems	1	7	2	2	0	3.6	General agreement
e. Helped stakeholders in ensuring their resource management practices are equitable and accountable	0	4	4	3	0	3.1	Split opinion
f. Encouraged research and data gathering and analysis in order that solutions to resource problems can be better understood	3	8	1	0	0	4.2	High agreement
g. helped ensure that the catchment land use planning decision-making process is fair and accountable to all interests	3	4	1	3	0	3.6	General agreement

In summary, the majority of members either agreed or strongly agreed that the HRCCC role has been to:

- Encourage research and data gathering and analysis;

- Initiate key collaborative linkages/ arrangements with other organisations;
- Help negotiation among resource stakeholders;
- Help stakeholders in defining the source of resource problems;
- Help stakeholders in identifying solutions to resource problems; and
- Help ensure that the catchment land use planning decision-making process is fair and accountable to all interests

However there was a clear divergence of opinion amongst members on whether or not the HRCCC had helped stakeholders in ensuring their resource management practices were equitable and accountable.

2.3.7 Activities important to Integrated Catchment Management programs

Members were asked to rate the importance of a range of activities as part of ICM in the Herbert. Respondents considered that all the specified activities were an important part of ICM with all statements having a mean rating of moderate importance to very high importance. The ratings are provided in Table 2.9.

Table 2.9. Important activities for ICM programs.

How important is it that the following activities are part of ICM in the Herbert:	5. Very high	4. High	3. Moderate	2. Low	1. Very low	Mean Rating	Overall agreement
a. Encourage community *action* at a catchment level	6	7	2	0	0	4.3	High agreement
b. Raise the level of local awareness and knowledge of environmental issues on the catchment	8	5	2	0	0	4.4	High agreement
c. Encourage Local Government to take an active role in environmental management issues	11	4	0	0	0	4.7	High agreement
d. Encourage coordination of state government programs	5	6	4	0	0	4.1	High agreement
e. Undertake specific on-ground projects with other bodies	2	8	2	3	0	3.6	General agreement
f. Providing a continuing source of advice to local government on catchment issues	9	2	1	1	0	4.5	High agreement
g. Encourage research	3	10	1	0	0	4.1	High agreement
h. Develop solutions for, and better understanding of, environmental problems in the Herbert catchment	4	7	1	1	0	4.1	High agreement
i. Encourage discussion between community interest groups on environmental issues	7	6	0	0	0	4.5	High agreement
j. Separate ICM programs for the Upper and Lower Herbert catchments	6	4	2	1	2	3.8	High agreement
k. Encourage joint projects between community, industry and state and local government	6	2	1	0	0	4.6	High agreement

Activities rated as high to very high importance to ICM in the Herbert are (in order of relative importance):

- Encourage Local Government to take an active role in environmental management issues
- Encourage joint projects between community, industry and state and local government
- Provide a continuing source of advice to local government on catchment issues
- Encourage discussion between community interest groups on environmental issues
- Raise the level of local awareness and knowledge of environmental issues on the catchment
- Encourage coordination of state government programs
- Encourage research

- Develop solutions for, and better understanding of, environmental problems in the Herbert catchment.

However HRCCC considered roles of moderate to high importance were:
- Separate ICM programs for the Upper and Lower Herbert catchments.
- Undertake specific on-ground projects with other bodies.

2.4 Catchment Management Strategy

2.4.1 The current status of the Herbert River Catchment Management Strategy?

Only five members (35% of respondents) were aware of the current status of the catchment management strategy (ie. second interim endorsement). Nine members (65% of respondents) were either unsure or not familiar at all with the strategy and its status.

2.4.2 Is the Strategy being used by the HRCCC?

Nine members (65% of respondents) considered that the strategy was being used by the HRCCC in a number of ways including:

> "Gives committee and catchment Coordinator direction and keeps them focussed on the priority issues in catchment."
>
> "Sets directions"
>
> "Provides a framework to work in and a reference document for eg. chasing subsidies, etc"
>
> "In background, providing direction"
>
> "Guiding principle (to see whether an issue should be dealt with)"
>
> "So broad, can provide useful direction"

However, five members (35% of respondents) did not think that the strategy was being used by the HRCCC for a number of reasons including:

> "Not being used directly (too many around). People don't refer to it - just a set of guidelines".
>
> "Not physically used (maybe used "sublimely")"

2.4.3 Is the Strategy adequate?

Ten of the members felt that the current strategy was adequate. The reasons given included:

> "Could be better. Outdated at moment - needs updating - NRM is changing and needs to be kept as a live document and continually move on"
>
> 'Adequate as a starting point."
>
> "Strategic plan not an operational plan – should do operational plan when agree on implementation"
>
> "It's comprehensive. It's just a requirement"
>
> "Ok in general. Needs more time frames, and action plan"

Three members however considered that it was not adequate, and reasons given were:

> "Things change"
>
> "It is too general and has no teeth"
>
> "It's a first up effort."

2.4.4 What needs to be done to improve the strategy?

The members who did not think that the current strategy was adequate suggested improvements such as:

> "Make it more meaningful (e.g tougher penalties)"
>
> "It needs action statements. "

"Needs updating. Identify more to be done by stakeholder groups"

Comments from other members on ways to improve the strategy include:

"Updating. More regular reviews (eg every 12 months) by all agencies. Tries to achieve too much - probably best to focus on a few priority issues"

"Obviously hasn't come back to members. Hasn't been discussed at meetings"

"Instead of being so general, it needs to be more action - oriented"

"Bring strategy back to the HRCCC and develop an action plan, by asking a few people to work on specific topics"

2.4.5 Role of the Catchment Management Strategy

Members were asked to rate their level of agreement or disagreement with several statements relating to the role and function of the Herbert Catchment Management Strategy. The responses are summarised in Table 2.10.

Table 2.10. Role of the Herbert Catchment Management Strategy.

Statement	5. Strongly Agree	4. Agree	3. Neither	2. Disagree	1. Strongly Disagree	Mean Rating	Overall rating
a. the catchment strategy will contribute to effective resource management in the Herbert?	2	4	1	2	0	3.7	General agreement
b. the catchment strategy will assist in resolving resource management conflicts	1	2	4	2	0	3.2	Split opinion
c. the HRCCC prepared a catchment strategy to ensure future funding support?	4	2	0	2	0	4.0	General agreement
d. the development of the strategy really helped to focus the HRCCC?	1	7	1	0	0	4.0	High agreement
e. the members' constituency groups fully support the implementation of the strategy?	1	4	1	2	0	3.5	General agreement
f. the Catchment Management Strategy is directing the HRCCC activities?	1	3	2	2	0	3.	Split opinion

Overall, most members agreed that:

- the HRCCC prepared a catchment strategy to ensure future funding support,
- the development of the strategy was helping to focus the HRCCC,
- the catchment strategy will contribute to effective resource management in the Herbert,
- their constituency groups fully support the implementation of the strategy.

However members were clearly divergent in their views on whether the catchment strategy will assist in resolving resource management conflicts or whether the Catchment Management Strategy is directing the HRCCC activities.

2.5 The ICM Program

2.5.1 Suitability of the ICM program in Queensland?

Members were asked to rate their opinion of the suitability of the ICM program in Queensland to addressing resource use and management issues within the Herbert catchment. Most members

(86% of respondents) rated it as moderately to very high suitability, but two members (14% of respondents) consider it to be of low suitability. The responses are given in Table 2.11.

Table 2.11. Rating of suitability of the ICM program in Queensland.

Rating	No responses (%)
1. Very high	5 (33)
2. High	5 (33)
3. Moderate	3 (20)
4. Low	2 (14)
5. Very low	0
Mean Rating	3.9

Reasons members gave in support of a low suitability rating included:

"Does not have any legislative power and has limited ways of achieving - more advisory body to local and state government"

"Token gesture - resources are very limited, funding for ICM has been retracted resulting in loss of Coordinators. It's a real shambles – it is Inadequately staffed. One rarely hears about the program from program managers in DNR."

"Thinning out of people statewide. Training needed for coordinators etc in methodologies and extension techniques. Poor communication through the entire network. Landcare/ICM program coordinators too busy in some areas"

Reasons members gave in support of a moderate suitability rating included::

"It's slow but powerful in the end."

"Provides some assistance, but the amount is too small. We could apply for more $s"

"Not a statutory thing makes you cooperate and get people to cooperate"

Reasons members gave in support of a high suitability rating included::

"It has stakeholder involvement – (ie. brings stakeholders together). There maybe conflict but it is good as it lets people see where others are coming from and recognise other viewpoints. Where all have input into strategy. It is an important forum for discussion. Not just a single interest group - nor a lobby group, or a single corporate agency to make money, but it is made up of all these. It is a neutral party on all issues."

"All user groups are involved. Local government involved from the outset. Major resource users, eg. CANEGROWERS, are involved and are driving ICM – but mainly to watch their backs. ICM is driven by local resource users"

"But not many people know about it."

"Takes time. Awareness. Voluntary"

"Only organisation that gets a lot of different groups round the table to address issues – We never had this before in the Herbert"

Reasons members gave in support of a very high suitability rating included::

"ICM work from the bottom up."

"Without it a lot of things wouldn't get done. Things go through with anyone looking at them. Get a lot of different people's views now (eg the Council previously made decisions without hearing the different sides of the issue - eg fisherman, conservationists.)"

"We have a Coordinator and are endeavouring to do right thing - letting local people get on with the job."

"Pulls stakeholders together. It has Government backing with funds."

"The forum process is important and it has a high profile in key local organisation."

2.5.2 Who should be represented on a Catchment Coordinating Committee?

Members were asked their opinion of whom or which groups should be represented on a Catchment Coordinating Committee. The responses are given in Table 2.12.

Table 2.12. Interest groups to be represented on a CCC.

Interest Group	No. Responses
All genuine stakeholders, (ie. anyone with a major interest in NRM in the catchment)	6
Aboriginal interests	4
Local business (eg. Chamber of Commerce)	4
Government agencies (eg. DEH big landholders in the district)	4
Better environment/conservation representation	3
Tourism	1

In general, members considered that all current groups on the HRCCC were important but several members also identified the need to include:

- aboriginal interests,
- local business interests (eg. Chamber of Commerce),
- state government agencies (some being big landholders in the catchment, eg. DOE), and
- tourism interests.

In addition some concern was expressed for better representation of the environment/conservation interest (ie. through more frequent attendance in meetings).

2.5.3 What do you consider are the important qualities of a Catchment Committee member?

14 members provided responses to the question of what are the important qualities of a good CCC member. They identified a range of important "qualities" of a CCC member as identified in Table 2.13.

Table 2.13. Views on necessary qualities of a Catchment Committee member.

Quality	No. responses (%)
Objective, open-minded, broad vision (including benefit of the community at heart, recognises needs of others, sees other point of view, prepared to compromise, able to give a little)	7 (50)
Believes in/is 'passionate about' or genuinely concerned about NRM/ICM issues	6 (43)
Good communication skills/can contribute to group discussion and take information back to own group.	5 (36)
Understands and is prepared to put forward the views of own interest group (ie. representative of own interest group and not only as an individual)	4 (29)
Good interpersonal skills (including willingness to listen to others views)	4 (29)
Vast local experience and aware of what is going on in the catchment	2 (14)
Progressive attitude (including willingness to accept change, learn things all the time)	2 (14)
Outspoken	2 (14)
Available time	2 (14)
Significant player in the catchment (to give Committee clout)	1 (7)
Understanding of the whole focus of ICM (eg. planning)	1 (7)
Prepared to look at the science of issues	1 (7)
Not too radical	1 (7)
Even temperament	1 (7)

2.5.4 The important qualities of a Catchment Coordinator?

Members were asked what they considered were the important qualities of a Catchment Coordinator. 14 members identified several different qualities as shown in Table 2.14.

Table 2.14. Important Qualities of a Catchment Coordinator.

Quality	No. responses (%)
Experience/knowledge of NRM issues and agricultural systems (ie. technical skills, understanding across disciplines, problem solving, eye for myths and legends)	8 (57)
Good communicator and outgoing	6 (43)
Good/highly developed interpersonal skills, able to handle a diverse group of people	5 (36)
Broad minded, tolerant, politically neutral on issues, ability to look at the big picture.	4 (29)
Tactful, able to bite tongue and keep cool	4 (29)
Confident, prepared to stand up and be accounted for	2 (14)
Good conflict resolution skills	2 (14)
Good listener	2 (14)
Strong leader, dedicated	2 (14)
Outspoken with personal drive, active	2 (14)
Organised, time management skills	1 (7)

2.6 Public Attitudes and Support for ICM

2.6.1 Level of Public Awareness on Natural Resource Issues

Members views were sought on the level of public awareness on natural resource issues within the Herbert catchment community on a five point scale from 'very low' to 'very high'. The results are summarised in Table 2.15.

Table 2.15. Perspectives on public awareness of natural resource issues in the Herbert catchment.

Rating	Rural Community No. of responses (%)	Urban Community No. of responses (%)
1. Very high	3 (21)	2 (14)
2. High	4 (29)	0 (0)
3. Moderate	3(21)	3 (21.5)
4. Low	4 (29)	6 (43)
5. Very low	0	3 (21.5)
Mean Rating	3.4	2.4

There was a clear divergence of opinion amongst members regarding the level of public awareness on natural resource issues. However, HRCCC members perceived that the rural community's awareness was overall substantially higher than the urban community's awareness. Foe example, 50% of respondents rated rural community awareness as high or very high but only 14% of members viewed the urban community as having a high or very high awareness of natural resource issues. Similarly 30% of the respondents rated the rural community awareness as low, while nearly 65% of respondents rated the level of awareness of the urban community as low to very low.

2.6.2 Has public awareness changed over the last year?

Members' perspectives were also sought on whether public awareness had changed over the last year, and if so, in what way. The 14 respondents were unanimous in feeling that awareness had improved, however fairly slowly. Reasons given are summarised in Table 2.16.

Table 2.16. Reasons for an improvement in public awareness.

Reason	No. Responses (%)
Lots of big issues/local debate/happenings/bad press recently (eg. fish kills, indiscriminate clearing, acid sulfate problems)	9 (64)
Message slowly getting through (ie. greater public awareness, evolution of the law is quite demanding)	3 (21)
A wet year that raised drainage issues and flooding problems	2 (14)
The Council's land use planning process	1(7)

2.6.3 Level of public support for the HRCCC in the catchment?

Members were asked to rate the level of public support for the HRCCC and their responses are identified in Table 2.17. Overall of the 13 respondents, the majority of members (77%) rated public support as moderate to high.

Table 2.17. Level of public support for the HRCCC.

Rating	No responses (%)
5. Very high	0
4. High	3 (23)
3. Moderate	7 (54)
2. Low	2 (15)
1. Very low	1 (8)
Mean Rating	2.9

2.6.4 Has public support for the HRCCC changed over the past year?

Members were asked whether or not they considered that public support for the HRCCC had changed in the last year. 9 respondents (nearly 70% of respondents) considered that it had improved for several reasons including:

"More aware of the drainage issues "

"Gone from low to moderate last year. Perhaps no longer just seen as a talkfest"

"Started to gradually win people over"

"getting better but low"

"Increasing, because of public debate"

"Increasing steadily (only one ever derogatory comment - about the Palm Ck project)"

"Coverage through things like owl boxes and Waterwatch"

"Increased because people know HRCCC is there and trying to improve their lot"

"Public generally is supportive. No public negative"

However 4 respondents (ie. 30%) felt that public support had not changed over the last year and identified several reasons:

"Not a great deal"

"Needs people to do its ground work"

"Not as yet but will change with IPA"

2.6.5 How can public support for ICM in the Herbert be improved?

Members were asked whether there was any way that public support for ICM in the Herbert could be improved. There were 14 respondents and there suggestions relating to better publicity, proactive action, improved resources and greater local involvement are summarised in Table 2.18.

Table 2.18. Ways in which public support can be improved for ICM in the Herbert.

Suggestion	No. Responses (%)
More publicity and promotion of what the HRCCC is doing	11 (79)
More action, being more proactive (such as field days, demonstrations like artificial wetlands work)	4 (29)
More resources to promote ICM and the HRCCC (eg. more $s)	2 (14)
Getting more people involved	1 (7)

2.6.6 Effectiveness of the involvement of particular stakeholder groups in ICM?

The HRCCC members were asked to rate on a five point scale (from very effective to very ineffective) the effectiveness of the involvement in the Herbert ICM process of a range of stakeholder groups. The results are presented in Table 2.19.

Table 2.19. Opinions on the effectiveness of stakeholder group involvement.

	5. Very Effective	4. Effective	3. Neither	2. Ineffective	1. Very Ineffective	Mean Rating
a. Local government	7	4	0	0	0	4.6
b. State Government agencies:						
- DNR	1	8	0	2	0	3.7
- DPI (Fisheries)	0	0	0	1	1	(1.5)
Department of Environment	0	2	0	4	1	2.4
c. Federal Government agencies	2	1	0	0	0	-
CSIRO/LWRRDC						-
AIMS	3	0	0	0	0	-
GBRMPA	0	0	0	1	0	-
Wet Tropics Manag. Auth.	0	2	0	1	1	-
	0	2	0	0	0	-
d. Industry Organisations	2	3	0	0	0	-
CSR	1	2	0	1	0	-
CANEGROWERS	3	1	1	1	0	-
Cattlemens Union	1	1	0	0	0	-
QCFO	0	1	1	0	0	-
e. Conservation/environ groups	1	2	3	4	0	3.0
f.. The Media	0	8	1	1	1	3.5
g. Landcare Groups	1	9	0	1	0	3.9
h. Sporting Fishermen	1	1	0	0	0	-
i. Herbert River Improvement Trust	1	0	0	0	0	-

Although there was a divergence of opinion amongst respondents, overall most members considered that the effective/very effective groups involved in ICM in the Herbert were Local Government, DNR, Federal agencies (including CSIRO, GBRMPA and AIMS), industry organisations (especially CSR, CANEGROWERS, Cattlemen Union), the media, Landcare, and sporting/recreational fishermen. While ineffective or very ineffective involvement was considered to be from DOE, DPI (Fisheries) and conservation/environmental groups.

2.6.7 Improving the acceptance and involvement of relevant interest groups in the HRCCC process.

HRCCC members were asked what could or should be done to improve the acceptance and involvement of relevant interest groups in the HRCCC process. A diversity of opinions were expressed by the HRCCC members including:

> "Representatives should be more accountable. Coordinator should have meetings with each of the members on a regular basis."
>
> "Get the public involved more."
>
> "Representatives should use proxies when they cannot be present."

"Should be picking up issues and getting industry group management to make presentations to the Committee from their viewpoint."

""Attendance and representation are very important. Members should appoint deputies when they can't come."

"Need to get the Conservation groups more involved."

"Ask Chamber of Commerce and Tourism industry to have a representative."

2.7 State Government Involvement

2.7.1 Satisfaction with the involvement of state government agencies.

The HRCCC members were asked if they were satisfied with the overall level of involvement of state government agencies in ICM in the Herbert**.** Of the 11 respondents, seven were satisfied with the level of state government involvement but 4 were not.

Reasons given for dissatisfaction with state government involvement included:

"State is not involved except for the Catchment Coordinator and Wet Tropics Coordinator. There is lack of support for ICM at the district level e.g. from DNR (Townsville). The Department sees ICM as a low priority"

"State Government needs to provide better funding and resources"

"Need more back up data. Senior people to refer to and more money out"

"State Government has only *ad hoc* and reactive involvement without commitment.. There is an attitudinal problems – (eg DPI – cannot see why they should approve a strategy they haven't had involvement with)."

Reasons given for satisfaction with the level of state government involvement included:

"Anything we want to know, they are there to help us"

"Come and advise on specific problems and give presentation but could do more (but issue is that are constrained by politics of ICM to do this)"

"DNR is OK. Government in general could have been better ,but perhaps the HRCCC could have done more to encourage them (especially DEH in this respect)"

"At local level OK, but not at state level"

"DNR – we are using their facilities, contacts"

"Main Roads consulting with us on drainage issues relating to road bridges and railways. DPI is OK. Forestry haven't been following their own codes of practice"

2.7.2 Importance of state government involvement to ICM

Members were asked to comment on the importance of state government involvement to the success of ICM in the Herbert. 9 members (82% of respondents) considered that state government involvement was very important or critical to the success of ICM in the Herbert. The reasons included:

"Technical support has been absolutely critical"

"Very important. – eg. paying for Coordinator and a portion of the projects undertaken"

"Locally very important. State level is very important e.g. endorsement of strategy"

"Very important because you need to go through them to get things done"

"Very important in providing resources and data"

Two other members had specific issues relating to state government involvement:

"Need to help a lot more (eg. training for coordinators and regional workshops and networking amongst ICM groups."

""As long as there's a good relationship, government doesn't need to be involved. Give direction. Avoid duplication. People in contact with catchment groups are particularly

2.7.3 What more could state government do to help ICM in the Herbert?

Members were asked to comment on what more could state government do to help ICM in the Herbert. Respondents identified several ways in which State Government could improve its support for ICM in the Herbert, including:

> "To support a full time coordinator which should not be the responsibility of the NHT. This would lead to better direction. Need a longer term guarantee of support."
>
> "Increase $s for Coordinator and for projects."
>
> "Fund a Coordinator for five years, not just hand-to-mouth contracts."
>
> "More resources and funding."
>
> "The state government often uses issues to crucify local people which doesn't help ICM."
>
> "Provide a member to represent the Environment department."
>
> "Need to endorse Catchment Strategic plan and put more effort into working on issues. Perhaps provide some workshops on particular key issues - good example is local government study.

However three respondents did not seem to consider that there was much that needed to be done:

> "Nothing in particular."
>
> "Probably not much more here in the Herbert - otherwise it might detract from community involvement."

2.7.4 Importance of coordination between state government agencies

Members were asked to rate on a five-point scale (from very low to very high) the importance to ICM in the Herbert of coordination between state government agencies on issues relating to land and water resources management. All respondents considered this coordination of moderate to very high importance with a mean rating of 4.6 (ie. high to very high importance). The results are presented in Table 2.20.

Table 2.20. The importance of coordination between state government agencies to ICM.

Rating	No responses (%)
5. Very high importance	8 (67)
4. High	3 (25)
3. Moderate	1 (8)
2. Low	0
1. Very low importance	0
Mean Rating	4.6

The reasons given by respondents for a very high rating included:

> "Lack of cooperation leads to confusion and conflict. Pomona is a good example - in terms of what is a water course etc."
>
> "Give community confidence to get some information from the different departments"
>
> "Need to coordinate roads, rail trams etc. Can't always assume it would happen."
>
> "Need to go to several different departments who each wear different hats."
>
> "You need to satisfy all the regulations/frameworks of agencies. You can use their people/maps etc to help ICM"
>
> "Need to get better performance of agencies"

The reasons given by respondents for a high or moderate rating included:

> "They tend to have a one track mind (eg. DPI Fisheries) and they blow in and blow out again."
>
> "Hynenachne is a good example of problems - one is recommending to plant it, another sees it as a weed."
>
> "Waterwatch etc. They know rules and regulations about Acts."

"All agencies need to put their view - to get balanced view."

2.7.5 The benefit in practice of cooperation with government departments

Members were asked to rate on a five point scale (from 1 = not beneficial to 5 = extremely beneficial) how beneficial in practice cooperation with government departments (eg. DNR, DPI, DEH) has been to ICM in the Herbert. There was a divergence of opinions amongst members but the mean overall rating show that cooperation had been quite beneficial in practice. Significantly no respondent considered that it had not been beneficial. The ratings are presented in Table 2.21.

Reasons for a very or extremely beneficial rating included:

"Cooperation has helped provide a Coordinator and links"

"Could not have achieved things without cooperation of (eg. Main Roads and Transport for drainage/bridges railways)."

Reasons for a slightly or quite beneficial rating included:

"Been some synergy by getting them to talk to one another has been a major issue (eg funding applications)"

"It hasn't happened much."

"Getting closer now. Depends on the people"

"Not a problem on the Committee but has been a big issue outside it, where cooperation hasn't necessarily been good"

"Come when want them to come without being pushy"

"Until Simon started participating in the last 6 months, no one from Government came to meetings. There was no commitment""

Table 2.21. Perceived benefit of Government cooperation in practice to ICM.

Rating	No responses (%)
5. Extremely beneficial	1 (8)
4. Very beneficial	3 (25)
3. Quite beneficial	3 (25)
2. Slightly beneficial	5 (42)
1. Not beneficial	0
Mean Rating	3.0

2.7.6 Level of community/public participation in government

Members were asked to rate on an eight point scale from their experience in the Herbert catchment, what sort of community/public participation in government decision making (a) in practice *mostly occurs* and (b) *should occur* in relation to a range of specified natural resource management activities or processes. The seven point scale were:

1. *No interaction* between the government department and the community
2. *Informing* the community of the decisions that have been made
3. *Consulting* the community through advertisements and invitations for formal submissions with the final decision being made by the department
4. *Involving* the community in workshops and meetings to help define the problem and scope the community's issues with the final decision being made by the department
5. *Shared* planning and decision making between the government department and the community
6. *Decisions made by the community*
7. *Community control and management*
8. Multiple variations of 1-7 above.

Members had a diversity of opinions and the results are presented in Tables 2.22 and 2.23 and discussed briefly below.

Table 2.22. Opinions on the level of public/community participation mostly occurs..

Activity or process	1.	2.	3.	4.	5.	6.	7	8.
(a) land use planning	1	3	5	1	1	0	0	0
(b) environmental protection	5	5	1	0	0	0	0	0
(c) land clearing guidelines	4	2	1	2	1	0	0	0
(d) coordination of drainage	2	0	2	1	2	2	0	1

Table 2.23. Opinions on the level of public/community participation should occur.

Activity or process	1.	2.	3.	4.	5.	6.	7	8.
(a) land use planning	0	0	2	3	7	0	0	0
(b) environmental protection	0	0	2	4	6	0	0	0
(c) land clearing guidelines	0	1	2	2	7	0	0	0
(d) coordination of drainage	0	1	0	7	2	2	0	0

(a) *Land use planning.* Although there was a diversity of opinions, the majority of members (over 70% of respondents) considered that in practice the level of public participation in the Herbert for catchment land use planning occurs mostly through two participatory approaches:

- *Consulting* with the community (eg. through advertisements and invitations for formal submissions) but with the final decision being made by the organisation concerned, or
- *Informing* the community of the decisions that have been made.

However, the majority of members (83% of respondents) felt that public participation in land use planning should occur through greater community involvement, that is:

- *Shared* planning and decision making between the government department and the community, or
- *Involving* the community in workshops and meetings to help define the problem and scope the community's issues with the final decision being made by the department.

(b) *Environmental protection.* Although there was a diversity of opinions, the majority of members (over 90% of respondents) considered that in practice the level of public participation in the Herbert on environmental protection occurs mostly through:

- *No interaction* between the government department and the community; or
- *Informing* the community of the decisions that have been made.

However, the majority of members (83% of respondents) felt that public participation in the Herbert on environmental protection should involve greater community involvement, that is:

- *Shared* planning and decision making between the government department and the community.
- *Involving* the community in workshops and meetings to help define the problem and scope the community's issues with the final decision being made by the department

(c) *Land clearing guidelines.* There was a divergence of opinions on the level of public participation in the Herbert on the development of land clearing guidelines. However, the majority of members (60% of respondents) considered public participation for this issue has occurred mostly through:

- *No interaction* between the government department and the community; or
- *Informing* the community of the decisions that have been made.

However, seven members (58 % of respondents) felt that public participation in the Herbert on land clearing guidelines should involve greater community involvement, that is: through:

- *Shared* planning and decision making between the government department and the community.

While a further four members (32% of respondents) considered the level of public participation should be either:

- *Involving* the community in workshops and meetings to help define the problem and scope the community's issues with the final decision to be made by the department concerned; or
- *Consulting* the community through advertisements or formal submissions with the final decision to be made by the department concerned.

(d) *Coordination of drainage.* There was a distinct divergence of opinion amongst members on the level of public participation that actually occurs in the Herbert catchment with regard to the coordination of drainage in practice. Some members considered that there was no interaction while others considered that decisions were mostly made by the community. However, the majority of members (nearly 60% of respondents) considered the level of public participation for this issue should be through:

- *Involving* the community in workshops and meetings to help define the problem and scope the community's issues with the final decision being made by the department concerned.

A further 4 members (33% of respondents) considered that decision on coordination of drainage should be through:

- Decisions made by the community themselves, or
- Community control and management.

Overall HRCCC members considered that for each of the four issues there should be much greater community influence in decision-making than what occurs at present. Several members also commented that the level of community involvement/public participation in decision-making needs to vary depending on the particular issue of concern between 'Consulting', 'Involving', and 'Shared planning and decision making'.

2.8 Local Government and ICM

2.8.1 Satisfaction with the involvement of local government

Members were asked to comment on their satisfaction with the level of involvement of local government in ICM in the Herbert. Of the 10 members responding to this question, all expressed satisfaction with the level of local government involvement. Local Government was seen to be involved in a number of ways, including:

> "Working together on projects, issues, funding applications, putting together riparian vegetation guidelines, and guidelines for conversion to intensive agriculture."
>
> "ICM had an input into the Shire Strategic Plan.– Local Government consult ICM for advice - Hinchinbrook Shire Council supports ICM in the Herbert."
>
> "Yes, the Shire Councils send representatives to meetings. They have powers to set conditions."
>
> "Yes especially the case study on planning in Hinchinbrook Shire. It is a fairly symbiotic arrangement"

"Highly involved (eg Shire strategic plan), the Integrated Pest Management Plan. Local Government gets involved in meetings - and it is valuable"

"Two councillors (including the Mayor) and Shire Engineer attend meetings"

"The Hinchinbrook Shire Planning study was very useful. Council looks to the ICM group for direction on land and water management issues."

"ICM has supportive Councils - including one Mayor involved in the group. Also many projects administered by Councils."

"I am not sure how they've gone with the Local Government Planning schemes - it if has been implemented it's great"

Importantly, local government involvement was perceived by all members to be of high or critical importance to the success of ICM in the Herbert, and that effectively, ICM could not really function well without local government involvement.

2.8.2 What local government can do to help ICM

Members were asked to comment on what more local government could do to help ICM in the Herbert catchment. In general, members felt that local government was doing all that had been asked of them by the HRCCC. However specific comments on what more they could do included:

"If do what have in place and carry through with it, not much more could do"

"The Council has said they would do stuff, but this has yet to be proven. When any development application is made, they should consult the HRCCC."

"Going well and well supported by council. Done all that was asked."

"Local Government should give their program of work in advance to committee, particular in relation to resources - sharing of planning applies to industry as well."

"More money should be diverted to floodplain management issues (instead of halls, swimming pools)."

"Not really - continue support involved in meetings. Perhaps support for funding of activities."

"Could be doing more as a land manager (where education etc fails). They should have environmental strategies."

2.8.3 Opinions of the Hinchinbrook Shire Agricultural Planning Process

Members were asked their opinions of the new/proposed Hinchinbrook Shire Agricultural Planning Process. All members who were aware of the new planning process supported it.

Members were also asked if they considered that it was fair to all interests. The nine respondents to this question all considered it to be fair to all interests. The reasons given included:

"It appears to be fair but six different bodies have to give approvals - could be time-consuming."

"Yes if it is done properly."

"It is fair - although some people may think not."

"Yes – it only affects new applications."

"Providing it is discussed with people involved."

Members were then asked if they thought that the new process would change the way land and water resources are used and managed in the Shire/catchment. The nine respondents felt that it would change the way land and water resources are managed in the Shire/catchment for a variety of reasons including:

"Yes, for the better. It will be done on a more coordinated sustainable manner."

"It will - needed a long time ago."

"Yes – it has to (ie in relation to new developments)."

"Only with new development. Problem with policing. There will be powers under new legislation to de-assign land."

"Yes – now someone else can take the flack."

"Yes it will (eg acid sulfate soil risk areas). It will give codes of practice a bit of bite"

"Yes it will change it in the lower catchment."

2.9 Influences on ICM

2.9.1 Difficulties of ICM implementation

HRCCC members were asked to rate their opinion on a five point scale (strongly disagree to strongly agree) on a series of statements concerning difficulties of ICM implementation. The statements relate to members views on ability to control and the tractability of resource issues, views on government, community involvement or willingness to participate, and reaching community consensus. The findings are presented in Table 2.24 and discussed below.

When greater than 80% of respondents agreed (ie. a rating of either 'agree' or 'strongly agree') or disagreed (ie. a rating of either 'disagree' or 'strongly disagree') with the statement, this was given an overall rating of 'high agreement' or 'high disagreement' respectively. When 60 to 80% of respondents agreed or disagreed with the statement, this was given an overall rating of 'general agreement' or 'general disagreement'. Where there was a clear divergence of opinions amongst members with a spread of responses from disagree to agree (and a mean rating of 2.5 to 3.5), this was given an overall rating of 'split opinion'.

Ability to Control/Tractability of Resource Issues. Members were asked to consider five statements relating to the ability of the community to control ICM implementation or the tractability of resource issues in terms of the difficulty they posed to ICM implementation (on a five point scale from strongly agree to strongly disagree). The results are presented in Table 2.24.

Table 2.24. Level of influence on ICM implementation of factors relating to the community ability to control.

The implementation of ICM in the catchment is difficult because:	5. Strongly Agree	4. Agree	3. Neither	2. Disagree	1. Strongly Disagree	Mean Rating	Rating
a. The large size of the catchment (or poor linkages between parts of catchment)	1	9	0	2	0	3.8	High agreement
e. The perception that ICM has been forced on the catchment by the state government	0	0	0	9	3	1.8	High disagreement
j. The lack of financial resources within the community - upper	1	9	0	0	0	4.1	High agreement
k. The lack of financial resources within the community - lower	0	6	1	4	0	3.2	Split opinion
n. There is no single acute resource management problems within the catchment	0	1	0	8	0	2.2	High disagreement

There was a strong consensus amongst respondents that ICM was difficult to implement because of:

- The large size of the catchment (or poor linkages between parts of catchment).
- The lack of financial resources within the community in the upper catchment.

Similarly there was a strong consensus of opinion amongst respondents that they clearly disagreed with the statements that ICM was difficult because of:

- A perception that ICM has been forced on the catchment by the state government, or
- There is no single acute resource management problem within the catchment.

However there was a clear divergence of opinion amongst members on whether or not the lack of financial resources within the community of the lower catchment made ICM implementation difficult.

Views on Government. Members were asked to consider four statements relating to members' views on trust and coordination in government and its influence on ICM implementation. The results are presented in Table 2.25.

Table 2.25. Level of influence on ICM implementation of factors relating to trust and coordination in government.

The implementation of ICM in the catchment is difficult because:	5. Strongly Agree	4. Agree	3. Neither	2. Disagree	1. Strongly Disagree	Mean Rating	Rating
c. State government agencies do not cooperate with each other	3	6	2	1	0	3.9	High agreement
g. State government agencies do not listen to the Herbert community concerns	0	4	2	5	0	2.7	Slit opinion
i. The public's lack of trust in state/local government-sponsored initiatives	1	1	2	7	0	2.6	General disagreement
o. The lack of coordination between state government agencies in addressing issues	2	2	1	2	0	3.6	General agreement

There was a general consensus of opinion amongst respondents that ICM was difficult to implement because of:

- The lack of cooperation between State government agencies, and
- The lack of coordination between state government agencies in addressing issues.

There also was a strong concurrence of opinion amongst members that they *disagreed* with the statement that ICM was difficult because of:

- The public's general lack of trust in government-sponsored initiatives.

However there was a clear divergence of opinion amongst members on whether or not the implementation of ICM implementation was difficult because of the failure of State government agencies to listen to the Herbert community concerns.

Community Involvement/Willingness to participate. Members were asked to consider three statements relating to members' views on influence of community involvement and willingness to participate on ICM implementation. The results are presented in Table 2.26.

Table 2.26. Level of influence on ICM implementation of factors relating to community involvement and willingness to participate.

The implementation of ICM in the catchment is difficult because:	5. Strongly Agree	4. Agree	3. Neither	2. Disagree	1. Strongly Disagree	Mean Rating	Rating
d. Some important constituency groups are not represented in the ICM process	1	4	2	5	0	3.1	Split opinion
f. The public's lack of interest in community type activities	1	4	2	4	1	3.0	Split opinion
h. The lack of an effective level of interest by HRCCC members	0	3	2	7	0	2.7	General disagreement

In general, there was a consensus amongst respondents that they disagreed with the statement that ICM was difficult in the Herbert catchment because of the lack of an effective level of interest by HRCCC members. However there was a clear divergence of opinion amongst members on whether or not the implementation of ICM implementation was difficult because of:

- The lack of representation of some important constituency groups in the ICM process, or
- The lack of public interest in community type activities.

Reaching Consensus.
Members were asked to consider three statements relating to members' views on the difficulty posed to ICM implementation by the level of community consensus. The results are presented in Table 2.27.

Table 2.27. Level of influence on ICM implementation of factors relating to community consensus.

The implementation of ICM in the catchment is difficult because:	5. Strongly Agree	4. Agree	3. Neither	2. Disagree	1. Strongly Disagree	Mean Rating	Rating
b. The wide variety of values and beliefs among HRCCC members seriously detracts from an effective level of cooperation developing among them	0	2	1	7	2	2.3	General disagreement
l. The lack of agreement among HRCCC members concerning its objectives	0	4	2	6	0	2.8	Slit opinion
m. The lack of agreement on feasible solutions to catchment issues	0	6	1	4	0	3.2	Slit opinion

In general there was a consensus amongst respondents that they disagreed with the statements that ICM was difficult in the Herbert catchment because of the wide variety of values and beliefs among HRCCC members seriously detracts from an effective level of cooperation developing among them. However there was a clear divergence of opinion amongst members on whether or not the implementation of ICM implementation was difficult because of:

- The lack of agreement among HRCCC members concerning its objectives.
- The lack of agreement on feasible solutions.

In summary, there was a strong consensus amongst respondents that the implementation of ICM was difficult because of:

- The large size of the catchment (or poor linkages between parts of catchment).
- The lack of financial resources within the community in the upper catchment.
- The lack of cooperation between State government agencies.

There was also a strong consensus amongst respondents that ICM implementation was *not* made difficult because of:

- The lack of a single acute resource management problem within the catchment (eg. to focus attention), or
- A perception that ICM has been forced on the catchment by the state government, or
- The presence of a wide variety of values and beliefs among HRCCC members that was seriously detracting from an effective level of cooperation developing amongst them; or
- The public's general lack of trust in government-sponsored initiatives.

The relationship between ICM and Landcare in the Herbert catchment

Members were asked in their opinion what they considered was the relationship *in practice* between ICM and Landcare in the Herbert. Nine respondents considered that there is a strong or close relationship between Landcare and ICM in the Herbert River catchment. Comments included:

> "Very strong. - Coordinator runs both. There is an overlap in that the HRCCC does Landcare activities. Credit is split. - Nearly 50% of HRCCC is in Landcare."
>
> "Very close. Significant overlap of people. ICM is Landcare's secretariat."
>
> "Its very good - ICM arrange/raise things and Landcare is the "doer".
>
> "Close - separate committee. Landcare focuses move on on-ground works and involves small groups of landholders. ICM focuses on overall catchment issues."
>
> "Strong (eg. the Wharp's tree planting program, Waterwatch). ICM raises issues as a group, while Landcare get "fingers dirty."

"Lots of interaction because many people belong to both. But ICM needs separate a identity."

"Good. Landcare just started up again. ICM has actually in past done Landcare things but now ICM is moving to more policy areas and Landcare is more hands on."

"There is a good relationship. Landcare is dealing with smaller issues, and it is helping implement the catchment strategy."

However two other members were not as convinced that the relationship was close and comments included:

"No communication but they all talk about the same things."

"Landcare is just crawling along and is the poor relation to ICM. Starting to crank it up, but not doing enough."

Members were also asked what they considered *should be* the relationship between ICM and Landcare in the Herbert. Most respondents considered that the relationship should be strong and complementary. Comments included:

"ICM as the planning agency/Landcare as the doers"

"Complementary, with Landcare doing the onground stuff"

""ICM/Landcare could be combined. Landcare does on-ground works."

"The current relationship is OK. But ICM isn't getting the recognition it deserves from this."

"ICM should be planners. Landcare the doers"

"In the future will be under one umbrella"

"As is, it works well"

"The current relationship is- appropriate"

"Linkage OK in lower catchment, but needs to be stronger in upper"

2.9.2 Member's perspectives of ICM and its influence

Members were asked to rate their opinion on a five point scale (from strongly agree to strongly disagree) on a range of statements relating to responsibility and ability to control, trust and confidence in government, level of awareness and fairness in land and water resources management. These were all considered potential influences on the implementation of ICM in the Herbert catchment.

When greater than 80% of respondents agreed (ie. a rating of either 'agree' or 'strongly agree') or disagreed (ie. a rating of either 'disagree' or 'strongly disagree') with the statement, this was given a rating of 'high agreement' or 'high disagreement' respectively. When 60 to 80% of respondents agreed or disagreed with the statement, this was given a rating of 'general agreement' or 'general disagreement'. Where there was a clear divergence of opinions amongst members with a spread of responses from disagree to agree (and a mean rating of 2.5 to 3.5), this was given a rating of 'split opinion'.

Responsibility. 'Responsibility' includes views on assigned responsibility for dealing with land and water management issues. Members were asked to rate their level of agreement or disagreement with five statements relating to responsibility and their responses are provided in Table 2.28.

There was a strong consensus among respondents that

- ICM should remain a voluntary activity by community members, and
- Many environmental problems come from the way people manage their properties

However there was a clear divergence of member's opinions on whether:

- Catchment management should be paid for by the government;
- Many environmental problems come from the way people manage their properties;
- Laws should be changed to make landholders more responsible for the consequences of their activities.

Table 2.28. Member views on responsibility and control.

Statement	5. Strongly Agree	4. Agree	3. Neither	2. Disagree	1. Strongly Disagree	Mean Rating	Rating
Catchment management should be paid for by the government	1	8	1	5	0	3.3	Split opinion
ICM should remain a voluntary activity by community members	2	11	2	0	0	4.0	High agreement
Many environmental problems come from the way people manage their properties	3	11	0	1	0	4.1	High agreement
The government expects too much from local communities in catchment management	2	4	3	6	0	3.1	Split opinion
Laws should be changed to make landholders more responsible for the consequences of their activities	2	4	1	8	0	3.0	Split opinion

Overall members clearly felt that the community had a responsibility regarding land and water management. However views on government responsibility and the degree of control necessary for addressing land and water management were unclear.

Trust in Government. Views on government include member's perspectives on trust and perceived competence in government. Members were asked to rate their level of agreement or disagreement with five statements relating to trust in government and their responses are provided in Table 2.29.

Table 2.29. Views on trust in government.

Statement	5. Strongly Agree	4. Agree	3. Neither	2. Disagree	1. Strongly Disagree	Mean Rating	Rating
The government needs to give more resources to voluntary groups	4	10	0	1	0	4.1	High agreement
Different government agencies often give conflicting advice/information on land and water management issues	6	7	1	0	1	4.1	High agreement
There should be better government incentives for landholders to address environmental issues/problems	6	7	0	0	0	4.5	High agreement
ICM programs should have legislative backing	1	7	2	4	1	3.2	Split opinion
The government gives plenty of resources to voluntary groups	0	2	0	10	1	2.2	High disagreement

There was a strong consensus among respondents that:
- The government needs to give more resources to voluntary groups
- Different government agencies often give conflicting advice/information on land and water management issues; and
- There should be better government incentives for landholders to address environmental issues/problems

However there was a clear divergence of member's opinions on whether the ICM program should have legislative backing. Significantly there was a consensus amongst respondents that they disagreed with the statement that the government gives plenty of resources to voluntary groups.

In general there was a clear agreement amongst members that there was a need for better incentives for landholders and greater resourcing of community groups for catchment management. However HRCCC members views on legislative control of ICM were not clear.

Awareness and Fairness. "Awareness and fairness' includes members views on level of awareness and perceived fairness (both procedural and outcome). Members were asked to rate their opinion on a five point scale (from strongly agree to strongly disagree) on a range of statements relating to fairness and awareness issues. Members responses are presented in Table 2.30.

There was a strong consensus of opinion amongst respondents on the importance of procedural fairness, that is:

- If the decision making process is fair, people should accept the final planning or land allocation decision.
- The new proposed land allocation decision process for the Hinchinbrook Shire is fair to all interests.
- Land should be managed for the public good because it belongs to everyone.

Table 2.30. Views on fairness and level of awareness.

Statement	5. Strongly Agree	4. Agree	3. Neither	2. Disagree	1. Strongly Disagree	Mean Rating	Rating
There aren't any environmental problems that need urgent action	1	3	0	2	7	2.2	General dis-agreement
Landholders have the right to use their land as they see fit	0	2	1	8	4	2.1	High dis-agreement
Land should be managed for the public good because it belongs to everyone	2	7	2	1	1	3.6	High agreement
All sections of the community have the right to have a say on planning proposals	2	8	1	3	0	3.6	General agreement
If the decision making process is fair, people should accept the final planning or land allocation decision	0	10	0	1	0	3.8	High agreement
Land use planning should maximise the overall economic income of the community	2	4	0	5	1	3.1	Split opinion
The new proposed land allocation decision process for the Hinchinbrook Shire is fair to all interests	2	9	0	0	0	4.2	High agreement

There was also a general level of consensus relating to the fairness of outcomes of decision-making that:

- All sections of the community have the right to have a say on planning proposals.

However members were clearly divergent in their views on whether land use planning should maximise the overall economic income of the community.

Importantly, there was a consensus amongst respondents that they disagreed that

- there weren't any environmental problems that need urgent action, or
- landholders have the right to use their land as they see fit.

In summary there was clear agreement amongst members on the need for both fairness of process in land allocation and planning decisions and broad community involvement. However views on the fairness of outcomes were less clear.

2.9.3 Cost sharing

Members were asked for every $100 spent on catchment management and Landcare, how much of it they thought *SHOULD* be contributed by each tier of government, industry and individual farmers. Their responses are presented in Table 2.31.

Table 2.31. Views on cost sharing on catchment management and Landcare.

Party	Mean Amount in $s (Range)	Rank
(a) The Commonwealth Government?	29.5 (20-50)	1
(b) The Queensland Government?	29.1 (20-50)	2
(c) Local Government on the Herbert Catchment?	17.0 (10-30)	3
(d) Industry?	13.9 (0-30)	4
(e) Individual farmers?	9.8 (0-20)	5
TOTAL	$100	

Overall members considered that all parties (ie. all three tiers of government, industry and individual farmers) should contribute to catchment management. However on average members felt that the Commonwealth and State Governments should contribute considerably more than other parties with individual farmers contributing the least. Comments in support of these views of respondents included:

> "ICM is a State responsibility."
>
> "Cost should be shifted slightly to local government (through the rates system)"
>
> "Commonwealth Government should pay the bulk. Local Government, industry and individual farmers to all have some "local" contribution"
>
> "Commonwealth is the "big picture" and they and the state should be equal. However, too much in the past has been left to Government to come in and clean up afterwards - industry should contribute more."
>
> "Because of NHT and the sale of Telstra, the Commonwealth and Queeensland Government should contribute the greatest. However Local Government have powers and should back with $s too"
>
> "Costs should be shared. Industry should contribute more – much more - especially at the local level"

2.9.4 Personal demands.

Members were asked to identify on average, how many hours per month they devoted to ICM. The results are presented in Table 2.32.

Table 2.32. Hours spent on ICM, 1998

No. of Hours per Month	No. Responses
<2	0
3-6	4
7-10	3
11-15	0
16-19	1
20-30	3
>30	2
Average (Voluntary only)	11.4

The Catchment Coordinator for the Herbert ICM and the State Government representative from DNR participating in HRCCC meetings are fully employed on ICM matters and spend over 100 hours per month. The average number of hours devoted by the voluntary members to the Herbert ICM process was 11.4 hours (ranging from 3 hours per month to 25-30 hours).

3. COMPARATIVE ANALYSIS OF 1995, 1997 AND 1998 SURVEY FINDINGS

3.1 Introduction

This section of the report provides a comparison of the opinions of HRCCC members on specific aspects of ICM in the three surveys of HRCCC survey members conducted in November 1995 (McDonald and Shrubsole 1996), November 1997 (Bellamy *et al.* 1998) and the current survey. The main focus of the discussion is to identify any changes or differences in member's perspectives.

3.2 HRCCC Membership

Changes in Membership
The membership of the HRCCC between 1997 and 1998 declined by two representatives; one being a Councillor from the upper catchment (deceased) and the other a community organisation in the lower catchment, which had ceased to be an operative group in the community by 1998. The stability and continuity of the membership remained between 1997 and 1998 with 9 of the 16 members being the original foundation members of the HRCCC. By June 1999, a new representative from the State government Environmental Protection Agency (EPA) had been invited to join the Committee. Previously the EPA (formerly the Department of Environment) had been involved as Technical advisers to the HRCCC. The invitation to join the Committee arose in response to difficulties with the EPA in getting their endorsement for the Catchment Management Strategy. The Department of Natural Resources, however, has still only formally involved as technical advisory capacity to the Committee.

The Upper Herbert River Catchment Group
A Sub-Committee of the HRCCC was formally formed for the upper catchment in December 1998 to discuss and raise issues of particular relevance to the upper catchment. This sub-committee, the Upper Herbert River Catchment Group, arose because community members in the upper catchment felt that they were not equally represented on the HRCCC. The HRCCC membership has been overwhelmingly dominated by members from the lower catchment and has inevitably tended to have a focus on issues affecting the lower floodplain. In addition, there were logistical issues relating to the long distance between the upper and lower catchments (ie. a 4-5 hour drive). The new sub-Committee has 16 members selected to represent a broad range of catchment stakeholders from the community, industry and government as identified in Table 3.1.

Table 3.1. Upper Herbert River Catchment Group representation.

Industry Organisations	Mining industry Cattle industry/AG FORCE (2) Dairy industry Timber industry Red Bend Irrigators

Government	Herberton Shire Council Queensland National Parks and Wildlife Service Environmental Protection Agency

3.3 Problem Characterisation

3.3.1 Key resource management issues

The most important resource management issues in the catchment identified by HRCCC members in 1995, 1997 and 1998 are compared in Table 3.2. In general, member's perspectives on natural resource management issues had broadened and become more strategic in scope since 1995. Rural drainage, flooding, river management and sugar industry expansion and related land clearing have remained key issues for the HRCCC members across all surveys. However since 1997 additional issues identified were water quality (particularly relating to fish kills, and stream sedimentation), riparian vegetation and wetlands management, pest and weed management, land use planning and a coordinated approach to catchment management. While in 1998, with closer linkages to the upper catchment community seeming to develop, two further issues largely important to the upper catchment were also identified as grazing land degradation/erosion and water availability issues.

Table 3.2. Comparison of Perceived Key Resource Management Issues by the HRCCC 1993-1998.

November 1995	November 1997	November 1998
Rural drainage	Rural drainage	Drainage coordination/ management on floodplains
Stream bed/bank erosion	River management	Waterways management and flooding
Urban flooding		Sugar industry expansion
Allocation of sugar caneland	Caneland expansion	Land clearing
Land clearing		Water quality
	Water quality	Riparian vegetation management
	Riparian management	Wetland degradation/ management
	Wetland degradation	Weed management
	Pest and weed management	
	Coordinated extension approach	
	Catchment planning	Land use planning, catchment management
		Grazing land degradation/erosion
		Water quantity/availability (upper)

In 1998, HRCCC members were asked a repeat question from the 1995 survey relating to their perspective of the significance of specified of natural resource management issues affecting people in the Herbert. In both surveys they rated their opinion on a five-point scale from very high significance (5) to very low significance (1). The results are compared in Table 3.3. In general, member's perspectives on the relative importance of these specified issues have remained predominantly the same.

Table 3.3. Significance of natural resource management issues affecting people in the Herbert catchment.

Issue	1995 Mean Rating	1998 Mean Rating
Land degradation	2.8	2.6
Grazing land degradation	2.8	2.6
Water quality problems	3.1	3.4
Water quantity problems	2.4	1.9
Rural flooding	3.5	4.1

In early 1999, the new Upper Herbert River Catchment Group identified and prioritised the key issues for the upper catchment as detailed in Table 3.4. Although there are some commonalities with those issues identified by the formal HRCCC, the focus of the issues identified by the upper catchment sub-committee is quite different in that they are largely concerned with specific land and water management issues rather than including broader planning and public good issues.

Table 3.4. Key issues in priority order for the Upper catchment.

1. Weeds in general (ie. noxious weeds, ponded pastures, stream blockers)
2. Erosion (ie. cost effective measures)
3. Water conservation (ie. crop water requirements, changed water requirements (eg. for dairy, cane), best practices water harvesting, storage)
4. Water quality (ie. turbidity, chemical, sediment)
5. Land clearing (ie. best practice in native forest, management (fire, grazing, timber), potential cropping areas)
6. Soil fertility (ie. potential for cropping – forage and fruit, salinity, manganese, nitrification)
7. Wetland/wildlife preservation (ie. birds/maintenance of habitat (natural, artificial), feral animals)
8. Land subdivision (ie. more and larger approvals, water quality implications, licensing, multiplier effects of dams)
9. Creek and river restoration (ie. repair and cleaning)

3.3.2 Key impacts of issues

A comparison of the perceived impacts of issues by members for 1995 and 1998 are presented in Table 3.5. Some significant differences can be seen in the member's perceptions of impacts of issues between 1995 and 1998 both in terms of the relative importance of specific impacts as well as their rank level. In 1995 all impacts were rated by members as moderate or high. In contrast, in 1998 several impacts were rated overall as low to very low. In particular poor drinking water quality, high cost of water, loss of access to recreation and loss of environmental uses or benefits were all rated more lowly as impacts, while loss of farm productivity was ranked relatively higher in 1998. In the case of poor drinking water and the high costs of water, the significant drop in perceived level of impact probably relates to the fact that due to the problem of water turbidity the Hinchinbrook Shire Council established a new source of water supply for the lower catchment (ie. groundwater bores). In addition, members in 1998 were more concerned than previously with the likely impact of land and water management issues on farm productivity, but they rated loss of access to recreation and loss of environmental uses or benefits as of lower concern than previously.

Table 3.5. Perceptions of impacts of specified issues on Herbert community.

Issue	1995 Mean Rating	1995 Rank	1998 Mean Rating	1998 Rank
High cost of water	3.3	10	1.6	10
Loss of farm productivity	3.5	7.5	4.1	1
Higher production costs	3.9	3	3.8	2
Poor drinking water	4.1	1	2.2	9
Emotional stress	3.7	4.5	3.0	6
Higher taxes	3.7	4.5	3.7	4
Lower fish numbers/fish kills	3.4	9	3.7	4
Loss of access to recreation	3.5	7.5	2.4	7
Loss of confidence in government's ability to manage land and water resources	4.0	2	3.7	4
Loss of environmental uses or benefits	3.6	6	2.3	8

3.4 HRCCC Progress and Achievements

3.4.1 Major achievements of the HRCCC

The major achievements of the HRCCC identified by members in the 1995, 1997 and 1998 surveys have been summarised into key points and these are presented in Table 3.6.

There is considerable commonality in the achievements identified by members in each of the surveys. However, the achievements recognised broadened have overall broadened since the

1997 survey to encompass community impact (e.g. awareness raising) and HRCCC role as a recognised and influential body on natural resource management issues in the catchment.

3.4.2 Significant projects

Across the three surveys there was a significant increase in the number and type of project that the HRCCC became engaged in as shown in Table 3.7. They broadened from tin mines and tailing dam inventory in the upper catchment in 1995 to include in 1997 and 1998 a joint project with Herbert River Improvement Trust (HRIT) at Long Pocket on bank stabilisation, the owl nesting box program, a Catchment Atlas, several restoration and revegetation projects, riparian vegetation mapping study, weed control, riparian "community" forum, acid sulphate soils awareness, and a cooperative project to link ICM and local government planning.

Table 3.6. Members opinions of HRCCC achievements.

1995 Achievements	1997 Achievements	1998 Achievements
• Establishing a group that is bringing key catchment group representatives together to talk and share ideas. • Preparation of an initial draft catchment strategy. • Assisting community groups and agencies to undertake projects (e.g. tin mining sites in upper catchment).	• HRCCC meetings providing a forum that brings people together in the catchment with very different views. • The preparation and launching for public review of the Draft Herbert River Catchment Strategy. • Getting funding and undertaking a range of projects. • Raising awareness of catchment problems amongst HRCCC members and within the community • Taking on a coordinative and integrative role on natural resource issues in region • Recognition as a source of advice on natural resource issues in the catchment.	• Providing a forum that brings very different people in the catchment together to exchange ideas and providing a catalyst for change • Supporting and brokering funding for a wide range of projects on natural resource management (including the development of a catchment management strategy) • Raising community awareness of catchment NRM issues • As an influential group on NRM in the catchment

Table 3.7. Comparison of key projects undertaken by the HRCCC, 1995-1998.

November 1995	November 1997	December 1998
• Funding for tin mine and tailing dams inventory.	• Project with HRIT at Long Pocket wash away. • Several Owl nesting box program • Joint restoration and revegetation projects (e.g. Wharps area, riparian area management, artificial wetland development, tree planting). • Riparian vegetation mapping study • Riparian "community" forum. • Acid sulphate soils awareness.	• Mine tailing dam survey (upper) • Joint project with HRIT at Long Pocket on riverbank rehabilitation • Owl nesting boxes • Getting community involved in Landcare projects (eg. Wharps Estate, creek restoration, tree planting, Waterwatch) • Riparian vegetation mapping • Acid sulfate soils awareness • Herbert River Catchment Management Strategy • Catchment Atlas • Support for Herbert Mapping Project which led to the establishment of the Herbert Resources Information Centre (HRIC) • Weed control/clearing of waterways • ICM/Local Government wetlands study

3.4.3 Satisfaction with progress

Members were asked in both 1995, 1997 and 1998 about their level of satisfaction with progress in the HRCCC on a five-point scale from very satisfied to very unsatisfied. Over the period 1995 to 1998, there appears to be a general improvement in satisfaction with progress. In 1995, 55% of members gave a rating of 'satisfied' or 'very satisfied'; in 1997 this had increased to 78% of members, and by the end of 1998 risen to 86% of respondents. A comparison of the results is presented in Table 3.8.

Table 3.8. Comparison of level of satisfaction on progress in the HRCCC for 1995, 1997 and 1998.

Satisfaction Level	1995 No. (%)	1997 No. (%)	1998 No. (%)
Very satisfied	1 (9)	1 (6)	3 (20)
Satisfied	5 (45)	13 (72)	10 (66)
Neither	3 (27)	1 (6)	1 (7)
Unsatisfied	1 (9)	3 (16)	1 (7)
Very Unsatisfied	1 (9)	0 (0)	0 (0)

3.4.4 Improving the HRCCC's performance

Members were asked in both the 1997 and 1998 surveys their views on the ways that the HRCCC could improve its performance. As Table 3.9 shows, member's views had not substantially changed with the most common issues being raising the profile of ICM and the HRCCC in the community through more targeted publicity as well as the adequacy and security of funding to support the ICM process. In both surveys maintaining legitimacy with appropriate and broad representation was also a major issue for a number of members.

Table 3.9. Comparison of view on improving performance, 1997 to 1998

1997	1998
• Better publicisation of ICM and the HRCCC in the community, • Adequacy and security of funding • Ensuring ICM's legitimacy (through representation) • Better coordination and cooperation amongst state government agencies • Support of legislative powers/backing	• More publicity to raise the profile of ICM/HRCCC in the community. • More resources/funding to undertake community or general awareness raising projects. • Broaden representation of views on the HRCCC (eg. direct involvement of local business through the Chamber of Commerce; active involvement of environment interests; representation of government technical expertise). • Improve input from technical expertise to move the process forward more quickly and effectively.

3.5 HRCCC Role

In both 1997 and 1998, members were asked their level of agreement with a range of statements on the HRCCCs role, as detailed in Table 3.10. There was again much commonality in member's views on the role of the HRCCC across both the 1997 and 1998 surveys with most members agreeing or strongly agreeing that the HRCCC's role has been to:

- Encourage research and data gathering and analysis;
- Initiate key collaborative linkages/ arrangements with other organisations;
- Help negotiation among resource stakeholders; and
- Help stakeholders in defining the source of resource problems;

However, there was substantially less agreement in 1998 than in 1997 regarding whether the HRCCC's role was to:

- Help stakeholders in identifying solutions to resource problems; or
- Help stakeholders in ensuring their resource management practices are equitable and accountable.

Table 3.10. Comparison of level of agreement/disagreement with statements on the HRCCC's role for 1997 and 1998.

Statement	1997 Mean Rating	1997 Rating	1998 Mean Rating	1998 Rating
a. Helped negotiation among resource stakeholders to accommodate a wide range of resource uses	3.7	High agreement	4.0	High agreement
b. Initiated key collaborative linkages/ arrangements with other organisations to actively address key land and water use issues in the catchment	-		4.1	High agreement
c. Helped stakeholders in defining the source of resource problems	(3.8)	High agreement	3.8	High agreement
d. Helped stakeholders in identifying solutions to resource problems	(3.8)	High agreement	3.6	General agreement
e. Helped stakeholders in ensuring their resource management practices are equitable and accountable	3.8	High agreement	3.1	Split opinion
f. Encouraged research and data gathering and analysis in order that solutions to resource problems can be better understood	4.1	High agreement	4.2	High agreement

3.6 Public Attitudes, Support and Involvement

3.6.1 Level of public awareness on natural resource use issues

In all three surveys members' views were sought on the level of public awareness on natural resource issues within the Herbert River catchment as detailed in Table 3.11. In 1995, responses were given for the Herbert community as a whole. In 1997 and 1998, members views differentiated between rural and urban communities.

Overall members considered that public awareness in the rural community has improved substantially since 1995 but were less convinced of an improvement in urban awareness. For example, 42% of those responding in 1995 gave a moderate to very high rating to public awareness, while in contrast, 72% of members in 1997 and 71% in 1998 considered rural awareness to be moderate or higher. However members were less convinced of urban awareness in 1998 than in 1997 with 53% of members in 1997 rating urban awareness as moderate or higher, but this rate dropped to only 35% in 1998.

Table 3.11. HRCCC Perspectives on the Level of Public Awareness on natural Resource Issues for 1995, 1997 and 1998.

Rating	1995	1997 - Rural	1997 - Urban	1998 - Rural	1998 - Urban
Very high	1 (8)	3 (17)	1 (6)	3 (21)	2 (14)
High	0 (0)	7 (58)	2 (12)	4 (29)	0 (0)
Moderate	5 (42)	3 (17)	6 (35)	3(21)	3 (21.5)
Low	6 (50)	3 (17)	1 (6)	4 (29)	6 (43)
Very low	0 (0)	2 (11)	7 (41)	0 (0)	3 (21.5)
Average	2.7	3.3	2.4	3.4	2.4

3.6.2 Public support for the HRCCC

In each of the 1995, 1997 and 1998 surveys, HRCCC members were asked to rate their perception of the level of public support for the HRCCC on a five-point scale (from very high to very low). The results are presented in Table 3.12 below. Although there was a divergence of

opinion amongst HRCCC members on this question in all surveys, overall members perceived that support for the HRCCC had increased from a low to moderate level. In 1995 and 1997, 58% and 59% of members respectively rated public support as moderate or higher but in 1998 it had risen to 77% of respondents reflecting an increased confidence by members in public support for ICM.

Table 3.12. Comparison of members opinions of public support for the HRCCC for 1995 to 1998 (numbers and percentages).

Rating	1995	1997	1998
Very High	0 (0)	1 (6)	0
High	1 (8)	3 (18)	3 (23)
Moderate	6 (50)	6 (35)	7 (54)
Low	3 (25)	6 (35)	2 (15)
Very Low	2 (17)	1 (6)	1 (8)
Mean	2.5	2.8	2.9

3.6.3 Improving stakeholder involvement

In each of the three surveys, HRCCC members were asked what could be done to improve the acceptance and involvement of relevant groups and the general public in the HRCCC process. A diversity of opinions were expressed in each surveys. However, there are some common elements as well as some distinct differences. The members' suggestions for each survey are summarised in Table 3.13..

In both 1995 and 1997 members identified the need for a legislative base for ICM. However this issue was not raised in 1998, which may relate to the evolving linkage of ICM and local government planning schemes in the Herbert in this period. In 1995, members also identified the need to get better involvement of local government, funding for projects, and raising public awareness. All of these were addressed/achieved by 1997 to the satisfaction of HRCCC members (as identified previously). In 1997 and 1998, members also identified improving representativeness of the HRCCC and effectiveness of State Government agency involvement as key issues of concern. In addition, in 1998 members identified that representatives had a duty to be accountable to their constituents by arranging proxies when they personally were unable to attend HRCCC meetings.

Table 3.13. Member suggestions on ways stakeholder involvement could be improved.

1995	1997	1998
• Greater publicisation and promotion of the HRCCC and its activities (particularly in the media) • Recognising the role of the CCC through legislation • Greater involvement of local government • Getting funding for on-ground works/projects • Raising community/public awareness of natural resource issues. • Greater public consultation	• Greater publicisation and promotion of the HRCCC and its activities (particularly in the media) • ICM to be given legislative power/base • Improve representativeness of the CCC (e.g. Some stakeholder groups were not involved in the HRCCC) • More effective government agency involvement • Government agencies to consult with the HRCCC on all their programs in the Herbert catchment.	• Include representatives from Chamber of Commerce and tourism industry. • Improve representation of conservation interests on the CCC • Representatives should be more accountable and use proxies when they cannot be present • More effective government agency involvement

3.7 Factors Influencing ICM Process

3.7.1 Difficulties of ICM implementation

In the 1995, 1997 and 1998 surveys, HRCCC members were asked to rate their opinion on a five point scale (strongly agree to strongly disagree) on a series of statements relating to difficulties in ICM implementation. The statements and responses are compared below for the three surveys.

a. The large size of the catchment (or poor transportation links between parts of catchment).

In all surveys, the majority of HRCCC members 'strongly agreed' or 'agreed' that the large size of the catchment made ICM implementation difficult. However 4 members in 1997 disagreed with this statement and 2 in 1998.

	Strongly Agree	Agree	Neither	Disagree	Strongly Disagree	Mean Rating	Rating
1995	0	11	1	0	0	3.9	High agreement
1997	4	9	0	4	0	3.8	High agreement
1998	1	9	0	2	0	3.8	High agreement

b. The wide variety of values and beliefs among HRCCC members seriously detracts from an effective level of cooperation developing among them.

In 1995, the majority of members (75%) 'strongly agreed' or 'agreed' that the wide variety of values and beliefs among HRCCC members seriously detracted from an effective level of cooperation developing, and only 25% disagreed. However members' opinions have shifted such that they did not perceive this as such an issue with 55% giving a 'disagree' or strongly disagree' rating in 1997 and rising to 75% of respondents in 1998.. This shift suggests a greater acceptance/tolerance of the diversity of views amongst members.

	Strongly Agree	Agree	Neither	Disagree	Strongly Disagree	Mean Rating	Rating
1995	3	6	0	3	0	3.8	General agreement
1997	1	6	0	8	2	2.8	Split opinion
1998	0	2	1	7	2	2.3	General disagreement

c. Some important constituency groups are not represented in the ICM process.

Overall there has been an apparent shift in member's opinions on whether ICM was difficult because important constituent groups were not represented in the ICM process. Specifically, the majority of members (approx. 80%) in both the 1995 and 1997 surveys 'disagreed' or 'strongly disagreed'with the statement, while in 1998 there was a clear slit opinion amongst members with only 42% of respondents 'diagreeing' or strongly disagreeing'. While only 1 member 'strongly agreed' with this statement in 1995, 3 members 'agreed' in 1997 and.4 members 'agreed' and 1 strongly agreed' in 1998.

	Strongly Agree	Agree	Neither	Disagree	Strongly Disagree	Mean Rating	Rating
1995	1	0	1	10	0	2.3	High Disagreement
1997	0	3	0	9	5	2.1	High Disagreement
1998	1	4	2	5	0	3.1	Split opinion

d. The perception that ICM has been forced on the catchment by the state government.

In 1995, there was a divergence of opinion amongst HRCCC members on the statement that ICM implementation was difficult because there was a perception that State Government had forced ICM on the catchment. However the majority of HRCCC members 'disagreed' or 'strongly disagreed' with this statement. In contrast in 1997 and 1998, all respondents 'disagreed' or 'strongly disagreed' that this was an issue.

	Strongly Agree	Agree	Neither	Disagree	Strongly Disagree	Mean Rating	Rating
1995	1	1	2	5	2	2.5	General disagreement
1997	0	0	0	10	6	1.6	High disagreement
1998	0	0	0	9	3	1.8	High disagreement

e. The lack of an effective level of interest by HRCCC members.

Across the three surveys there was a divergence of opinion amongst members on whether ICM in the Herbert was difficult because of the lack of an effective level of interest by HRCCC members. However in 1997 and 1998, the majority of members 'disagreed' or 'strongly disagreed' that this was an issue indicating a slight shift in opinion from 1995 to 1997.

	Strongly Agree	Agree	Neither	Disagree	Strongly Disagree	Mean Rating	Rating
1995	1	2	3	5	1	2.8	Split opinion
1997	1	3	1	7	5	2.3	General disagreement
1998	0	3	2	7	0	2.7	General disagreement

f. The public's lack of trust in state/local government-sponsored initiatives.

There was a clear shift of opinion on this statement over the three surveys. In 1995, the majority of members (67%) were in general agreement with the statement that the public's lack of trust in state/local government-sponsored initiatives made ICM implementation difficult. In 1997, there was a stronger divergence of opinion amongst members on this statement with 39% 'disagreeing' or 'strongly disagreeing'. But by 1998 there was general disagreement with 64% disagreeing with the statement.

	Strongly Agree	Agree	Neither	Disagree	Strongly Disagree	Mean Rating	Rating
1995	3	5	1	2	0	3.8	General agreement
1997	1	8	0	4	3	3.0	Split opinion
1998	1	1	2	7	0	2.6	General disagreement

g. The public's lack of interest in community type activities.

In 1995, the majority of members (67%) were in general agreement with the statement that the public's lack of interest in community type activities made ICM implementation difficult. In 1997 and 1998, there was a stronger divergence of opinion amongst members on this statement. However a greater number of members 'disagreed' in 1997 or 'strongly disagreed' (i.e. 39%) and 1998 (42%) than in 1995 (i.e. 17%).

	Strongly Agree	Agree	Neither	Disagree	Strongly Disagree	Mean Rating	Rating
1995	3	5	2	2	0	3.8	General agreement
1997	1	7	2	7	0	3.1	Split opinion
1998	1	4	2	4	1	3.0	Split opinion

h. The lack of financial resources within the community.

In 1995, the majority of members (67%) were in general agreement with the statement that the lack of financial resources within the community made ICM implementation difficult. In 1997, although there was a stronger divergence of opinion on this statement, a greater number of members (i.e. 44%) 'disagreed' or 'strongly disagreed' than in 1995 (i.e. 25 %). However, in the 1998 survey members were asked to express their views on this statement separately for the upper and lower catchment communities. Notably, there was a clear split opinion amongst members on whether the lack of financial resources within the lower catchment community made ICM implementation difficult, but a clear agreement that in the upper catchment it did make ICM implementation more difficult.

	Strongly Agree	Agree	Neither	Disagree	Strongly Disagree	Mean Rating	Rating
1995	3	5	1	2	1	3.6	General agreement
1997	3	3	2	8	0	3.1	Split opinion
1998- upper	1	9	0	0	0	4.1	High agreement
1998 - lower	0	6	1	4	0	3.2	Split opinion

i. There is no single acute resource management problems within the catchment.

There is an apparent shift in opinion of members from 1995 to 1998 on whether the absence of a single acute resource management problem (eg. of the magnitude of salinity) made ICM nore difficult. There is a clear split opinion amongst members in 1995 and 1997. However in 1998 there was clearly disagreement with this statement with nearly 90% of respondents 'disagreeing'.

	Strongly Agree	Agree	Neither	Disagree	Strongly Disagree	Mean Rating	Rating
1995	1	5	1	5	0	3.2	Split opinion
1997	0	8	0	5	1	3.2	Split opinion
1998	0	1	0	8	0	2.2	High disagreement

3.7.2 Demands on members of ICM involvement

In each of the surveys HRCCC members were asked on average what number of hours per month did they devote to ICM as presented in Table 3.14. There is a clear increase in the average time spent by members on ICM matters over the period 1995 to 1998. In 1995 and 1997, the majority of members (ie. 75% of respondents in 1995 and 72% in 1997) spent 10 hours or less per month on ICM matters. However by 1998, this had dropped to only 30% of respondents with approximately 46% of members committing more than 16 hours per month to ICM.

Table 3.14. Comparison of hours spent on ICM, 1995-1998

Hours/Month	Responses 1995	Responses 1997	Responses 1998
<2	0	1	0
3-6	8	6	4
7-10	1	6	3
11-15	2	3	0
16-20	0	1	3
> 20	1	1	3
Average			11.4

APPENDIX 1.

1998 Questionnaire for HRCCC Members

HERBERT RIVER CATCHMENT COORDINATING COMMITTEE MEMBER

OPINIONS

HRCCC Member's Name: …….

BACKGROUND

1. How long have you lived in this catchment?

……Years

2. What year did you become a member of the HRCCC?

……Years

3. Which of the following groups do you represent on the HRCCC? (please tick)

? Local government
? State government agency
? Sugar industry
? Grazing industry
? Fishing industry (commercial)
? Horticulture/Rare Fruits
? Sporting/recreational Fishing
? Tourism
? Community group
? Conservation
? Other (please specify)

……

……(b)

4. (a) **Are there any other groups, organisations or committees that you are involved with in the Herbert?**

……

……

……

……

(b) **What is your role/position or level of involvement in them?**

……

……

……

……

……

5. Does the organisation you represent have any regulatory/statutory or other linkages with other organisation involved in the Herbert?

……

……

……

……

……

……

……

6. Do you live upstream or downstream from Abergowrie? (please tick)

? Upstream (not including Abergowrie)

? Downstream (includes Abergowrie)

7. What is your occupation?

……

CATCHMENT ISSUES: NATURE AND TRACTABILITY

8. From your perspective we would like to know what are the three key catchment land and water management issues facing people in the Herbert?

Issue	Degree of Complexity	Intensity of Conflict
1. (a1)	(b1)	(c1)
2. (a2)	(b2)	(c2)
3. (a3)	(b3)	(c3)

For each issue identified, can you rate on a 5-point scale:

1 - very low
2 low
3 - moderate
4 high
5 very high
6 - not applicable/don't know

1. the degree of complexity involved in dealing with the issue

2. the level/intensity of community conflict in relation to it

Use the following scale:

1 - very low
2 low
3 - moderate
4 high
5 very high
6 - not applicable/don't know

9.

In your opinion, HOW SIGNIFICANT are each of the following natural resource management issues (1) to you personally, and (2) to the people in the Herbert generally?	**Affects you personally**	**Affects people in Herbert**
(a) Land degradation	(a1)	(a2)
(b) Grazing land degradation	(b1)	(b2)
(c) Water quality problems	(c1)	(c2)
(d) Water quantity problems (Insufficient water)	(d1)	(d2)
(e) Rural flooding	(e1)	(e2)
(f) Rural drainage	(f1)	(f2)
(g) Vegetation on river banks	(g1)	(g2)
(h) Wetlands degradation	(h1)	(h2)
(i) Loss of biodiversity	(i1)	(i2)
(j) Other/s .....(j0) ……(k0)	(j1) (k1)	(j2) (k2)

10.

In your opinion, how much do each of the following IMPACT on, (1) you personally, and (2) people in the Herbert generally?	**Affects you personally**	**Affects people in Herbert**
(a) High cost of water	(a1)	(a2)
(b) Loss of farm productivity	(b1)	(b2)
(c) Higher production costs	(c1)	(c2)
(d) Poor drinking water quality	(d1)	(d2)
(e) Emotional stress	(e1)	(e2)
(f) Higher taxes	(f1)	(f2)
(g) Lower fish numbers/fish kills	(g1)	(g2)
(h) Loss of access to recreation	(h1)	(h2)
(i) Loss of confidence in government's ability to manage land and water resources	(i1)	(i2)
(j) Loss of environmental uses or benefits (eg. wildlife habitat)	(j1)	(j2)
(k) Other/s .....(k0) .....(l0)	(k1) (l1)	(k2) (l2)

11. Using the scale below, rate how much you agree or disagree with the following statements:

1 - strongly disagree
2 - disagree
3 – neither agree nor disagree
4 - agree
5 – strongly agree
6 - not applicable/don't know

Managing land and water in the Herbert is difficult because:	**Rating**
(a) Problems aren't well understood	
(b) Local people lack the money to spend on solutions	
(c) Government strategies are too slow	
(d) Solutions are expensive	
(e) There are few benefits and many costs	
(f) Local people don't want to spend money on solutions	
(g) The Herbert catchment covers a large area	
(h) Local people don't trust government programs	
(i) Local people aren't that interested in community-type activities	
(j) The government doesn't want to spend money on solutions	
(k) Government departments and other agencies are too slow to react to new issues or problems	
(l) People in the catchment lack access to the information needed to respond to/deal with new catchment issues or problems	

THE HRCCC: ACHIEVEMENTS AND ROLE

12. (a) **What have been the major achievements of the HRCCC to-date?**

……
……
……..
……..
……..
……

(b) **Why?**

……
……
……..
……..
……..
……

13. (a) **In your opinion, what are the most significant projects undertaken by the HRCCC?**:

……
……
……..
……..
……..
……

(b) **Why?**

……
……
……..
……..
……..
……

14. How satisfied are you with the overall progress of the HRCCC? (tick)

- ☐ very unsatisfied
- ☐ unsatisfied
- ☐ neither satisfied nor unsatisfied
- ☐ satisfied
- ☐ very satisfied
- ☐ don't know

15. Why? What are some of your reasons

……

……

……

……

……

……

……

……

……

16. Is there anything that should be done to improve the HRCCC's performance?

……..

……

……

……

……

……

……

……

……

17. .....In your opinion, is the HRCCC heading in the right direction?.

……
……
……
……
……
……
……
……
……
……
……

18. In respect of the following statements about the role that the HRCCC has played in resource management, can you rate your agreement on a five point scale from:

1 --strongly disagree
2 --disagree
3 – neither agree nor disagree
4 --agree
5 –strongly agree
6 --not applicable/don't know

	Rating
(a) The HRCCC has helped negotiation among catchment stakeholders to resolve land and water management issues	
(b) The HRCCC has initiated key collaborative linkages/arrangements with other organisations to actively address key land and water use issues in the catchment	
(c) The HRCCC has helped stakeholders in defining the source of resource problems	
(d) The HRCCC has helped stakeholders in identifying solutions to resource problems	
(e) The HRCCC has helped stakeholders in ensuring their resource management practices are equitable and accountable.	
(f) The HRCCC has encouraged research and data gathering and analysis in order that solutions to resource problems can be better understood	
(g) The HRCCC has helped ensure that the catchment land use planning decision-making process is fair and accountable to all interests	

19. How important is it to you that the following activities are part of Integrated Catchment Management in the Herbert:

1 - very low importance
2 - low
3 - moderate
4 - high
5 - very high importance
6 - not applicable/don't know

	Your Rating
(a) Encourage community *action* at a catchment level	
(b) Raise the level of local awareness and knowledge of environmental issues on the catchment	
(c) Encourage Local Government to take an active role in environmental management issues	
(d) Encourage coordination of state government programs	
(e) Undertake specific on-ground projects with other bodies	
(f) Providing a continuing source of advice to local government on catchment issues	
(g) Encourage research	
(h) Develop solutions for, and better understanding of, environmental problems in the Herbert catchment	
(i) Encourage discussion between community interest groups on environmental issues	
(j) Separate ICM programs for the Upper and Lower Herbert catchments	
(k) Encourage joint projects between community, industry and state and local government	

THE HERBERT RIVER CATCHMENT MANAGEMENT STRATEGY

20. What is the current status of the Herbert River Catchment Management Strategy?

……
……
……
……

21. **(a)** Is the Herbert catchment management strategy being used by the HRCCC? **Yes/No**

(b) If so, for what purpose and is it useful?

……
……
……
……
……

22. **(a)** In your opinion, is the Herbert catchment management strategy adequate? **Yes/No**

(b) Why do you think this?

……
……
……
……
……
……
……

23. What needs to be done, if anything, to improve the strategy?:

. ……
……
……
……
……

24. Please indicate your level of agreement with the following statements:

1 --strongly disagree
2 -- disagree
3 – neither agree nor disagree
4 -- agree
5 – strongly agree
6 --not applicable/don't know

(a) The catchment strategy will contribute to effective resource management in the Herbert	
(b) The catchment strategy will assist in resolving resource management conflicts	
(c) The HRCCC prepared a catchment strategy to ensure future funding support	
(d) The development of the strategy really helped to focus the HRCCC	
(e) My constituency group fully supports the implementation of the strategy	
(f) The Catchment Management Strategy is directing the HRCCC activities	

THE ICM PROGRAM

25. (a) **From your perspective how well suited is the ICM program in Queensland to addressing resource use and management issues within the Herbert catchment?**

? very low
? low
? moderate
? high
? very high
? don't know

.....(b)

Why?……
……
……
……
……
……
……
……
……
……

26. **In your opinion, who/what types of interest groups should be represented on a Catchment Coordinating Committee?**

……
……
……
……
……
……
……
……
……
……

27. **What do you consider are the important qualities of a Catchment Committee member?**

……
……
……
……
……
……
……
……
……
……

28. **What do you see are the important qualities of a Catchment Coordinator?**

……
……
……
……
……
……
……
……
……
……
……
……
……

Public attitudes and support for ICM

29. In your opinion, what is the level of public awareness about land and water resource issues in general in the Herbert catchment for the rural community and the urban community?

(a) **Rural**		(b) **Urban**	
?	very low	?	very low
?	low	?	low
?	moderate	?	moderate
?	high	?	high
?	very high	?	very high
?	don't know	?	don't know

30. (a) **Has public awareness changed over the last year?**
Yes/No

(b) If so, how or in what way?

……
……
……
……
……
……
……

31. What level of public support do you believe the HRCCC has in the catchment?

? very low
? low
? moderate
? high
? very high
? don't know

32. (a) Has public support for the HRCCC changed over the past year? Yes/No
(b) If so, how or in what way:

……
……
……
……

33. Is there any way that you think public support for ICM in the Herbert can be improved?

……
……
……
……
……

34. How effective has the involvement of the following groups been to ICM in the Herbert Catchment?

1 - very ineffective
2 - ineffective
3 - neither effective or ineffective
4 - effective
5 - very effective
6 - not applicable/don't know

	Rating
(a) Local Government	
(b) State Government Agencies (specify) …… (b1t) …… (b2t)	 …… (b1) …… (b2)

(k) Any comments?

……
……
……
……

35. What could or should be done to improve the acceptance and involvement of relevant interest groups in the HRCCC process?

……
……
……
……
……
……
……
……
……
……
……

STATE GOVERNMENT INVOLVEMENT

36. (a) Are you satisfied with the overall level of involvement of state government agencies in ICM in the Herbert? Yes/No

(b) How is the state government involved in ICM in the Herbert?

……
……
……
……
……
……
……
……
……
……
……

37 In your opinion, how important is this involvement to the success of ICM in the Herbert?

……
……
……
……
……
……
……
……

38. What more could state government do to help ICM in the Herbert?

……
……
……
……
……
……
……
……
……
……

39. On a five point scale:

1 - very low importance
2 - low
3 - moderate
4 - high
5 - very high importance
6 - not applicable/don't know

(a) **Can you rate the importance to ICM in the Herbert of coordination between state government agencies on issues relating to land and water resources management?**

(b) **Can you give reasons for your rating?**

……
……
……
……
……
……
……

40. (a) **How beneficial IN PRACTICE has cooperation with government departments (eg. DNR, DPI, DEH) been to ICM in the Herbert?**

1 – not beneficial
2 – slightly beneficial
3 – quite beneficial
4 – very beneficial
5 – extremely beneficial
6 --not applicable/don't know

(b) **Can you give reasons for your rating?**

……
……
……
……
……
……
……
……
……
……
……
……
……

Using the following seven point scale:

1. *No interaction* **between the government department and the community**
2. *Informing* **the community of the decisions that have been made**
3. *Consulting* **the community through advertisements and invitations for formal submissions with the final decision being made by the department**
4. *Involving* **the community in workshops and meetings to help define the problem and scope the community's issues with the final decision being made by the department**
5. *Shared planning and decision making* **between the government department and the community**
6. *Decisions made by the community*
7. *Community control and management*
8. Multiple variations of 1-7 above
9. Don't know

41. From your experience in the Herbert catchment, what sort of community/public participation in government in practice mostly occurs in relation to

	Mostly occurs
(a) land use planning	
(b) environmental protection	
(c) land clearing guidelines	
(d) coordination of drainage	

42. From your experience in the Herbert catchment, what sort of community/public participation in general should occur in relation to

	Should occur
(a) Land use planning	
(b) environmental protection	
(c) land clearing	
(d) coordination of drainage on rural lands	

LOCAL GOVERNMENT AND ICM

43. (a) Are you satisfied with the involvement of local government in ICM in the Herbert?

Yes/No

(b) How is local government involved in ICM in the Herbert?

……
……
……
……
……
……
……

44. In your opinion, how important is this involvement to the success of ICM in the Herbert?

……
……
……
……
……
……
……
……

45. Is there anything local government could do to help ICM?

……
……
……
……
……
……
……
……
……
……

46. Do you support the proposed/new Hinchinbrook Shire Agricultural Planning Process

Yes/No

47. Is it fair to all interests?

……
……
……
……
……
……
……
……
……

48. In your opinion, do you think the new process will change the way land and water resources are used and managed in the Shire/catchment?

……
……
……
……
……
……

INFLUENCES ON ICM

49. Please indicate your level of agreement with the following statements:

1 strongly disagree
2 - disagree
3 – neither agree nor disagree
4 - agree
5 – strongly agree
6 --not applicable/don't know

The implementation of ICM in this catchment is difficult because:	Your Rating
(a) The large size of the catchment (or poor linkages between parts of catchment)	
(b) The wide variety of values and beliefs among HRCCC members seriously detracts from an effective level of cooperation developing among them	
(c) State government agencies do not cooperate with each other	
(d) Some important constituency groups are not represented in the ICM process	
(e) The perception that ICM has been forced on the catchment by the state government	
(f) The public's lack of interest in community type activities	
(g) State government agencies do not listen to the Herbert community concerns	
(h) The lack of an effective level of interest by HRCCC members	
(i) The public's lack of trust in state/local government-sponsored initiatives	
(j) The lack of financial resources within the community - upper	
(k) The lack of financial resources within the community - lower	
(l) The lack of agreement among HRCCC members concerning its objectives	
(m) The lack of agreement on feasible solutions to catchment issues	
(n) There are no single acute resource management problems within the catchment	
(o) The lack of coordination between state government agencies in addressing issues	

50. In your opinion, what is the relationship IN PRACTICE between ICM and Landcare in the Herbert?

……
……
……
……
……
……
……

51. In your opinion, what SHOULD BE the relationship between ICM and Landcare in the Herbert?

……
……
……
……
……
……
……
……

52. Rate your level of agreement with the following statements:

1 -- strongly disagree
2 -- disagree
3 – neither agree nor disagree
4 -- agree
5 – strongly agree
6 -- not applicable/don't know

	Your Rating
(a) There is a strong consensus among HRCCC members concerning HRCCC functions	
(b) At HRCCC meetings, all HRCCC members participate actively	
(c) The local ICM process effectively resolves resource conflicts	
(d) The ICM process is responsive to local needs	
(e) The HRCCC is solving the priority natural resource management problems in the catchment	
(f) The process of allocating land use in the catchment is fair to all	
(g) All sections of the community have equal access to information on land management and planning	

53. Rate how much you agree or disagree with the following statements:

1 -- strongly disagree
2 -- disagree
3 – neither agree nor disagree
4 -- agree
5 – strongly agree
6 -- not applicable/don't know

		Your Rating
(a)	The government needs to give more resources to voluntary groups	
(b)	Catchment management should be paid for by the government	
(c)	ICM should remain a voluntary activity by community members	
(d)	Many environmental problems come from the way people manage their properties	
(e)	The government expects too much from local communities in catchment management	
(f)	Laws should be changed to make landholders more responsible for the consequences of their activities	
(g)	Different government agencies often give conflicting advice/information on land and water management issues	
(h)	There should be better government incentives for landholders to address environmental issues/problems	
(i)	There aren't any environmental problems that need urgent action	
(j)	ICM programs should have legislative backing	
(k)	The government gives plenty of resources to voluntary groups	
(l)	Landholders have the right to use their land as they see fit	
(m)	Land should be managed for the public good because it belongs to everyone	
(n)	All sections of the community have the right to have a say on planning proposals	
(o)	If the decision making process is fair, people should accept the final planning or land allocation decision	
(p)	Land use planning should maximise the overall economic income of the community	
(q)	The new proposed land allocation decision process for the Hinchinbrook Shire is fair to all interests	

For every $100 spent on catchment management and landcare,

54. How much of it do you think IS being contributed by:

(a) The Commonwealth Government?	
(b) The Queensland Government?	
(c) Local Government on the Herbert Catchment?	
(d) Industry?	
(e) Individual farmers?	
TOTAL	$100

55. How much of it do you think SHOULD be contributed by:

(a) The Commonwealth Government?	
(b) The Queensland Government?	
(c) Local Government on the Herbert Catchment?	
(d) Industry?	
(e) Individual farmers?	
TOTAL	$100

56. Please Comment on why you have chosen these amounts?

……
……
……
……
……
……

PERSONAL DEMANDS AND MOTIVATIONS

57. On average, how many hours per month do you devote to ICM? ……Hours/months

Other Comments

Chapter 4

Organisational Linkages on Natural Resource Management in the Herbert River Catchment, 1992-1998

Jennifer Bellamy[1] and David Horsley[2]

[1] CSIRO Tropical Agriculture, Brisbane. 4072
[2] CSR Herbert and Burdekin River Mills, Ingham. 4850

Originally Published as:
Bellamy, J.A. and Horsley, D. (1999). Organisational linkages in the Herbert River Catchment. CSIRO Tropical Agriculture, Brisbane.

1. INTRODUCTION

Stakeholder representation and participation is well recognised as an essential element of legitimate and successful natural resource management policy initiatives (eg. Lang 1990; RAC 1993; Gardner and Stern 1996). The degree to which there is adequate and responsive communication and coordination between stakeholders of these initiatives is a key factor underlying the effectiveness and fairness of their outcomes.

Fundamental to the conception of the Integrated Catchment Management (ICM) policy initiative in Queensland is that it will rely on existing authorities/organisations and varied programs of federal, state and local governments and private sector activities to accomplish ICM objectives and implement the catchment management strategy (eg. Department of Primary Industries 1991; Rowland and Begbie 1997). In this institutional context, the system of organisational structures and linkages is a critical mechanisms for facilitating the exchange of information and supporting a coordinated and inclusive approach to catchment management decision-making.

A broad range of community, industry and government organisations with some level of responsibility or an interest in resource use management and planning are present in the Herbert River Catchment. This study investigates the change in the system of organisational structures and linkages on natural resource management within the Herbert River catchment from the inception of the Herbert River Catchment Coordinating Committee in 1993 to 1998.

2. METHODS FOR MONITORING ORGANISATIONAL LINKAGES

1.1 Data Sources

The investigative methodology for this longitudinal study was based on:

- Periodic semi-structured interviews with key members of the Herbert River Catchment Coordinating Committee (HRCCC) to identify government, industry and community organisations with an interest or functional role in natural resource management in the catchment;
- Review of documentation (eg. annual reports, strategic plans, consultancy reports) on local government, statutory authorities and industry organisations s in the Herbert River catchment from 1992/93 to 1998/99 to identify linkages and their presentation of natural resource management issues; and
- Review of the minutes of HRCCC meetings and supporting documentation from its inception in March 1993 to December 1998 to identify linkages and related programs.

2.2 Organisational Mapping

The information from the three sources was synthesised to produce organisational mapping of the system of organisational structures and linkages on natural resource management for 1993, 1995 and 1998 for the Herbert River catchment. Organisations were identified under the following groups:

- Federal government
- State government
- Local government
- Industry
- Community
- Collaborative/Joint Ventures

Linkages between organisations were classified as:
- Regulatory/statutory
- Membership
- Secretariat support
- Coordinative/collaborative arrangement/venture
- Proposed joint funding arrangement

Figures 1, 2 and 3 identify the organisations with some role or responsibility on natural resource management in the Herbert River Catchment in 1993, 1995 and 1998 respectively.

3. RELEVANT COMMONWEALTH AND STATE AGENCIES ACTIVE IN THE HERBERT RIVER CATCHMENT, 1993-1998

The key roles and responsibilities of the federal and state government agencies and the related legislation actively engaged in the Herbert River catchment in 1993 are briefly outlined in Table 1.

An examination of Figures 1, 2 and 3 shows that Commonwealth and State Government organisational structures on natural resource management have evolved since the inception of ICM in the Herbert. In 1993, their functional role was predominantly concerned with regulation in respect of land, water, vegetation and coastal management and the provision of research. Over time the number of organisations with an interest has increased and the functional role of these linkages has expanded from this regulatory and research role to also encompass joint funding of collaborative ventures (eg. Herbert Resources Information Centre, Sugar Industry Infrastructure Package).

4. LOCAL GOVERNMENT, INDUSTRY AND COMMUNITY ORGANISATIONS AND THEIR LINKAGES ON NATURAL RESOURCE MANAGEMENT, 1993-98.

The functional roles and responsibilities of the key local government and related statutory authorities, and industry and community organisations in the Herbert River catchment and their involvement in and presentation of natural resource management issues in organisational documentation are briefly outlined below

4.1 Local Government

Local Governments in Queensland are constituted under the *Local Government Act* with responsibilities for:
- Operation of water supply and sewerage treatment works; solid waste disposal; local roads; urban stormwater drainage under the *Local Government Act*.
- Town planning and sub-division; building approvals; camping grounds; regulation of quarrying activities; impact assessment under the *Local Government .(Planning and Environment) Act*.
- Management of erosion prone areas and coastal management control districts under the *Beach Protection Act.*

Figure 1. Organisations in the Herbert Catchment with an Interest or Role in Natural Resource Management in 1993

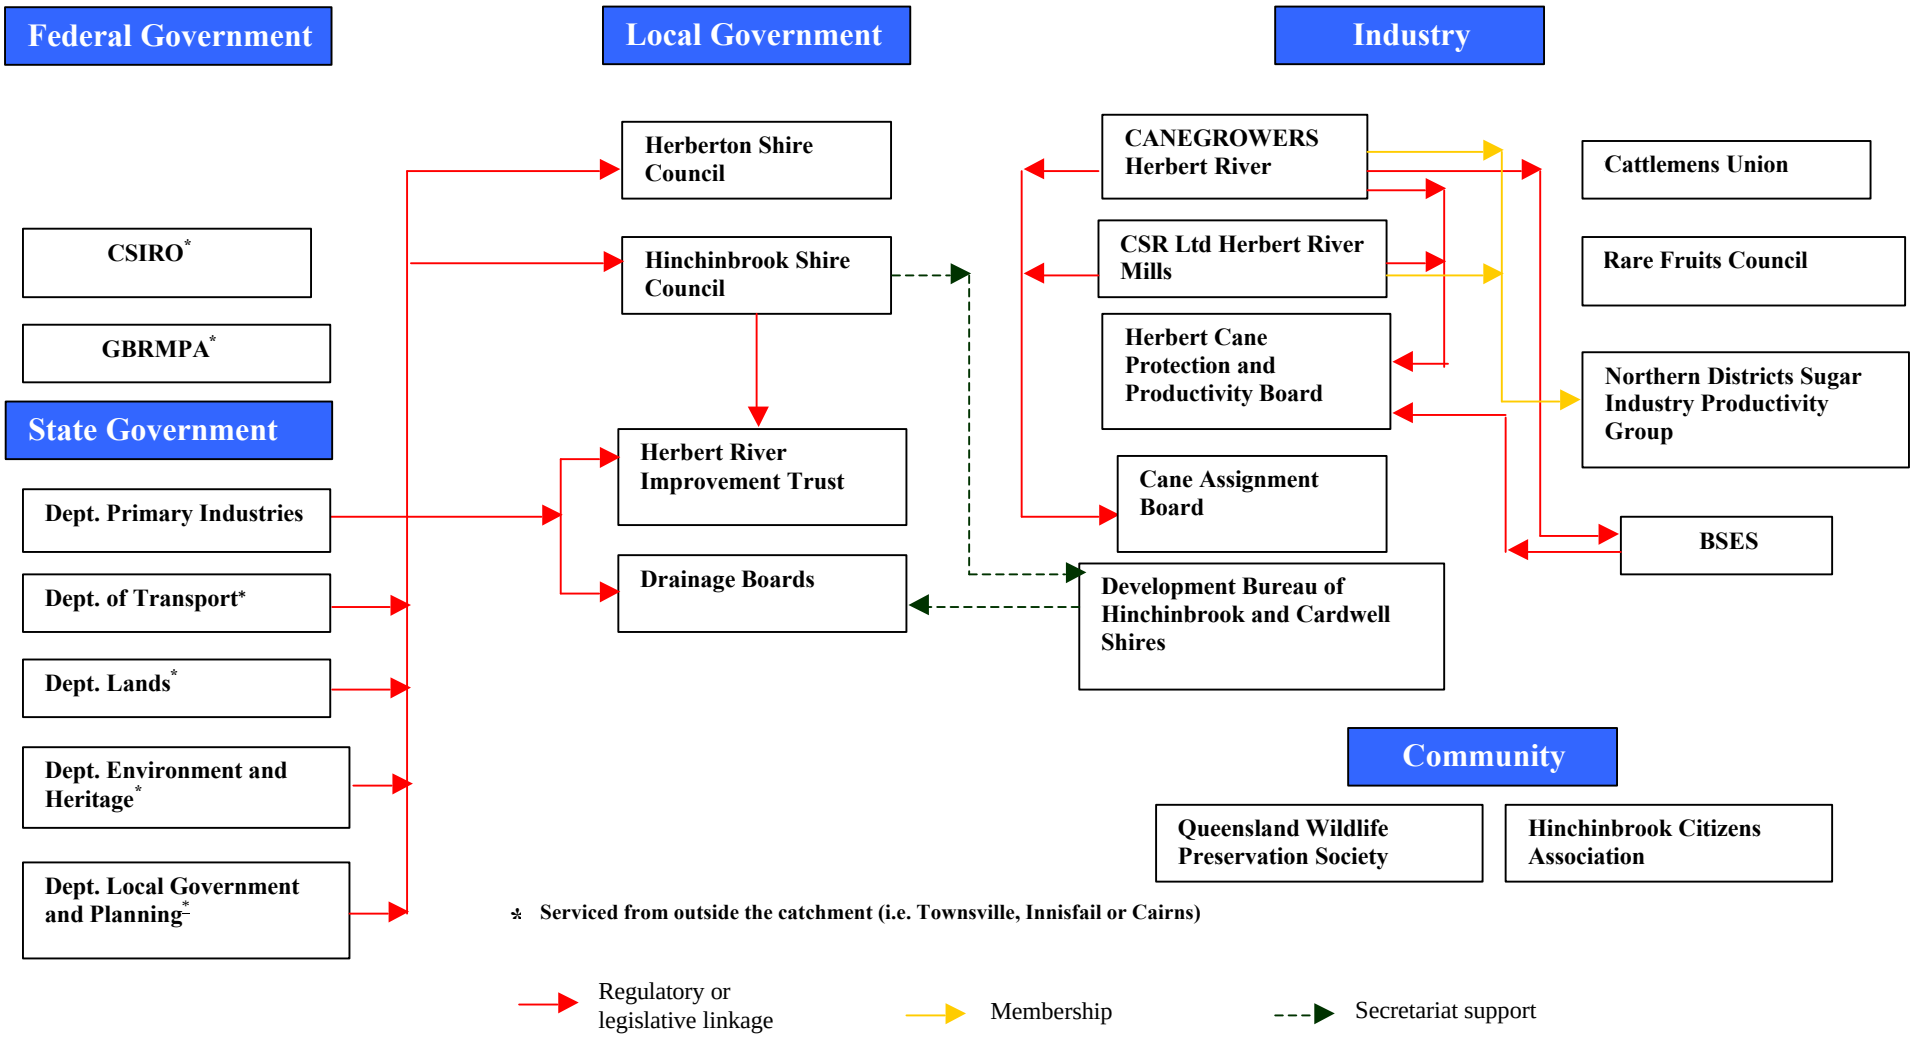

Figure 2. Organisations in the Herbert Catchment with an Interest or Role in Natural Resource Management in 1995

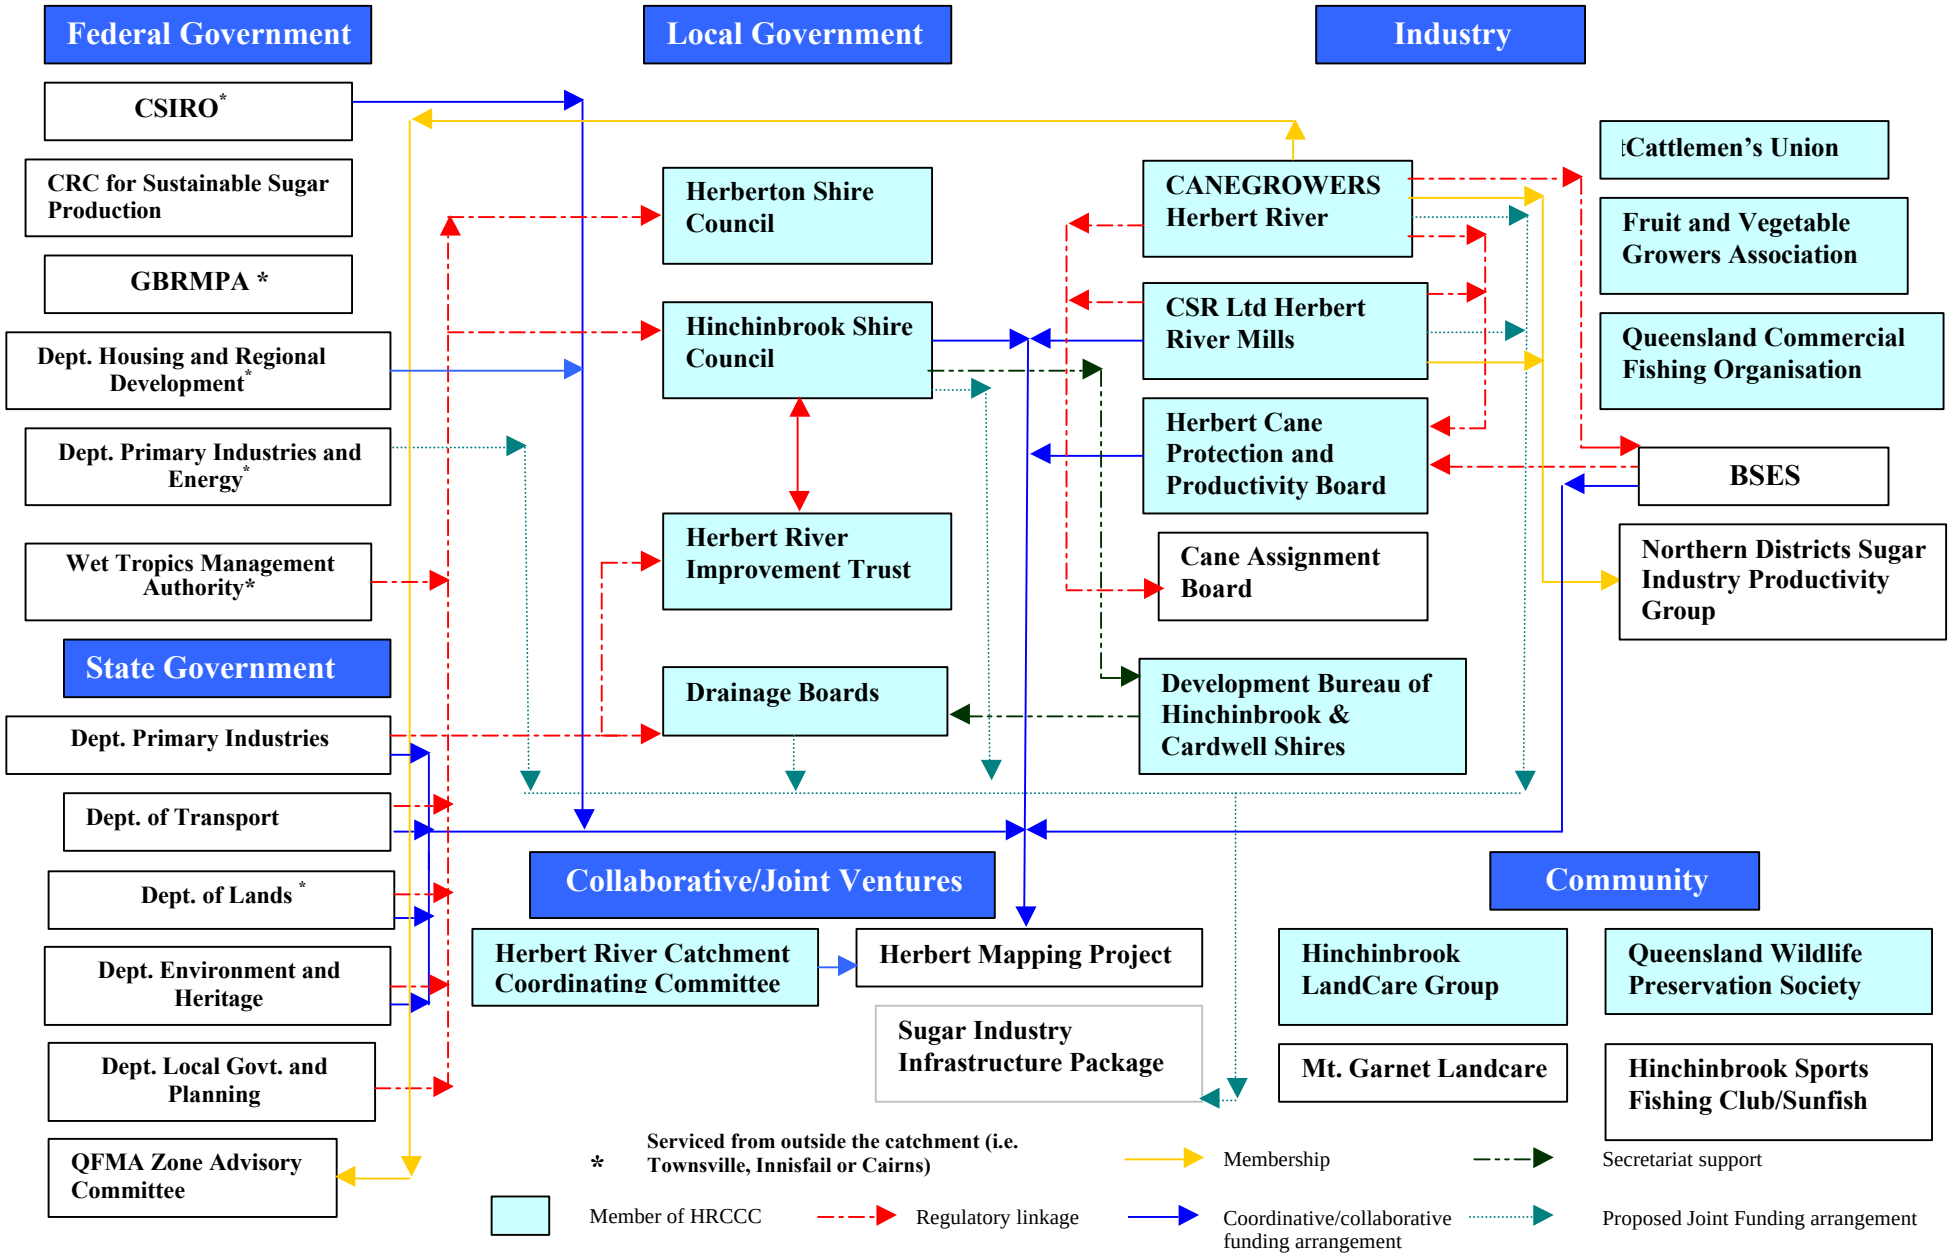

Figure 3. Organisations in the Herbert Catchment with an Interest or Role in Natural Resource Management in 1998

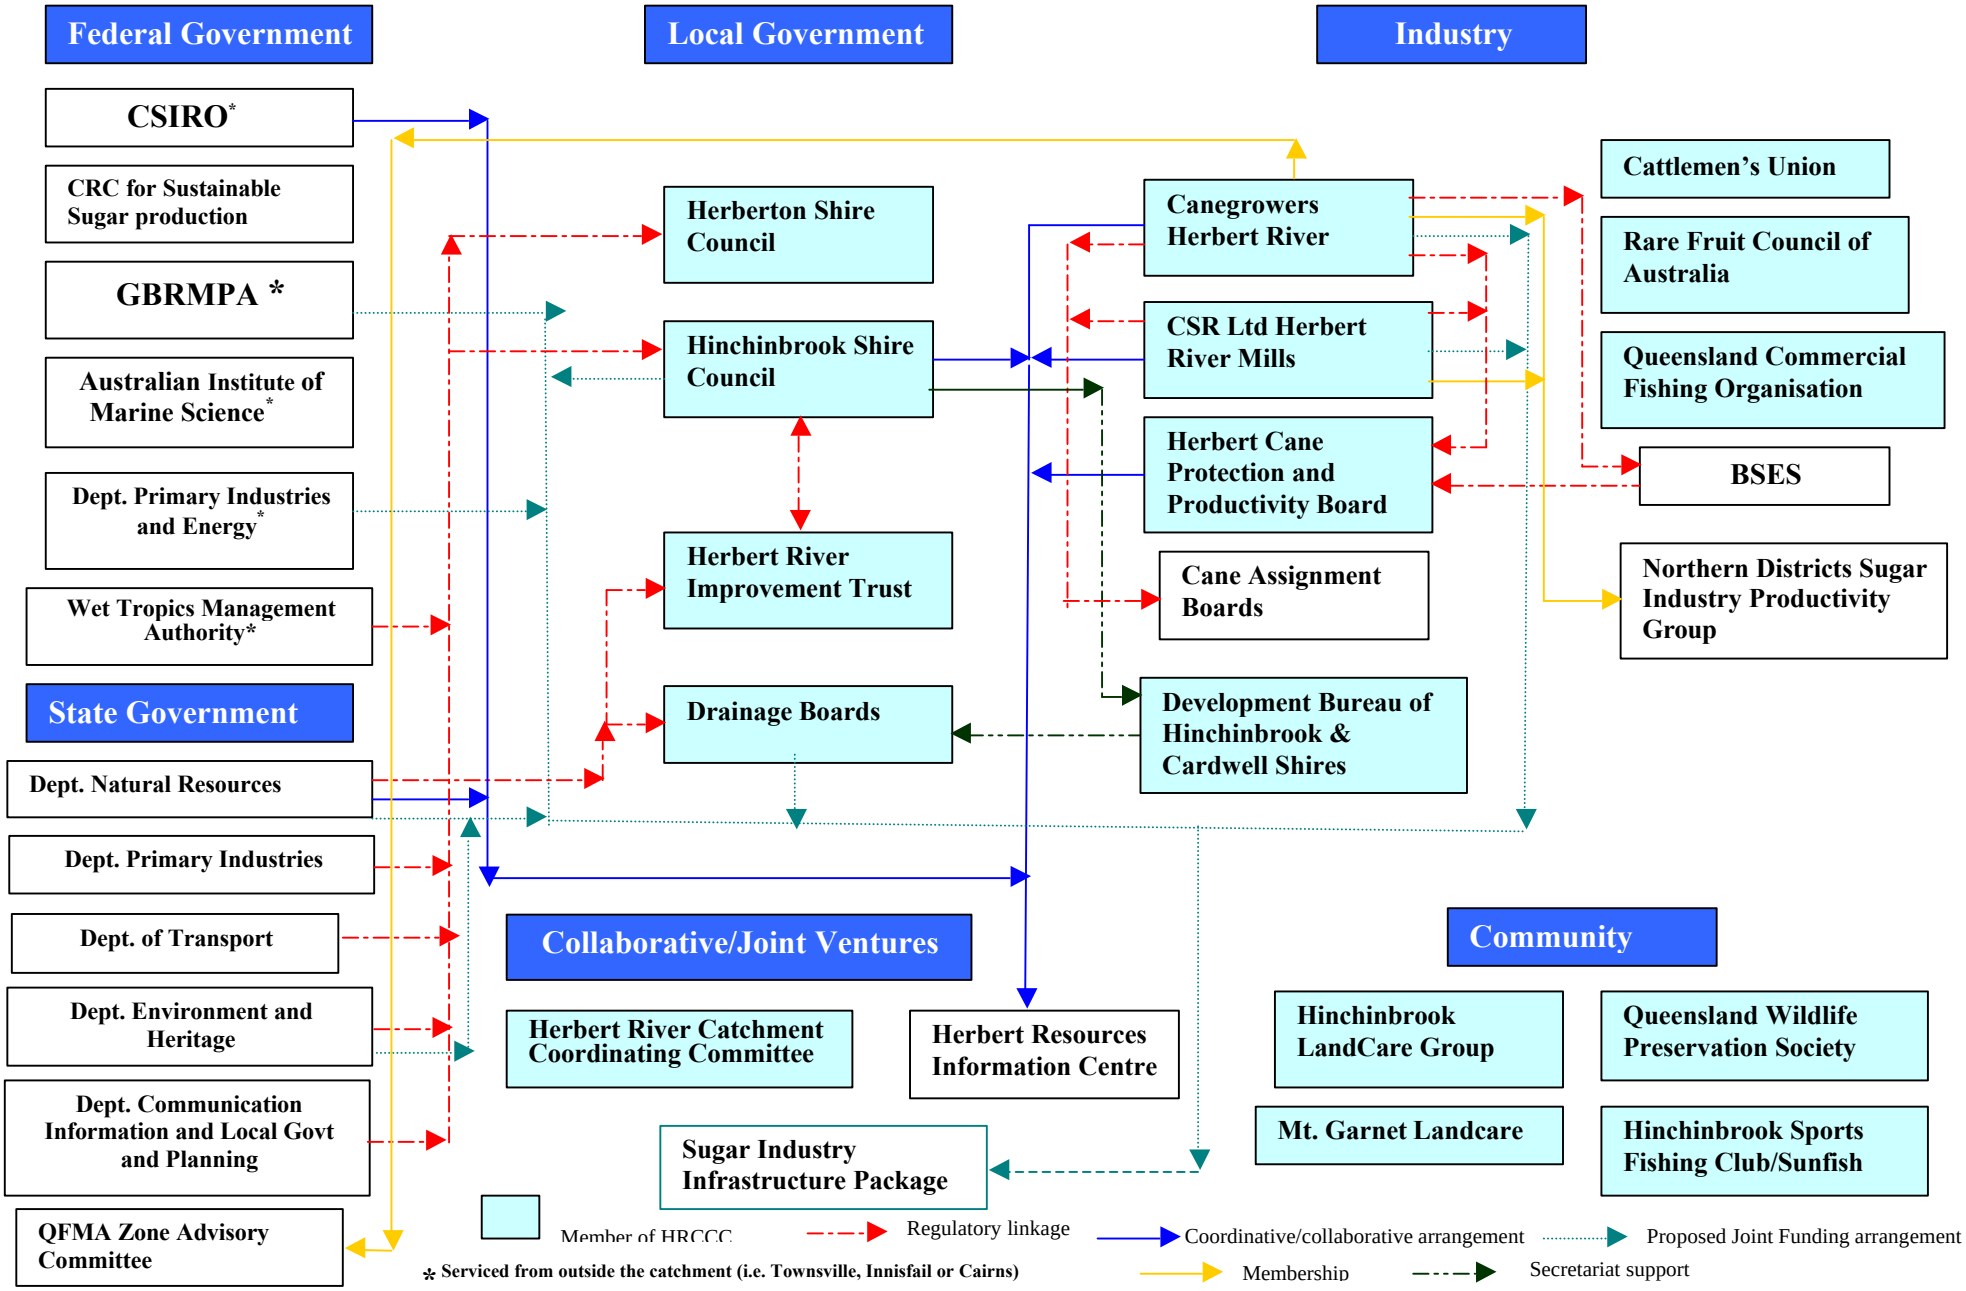

TABLE 1. Roles and Responsibilities of Commonwealth and Sate Agencies with an Interest in Natural Resource Management in the Herbert River Catchment in 1993.

ORGANISATION	MAJOR AREAS OF RESPONSIBILITY	LEGISLATION
COMMONWEALTH GOVERNMENT		
Great Barrier Reef Marine Park Authority	Management of Great Barrier Reef Marine Park (GBRMP); water quality monitoring in Park waters; conducting and arranging research and investigations; preparing zoning plans for individual sections of the Park; providing or arranging education, advisory and information services	GBRMP Act 1975
Wet Tropics Management Authority	Protection and management of the Wet Tropics World Heritage Area	Wet Tropics World Heritage Protection and Management Act 1993
Commonwealth Scientific and Industrial Research Organisation	To carry out scientific research for assisting Australian industry, furthering the interests of the Australian community, and contributing to the achievement of Australian national objectives or the performance of the national and international responsibilities of the Commonwealth. It's work covers a broad range of areas of economic or social value to the nation, including agriculture, minerals and energy, manufacturing, communications, construction, health and the environment.	Science and Industry Research Act 1949
STATE GOVERNMENT		
Department of Primary Industries (DPI)	Management of rivers and water resources; allocation of water resources licensing and permits to pump water (surface and groundwater); stream gauging; management of sand and gravel extraction and licensing	Water Resources Act
	Implementation of Integrated Catchment Management	
	Co-ordination of Landcare	
	Land resource assessment and research	
	Control of soil erosion	Soil Conservation Act
	Management of State Forest and Timber Reserves	Forestry Act
	Protection, conservation and management of fisheries resources of Queensland; designation and management of fisheries reserves	Fisheries Act
Department of Environment and Heritage (DEH)	Conservation and management of State marine parks Day-to-day management of GBR Marine Park	Queensland Marine Parks Act; Great Barrier Reef Marine Park Act (Common.)
	Control of pollution and protection of water quality; licensing of point source discharges	Clean Waters Act
	Approvals for canal development	Canals Act
	Management of national parks and joint management with aboriginal groups; conservation of fauna	Nature Conservation Act; National Parks and Wildlife Act (Common.)
	Control of reclamation, dredging and structures below high water mark	Harbours Act (part)
	Declaration and management of Recreation Areas	Recreation Areas

ORGANISATION	MAJOR AREAS OF RESPONSIBILITY	LEGISLATION
	Co-ordination of Impact Assessment studies	Management Act State Development Public Works Organisation Act
	Protection of items of cultural heritage	Queensland Heritage Act
	Identification, assessment and management of contaminated land	Contaminated Land Act
Department of Lands	Reservation and management of Crown lands for public purposes; leasing of Crown lands and setting lease conditions; reclamation of lands below high water	Land Act
	Definition of legal coastal cadastral boundaries	Surveyors Act
	Control of noxious plants and animals	Rural Lands Protection Act
Department of Transport (DOT)	Licensing commercial boating activities, small craft facilities; strategic port planning; reclamations of lands below high water	Marine Act/Harbours Act
	Regional transport planning, construction and maintenance declared roads	Transport Infrastructure (Roads) Act
Department of Housing, Local Government and Planning (DHLGP)	State planning policies, land use strategic planning and development; approval of local authority town planning schemes; impact assessment guidelines	Local Govt. (Planning and Environment) Act
	Integrated Development Approval System	---
	Regional planning advisory committees	---
	Establishment and management of integrated resort developments	Integrated Development Resort Act
Dept. of the Premier, Economic and Trade Development	Facilitation of major projects and strategic planning	State Development and Public Works Organisation Act
River Improvement Trust	Protection, repair and improvement of beds and banks of rivers; prevention and mitigation of flooding	River Improvement Trust Act
Drainage Boards	The construction, maintenance, protection and administration of drainage works under its control and management in gazetted drainage board areas	Water Resources Act
Beach Protection Authority	Control of coastal land use and development in a zone 100 metres landward of the mean spring AHD	Beach Protection Act
Bureau of Sugar Experimental Stations (BSES)	To conduct research into sugar cane growing and sugar milling and to communicate these results to growers and millers.	BSES Board under the Sugar Experimentations Act

Local Government is involved in resource and environmental management and planning by way of referred powers from the State Government. The nature of powers given to local governments in Queensland extends from powers to make by-laws or ordinances, to licensing, to the carrying out of works, and to impact assessment and effective decision-making on development. Moreover, strategic plans prepared by local authorities have force of law in Queensland.

The Herbert River catchment is located within the local authority boundaries of Hinchinbrook Shire Council and Herberton Shire Council.

Hinchinbrook Shire Council
The Hinchinbrook Shire (HSC) is a dominantly rural shire that covers an area of 2,600 sq. km and a population of 13,434 persons in 1996. In 1993, the Hinchinbrook Shire Council's responsibilities on regional development and land use planning focussed on community service delivery in accordance with the *Local Government Act* (ie. transport infrastructure, water supply, sewerage, rural and urban drainage), town planning and subdivision including impact assessment in accordance with the *Local Government (Planning and Environment) Act*, and management of erosion prone areas and coastal management control districts in accordance with the *Beach Protection Act*.

The Hinchinbrook Shire Council's Annual Reports for 1992/93 identify the "Protection of the Environment" program which included street cleaning and watering, beach restoration and protection, flood and river management (see Herbert River Improvement Trust), anti-litter enforcement, pest/noxious plant destruction, community amenities and cemeteries maintenance. In 1997/98 this program had broadened to include environmental management activities (HSC 1997):

- "Revegetation of damaged riverbanks and planting at Longpocket in association with the local Catchment Coordinating Committee resulted in a major land protection scheme being put in place. The "soft" aspects of tree planting in the scheme achieved not only a buffer against floods but enhancement to the area and an aesthetically pleasing appearance" (HSC 1997, p.19).
- "Tyto" wetlands project – creation of a wetland reserve "to provide for an environmentally acceptable standard of disp[osal of sewerage effluent as an alternative to existing treatment practices through the development of wetland areas/methods".

Importantly the Council gazetted a new strategic plan in 1997 under the new *Integrated Planning Act* that "captures current day planning processes which will provide greater flexibility in Council's decision-making when assessing land-use applications". The new plan is discussed in detail in Vella (1999) including its links to ICM in the Herbert.

4.2 Herbert River Improvement Trust

The Herbert River Improvement Trust (HRIT) is a statutory authority constituted under the provision of the *River Improvement Trust Act 1940* by Order-in-Council dated 8 May 1942. Its key functions are to protect and improve the beds and banks of rivers; to repair and prevent damage to the bed and banks of rivers; and to prevent or mitigate flooding of land by riverine flood. The primary role of the HRIT is to plan, design, finance, undertake and maintain stream improvement works for the benefit of the community within the Hinchinbrook Shire area. The *RIT Act* provides the HRIT with the powers to undertake these functions, including ability to raise funds, enter onto land, occupy land, enter into contracts, and carry out works. The HRIT is sponsored by the Hinchinbrook Shire Council and its jurisdiction essential covers the lower Herbert River floodplain..

Membership in 1998 comprised a Chairman appointed by the Governor in Council, two representatives appointed by the Hinchinbrook Shire Council, and a 'special interest member' appointed from the DNR.

The HRIT supported a Herbert River Catchment and Management Scoping study to provide a blueprint for addressing river management issues. Since 1994/95 its Annual Reports have identified a key aim of maintaining "a close liaison with the local ICM Committee and consulting with them on relevant issues". The Trust also jointly supported a land protection scheme with the Herbert River Catchment Coordinating Committee (HRCCC) at Long Pocket on the Herbert River which received funding from the National Landcare programme following an application from the HRCCC. This project involved revegetation of damaged riverbanks.

4.3 Drainage Boards

Under the *Water Resources Act* Drainage Boards are constituted with the responsibility for the construction, maintenance, protection and administration of drainage works under its control and management in gazetted drainage board areas.

There are four formal 'gazetted' drainage boards (Ripple Creek/Seymour, Foresthome, Loder Creek and Mandam) and three informal boards (Lagoon Creek, Ti Tree Creek and Macknade) that operate within the lower catchment in the Hinchinbrook Shire and cover approximately 11,000 hectares. These boards assess drainage applications in their respective areas.

The structure and functional roles of drainage boards are currently being reviewed under the Sugar Industry Infrastructure Package (SIIP) with the intent of amalgamating formal and informal boards.

4.4 Development Bureau of Hinchinbrook and Cardwell Shires

The Development Bureau is an incorporated body responsible to the Hinchinbrook Shire Council. It is responsible for promoting rural development activities in the region of the Hinchinbrook and Cardwell Shires. It also acts as a secretary and administrator of 3 District Drainage Boards in the Hinchinbrook Shire and the local Chamber of Commerce. It has a primary focus on tourism and related activities as well as employment programs in the region.

The Bureau is an incorporated body managed by a Board of Management and in 1998 comprised 21 members:

- An Executive Committee of 4 members
- 6 elected members from the Hinchinbrook Shire
- 6 elected members from the Cardwell Shire
- 2 appointed members from the Hinchinbrook Shire
- 2 appointed members from the Cardwell
- 1 appointed member from North Queensland Economic Development Board (NORQEB)

In 1997/98 it received financially support from both the Hinchinbrook and Cardwell Shire Councils, and in the past it has also had financial support from NORQEB. In addition, it receives secretariat fees from the Drainage Boards and the Hinchinbrook Chamber of Commerce. Other important sources of funding are membership fees from individuals, businesses and industry in the region, as well as project funding from various Government Agencies (eg. Dept. Tourism, Small Business and Industry).

The Bureau's focus has remained much the same since 1991. Importantly, the Bureau has continued to lobby for integrated approach to drainage in the Herbert catchment, and it has been actively involved in ICM in the Herbert River Catchment as a founding member of the Herbert River Catchment Coordinating Committee in 1993. It has also been involved in issues of drainage of agricultural lands

through both on-farm advice and through the establishment of formal and informal Drainage Boards and Committees in the lower Herbert River community.

4.5 Herbert River District CANEGROWERS

CANEGROWERS is a statutory organisation established under the *Primary Producers' Organisation and Marketing Act 1926* as the formal body representing all canegrowers in Queensland. It is financed by a levy on growers based on tonnes of cane supplied. The Herbert River District Canegrowers' Executive aims to promote the prosperity of all canegrowers in the Herbert River catchment by addressing common district issues and problems and also providing client service for individual growers (CANEGROWERS Victoria Area Annual Report 1993). It has two Mill Supplier's Committees – one for the Macknade Mill area and one for the Victoria Mill area – and it is responsible for the Harvesting Equity Tribunal and the Caneland Assignment Committees. It also provides secretary and administrative support for the Mandam Drainage Board, the Hinchinbrook Landcare Group and in the past the Herbert River Catchment Coordinating Committee. The CANEGROWER Executive also has a representatives on the Queensland Fish Management Authority Zone Advisory Committee – the regulatory agency for Queensland Fishing.

Key issues identified in the 1992 and 1993 Annual Reports of the Mill Supplier Committees were:

- industry expansion and the introduction of a Continuous Crushing Agreement and rostered harvesting;
- water management and a submission to the Commonwealth and Queensland Governments for drainage infrastructure (ie. SIIP);
- cane transport and handling (in particular siding capacity limitations transport servicing issues);
- the cane price formula based on the measurement of CCS; and
- Commonwealth Government proposal for the deregulation of the industry including the phasing out of tariff support.

Important activities in which the District Executive was involved in 1993 included:

1. *Support for the formation of the HRCCC under the Queensland's Government Integrated Catchment Management program.* CANEGROWERS had direct representation in ICM in the Herbert through one Executive member and indirect representation through the Landcare representative and the Canegrowers Executive Manager who acted as Secretary for the HRCCC. Its role was described as:
2. "*The HRCCC provides industry and community groups with representation on a body that is focussed on coordinating land use and water management in the catchment and dealing with issues that have impact*" (p.8).
3. *Sugar Industry Infrastructure Package (SIIP).* A collaborative bid was made with the millowner, CSR Limited, and the support of the Water Resources section of the DPI, Hinchinbrook Shire Council, the combined Drainage Boards, the HRIT and the HRCCC, for funding for projects in the Herbert River district for both water management (drainage) and cane transporting infrastructure. The bid was partially successful in that water management projects in existing cane areas were granted conditional approval for funding subject to the formation of a Water Management Board covering the project's entire area and the provision of one third local funding of the project's total estimated cost of $5.82M. The CANEGROWERS concluded that "the conceptual ideas are in general in line with those in the Cameron McNamara Rural Drainage Plan".
4. *Land Opening Project – Lower Stone (Wharps Holding).* The CANEGROWERS Executive worked with the Department of Lands, Hinchinbrook Shire Council and CSR Limited to open up 1100 hectares of land for future sugarcane farming. A provisional allocation of land has been made to applicants.
5. *Herbert Mapping Project.* A joint venture was being negotiated with several government departments, CSR, CSIRO, Hinchinbrook Shire Council and the HCPPB for more accurately

mapping the area which would "be of enormous benefit for planning anything to do with the use of land including drainage, the location of sidings, roads, etc." (p.9).

In 1994 and 1995, the major issues identified in the Herbert District CANEGROWERS Annual Report related predominantly to cane supply and mill capacity issues:

- The emerging problem of the reliability of mill crushing capacity with the "season being plagued with mill performance difficulties that tested the endurance of harvesting crews and prompted groups to consider risk sharing arrangements with rotation agreements" (Canegrowers Annual Report 1995, p.2).
- Estimating accuracy was continuing to be a concern in the management of harvesting equity.
- Cane transport and handling needs of growers and contractors, including lengthy delays in obtaining approvals for new cane railway line to Crystal Creek.

Other local issues raised in the Annual Report included:

- Involvement in the development of a district code of practice for sustainable cane growing. Cane land expansion and conditions for granting assignment needed to "reflect an appropriate level of care for the environment" with:
  - "local issues such as the mahogany glider protection plan and riparian zones for new cane areas being addressed in conditions for the allocation of assignment".
  - Collaboration in a BSES-monitored trial to assess the potential for rat baits to harm non-target species such as owls.
- CANEGROWERS had contributed $22K to the Herbert Mapping Joint Venture (or 6.3% of the cost) which provides it with full right to all mapping products. A flow on result of this venture was the decision to establish a Herbert Resources Information Centre (HRIC).
- The preliminary design for SIIP water management projects were completed and an Impact Assessment Study (IAS) and Environmental Management Plan (EMP) was being prepared.

The 1994 Annual Report notes the appointment of a Catchment Coordinator funded by NLP and the State's Integrated Catchment Management Program. The primary function of the Committee was described as "to work towards the development of a land and water management strategy for the catchment" while the HRCCC itself "provides a venue for industry, community groups and local governments with an interest in land and water management issues in the catchment to focus on those issues"(Annual Report 1994, p.4). Expenditure on administrative support for the HRCCC was recorded as $5042 and $5043 in 1994 and 1995 respectively.

By end of 1997, the main issues identified in the Annual Report were:

- Recommendations on Industry Structure evolving from the Sugar Industry Review Working Party Report, especially:
  - the focus on localising the commercial arrangements for raw sugar production through a negotiated contract with the millowner in place of the annual Award;
  - The loss of the Tariff; and
  - the move towards export parity pricing of raw sugar sales to domestic refiners.
- Recommendation for the negotiation of a single-district crushing season agreement, a single Local Award and a single district CCS. The important issues involved are season length, risk management and appropriate financial incentives, cane transport infrastructure and inter mill transfers.

Other local issues raised included:

- The sustained improvement in district yield and the increase in the assigned area presented challenges to mill crushing capacity. Therefore the district did not participate in any expansion in

1997, and it was agreed that the assigned area in 1998 will be the maximum area until further allocations are considered.
- Broader community expectations are creating greater pressure for the sugar industry to manage its impacts and downstream effects, and so the industry has been proactive in conducting an environmental audit.
- The District Executive provides secretarial support for the Hinchinbrook Landcare Group and is supporting a NHT application for tree planting.
- The District Executive also provides secretarial and administrative support to the HRCCC and been actively involved including providing funding support for the CD version of the Herbert River Catchment Atlas. The report notes that the HRCCC "provides a forum for community and industry groups interested in catchment issues to exchange views on overall catchment management strategies" (Canegrowers' Annual Report 1997, p. 9).
- The delay again in the implementation of water management projects under SIIP attributed to a combination of resource limitations, landholders concerns regarding design and the need to alter designs to ensure that they impact less on the sensitive fish habitat areas. Constraints being imposed by the regulations covering fish habitat and mangrove protection.
- Following damage by the January 1998 flood, catchment management issues were emerging in regard to tramlines, drainage and levee bank coordination.

Recently Herbert River CANEGROWERS have developed a protocol with DPI Fisheries for cane farming activities and work adjacent to tidal areas which allows different levels of permit relating to impacts of activities on marine plants (eg. mangroves).

4.6 Herbert Cane Protection and Productivity Board

The Herbert Cane Protection and Productivity Board (HCPPB) is a statutory authority under the *Sugar Industry Act 1991* responsible for administering regulations concerning plant quarantine, pest and disease control in the sugar industry. It was formed in April 1993 following an amalgamation of the compulsory Victoria Mill area Board and the voluntary Macknade Mill area Board. Its jurisdiction covers the whole lower Herbert River floodplain sugar growing area and it has a regulatory linkage to the BSES. The HCPPB comprises 9 members:
- 3 representatives of canegrowers from the Macknade Mill area;
- 3 representatives of canegrowers from the Victoria Mill area;
- 3 representatives of the millowner CSR Ltd.;
- 1 officer of the BSES.

The Board's funding is based on an equal contribution from growers and millers based on a levy on total tonne of cane delivered annually.

In 1993, the key focus as identified in the HCPPB Annual Report for 1993 was pest, weed and disease control, a study of rat damage in cane, and farm extension on productivity. The key issues for cane productivity were cane varieties, rodent control (particularly the importance of baiting, weed control and harbourage manipulation as a component of rat control), and the spread of Sicklepod. The area damaged by rodents in 1993 encompassed an area of 5260 hectares of cane for a calculated loss of 28,265 tonnes of cane. However, the damage by rats in 1997 was estimated as 6576 tonnes with another 10,701 tonnes lost due to pig damage.

In 1998, the HCPPB had expanded its services into laser levelling using the latest technology, caneland mapping by remote sensing and GIS for assessing productivity and its variation in the region, and encouragement of a philosophy of an environmentally sustainable production, including Integrated Pest Management (IPM) and Integrated Catchment Management (ICM).

The HCPPB mission as identified in the HCPPB's Strategic Plan 1998-2002 is:

> *To enhance the productivity of the sugar industry in increasing the quantity and quality of sugar cane grown in the Herbert Valley in an environmentally sustainable and economically viable manner.* (HCPPB, October 1997).

To this end, the HCPPB role in 1998 is identified as:

- Actively encourage the adoption of farming techniques and practices which improve the cane growing environment to maximise the productivity of cane varieties, in a sustainable way.
- Accommodate requests from the BSES and other research organisations for assistance and cooperation with research activities.
- Provide the necessary advice to control losses from pests and diseases.
- Encourage growers to accept the philosophy of Integrated Catchment Management.
- Provide the necessary training to the Board's staff in response to technological advances.
- Extend research findings to improve industry productivity and profitability.
- Determine productivity trends, using GIS technology.
- Long term financial and managerial support to the Herbert Resource Information Centre (ie. HRIC).
- Encourage and advise practices that will maintain and enhance sugar quality.
- Provide a laser survey-design service to the local industry.
- Encourage sound environmental practices to ensure long term industry sustainability.

The key issues identified in the Strategic Plan for 1998 (CPPB 1997 Annual Report) were:

- Drainage and conservation of water
- Reduction of ratoon stunting disease
- Integrated Pest Management (IPM) strategies for rodent control
- Planting methods and practices
- Land usage
- Productivity analysis and productivity reports
- Sustainable agriculture/environmental integrity
- Noxious (plant and animal) pest control.

4.7 Caneland Assignment Boards

While the Queensland Sugar Corporation (QSC) is responsible for implementing the *Sugar Industry Act 1994*, it has delegated much of the responsibility for mill-area decision-making to Local Boards. The Local Board acts as an 'agent' for the QSC and receives and determines applications for new and increased assignment (Shrubsole 1997). A caneland assignment provides an entitlement to have cane harvested, crushed and paid for under a collectively bargained Award arrangement with existing mill capacity (CANEGROWERS Victoria Area Annual Report 1996, p.6).

In the Herbert River District, each of the two CSR mills – Victoria and Macknade –has its own Local Board. Shrubsole (1997) found that since 1993 the Local Boards in the Herbert River District have incorporated environmental considerations into decision-making on cane assignment through (i) forming *ad hoc* technical review committee in 1995; (ii) requiring all applicants to submit a property management plan, and (iii) developing conditions of assignment. Shrubsole *et al.* 1999 provides a more comprehensive analysis of the cane land allocation process in the Herbert River catchment.

4.8 Northern Districts Sugar Industry Productivity Group

Essentially a lobby group for improved drainage in sugar areas in the 1970s and 1980s. By the early 1990s it ceased being very active and overtaken by other processes such as ICM and the SIIP.

4.9 Sunfish

Initially Sunfish was established as the Queensland Sport and Recreational Fishing Council, which during its 20th year of operation underwent an official name, change to Sunfish. Sunfish is the peak body representing over 882,000 recreational anglers throughout Queensland and is composed of representatives from State organisations such as the Queensland Game Fishing Association, the Australian National Sportfishing Association, the Queensland Amateur Fishing Clubs Association, the Australian Underwater Association Queensland Branch, the Freshwater Stocking and Fishing Association of Queensland, 10 Regional Branches and Individual Membership.

The Branch structure of Sunfish allows local fishers to play an active role in local fishery management and issues. Sunfish is an apolitical body, which liaises with the Queensland Government, and statutory bodies on recreational fisheries issues. It works closely with the Department of Primary Industries Fisheries Branch and the Queensland Fish Management Authority

5.0 COLLABORATIVE GROUPS/VENTURES

5.1 Herbert River Catchment Coordinating Committee (HRCCC)

Integrated Catchment Management (ICM) in the Herbert River Catchment operates under the Queensland Government's ICM policy framework (DPI 1991). An ICM Strategy for Queensland was released by the Queensland State Government in October 1991 outlining broad policy and structural arrangements. It provides a framework for fostering cooperation and coordination between landholders and other resource users, community groups and government agencies from all levels (i.e. federal, state and local) involved in the use and management of natural resources. The strategy promotes ICM as a participative and consultative process that takes a strategic and planned approach to tackling important natural resource management issues. The Queensland Department of Natural Resources is the lead government agency for implementing the Strategy. Other state government agencies, such as the Department of Primary Industries, Department of Environment and Heritage, and the Department of Local Government and Planning, also play a role in promoting and supporting relevant aspects of the ICM policy initiative. As ICM in Queensland is a voluntary community-based policy initiative that has no legislative basis, its success will ultimately reflect the ability of relevant public and private interests to voluntarily effect required action.

An ICM process commenced in the Herbert Catchment in 1992 with the formation of a Catchment Steering Committee of community leaders and government agency representatives, which established the Herbert River Catchment Coordinating Committee (HRCCC) in early 1993. A full-time Catchment The HRCCC involves representatives of a broad range of rural industry, community and local government and other statutory organisations that have an interest and/or role in natural resource management in the catchment. As such, the membership reflects the influential groups, power structures, and prominent community interests in the catchment. In 1998, the HRCCC had a local Chairman and 16 other members representing community, industry and local government and statutory bodies in the catchment (see Fig. 3). A full-time Catchment Coordinator facilitates the process.

Significantly, until 1999 the HRCCC had no formal State Government agency representatives although locally-based officers from the Department of Natural Resources frequently participate in meetings.

The Catchment Coordinator is funded from the federal government's National Landcare Program with additional support provided by the Department of Natural Resources. In addition, local stakeholder groups including Local Government and sugar industry bodies have provided in-kind support in terms of office accommodation, administrative support and their HRCCC member's time. State and federal government grants that are awarded through a competitive bidding process also provide financial support for many on-ground HRCCC activities. Through involvement in HRCCC meetings and activities, ICM in the Herbert Catchment is attempting to engage a range of key stakeholders in ESD.

The HRCCC has identified its role as (HRCCC 1998):

(i) Coordinate government agencies and the community to pursue common goals;
(ii) Seek community involvement in Catchment management;
(iii) Identify and rectify natural resource degradation;
(iv) Promote ways to prevent and reduce natural resource degradation;
(v) Promote the wise use of all natural resources within the Catchment;
(vi) Identify key indicators of biodiversity and monitor as a measure of catchment health;
(vii) Encourage the retention of significant natural habitats within the Catchment.

In May 1997, the HRCCC released a Herbert River Catchment Management Strategy for public comment (HRCCC 1998). This strategy is intended to provide a strategic framework for the future management of the Herbert River catchment's natural resources. It was prepared by HCCC members through a series of working groups and internal workshopping. The strategy identifies a broad range of priority management and planning issues. These issues involve not only interaction between many components of the catchment, but also many individuals and organisations with an interest in the catchment.

Bellamy and Johnson (1999) have identified the key achievements of ICM in the Herbert River catchment as:

(i) Initiating a range of focussed or single-issue land management projects to establish credibility and raise awareness of ICM process and natural resource management in general with the Herbert community (rather than focussing on issues of strategic importance to catchment management).
(ii) Achieving recognition as a legitimate community referral agency for the state and local government authorities on proposed developmental and infrastructure projects and other natural resource issues in the catchment.
(iii) Development of a Herbert River Catchment Management Plan that provides the essential elements of a 'sustainable' vision for the catchment.
(iv) Establishing a lead role within the Herbert River community as a principal broker negotiating funding for industry and community groups to undertake natural resource management projects and activities in the catchment.
(v) Providing an effective community forum for discussing and progressing catchment issues, including revealing the range of different stakeholder perspectives on these issues as well as highlighting potential areas of community conflict.
(vi) Information provider and disseminator through HRCCC meetings providing a 'community forum', initiating focussed activities that locally have a relatively high profile, as well as through the existing communication networks of HRCCC member organisations.

5.2 Herbert Mapping Project

The Herbert Mapping Project (HMP) was a cooperative mapping project started in 1993 in to collect geographic information relevant to industry, the community and researchers on the Lower Herbert River catchment. The HMP mapped the Herbert River flooplain at a scale of 1:10 000. This data capture process resulted in an orthophoto map series and some subsequent digital data as a by-product.

The data sets collected included sugarcane blocks, digital elevation model, houses, hydrology, rail, roads, topography, and waterbodies.

5.3 Herbert Resources Information Centre

The HRIC is a rural, collaborative, community focussed GIS. It has six signatory partners to a 10 year agreement - CSR Sugar Mills; Herbert Cane Protection and Productivity Board, CSIRO, Hinchinbrook Shire Council; Canegrowers Herbert River; and Queensland Department of Natural Resources.

The HRIC aims to provide essential resource information to assist in the planning and decision making activities of key venture partners. The core business of the HRIC is to manage and coordinate the joint venture resources for the:

- identification, collation, and capture of geographic information;
- support of Joint Venture Partners and community based resource planning and management initiatives, through the provision of geographic information, GIS expertise, and technology;
- management and maintenance of HRIC digital data sets;
- maintenance of a high level of GIS technical skills; and
- provision of training for Joint Venture Partners and the wider community.

5.4 Sugar Industry Infrastructure Package

The Queensland Sugar Industry Infrastructure Package (SIIP) is an initiative of the Federal Government, Queensland Government and the Sugar Industry to increase sugar production. Approximately $3.3M has been made available for infrastructure development in the Herbert River district under a project jointly funded by CANEGROWERS Herbert River District, CSR Herbert River Mills and Hinchinbrook Shire Council. The total scheme intends to develop and implement a program of structural works and non-structural measures which will provide for enhanced sugarcane production by improving drainage conditions for existing and future cane growing lands. Phase I relates to existing cane areas and Phase II mainly to expansion areas.

Within the five schemes which constitute the Phase I Herbert Existing Cane Area Water Management Project, a combined total of up to 15600 hectares of existing caneland currently suffers productivity losses due to flooding and waterlogging associated with heavy rainfall events (SIIP 1993; 1995; 1998). Four of the schemes (Macknade Scheme, Foresthome Scheme, Lagoon, Loder & Ti-tree Creeks Scheme, Mandam Scheme) concern coastal canelands adjoining mangrove wetlands. While the fifth, the Ripple Creek-Seymour River Scheme, concerns canelands adjacent to a freshwater wetland on an old distributary channel.

The primary purpose of the Phase I project is to increase cane production on the Herbert River floodplain by addressing the needs of the existing canefarmers with regard to wet season crop losses and yield decline associated with poor residual drainage and waterlogging. The intent is that this will be achieved through the coordinated implementation of drainage improvements including improved capacity drains and outfalls, and controlled inter-catchment transfers (SIIP 1995). Funding for Phase I was approved conditional upon:

- Approval of an Impact Assessment Study and associated Environmental Management Plan for the project by the SIIP Central Review Committee.
- The formation of a Water Management Board under Section 9 of the Water Resources Act 1989 to undertake construction of works and ongoing scheme management;
- One third funding of the total project cost being contributed by the local community.
- Negotiations are still continuing in late 1998 with implementation/approval not expected until 1999.

The Phase II project proposal involves:

(i) the expansion of the 'Hinchinbrook Rural Drainage Plan' (originally produced in 1984) "to facilitate orderly, properly drained new farm uptakes in proposed expansion areas; and

(ii) aerial photography and data capture of existing cane blocks as a future satrting point for future cane farm development proposals by the Hinchinbrook Council (Herbert SIIP Project – Phase II, 1997)

A consultancy will be let shortly for the new land and water management plan, and it is anticipated that it will have strong links to the Hinchinbrook Shire Planning Scheme.

5.5 Agricultural Planning for the Hinchinbrook Shire

The 'Agricultural Planning for Hinchinbrook Shire' package provides information to landholders on planning for material change of use under the Integrated Planning Act 1997 for the Hinchinbrook Shire and to assist cane growers in planning for further assignment. A Property Development Plan is required by the Hinchinbrook Shire Council as part of the application for converting land to intensive agriculture. Intensive agriculture in this context means the use of more than 5 hectares of land for the intensive production of crops including the growing of cane, watermelons and bananas.

The Shire Council cannot refuse an application but may impose reasonable and relevant conditions on the proposal. In addition Local Sugar Assignment Boards require Property Development Plans for applications for increases in assignment or any variation of assignment description that includes land not currently in their 'Present Assignment Description'.

The HRIC, Canegrowers and BSES assist individual farmers to design a farm layout. The applicant then submits the plan to a Technical Committee made up of DNR, DPI, DEH and BSES staff who appraise the plan against legislative requirements, such as the Water Resources Act, Environment Protection Act and Policies, the Nature Conservation Act, 'The Codes of Practice for Sustainable Cane Growing in Queensland', Local Board conditions and other applicable guidelines. The process is illustrated in Fig. 4 and the organisations involved and the organisations involved and their linkages in Fig. 5.

The important development in this package is the formal linking and coordination of the approach to land use planning between State Government, Local Government and industry in the lower Herbert River catchment.

Figure 4. Agricultural Planning Process

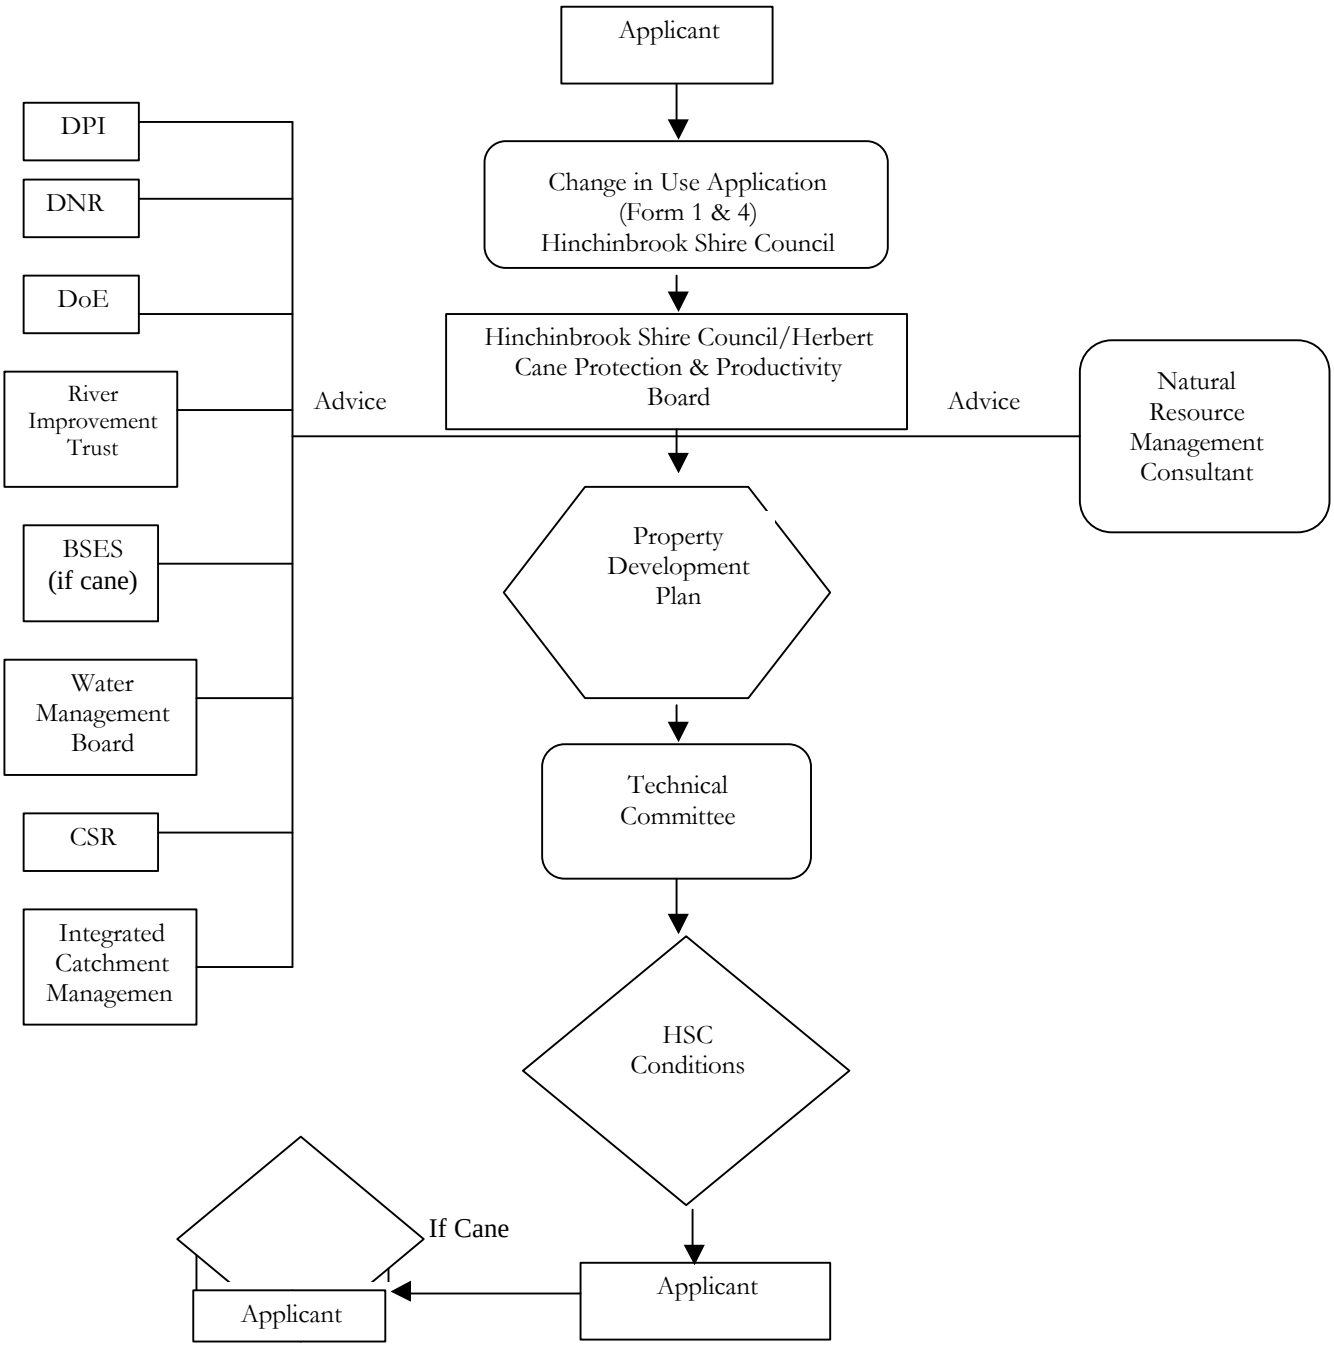

Figure 5. Organisations involved in the new Agricultural Planning Process for the Hinchinbrook Shire in 1999

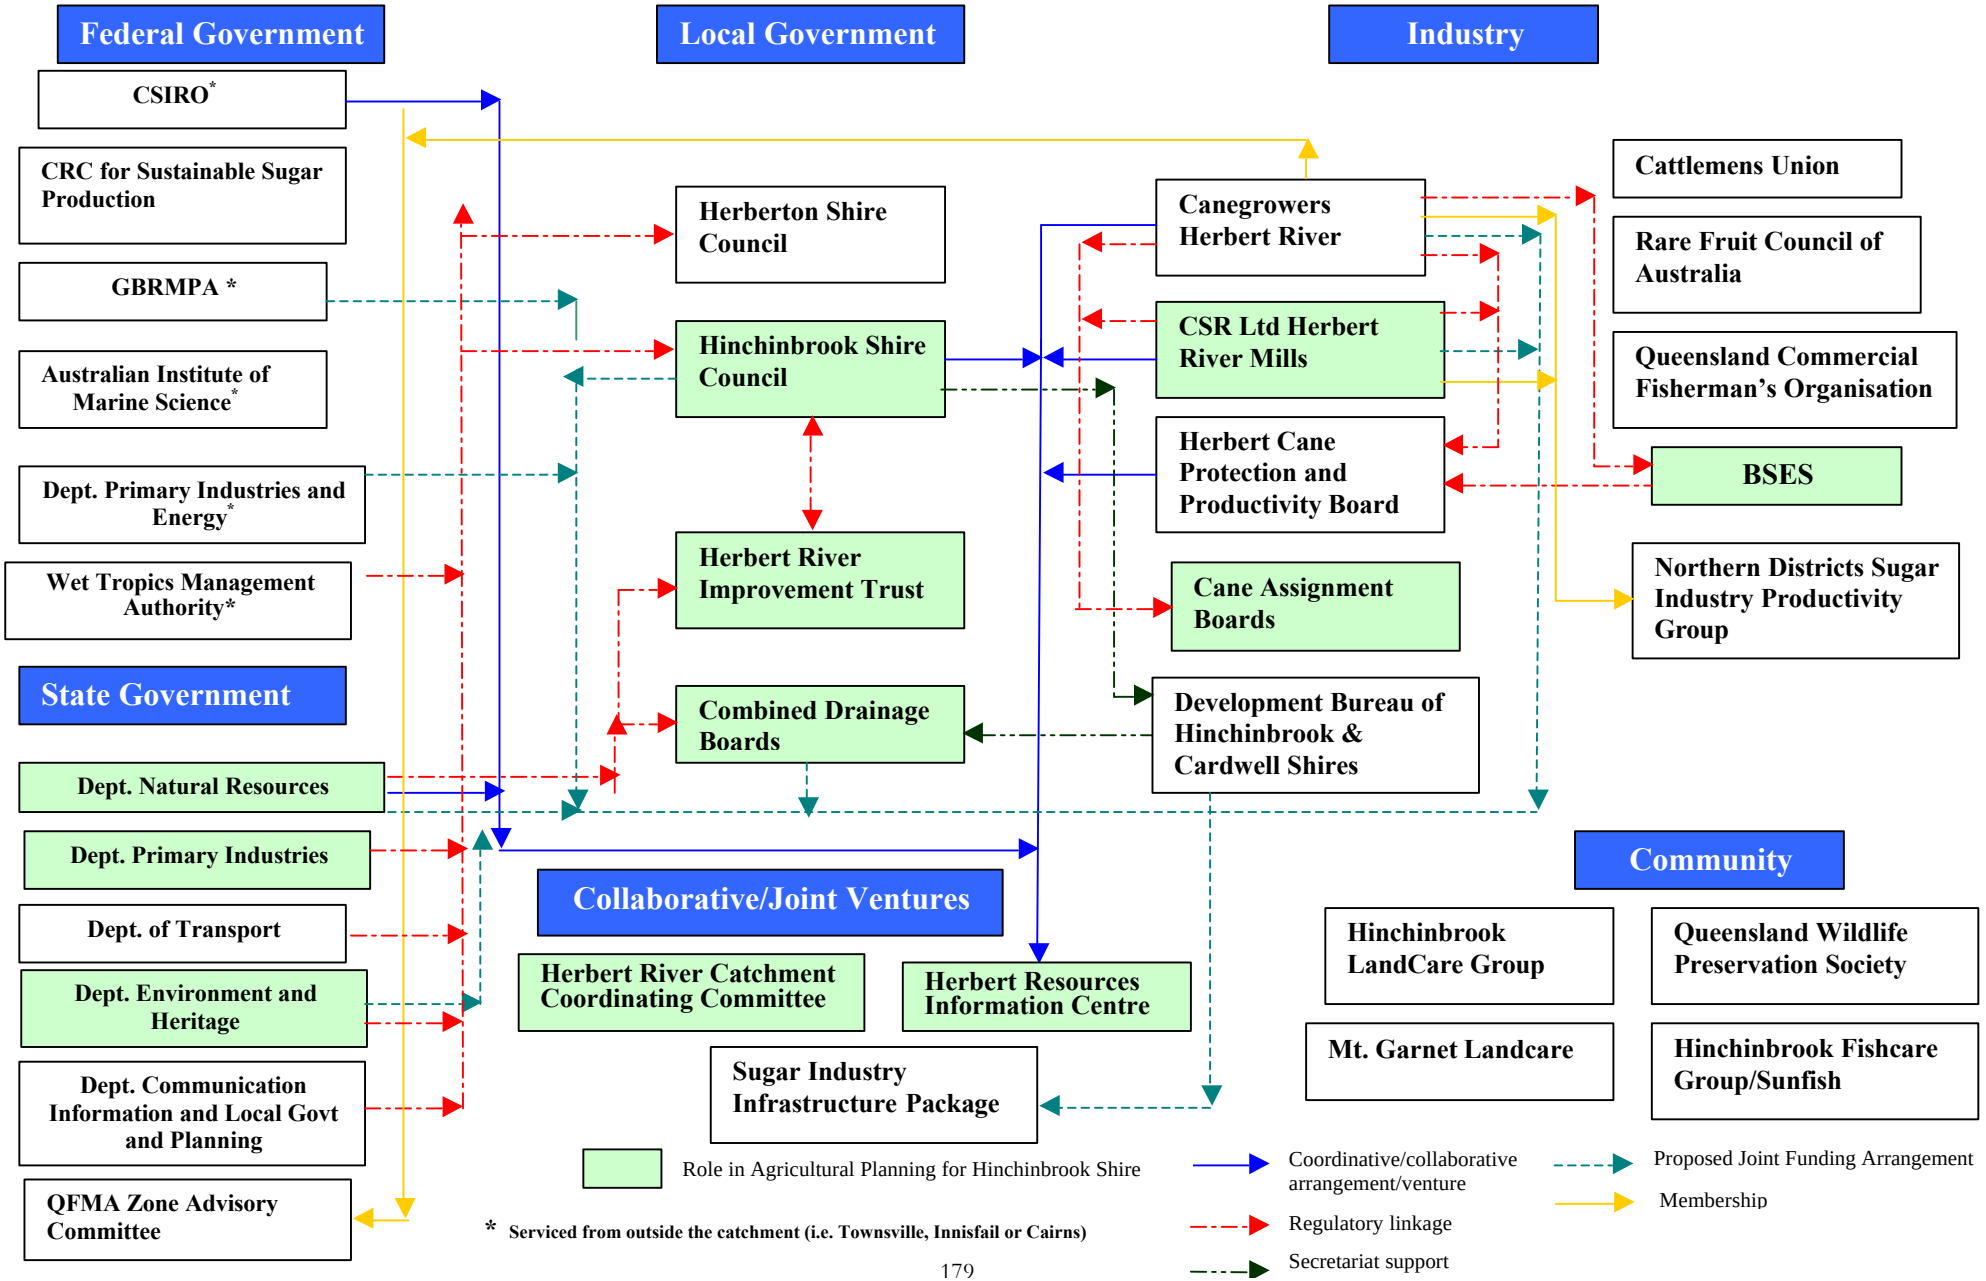

6. EVOLUTION IN ORGANISATIONAL ROLES AND LINKAGES ON NRM IN THE HERBERT RIVER CATCHMENT

This study shows that there have been significant changes in the system of organisational linkages on natural resource management in the Herbert River catchment since the inception of an ICM process in 1992. Key elements of these changes include:

- *Increased number of linkages:* A demonstrable increase has occurred in the number of linkages (both regulatory and non-regulatory) between (a) local government and related statutory bodies and industry and other community organisations in the Herbert catchment and (b) these Herbert River organisations and state and federal agencies.
- *Increased linkages based on collaboration*: There has been an emergence of a number of significant coordinative, collaborative and/or joint funding initiatives for NRM purposes. The Herbert Mapping Project and the establishment of the HRCCC in 1993 appear to have provided the catalyst for further collaborative ventures on NRM.
- *Local Government developing a significant role in NRM:* A significant increase has occurred in the role and responsibility of local government in catchment management and planning. This has emerged through (a) an influential role based on active membership on the HRCCC and (b) regulatory and statutory processes (including major changes to the Hinchinbrook Shires Planning Scheme and HRIT activities).
- *Emergence of the HRCCC as an coordinative and informative forum for NRM issues*: The ICM process in the Herbert River catchment through the activities of the HRCCC has provided a key integrative forum for facilitating information exchange and more inclusive debate on NRM issues that had not existed before in the catchment.
- *Broadening of the focus of industry organisations to encompass NRM concerns*: several industry organisations (notably the Herbert Cane Protection and Productivity Board and CANEGROWERS) have shifted their focus from a almost exclusive concern with productivity and efficiency issues and impacts to a recognition (at least in principle) of the importance of natural resource management to the long term sustainability of the industry. In the case of the HCPPB a demonstrable change has occurred in its functional role from a prime focus on productivity to also encompass and promote environmental sustainability.
- *Improvement in NRM data capture and delivery mechanisms*: There has been an emergence of collaborative ventures between local government, industry and state and federal government agencies to improve the capture of relevant data on NRM issues (eg. Herbert Mapping Project and a Catchment Atlas) and provide locally accessible mechanisms for integrating data and information delivery or service provision.

In sum, the system of organisational structures and linkages on natural resource management in the Herbert River Catchment has evolved to be more coordinated and more inclusive of key stakeholder groups with the establishment of the HRCCC in 1993. Significantly, the HRCCC is providing a key integrating and informing functional role on NRM within this system.

Bellamy, J.A. and Johnson, A.K.L. 1997. ICM and Sustainable Agriculture: moving from rhetoric to practice. Proceedings of 2nd National Workshop on Integrated catchment Management. Advancing Integrated Resource Management: Processes and Policies, 29 Sept. - 1 Oct. 1997, ANU, Canberra. (River Basin Society Inc.: Victoria)

Summary: Operationalising the concept of sustainability through community-based approaches to Integrated Resource Management (IRM) poses enormous challenges for both the agricultural communities and government agencies concerned. This paper reviews some of the challenges to change in agriculture and key impediments to the implementation of community-based IRM approaches. A relatively new community-led Integrated Catchment Management (ICM) process in an agricultural community in north Queensland is examined in terms of some of the lessons learned that may be relevant to other similar IRM processes. It reveals a pragmatic, opportunistic and adaptive approach to implementation rather than a process of 'rational' planning. In this case study, the strategy was emergent as the various actors came to know the problem and its context and their capability of dealing with it. We conclude by identifying some essential characteristics of an agricultural context that an IRM process can utilise to assist a community to adapt to and manage change for sustainable agriculture.

1. INTRODUCTION

Agriculture, as both a major "user" of natural resources and a "supplier" of environmental services, is a key sector in the move toward ecologically sustainable development (ESD) (Steenblik *et al.* (1)). In attempting to operationalise the goals of ESD, a number of Australian states have introduced and fostered community-based approaches to integrated resource management (IRM). The impetus for implementation has come from:

- the degradation of land, water and vegetation resources in many rural areas due to a combination of unrealistic expectations and inappropriate management over a long time period (eg., SEAC (2));
- federal government commitment to a range of international and national agreements and strategies on the environment (eg., National Strategy for Ecological Sustainable Development, Intergovernmental Agreement on the Environment; National Strategy for the Conservation of Australia's Biological Diversity);
- the move to greater diversification in the use of, and values placed upon, natural resource systems;
- the fragmentation of decision making and responsibilities for natural resource management across a multiplicity of public and industry agencies (including all three tiers of government);
- trends in state and federal governments toward the devolution of responsibilities for environmental stewardship to the local level (eg., ANAO (3)); and,
- increasing community expectations for greater involvement in decision-making and higher standards of accountability in environmental protection.

Translating the principles of IRM into practice has proved difficult and poses enormous challenges for both agricultural communities and responsible agencies. These challenges are compounded by the current crisis in agriculture as evidenced by deteriorating terms of trade coupled with financial inability to implement sustainable management practices (PMSEC 1995; ANAO 1997). The management of agricultural lands in Australia will continue to be undertaken in an environment of increasing demands for agricultural outputs (IC (5)). However, any intensification or expansion of agriculture is very likely to have environmental implications. At the same time, Australia as an agricultural exporter faces increasingly environmentally conscious international markets.

This paper examines how a community-led Integrated Catchment Management (ICM) process is attempting to facilitate the move towards sustainable agriculture. It reveals a pragmatic, opportunistic and flexible approach to ICM such that the strategy is emergent as the various actors come to know the problem and its context and their capability of dealing with it. We conclude by proposing how ICM or similar approaches may in the future contribute to best practice in agriculture.

2. THE RHETORIC

The well recognised core principles of ESD are to maintain ecological integrity, biological diversity and natural capital. The principles of sustainable agriculture however are much more focussed and narrowly defined. As recommended by the Standing Committee on Agriculture the five principles of sustainable agriculture 'against which policies at all levels of government could be judged' are (SCA (6)):

1. Farm productivity is sustained or enhanced in the long term.
2. Adverse impacts on the natural resource base of agriculture and associated ecosystems are ameliorated, minimised or avoided.
3. Residues resulting from the use of chemicals in agriculture are minimised.
4. The net social benefit derived from agriculture is maximised.
5. Farming systems are sufficiently flexible to manage risks associated with the variables of climate and markets.

Notably, these principles do not make specific reference to the maintenance of biological diversity. With over 80% of Australia's agricultural land in private hands (SEAC (2); ANAO (3)), the protection of biodiversity and the maintenance of ecological integrity and natural capital have to be seen as an integral part of agricultural land management if ESD is to remain a national goal. Agriculture must not be considered in isolation of other resource uses, rather it needs to be considered within a broader regional or catchment context. Recognition of these issues has led to increasing calls for integrated systems approaches to resource management (eg. RAC (7)).

In parallel with the move to ESD, the emerging paradigm of IRM is one which recognises the interdependencies of natural systems, political systems, social systems, and technology. This new paradigm recognises:

- an integrated systems approach;
- a long term perspective and broad spatial scale focus;
- the concept of 'the whole being more than the sum of the parts';
- technical solutions to biophysical complexity;
- the need to deal with both complexity and uncertainty;
- non-linear processes and connectivity between problems;
- people as part of the problem and not external to it;
- the need for coordination of decision-making amongst stakeholders in government, industry and the community; and
- the need for active involvement of the whole community that leads to community ownership of the problem and its solution, and ultimately the adoption of sustainable resource use and management practices.

This new paradigm has emerged from a recognition of the failures of current approaches (RAC (7)), and from insights from domains other than agriculture. These insights are challenging assumptions underlying the more traditional 'rational' approaches to management and provide an emerging learning paradigm based on an adaptive approach to ecosystem management and collaborative decision-making.

A number of Australian states are attempting to implement IRM approaches, such as ICM in Queensland, Total Catchment Management (TCM) in NSW and catchment management in Victoria. Although approaches to implementation and organisational structures for IRM vary significantly across the different states of Australia, the rhetoric underlying these approaches requires the integration process to move beyond a purely coordination function to one that involves roles and responsibilities for both the implementation and the monitoring of integrated planning strategies and decisions on resource management at the catchment level.

3. RESPONDING TO THE RHETORIC

Australian agriculture is taking a number of positive steps towards addressing public and private concerns for the environment. At industry level, it has, for instance, conducted environmental audits of farming activities (eg, cotton, sugar) and developed industry best management practices (eg., sugar, dairy). At a national level, the 1992 Intergovernmental Agreement on the Environment, commits all state and territory governments, the Commonwealth Government and Local Government to the principles of ESD. However land degradation continues to be the major issue for resource use and management in Australia (SEAC (2); IC (5)).

3.1 Challenges to Change in Agriculture

In responding to the rhetoric on sustainability and in attempting to achieve real change, Australian agriculture faces a number of significant challenges. These include:

- inadequate incentives for the adoption of more sustainable agricultural practices resulting in poor linkage of land and water management issues to market signals such that short term incentives for the adoption of more sustainable agricultural practices are lacking (AACM (8); ANAO (3));
- agricultural "technology" is typically single issue or problem oriented and does not necessarily lend itself to a systems focus;
- "selling" the adoption of environmental management practices and "selling" commercial innovations in agriculture are different processes;
- options for achieving change are long term and do not match the typical business and political timeframe of agriculture and government processes;
- the diversity in, and the dominant individualistic approach of, farm enterprises mitigates against the achievement of "integration" (eg. a pastoralist's decision-making is predominantly focussed within farm gates) except where there is a clear off-farm focus around processing infrastructure (such as the sugar industry);
- significant difficulties are associated with balancing public and private costs and benefits of IRM and the associated issue of "who should pay"; (ANAO (3))
- Australia's national origins give rise to a culture that places a high value on the right of individual landowners to determine land use, which creates a major obstacle to internalising the external costs of agriculture (Reeve (9));
- the 'not in my back yard' syndrome in the agricultural community (AACM (8));
- the effects of changes in management on complex natural systems take a long time to appear, and they are frequently hard to directly link to causes; and,
- declining funding and general resourcing with state and federal governments scaling down their support for agriculture, while industry funding is still not recognising its natural resource management obligations.

3.2 Challenges for IRM Implementation

For IRM approaches to move beyond principle and to effect action, they must also overcome significant impediments to implementation. These include:

- the lack of certainty and/or coordination of many government priorities, policy and institutional arrangements relating to natural resource use and management;
- the lack of government support for IRM (for example state government rhetoric is not matched by the resources provided, and Commonwealth funding is allocated to States frequently on a basis unrelated to the programs they are trying to address (AACM (8));
- the lack of tangible incentives for institutional reform or behavioural change that will effect changes that move either organisations or land managers towards sustainable development (AACM (8));

- the absence of institutional and statutory underpinning for IRM approaches in many states to indicate long term government commitment and financing (eg., ICM in Queensland and WA);
- poor recognition of local government as an integral part of catchment management in state and federal policies (AACM (8));
- the current limited capacity (ie., human, financial, and knowledge-base) at the local level to address natural resource management problems and implement action;
- the lack of appropriate cost-sharing mechanisms to accompany the transfer of resource management responsibilities to regional and community groups (ANAO (3)); and,
- significant disparities in wealth and power at the local level that makes it difficult to put IRM into effect in a more inclusive way.

In addition to these impediments, attempts to address sustainability within existing community and institutional frameworks have met with mixed success due to their inability to account for, amongst other things, multiple objectives, multiple players, poorly defined objectives, unclear outcomes and multiple pathways (eg., Syme *et al* (10)). Much of the literature on ICM has focussed on its conceptualisation and alternative organisational structures, but it lacks practical guiding principles for effective implementation of an integrated systems-based approach. Many IRM approaches have tended to be *ad hoc* responses to urgent and emerging problems rather than being focussed on achieving strategic change. In other words, operationalising the concept of sustainability remains a significant challenge given that in many ways IRM does not fit the traditional 'rational' planning approach to decision making.

4. THE REALITY: A COMMUNITY RESPONSE IN THE WET TROPICS

The Queensland initiative on ICM which commenced in 1991 is a policy or planning process that has no legislative basis but is implemented through administrative and financial arrangements by the state government. As such, its success will ultimately reflect the ability of relevant public and private interests to voluntarily effect required action.

In the following sections we examine how an agricultural community in north Queensland has attempted to bridge the gap between rhetoric and practice within an ICM context and in so doing comment on how this experience may lead to best practice in the future. The discussion draws on research findings from a LWRRDC-funded project to evaluate the implementation of an ICM process in the Herbert River catchment of north Queensland.

4.1 The Context: ICM in the Herbert River Catchment, Queensland

The Herbert River catchment has an area of nearly 10,000 km^2 and is located on the southern end of the wet tropical coast of north Queensland. It drains directly into the Hinchinbrook Channel, part of the Great Barrier Reef Marine Park. Agriculture is the dominant land use in the catchment consisting of mainly beef production on native pastures in the upper catchment and intensive sugarcane production on the lower coastal plain. Other significant land uses are forestry, conservation areas (ie. significant parts are within the Wet Tropics World Heritage Area), and smaller areas for horticulture and fodder cropping. There are no 'critical' issues in the catchment of the magnitude of for example salinity, rather the key natural resource management issues prior to the ICM initiative related to:

(a) concerns for the potential impact of agriculture on the Great Barrier Reef and nearshore environments (eg., mangroves and seagrass beds in the Hinchinbrook Channel) and the potential implications for conservation, tourism and commercial fishing; and

(b) community conflicts relating to flooding and drainage issues, as well as future land development for sugarcane and its potential impact on production particularly in the lower Herbert catchment.

The sugar industry dominates the lower Herbert both socially and economically, with the two processing mills being owned and operated by CSR Ltd. The contrasts in the physical and socio-economic contexts of the upper and lower parts of the catchment are very strong, with little interaction between authorities or community members. Landcare has been active in the upper catchment pastoral areas for some time but has not succeeded in obtaining a foothold within the lower catchment. The sugar industry in general, however, has been a dominant player in ICM in the lower Herbert since its inception.

ICM in the Herbert River catchment is a voluntary process initiated by key actors in the local community. Commencing in 1993 with the formation of the Herbert River Catchment Coordinating Committee (HRCCC), it is a relatively new process which is still in its formative stages. The impetus for ICM in the Herbert catchment was twofold: (a) broad community-based concern over the ineffectiveness of the fragmentation of government decision-making on river management issues and the perceived need for better community participation, and (b) the personal and political agendas of influential stakeholders in the lower Herbert catchment, who to a large extent were motivated by a desire for 'a piece of the action' (ie. ICM in Queensland), including potential funding opportunities for 'pet projects'.

Current representation on the HRCCC includes industry (sugar, cattle, fishing, horticulture), local government and other statutory bodies, conservation and community interests. Most of the 15 members have multiple allegiances and/or responsibilities. The HRCCC has no state government departmental representation, however the Catchment Coordinator (CC) is an NLP-funded position based in the Department of Natural Resources (the lead government agency for ICM in Queensland).

The HRCCC have identified a challenging set of objectives as detailed in its Draft Catchment Strategy (HRCCC (11)) recently released for community comment, namely:

- coordinate government agencies and the community to pursue common goals;
- seek community involvement in catchment management;
- identify and rectify natural resource degradation;
- promote ways to prevent and reduce natural resource degradation;
- promote the wise use of all natural resources within the Catchment;
- identify key indicators of biodiversity and monitor as a measure of catchment health; and
- encourage the retention of significant natural habitats within the Catchment.

4.2 The Process To-date: An emergent strategic approach

Initially, ICM in the Herbert was hampered by diverse HRCCC member perspectives on ICM and a lack of a common understanding of what the HRCCC might realistically be able to achieve. There was also a lack of shared understanding of natural resource management issues in the Herbert and their relative importance. As previously noted, personal objectives and 'pet projects' frequently clouded the agenda. The process was also inhibited by an initial lack of clear direction and strong leadership within the HRCCC, including a one-year delay in the appointment of a full time CC until April 1994. The CC adopted an initial aggressively proactive role within the HRCCC in setting the agenda to gain personal credibility with the 'established' Herbert community leaders of the HRCCC. Over time the CC has moved to play a more facilitatory role within the HRCCC, particularly with the appointment in 1996 of a new Chairman who has taken a more proactive approach in setting and negotiating the role and

agenda for ICM in the Herbert. Hence the HRCCC has undergone what might be called a process of 'evolving reality' largely in response to the novel situation members found themselves in.

In addressing this situation, the HRCCC adopted a pragmatic and opportunistic approach to ICM implementation. This approach has focussed in the first instance on building a credible and influential relationship with the Herbert community. This is demonstrated in a number of ways:

(i) The composition of the HRCCC membership recognises the *influential groups, power structures, and local interest groups* in the Herbert community, including recognising the situation that community actors (both individuals and agencies) generally have multiple allegiances and/or responsibilities. Although the ICM initiative originated in the lower catchment, the HRCCC from the start actively sought the involvement of representatives from the upper catchment. In respect of the latter, the HRCCC negotiated funding for on-ground works to address issues relating to derelict mining dams which were a potentially divisive issue between the upper and lower catchment communities (ie., poor domestic water quality and reduced river capacity due to increased sedimentation in the lower catchment).

(ii) To *raise awareness of ICM within the Herbert community and get 'runs on the board'*, the HRCCC has undertaken and supported a number of *ad hoc* but focussed land management activities including: (a) raising the profile and even 'creating' resource management issues in the catchment, eg. the HRCCC fostered the construction of over 50 owl boxes on farms for rat management and promoted them as a key element of integrated pest management for improved sugarcane production and nature conservation; (b) supporting on-farm tree planting of commercial hardwoods and rainforest species on odd-shaped or difficult caneland blocks; (c) undertaking with canegrowers the removal of para grass blocking drainage lines and replanting with riparian vegetation; (d) developing artificial wetlands both on-farm (with canefarmers) and on public lands (eg. jointly with the CSR mill and Hinchinbrook Shire Council to establish a wetland using sugar mill waste).

(iii) The HRCCC initially focussed its on-ground action on *symptoms of natural resource problems rather than causes* such as the revegetation of riparian lands rather than tackling the more contentious issue of management of remnant vegetation on private lands. For example, during a highly politicised controversy about the clearing of Mahogany Glider habitat, given the highly emotive nature of the issue within the local community and state government politicisation of the issue, the HRCCC chose not to fully engage in the community conflict. It was perceived to be beyond their control and there was significant internal conflict within the HRCCC membership. It opted in the first instance to lobby state government for a technical expert to be based in Ingham to provide appropriate expert advice and improve the communities capacity to deal with these issues in the future before they reach a crisis situation. Secondly it negotiated with landholders a flexible system of riparian zone width assessment.

(iv) More recently the HRCCC has adopted *a lead role as broker for external funding of community projects* that would initiate a move toward addressing the fundamental causes of natural resource management problems in the longer term. For example, the HRCCC undertook a process to develop a catchment management strategy predominantly to ensure eligibility for the catchment community for state and commonwealth project funding. The HRCCC also acted as the broker and coordinator for all new proposals submitted for National Heritage Trust funding from the catchment providing the catalyst for community activity in Commonwealth and state-funded initiatives.

(v) The HRCCC commencing to be *an information provider and distributor* within the Herbert catchment with some mixed success in terms of outcomes. For example, in attempting to improve and integrate the available knowledge-base in the catchment on ICM related issues and to improve the communities' capacity to deal more proactively with natural resource management issues, the HRCCC has initiated or contributed jointly with other local

government and industry organisations to a number of activities, such as: the preparation of a Herbert Catchment Atlas for use in schools and the general community; publicised the issue of the risk of acid sulphate soils including distributing available pamphlets in the community; initiated and conducting a Wetlands Forum in the catchment with key invited speakers from government, the research community and industry; and formally linking into the Herbert Resource Information Centre (HRIC) which is providing a community-based and sponsored resource to coordinate spatial/non-spatial, technical and socio-economic information on the catchment to underpin local decision-making.

The HRCCC's perception of its role appears to have evolved over time from one of delivering natural resource outcomes and solving natural resource management issues on the ground to a more strategic role (McDonald and Bellamy (12)). This emerging role involves establishing a decision-making culture relating to natural resource use and agricultural development based on ICM principles as 'a way of doing business', and providing a strategic direction on resource management for the catchment.

The HRCCC's response to the difficult task of moving the Herbert community toward more sustainable agriculture and development in general has been one of adopting: (a) an initial approach of predominantly *ad hoc* responses to opportunities or urgent issues that arose in the catchment which involved engagement in on-ground works; and (b) a concurrent emergent role that is more coordinative and strategic in focus, in particular one of raising and progressing issues rather than developing prescriptive solutions. Notably, the Herbert community is moving its prime focus from a concern with disaster management (ie. issues of river management including flood mitigation and drainage) to one that embraces the broader concept of natural resource management (McDonald and Bellamy (12)). This has been achieved largely through raising the HRCCC's profile amongst established and influential catchment actors, such that it is now becoming a central player in decision-making on natural resource management issues in the Herbert community.

To date the key achievements of ICM in the Herbert may be summarised as (McDonald and Bellamy (12)):

(i) Initiating a range of focussed or single issue land management projects to get runs-on the board and raise awareness of ICM with the Herbert community (rather than focussing on issues of strategic importance to catchment management).
(ii) Recognition as a key community referral agency for the state and local government authorities on proposed projects and other natural resource issues and projects in the catchment.
(iii) Development of a draft Herbert River Catchment Management Plan for public review and comment that provides the essential elements of a 'sustainable' vision for the catchment.
(iv) Establishing a role as principal broker for negotiating funding for others to undertake natural resource management projects and activities in the catchment.
(v) Serving as an effective community forum for discussing, 'airing' and progressing catchment issues, including revealing the range of different stakeholder perspectives on these issues as well as highlighting potential areas of community conflict.

The strategy for ICM implementation that has emerged in the Herbert ICM's first 4 years meets many of the elements of what Mintzberg (13) refers to as a visionary approach to deal with an uncertain world in a flexible way, to set the broad outlines of a strategy, and to provide the basis for adaptive learning. In essence, the strategy for ICM implementation has evolved through pragmatism, opportunism and adaptiveness on the part of the HRCCC.

4.2 The Response: 'The art of muddling through'

The Herbert ICM process has many common elements with Lindblom's (14) concepts of learning in complex policy contexts. It has not been a controlled process of rational planning but a messy one of trying to cope with a complex and dynamic world and much uncertainty regarding the problem at hand and the means of dealing with it and the goals to be aiming for. It has been essentially a process of learning over time with the various actors working it out by mutual adjustment, that is a process in which learning informs planning and strategies emerge as the key actors come to understand the problem and its context and their capability of dealing with it (Mintzberg (13)). The Herbert process being much more one that can be described as 'the art of muddling though ' than a 'science'. Reflecting on this experience, an IRM process may contribute to a move towards sustainable agriculture by:

- *Fostering communication* across sectoral and community interests facilitated through the establishment of an effective community based forum that reveals the diversity of perspectives and the importance attributed to specific catchment issues.
- *Providing a framework/structure that fosters cooperation* amongst community and industry groups and government organisations that leads to more equitable decision making and more sustainable natural resource outcomes on the ground.
- *Facilitating coordination* of effort across government, industry and community organisations to achieve outcomes that have benefits to a broad range of catchment stakeholders as well as the environment, and which could not be achieved by any one group alone.
- *Integrating* IRM principles into Local Government planning that provides a basis for implementing a strategic direction for the catchment.
- An IRM implementation process that supports an *emergent strategic approach* of adaptive learning involving key and influential community actors and moves the community towards a sustainable process of integrated planning of natural resource use.

There are still very significant challenges for ICM in the Herbert. In particular it has a long way to go to achieve tangible outcomes in respect of the key natural resource management issues. However, significant progress is being made in a long term process. The Herbert catchment is not unique, and its experiences in implementing ICM are relevant to other similar community-led IRM approaches; in particular, those catchments where there is not one critical issue of the magnitude of salinity, but rather a diversity of significant land and water management and biodiversity protection issues relating to sustainable agricultural development.

5. MOVING FROM RHETORIC TO PRACTICE: TOWARDS BEST PRACTICE

What is unsustainable in agriculture is a lot easier to establish than what is sustainable. The challenge therefore for IRM and sustainable agriculture is to deal with a situation in which the goal posts are shifting, and the goals are unclear, multiple and contested. This paper has identified a number of challenges to change in agriculture. However, significant opportunities exist for IRM to contribute to sustainable agriculture arising from a number of attributes of an agricultural context. These include:

- the strong culture of mutual support and information exchange in agricultural systems;
- locally-based industry regulations (eg. sugar assignment system) and industry codes of practice (eg. land clearing in grazing areas) which could be supported by incentive systems.
- the current move to operationalise the principles of ICM in local government planning schemes (McDonald and Bellamy (12));
- extension and other industry networks and new opportunities in information technology that can improve the capacity of communities to address resource management issues (including access to technical knowledge, people and group management skills, policy understanding);

- the traditional agricultural business concept of managing an asset that can be developed to establish strong market linkages for land and water resources management with enterprise outcomes.

The challenge for IRM is to utilise these opportunities to assist agricultural communities to adapt to and manage change and move towards sustainable agriculture.

(eds). *Management for Sustainable Ecosystems*. Centre for Conservation Biology, The University of Queensland, Brisbane. In Press.

ABSTRACT: Management for ecological sustainability cannot be achieved alone by fencing off protected areas within an overall managed landscape (eg. in parks, enclosures). It requires an approach that also addresses the issues associated with transaction costs and the uncertainty and interconnectedness of the behaviour of natural and human systems in a managed landscape. In response to these issues, all Australian governments have endorsed community-based integrated approaches to resource management. These approaches are based on a collaborative partnership between government and the community and as such involve multiple stakeholders with multiple and often conflicting objectives.

This paper examines an integrated approach to catchment management and the challenges of effectively engaging multiple stakeholders. It describes the issues experienced by an Integrated Catchment Management (ICM) organisation in Northern Queensland and the strategy adopted by that organisation to foster stakeholder involvement in ecological sustainable development (ESD). An examination of a number of activities undertaken by the organisation demonstrates how catchment resource use issues are being addressed and the means of engaging stakeholders in ecologically sustainable resource management. In conclusion, we consider, the distribution of outcomes of ICM and their implications for offering incentives for catchment stakeholders to engage in management and planning practices that will potentially impact on the ecological sustainability of the catchment system as a whole.

INTRODUCTION

An emerging paradigm for natural resource management is based on the two core concepts of ecosystem management and an integrated and adaptive approach to planning and management (Holling 1995, Wallace *et al.* 1996, Gardner and Stern 1997, Bellamy *et al.* 1999). These concepts have significant implications for the practice of conservation and the management of natural resources for ecological sustainability. The new paradigm implies a move away from a single-species, single-unit or single-use management focus toward a systems approach designed to ensure the long-term health of ecosystems and the preservation of biodiversity that extends across traditional management boundaries. The implications are also that ecological sustainability cannot be achieved alone by fencing off protected areas (eg. in parks, enclosures) within an overall managed landscape. The conservation of biodiversity and sustainable use of natural resources needs to be an integral part of an overall strategy for natural resource management that encompasses all elements of the landscape or regional ecosystem and its interaction with human management and use.

Under the new paradigm, sustainable use and management of ecosystems and other elements of biological diversity requires cooperative processes in planning and on-ground implementation of management strategies. These cooperative processes are expected to be inclusive of all managers responsible for the management of the multitude of inter-linked units of the landscape. Managers include not only individual landholders or resource users within a catchment or a regional ecosystem, but also organisations in all spheres of government, industry and the community with some role and responsibility or interest in the use, management and conservation of the natural resource. In response to the needs of the emerging paradigm, all state governments in Australia have endorsed integrated approaches to the planning and management of natural resources based on collaborative partnerships between government, industry and the community (Syme *et al.* 1994, Bellamy and Johnson 1999). Although implementation contexts and policy mechanisms may vary greatly, all of these approaches involve multiple stakeholders and are inherently characterised by multiple and often conflicting objectives and values. As such they invariably require negotiation and bargaining processes as stakeholders attempt to address conflicts from a broader systems perspective extending across traditional decision-making boundaries.

This paper examines an integrated approach to catchment management and the challenges of effectively engaging multiple stakeholders. It describes the issues experienced by an Integrated Catchment Management (ICM) organisation in Northern Queensland and the strategies being

used by that organisation to foster stakeholder involvement in Ecological Sustainable Development (ESD). An examination of a number of activities undertaken by the organisation demonstrates the challenges of addressing resource use issues at a catchment scale and engaging stakeholders in the process.

ECOLOGICAL SUSTAINABLE DEVELOPMENT AND MANAGED SYSTEMS

The three fundamental underlying assumptions of ESD are environmental sustainability, social well-being and economic development. In the first place, ESD places a burden of responsibility on all decision-makers including national, state and local governments, local communities, industry and individuals to take a long term perspective and commitment to achieving ecological sustainability. Secondly, it requires that social, economic and environmental issues are considered as essential components of natural resource management and planning. To this end, collaborative approaches based on systems thinking and systemic behaviour are increasingly being advocated to change the culture of decision-making of individuals, organisations and communities (Ison *et al.* 1997, Chambers 1997, Bellamy *et al.* 1999). The core principles of this systems approach are:

(i) the long-term sustainable use and management of natural resources;
(ii) the application of technically-sound environmental, economic and social assessment methods and understanding;
(iii) the coordination of government, industry and community policies and decision-making processes; and
(iv) the reconciliation of conflicting values, interests and expectations of stakeholders involved in the use and management of resources through more transparent structures of negotiation and bargaining.

The central challenges of a systems-based approach therefore include firstly addressing the issues associated with the heterogeneity, uncertainty, nested nature and interconnectedness of the behaviour of natural and human systems, and secondly ensuring that the distribution of the costs and benefits of resource management are appropriate.

Operationalising ESD

In the past, natural resource management and planning has invariably relied on top-down centralised governance. This has been typically expert-driven, single-agency initiated and enforced, frequently regulatory-based, and technocratic in practice (Wallace *et al.* 1996, Bellamy and Johnson 1999, Dale and Bellamy 1998). The organisational structure of federal and state government agencies typically involves centralised decision-making in which legislation and regulatory arrangements are passed by the respective governments with the objective of regulating and managing the use of natural resources at the management unit level, such as a farm, reserve, local government area, catchment or region. Examples of these approaches include conservation within protected areas (eg. parks and reserves), emission permits, water entitlements, land clearing permits, and tax/subsidy measures designed to equate social and private costs and benefits of resource use.

Approaches to natural resource policy based on centralised governance however have not generally lead to changes in the behaviour of individuals and communities toward more sustainable resource use and development (Vanclay and Lawrence 1995, IC 1997, Dale and Bellamy 1998). A review of the literature identifies a number of failures of centralised governance responses including:

(i) simplistic solutions and linear cause-and-effect assumptions that fail to deal with the uncertainty, complexity, and multi-dimensionality of the problems being addressed (Funtowicz and Ravetz 1990, RAC 1993, Dovers 1996);
(ii) the failure to recognise ESD as a continuous evolving process rather than a particular system state for which to aim (Bellamy *et al.* 1999);
(iii) the failure to address the distribution of costs and benefits of policy impacts (ANAO 1997, MDBC 1996);
(iv) flawed policy responses that de-emphasise the consideration of affected interests in favour of "objective" analyses and suffer from a lack of popular acceptance (Renn *et al.* 1995);
(v) an almost exclusive reliance on systematic observations and general theories that tends to ignore the local and anecdotal knowledge of the people most familiar with the problem and risk producing outcomes that are socially and economically unworkable (Renn *et al.* 1995);
(vi) uncoordinated, comparmentalised or sectorally-based implementation of policy, programs and planning initiatives (Bellamy and Johnson 1999);
(vii) the lack of appropriate institutional arrangements to facilitate participation that is inclusive of all interests in the community (Lang 1990);
(viii) the weaknesses of the strategies adopted to resolve conflict (Dorcey 1991); and
(ix) the failure to move beyond the development of management plans to on-ground implementation (Dale and Bellamy 1998).

In Australia "the incorporation of ecological sustainablility into policy has been ad hoc, incomplete and tentative" with continuing land degradation the major barrier to sustainable resource use and development (IC 1997, p.48). Despite favourable attitudes and known solutions, appropriate practices in many cases are not being adopted at the farm or management unit level (Vanclay and Lawrence 1995, ANAO 1997, IC 1997). This apparent contradiction has been attributed to a wide variety of social, economic, cultural, perceptual and situational reasons. Curtis and Lockwood (1998) contend that "most natural resource degradation results from the activities of people and improvement will only happen when people alter their behaviour" and that this requires "understanding of the organisation, beliefs and aspirations of people" (p.2).

To-date the achievement of a balance between environmental sustainability and social and economic objectives have been one of the major challenges to operationalising ESD. In practice, the social objectives have been frequently sidelined. In response, stakeholder-based approaches are emerging as a new approach to decision-making based on an adaptive approach to ecosystem management, social learning processes and collaborative decision-making (Wallace *et al.* 1996, Chambers 1997, Ison *et al.* 1997, Bellamy *et al.* 1999). Local groups in the community that have an identifiable 'stake' in the future of the community are linking together to create a vision for the future which has a set of goals and measurable criteria or indicators. This approach has the potential to engage stakeholders in ESD and enable the community to move forward together so that decisions are based on a shared set of values.

Issues in Engaging Stakeholders in ESD

As Renn *et al.* (1995) point out, " There is no such thing as a single 'public interest'. Rather, society consists of individuals with unique sets of interests, some of which are identical to those of others, and collectivities of people which form shared interests" (p.2). A stakeholder is "anyone who has an interest in or is affected by an issue, activity or transaction and therefore has a natural right to participate in decisions relating to it" (FAO and UNEP 1997, p.25). Stakeholders include not only those people having or needing access to, or use, or control of a

resource, but importantly also those who are affected by the use of a resource by others, and those who wish to influence the decisions of others with regard to the use of a resource for scientific, ethical or other reasons. Stakeholders include both present as well as future generations.

Approaches that are inclusive of all stakeholders however are proving challenging to put into practice both in Australia (Syme *et al.* 1994, Bellamy *et al.* 1999) and internationally (Dorcey 1991, Gunderson *et al.* 1995, Gardner and Stern 1996). In this section of the paper we discuss four key issues that constitute fundamental challenges to the implementation of stakeholder-based approaches:

- *participation*, that is dealing with the vast heterogeneity of interests and social values of the multiple stakeholders concerned.
- *coordination,* that is coping with the fragmentation of roles and responsibilities for natural resource management across multiple organisations within and between all three spheres of government (federal, state and local), industry and the community.
- *reducing uncertainty,* that is dealing with the uncertainty and ignorance which is an inherent characteristic of the interaction of human and natural systems (Funtowicz and Ravetz 1990).
- *cost-sharing,* that is addressing the distribution of public and private costs and benefits and their social impact.

Participation

The shift in focus of theories of social organisations from the individual to the community and the increasing emphasis on partnerships between the government and community in natural resource management and planning imply increased empowerment of local communities (Orstom 1990, Gardner and Stern 1997, Chambers 1997). Participatory approaches that foster purposeful and meaningful stakeholder involvement are perceived as potential or partial solutions to empowering communities to engage in ESD (Hollick 1993, Renn *et al.* 1995). As Gardner and Stern (1997) observe:

> *The needs to understand the actor's perspective, attract people's attention and gain their commitment, monitor and adjust programs, and design interventions that are within people's limits of tolerance all point to participatory processes as a solution* (p.169).

Participation is concerned with interaction among individuals, interest groups and institutions. Central to the philosophy of participation is a focus on both shared values and interests and learning processes:

> *By participating with others in democratic decision-making, people learn they have things in common. By bonding together, they can achieve goals and meet their needs. They also discover that other groups and individuals have interests and values in direct contradiction to their own. Resolving the conflict is not always the main purpose of participation, but acknowledging it is important.* (Renn *et al.* 1995, p. 8).

Participatory processes designed to engage a broad spectrum of stakeholders with often conflicting objectives are perceived to have a number of significant benefits (Syme and Sadler 1994, Hanna *et al.* 1995, Moote and McClaren 1997, Gardner and Stern 1997, Chambers 1997) including:

- prevention or amelioration of conflict;
- promotion of perceptions of fairness that lead to the design of policy or programs that lead to a more appropriate distribution of the costs and benefits of resource management in practice;
- attracting stakeholder attention to issues and setting more realistic expectations of the outcomes of a policy initiative or planning process;
- gaining commitment of multiple actors and the development of trust in the planning process or policy initiative;

- enhancing understanding of a policy initiative or planning process and a broader view of the key issues;
- enhancement of stakeholder information exchange and learning;
- improving stakeholder acceptance or ownership of the results or outcomes;
- generating feelings of personal satisfaction and control;
- designing interventions that are within people's limits of tolerance;
- supporting continuous stakeholder involvement and providing effective feedback mechanisms; and
- reducing the costs of information gathering, coordination, monitoring and achieving compliance.

Although a philosophy of participation has become widely accepted, there are considerable challenges in its implementation. Martin and Sherington (1997) caution that there is a significant gap between the rhetoric and reality in participatory approaches:

> *Participation has become institutionalised into a requirement in project design, rather than an indication of the more radical reversal of approach and attitude advocated in the participatory research. ….. Implementation of the empowerment agenda has been limited.* (Martin and Sherington 1997, p. 197).

Despite these challenges, we contend that participatory decision-making has the potential to provide a viable alternative to centralised, top down approaches to natural resource management. The principal intent of participatory decision-making in natural resource management through partnerships between government and community is to help organise an effective interaction program or process to achieve ESD goals. Perceived influence in decision-making is a fundamental element affecting such partnerships (Syme *et al.* 1997). Moreover, meaningful influence over the direction of a planning process or policy is a core principle of participatory approaches (Gardner and Stern 1997).

Coordination

Closely linked to the concept of participation in natural resource management and planning processes is a philosophy of coordinated government processes conducted in partnership with the community (Lang 1990, RAC 1993, Holling 1995, Gardner and Stern 1997, Dale and Bellamy 1998). Hall *et al.* (1977) define coordination as "the extent to which organisations attempt to ensure that their activities take into account those of other organisations" (p.457).

The degree to which there is communication and coordination between government and other relevant organisations is one of the fundamental factors underlying the effectiveness of partnerships in planning (Syme *et al.* 1997). Coordination in this sense is a way of trying to avoid overlaps in responsibility and conflicting messages from different organisations. Moreover, coordination may lead to significant reductions in transaction costs relating to data collection, analysis, design and implementation of regulations, communication, and conflict resolution (Hanna *et al.* 1995). In particular, Marshall *et al.* (1997) regard the reduction in transaction costs associated with negotiation over the use or management of resources over which there are no clear property rights as a major economic benefit from the process. Transaction cost savings are identified as being associated not only with bargaining for property rights over resources but with the flow of information and with the enforcement of solutions to resource degradation problems.

In light of the integrative nature of the new paradigm of natural resource management, coordination of policy and planning processes is therefore a fundamental challenge of stakeholder-based approaches to ESD.

Managing Uncertainty

Most resource management and planning contexts are faced with incomplete knowledge that leads to uncertainty or ignorance (Funtowicz and Ravetz 1990, Dovers 1996). Dealing with uncertainty and ignorance is a central challenge of ESD. As Funtowicz and Ravetz (1990) state, the challenge is that facts are uncertain, values in dispute, stakes high and decisions urgently needed. Also, there is considerable uncertainty about others' actions or behaviours.

There are many different forms of 'ignorance', which have different implications for resource management policy and planning (Dovers 1996). Dovers (1996) observes that neither type nor level of ignorance will be uniform across individuals, stakeholder groups, communities or organisations, "either in the sense of differing levels of access to, or possession of knowledge, or in the sense of varying perspectives, values or preferences" (p.17). Ignorance may be realised, unrealised, socially constructed or technically based. Effective management of ignorance and uncertainty across and within stakeholder groups in terms of type, level, equity of access and use, and their variation over time are fundamental challenges of the meaningful and equitable engagement of stakeholders in natural resource management and planning processes.

Cost-sharing

There is growing expectation in government and the community that stakeholders with common interests will share responsibility for sustainable natural resource management and planning for the long-term health of our natural resource base (ANAO 1997, IC 1996, 1997, MDBC 1996). Communities and governments are making long term investments in natural resource management infrastructure and other on-ground works. There is considerable social conflict however relating to the fairness of cost-sharing arrangements, that is, whether paying for sustainable natural resource management is a private, public or shared responsibility among resource users, the community and the three spheres of government.

An acceptable cost-sharing mechanism may improve the basis for negotiation for resource use planning and management by providing a principled and objective approach to determining the public and private benefits of on-ground works, such as revegetation, the fencing off of sensitive areas and water supply (MDBC 1996). To this end, cost shares represent the true split of benefits between individual landholders and the public (MDBC 1996, p.13). Benefits may relate to increased production, social and environmental benefits, and other goods and services produced by the works, while costs may relate to implementing and maintaining the works, production foregone, and monitoring the results of the works (MDBC 1996, p.5). Types and levels of benefits and costs, particularly environmental and social, will vary spatially across the landscape and over time, which introduces significant challenges to the achievement of the social justice aspects of ESD.

It is argued that communities and resource users will only accept cost-sharing arrangements and on-ground works after trusting partnerships have been developed, and after satisfactory levels of education and demonstration have been achieved (MDBC 1996, p.14). Stakeholder perceptions of levels of public and private benefits derived from policy implementation (eg. involving on-ground works) and the fairness of necessary cost-sharing arrangements will have an important influence on negotiation in natural resource management and planning.

A way forward?

Stakeholder-based approaches to sustainable resource use and management are still experimental, and much is to be learned from systematic study of such programs and their interactions with people, groups and organisations. The significant challenges posed by participation, coordination, uncertainty and transaction costs associated with the management of natural resource problems have influenced the effectiveness of these approaches. The next section of this paper examines

these issues in the context of a community-led stakeholder-based approach to integrated catchment management.

BREAKING DOWN THE FENCES: A COMMUNITY-BASED APPROACH

Integrated Catchment Management in Queensland

As one of the key platforms for operationalising the concepts of ESD, the Queensland Government established a stakeholder-based approach to natural resource planning and management through an Integrated Catchment Management (ICM) policy initiative. The overall purpose of ICM in Queensland is "to integrate the management of land, water and related biological resources to achieve their sustainable and balanced use" (DPI 1991). The ICM program is intended to promote and facilitate community involvement in the development and implementation of a coordinated approach between resource users, community groups and government agencies to the planning and management of natural resources.

The implementation of ICM in Queensland is based on the establishment of Catchment Coordinating Committees (CCCs) which provide a forum for discussion between various stakeholder interests in the catchment. CCCs work with and through existing organisations and agencies and as such do not have specific legislative support. The principal intent of the ICM approach as implemented by the Queensland Government may be summarised as (DPI 1991, Rowland and Begbie 1997):

- *Voluntary*: participation in ICM is voluntary for both community and government.
- *Community-based*: all structures have a majority of community members with formation of catchment coordinating committees (CCCs) being dependent on interest from the community and other sectors.
- *Partnership*: ICM is based on a partnership between the levels of government, industry and the community with all sectors and key stakeholders involved. As the CCCs do not have any legislative framework or statutory base, implementation of ICM strategies relies on negotiated and voluntary action by responsible agencies and individuals.
- *Participative*: all processes used in coordinating and integrating management of the catchment should be participative and consultative.
- *Strategic*: ICM is intended to be a strategic and long-term planned approach to achieving action in addressing priority natural resource management issues in the catchment that cross organisational boundaries.

To-date ICM programs have been implemented in 34 rural catchments in Queensland covering nearly 80% of the area of the state. The impact of land use on water quality, soil erosion and sedimentation of watercourses, salinity induced through clearing of vegetation, loss of habitat on land in rivers and streams, the impact of land and water use on freshwater and marine ecosystems, the spread of weeds by water and competition for land and water resources have been identified as important issues requiring a new catchment approach. These issues involve not only interaction between many components of a river catchment, but also many individuals and organisations, including landholders and other resource users, government agencies, local authorities, conservation groups and rural industry groups, each with a responsibility for different parts of a catchment or specific activities within it. Importantly, they require decision-making that extends across traditional property and other administrative unit management boundaries.

In the following sections, we draw on findings from a 5-year longitudinal study undertaken to monitor and evaluate the implementation of the ICM process in the Herbert River catchment of wet tropical north Queensland (Bellamy and Johnson 1999, Bellamy *et al.* 1999) to shed some light on some of the issues relating to stakeholder engagement in this community-based approach

to ESD. A brief overview of the Herbert River catchment and initial progress in the ICM process are provided in a companion paper in this volume by Johnson and Bellamy (1999).

Herbert River ICM Process

Background
ICM in the Herbert River catchment is a community-led and voluntary process in a formative stage initiated by key interests in the catchment. The impetus for the establishment of the Herbert River Catchment Coordinating Committee (HRCCC) in 1993 related to two key factors. Firstly, broad community-based concern over the ineffectiveness of fragmented government decision-making on river management issues, and the failure of past studies to move beyond the development of plans and lead to action on the ground to resolve these issues. Secondly, the perceived need within the catchment for more active and meaningful community involvement in decision-making on these issues, that is beyond a basic consultative approach.

The objectives of the ICM process in the Herbert Catchment have evolved since its inception to encompass a broader and more 'holistic' set of objectives as identified by the HRCCC in its draft Catchment Management Strategy (HRCCC 1996, p.i):

- Co-ordinate government agencies and the community to pursue common goals
- Seek community involvement in catchment management
- Reflect the requirements of the wider community within the Catchment
- Identify and rectify natural resource degradation
- Promote ways to prevent and reduce natural resource degradation
- Promote the wise use of all natural resources within the Catchment
- Identify key indicators of biodiversity and monitor as a measure of catchment health
- Encourage the retention of significant natural habitats within the Catchment.

Although these broad objectives are couched in terms that suggest an overall policy framework for the catchment, ICM has no legislative jurisdiction in Queensland. Success therefore will depend to a considerable extent on the degree to which the Herbert ICM process can engage public and private interests in a substantive way to voluntarily effect required action.

Engaging stakeholders in ICM in the Herbert River Catchment
The approach to the implementation of ICM in the Herbert River catchment in its early stages has been pragmatic and opportunistic motivated initially by a perceived need to raise the awareness of the organisation and natural resource management issues in the catchment and to "get runs on the board" (Bellamy and Johnson 1999). As such the Herbert River ICM process provides an opportunity to examine some of the broader issues relating to the engagement of stakeholders in ESD identified earlier in this paper.

The Herbert River Catchment Coordinating Committee
As previously noted the principal intent of a stakeholder-based approach to natural resource management like ICM in the Herbert Catchment is to help organise an effective stakeholder interaction program or process to achieve ESD goals. This requires broad stakeholder recognition of the legitimacy of the HRCCC as a community-based organisation concerned with facilitating a move toward ESD in the Herbert River catchment. To this end, the HRCCC involves representatives of a broad range of rural industry, community and local government and other statutory organisations that have an interest and/or role in natural resource management in the catchment (Table 1). As such, the membership reflects the influential groups, power structures, and prominent community interests in the catchment. In 1998, the HRCCC had a local Chairman and 16 other members representing community, industry and local government and statutory bodies in the catchment. A full-time Catchment Coordinator facilitates the process.

Nine of the current members (50%) have been involved with the HRCCC since its inception in March 1993. Most of the members are active community members with multiple sectoral interests or 'hats'. Eleven of the seventeen HRCCC members are either sugarcane farmers or employed within the sugar industry reflecting the economic, social and cultural importance of the sugar industry in the lower Herbert catchment community.

Table 1: HRCCC Sector Group Representation.

Industry:	**Community:**	**Government/Statutory Authority:**
CANEGROWERS (1) CSR Herbert River Mills (1) Cattlemans Union (1) Horticulture/Rare Fruits (1) Queensland Commercial Fishing Organisation (1)	Recreational/Sporting Fishing (1) Landcare (1) Wildlife Preservation Society of Queensland (1)	Hinchinbrook Shire Council (3) Herberton Shire Council (1) Herbert River Improvement Trust/Drainage Boards (1) Hinchinbrook Development Bureau (1) Herbert Pest and Productivity Board (1)

Significantly, in 1998 the HRCCC has no formal State government agency representatives although officers from the Department of Natural Resources may participate in meetings. The Catchment Coordinator is funded from the federal government's National Landcare Program with additional support provided by the Department of Natural Resources, the lead government agency for ICM in Queensland. In addition, local stakeholder groups including Local Government and sugar industry bodies have provided in-kind support in terms of office accommodation, administrative support and their HRCCC member's time. State and federal government grants that are awarded through a competitive bidding process also provide financial support for many on-ground HRCCC activities. Through involvement in HRCCC meetings and activities, ICM in the Herbert Catchment is attempting to engage a range of key stakeholders in ESD.

Table 2 identifies some of the activities undertaken by the HRCCC and the types of stakeholders that have been engaged by them. It is important to note, however, that the HRCCC does not work in isolation from government agencies, community groups or industry support organisations. The HRCCC works to co-ordinate the activities of all interested organisations and influence catchment decision-making on natural resource issues. As a result the possible outcomes from many of the activities undertaken by the HRCCC cannot be attributed solely to the endeavours of the HRCCC but to a cooperative effort from a number of organisations. We briefly discuss in the remainder of this section of the paper some of these activities in more detail.

Catchment Management Planning

The HRCCC's approach to ICM focussed in the first instance on establishing a legitimate role and building a credible and influential organisation dealing with natural resource management. To this end, the HRCCC prepared a Catchment Management Strategy that provides a vision for the future management of the Herbert River catchment's natural resources (HRCCC 1996). It was prepared by HRCCC members through a series of working groups and internal workshopping and released for public comment in June 1997. The strategy suggests a "community-based approach to solving problems – an approach that integrates the needs of individuals, community groups and industry" (HRCCC 1996, p.1).

Table 2. Examples of the range of stakeholders engaged in HRCCC Activities and the level of community influence

HRCCC ACTIVITY	Catchment Community	Individual Land Managers	Rural Industry Organisations	Local Government, Statutory Bodies	State Government Agencies	Research/Industry Support Organisation
Catchment Planning:						
• Management Strategy	✓	✓	✓	✓	✓	✓
• Catchment Atlas	✓					✓
Riparian/wetland Management:						
• Community forum	✓	✓	✓	✓	✓	
• Riparian Mapping				✓	✓	✓
• On-farm advice		✓			✓	✓
• Artificial wetland development		✓	✓	✓	✓	
Land Use Change/Caneland expansion:						
• Wharps area rural drainage		✓	✓	✓	✓	
• Shire Planning Scheme	✓			✓	✓	
Water Quality:						
• Tin mining dam inventory	✓	✓		✓	✓	
• Acid Sulfate Soils Awareness	✓	✓			✓	
River Management:						
• Bank stabilisation (Long Pocket)		✓		✓		
Pest/Weed Management						
• Owl Boxes	✓	✓		✓		✓

The strategy itself is issues-based and it identifies a broad range of priority management and planning issues, which are summarised in Table 3. Specifically, the strategy discusses key management and planning issues, identifies what needs to be done, who should take responsibility for undertaking the work and how the issue is to be addressed. An example of a strategy and the stakeholders to be involved is provided in Table 4. The strategy's issue focus is consistent with Laut and Taplin's (1989) view that an emerging trend for catchment management would be to concentrate on *issues* rather than on establishing a holistic strategic management approach in the catchment. Importantly, it clearly identifies the need for a coordinated effort amongst stakeholders in order to address these issues and move the community towards achieving ESD.

In a survey of HRCCC members conducted in 1997, Bellamy *et al.* (1998) found that the strategy was considered to provide an overall direction to the group and a guide for future actions. For example, it identifies issues, prioritises needs, identifies stakeholders and their roles, and in general provides an initial reference point for the HRCCC. In addition, the strategy helped to get resources and support for ICM in the Herbert River catchment, such as continued funding for a Catchment Coordinator and natural resource management projects. Once State Government endorsement is obtained, members expected it would provide the basis for gaining commitment of responsible State Government agencies to undertake projects in the Herbert catchment to address these issues. Importantly, the development of the Catchment Management Strategy is perceived by members to have been of value because of a number of qualities and outcomes of the development process that include:

1. *inclusive and transparent* to all members involved; bringing all viewpoints across organisations on issues together and out into the open.
2. *establishing a clear direction* for the HRCCC; helping to focus the HRCCC as an organisation and providing an overall vision for the catchment.
3. *raising awareness* of catchment issues; especially improving Committee member's awareness of issues as well as other stakeholder's viewpoints on those issues.
4. *highlighting areas of common ground*; by identifying areas of agreement across diverse sector groups on some catchment issues, it provided a basis for the Committee to move ahead and develop better natural resource management and planning projects.

The final endorsement of the strategy is currently being negotiated with the relevant State government agencies. Planned improvements to the strategy will address their concerns relating to better recognition of indigenous land issues and an apparent over emphasise on state government activities and responsibilities in addressing some catchment issues, that is the need better recognition of local community responsibilities and action

Table 3. Issues and key strategies identified in the Herbert River Catchment strategy (HRCCC 1996).

Key Issues	Recommended Strategies	
Land Management (LM) • Inappropriate land use allocation and its impact on resources and natural systems • Impacts of land management on productivity • Impacts on other values of land and adjacent land and water resources	LM1 LM2 LM3 LM4	Coordinate land use planning to achieve balanced use of land, water and related natural resources Encourage best management practices in all rural industries Implement arrangements to reduce adverse impacts of agricultural drainage on natural systems and existing developments Reduce adverse impacts of non-agricultural land uses.
Water Management (WM) • Full and over-allocation of existing resources • Increasing demands on finite surface and groundwater supplies • Limited monitoring of water quantity and quality • Threats to quality of surface and groundwater supplies	WM1 WM2 WM3 WM4 WM5	Assess available resources and develop appropriate allocation policies in consultation with stakeholders Promote efficient use of water resources within the Catchment Promote the coordinated planning and implementation of water management schemes in the catchment Reduce contaminant inputs to surface and groundwater systems from point and diffuse sources Establish and promote water monitoring priorities and standards for the catchment.
Stream Management (SM) • Lack of awareness of stream values shown in development actions • Stream bank erosion and stream migration • Sedimentation • Impact of uncoordinated levee banks and flood mitigation schemes • Impacts of degradation of riparian zones • Instream habitat degradation such as weed invasion and loss of water holes	SM1 SM2 SM3 SM4 SM5 SM6	Continue implementation of a strategic approach to stream management Facilitate appropriate protection and management of riparian zones throughout the catchment Ensure development and engineering works associated with streams take account of all stream functions and issues Identify and protect sensitive areas, to retain the function and health of our stream systems Develop fisheries and habitat management plan for the stream systems of the catchment, involving stakeholder groups and the broad community Provide community awareness, support and involvement in stream management
Habitat Management (HM) • Threats to significant terrestrial and aquatic habitats and species • Loss of wetland and instream habitat quality and subsequent impacts on fish stocks • Fragmentation of remaining habitats through loss of connectivity (ie. corridors)	HM1 HM2 HM3 HM4 HM5	Promote the values of habitat retention and restoration to the broader community through awareness, technical support and incentives Maximise the habitat values of existing protected areas Ensure the retention of significant habitat values outside protected area reserves Protect and rehabilitate wetland habitats on the Floodplain Re-establish and manage riparian vegetation on watercourses throughout the catchment and ensure retention of existing riparian vegetation.

Table 4. Example of the format for a strategy as identified in the Herbert River Catchment Management Strategy (HRCCC 1996).

#		*	
CCC	Catchment Coordinating Committee	1.	Immediate, commences within 6 months
DEH	Department of Environment and Heritage	2.	Short-term, commences within 12 months
DNR	Department of Natural Resources		
DPI	Department of Primary Industries		
LG	Local Government (Hinchinbrook and Herberton Shire Council		

What is to be done?	Who can do it?[#]	Priority[*]
Strategy HM1: Promote the values of habitat retention and restoration to the broader community through awareness, technical support and incentives		
a) Provide technical support in the areas of: • land development planning • habitat retention • habitat management	DEH, DPI, DNR	1 1
b) Encourage all levels of Government to provide for habitat management through realistic incentives and/or sufficient funding.	CCC, LG	
c) Develop and promote awareness programs to highlight the values of habitat retention and implement through farm planning	DEH, CCC, DPI, DNR	2

Riparian and wetland management

The HRCCC has identified wetlands destruction and riparian zone management as some of the major issues needing to be addressed at a catchment level. The mangroves and wetlands of the Herbert River Catchment are of national and local significance. However their distribution has been dramatically reduced since European settlement due to the expansion of agriculture, particularly the rapid expansion of the sugar industry on the coastal floodplain of the Herbert River. Significantly, Vella (1997) found that the conservation of wetlands and mangroves has been ineffective in the Herbert floodplain because of fragmented management arrangements, a failure to address environmental issues in the rural land development process and limited ability of government authorities to control harmful land management practices particularly on freehold land. This potentially could lead to high transaction costs in negotiating the appropriate management of riparian areas with relevant authorities. To this end, the HRCCC has facilitated artificial wetland development on-farm (with sugar cane producers) and supported their development on public lands (eg. jointly with the local sugar miller and the Hinchinbrook Shire Council to establish a wetland using sugar mill liquid waste and treated sewerage effluent).

The HRCCC has been successful in bidding for funding, through DNR, and implementing the mapping of riparian vegetation on the Herbert River floodplain (Petroeschevsky 1997). This information has been used to encourage the adoption of a flexible system of riparian zone width assessment with landholders and which is now being incorporated within the new Hinchinbrook Shire Council planning scheme for the lower catchment. It is also underpinning the development of a catchment rehabilitation plan. In addition the HRCCC, initiated a Riparian Community Forum in the catchment involving key invited speakers from government, the research community and industry to raise awareness of the need for better riparian and wetland management on the Herbert River floodplain.

Integrated pest management

Closely associated with activities to manage vegetation in riparian zones have been activities to encourage farmers to engage in ecologically sustainable pest management practices. A specific activity undertaken by the HRCCC has been the establishment of approximately 55 owl boxes throughout the lower catchment. Owl populations on the Ingham coastal lowlands, including

both the Barn Owl (*tyto alba*) and the Barking Owl (*ninox connivens*) have dropped noticeably over the last five years (John Young 1998 *pers. comm.*). Reduced populations have been attributed to the clearing of native vegetation to accommodate the expanding sugar industry resulting in the destruction of nesting habitats and hunting perches. In addition, the possibility of secondary poisoning linked to rat baits has been suggested (John Young 1998 *pers. comm.)*. By establishing nesting boxes and hunting perches for owls in areas which have virtually been cleared of native vegetation, hunting perches have been provided which has increased the owls' hunting range and increased their chance of survival in a changed habitat.

Halvorsen (1998) reports that "a single owl family can eat over 2,000 rats per year" (p.6). Aside from the number of rats an owl family can physically remove from the environment, there is some potential for owls to disrupt the breeding cycle of rats, further reducing their population. Rat damage to cane in the Herbert River District has been estimated by the Herbert Cane Protection and Productivity Broad (HCPPB) to range from 28,265 tonnes in 1993 to 6,576 tonnes in 1997. The farm-gate value of the damage to cane in the Herbert District is estimated to have been $763,155 in 1993 and $177,552 in 1997, or, 7% of the value total cane production in the district in 1993 and 1% of the value of production in 1997. The cost of establishing 55 owl boxes across the lower catchment has been estimated by the HRCCC as $4,000. The HCPPB as well as DNR have made contributions towards the cost. In addition, community members have made contributions in the form of voluntary labour.

The value of reduced rat damage to cane production does not need to be significant to show a return to the investment to establish owl boxes across the catchment. Specifically, the value of the avoided cost of lost cane production would need to be approximately $350 per annum (constant 1998 prices) over a 20 year period to offset the initial establishment costs and periodic maintenance work (assuming a discount rate of 0.06 per cent). Possibly the primary value of establishing owl boxes around the cane growing district is that they have raised the awareness of the catchment community to the advantages of encouraging farming practices to manage riparian vegetation as a wildlife habitat. Not only was this activity undertaken with the objective of promoting ecologically sensitive farming practices by cane farmers, it also represents a coordinated effort with the HCPPB, DNR, local wildlife enthusiasts and landholders.

Land development planning

A major achievement for the HRCCC has been its role in influencing the incorporation of ICM principles into the new Hinchinbrook Shire Planning Scheme (McDonald and Bellamy 1997). This Plan makes a strong commitment by local government to natural resource management on rural lands for the first time. It establishes a broad intent to conserve natural resources such as wetlands and riparian lands that will be implemented through development assessment and environmental impact assessment. Most importantly the scheme defines sugar production as intensive agriculture which is a regulated use in the scheme. If the political will is there to implement this plan to its full potential, it will enable the Shire Council to conserve significant habitats and implement ICM objectives by placing conditions on new agricultural land development.

Significantly, this development has contributed to the improved communication and coordination of effort between local government, state government agencies and stakeholder groups within the catchment, which has reduced the possibility of high transaction costs when the plan is implemented. It is currently being formalised as a streamlined process for agricultural land development involving the HRCCC, Hinchinbrook Shire Council, the Department of Natural Resources, the Department of Environment and the Local Sugar Board (DNR 1998).

Water quality
Water quality has increasingly been recognised within the local community as a major issue of concern, both in relation to town water supplies in the lower catchment and the potential detrimental impact on the adjacent Great Barrier Reef lagoon. To address this issue the HRCCC has supported two key activities. The HRCCC first negotiated funding for an inventory in the upper catchment of relict alluvial mines and tailing dams, which could adversely affect downstream water-users, natural drainage in the Lower Herbert, and the biodiversity of aquatic habitats. This was a potentially divisive issue between the upper and lower catchment communities resulting from poor domestic water quality at certain times in the lower catchment, as well as concerns that increased sedimentation from abandoned mine waste was reducing the river capacity and contributing to greater flooding problems. Secondly, the HRCCC has promoted and publicised the risk of acid sulphate soils in the lower floodplain in the public media (eg. in the local newspaper), by distributing informative pamphlets to residents and by facilitating a community workshop. Of particular importance is the risk of acid sulphate soils in the coastal wetlands of the Herbert floodplain. Disturbance of wetlands as a result of drainage works and agricultural development in the Herbert coastal wetlands has led to acidification of adjacent waters (with pH levels as low as 2 or 3) and have been locally linked to fish kills.

The outcome
These issues show that ICM in the Herbert River Catchment is contributing to improvement in the engagement of catchment stakeholders in ESD through increased community participation and better coordination of decision-making on natural resource management and planning in the catchment which could lead to reduced transaction costs when management plans are implemented. In addition, ICM in the Herbert has contributed to improved understanding and communication of information on natural resource management issues amongst catchment stakeholders. However a major challenge to achieving significant ESD outcomes relates to cost-sharing, that is, the distribution of public and private costs and benefits and their social implications. Importantly those who bear the costs of sustainable resource management may not either directly or indirectly reap the benefits. In addressing natural resource management issues, private benefits accrue to resource users and other private individuals, while public benefits accrue to the broader community (ANAO 1997, MDBC 1996). This issue poses real challenges for a voluntary community-based process like ICM in Queensland in achieving real on-ground outcomes. The next section of this paper uses a case study of the economic evaluation of activities to manage riparian vegetation undertaken by the HRCCC to discuss this challenge. This discussion is based on the findings of a more detailed economic evaluation of ICM as an organisation in the Herbert River catchment reported in Robinson *et al.* (1999).

Costs and benefits of riparian vegetation management: a case study

Although previous studies (CANEGROWERS 1998, LWRRDC 1996, SEAC 1996) have listed the potential benefits of revegetating riparian areas, few studies have established the distribution of the costs and the potential benefits (Robinson *et al.* 1999). This is important information because authorities cannot rely on moral suasion alone to encourage farmers to undertake the required investment. Farmers need to know what are the likely initial outlays, the likely loss of income and the potential return. In situations where farmers cannot be shown to benefit then there is potentially room for assistance.

Riparian vegetation management and the Herbert River Catchment
Protecting riparian vegetation has been a contentious issue for the HRCCC. McDonald and Bellamy (1997) cite a number of planning issues that need to be addressed by the HRCCC in relation to the management of vegetation in riparian zones. These include: should there be a

buffer zone along watercourses or preferred flow-paths? What constitutes a watercourse? How wide should the buffer zone be? And what management requirements apply to the buffer? There is currently no legislation to protect riparian vegetation beyond the top of the stream bank, except on leasehold land. Although there is no legislation to protect riparian vegetation on freehold land, it is recommended that, for the wet tropical coast, the vegetated riparian zone should be at least 20m each side of the banks of all minor watercourses, wetlands and drainage lines, and at least 40m each side of major watercourses (DNR 1998, p.13).

A report on the state of the rivers and streams in the Herbert River catchment describes the general state of vegetation in riparian zones as being poor to very poor (DNR 1996). The poor quality of the vegetation is attributed to the narrowness of the vegetation that has not been cleared for agricultural purposes and to the level of exotic plants present within the area (p.ii). Two issues arise for management of riparian vegetation: increasing the area and improving the quality of the vegetation.

A recent mapping project of riparian vegetation areas in the lower Herbert River catchment, supported and partly funded by the HRCCC, recommends that the riparian zone requirement be re-addressed to be sensitive to the local circumstances and needs. Specifically, it is suggested that the width of the buffer zone should be a product of consideration towards the risk of flood and bank erosion (Petroeschevsky 1997). This recommendation is supported by the DNR (1998) which suggests that riparian vegetation zone boundaries should be determined by consideration to ecological factors including a combination of topography, vegetation type as well as its effectiveness in flood conditions.

As the majority of agricultural land in the lower catchment is freehold land, the only course of action available to authorities managing these areas is to improve landowner and community awareness of the importance of maintaining vegetation in riparian zones. Activities undertaken by the HRCCC to address the management of vegetation in riparian zones meet their stated objectives of encouraging the retention of significant natural habitats within the catchment and also of promoting ways to prevent and reduce natural resource degradation (see Table 3).

Overview of costs and benefits

There is considerable support for riparian zone vegetation management from natural resource research organisations including SEAC (1996), LWRRDC (1996), DNR (1996, 1998) and sugar industry support organisations including the CANEGROWERS (1997, 1998), Sugar Research and Development Corporation and the Bureau of Sugar Experimental Stations. Management of riparian zones to encourage the retention, revegetation or rehabilitation of these areas with appropriate vegetation is believed to contribute towards:

- Stabilising the banks of rivers and creeks and helping to reduce slumping and undercutting. In addition, some of the energy of water flow during flooding is absorbed by riparian vegetation that can reduce erosion and scouring of adjacent land.
- Providing a natural habitat and source of nutrients for river plants and wildlife.
- The provision of shade which inhibits the growth and spread of grass and exotic plants. This results in the improved drainage of natural watercourses, which might otherwise be choked by exotic weeds and grasses. By reducing the light and heat reaching the stream, riparian vegetation improves the habitat for fish and crustaceans. In addition, the reduction in the growth of grass reduces the population of rats in these areas protecting the cane from destruction by rats.
- Water quality improvements. Riparian zones provide a buffer between terrestrial and aquatic ecosystems preventing nutrient and insecticide run-off into watercourses. Water quality improvements may reduce the number and/or size of fish-kills.

- In addition to these potential benefits it is claimed that rivers and creeks which have retained vegetation are aesthetically appealing and provide a valuable asset for local enjoyment as well as for eco-tourism.

There are, however, significant costs associated with the management of vegetation in riparian zones that need to be considered. These include the cost of establishing or rehabilitating vegetation in the area as well as loss of production from land, currently under crop, which would need to be revegetated. In the lower catchment, loss of agricultural production would be primarily sugar cane. This agricultural land, because of its proximity to a river or creek, is generally regarded as highly productive. In the upper catchment, grazing properties would potentially lose stock access to a water source.

To off-set reduced production resulting from loss of farm land in the lower catchment, there is the possibility of reduced rat damage to cane and a reduction in the infestation of cane land by exotic weeds. In addition, riparian vegetation can absorb some of the force from flood waters, reducing cane loss attributable to scouring and deposition of sediments. CANEGROWERS (1997) estimates the potential value of the avoided loss of cane production resulting from scouring, which has a probability of occurring during a major flood event (1:10 years), to be $1,000 for a 100 ha farm. Some protection of river or creek banks from erosion and protection of farmland from scouring and sediment deposition is possible in the Herbert River catchment if riparian zones are suitably vegetated (Kinhill Cameron McNamara 1991). These benefits are not necessarily enjoyed by all cane farmers but by those located in susceptible areas where washaways and scouring have historically been a problem. The period over which the cane is waterlogged and the maturity of the cane would determine the magnitude of the cane loss following a major flood event.

In some areas, the riparian vegetation provides a buffer, acting as a barrier between aquatic and terrestrial ecosystems. Water quality improvements are cited as a benefit of riparian vegetation, which can act as a sink for agricultural run-off and inhibit the growth of exotic aquatic weeds that can deplete oxygen levels in streams. These water quality improvements could potentially reduce the magnitude of fish kills.

Qualitatively, there are potentially significant benefits if vegetation of riparian zones is established where there is none, rehabilitated where it is not sufficiently wide or requires more appropriate vegetation or rehabilitated if it is infested with exotic plants. To quantify and estimate a monetary value for all of the potential benefits is difficult because detailed information about the willingness of people to pay for these benefits, which are not marketed, is currently unavailable. However, estimates can be made of the potential productivity benefits and of some water quality benefits. The costs associated with the initial establishment of vegetation in riparian zones and of reduced production resulting from land being taken out of production also can be estimated.

The potential benefits associated with the establishment of vegetation in riparian zones do not accrue to specific persons or groups of people. Specifically, a farmer undertaking investment to increase or establish the vegetation of a riparian zone on his/her property is not able to exclude others from enjoying the benefits associated with the establishment of this area. These potential benefits include improved water quality flowing down stream, or catching fish in a natural habitat on the farm. In addition, the removal of exotic plants from the area is likely to not only improve the drainage of water through an individual farmer's property but could also improve flows upstream. In brief, the farmer does not have a property right over the benefits (externalities) created as a result of establishing or rehabilitating vegetation of a riparian zone on his/her property. Neither is the farmer able to exclude others from enjoying all of the benefits he/she

has created. This raises the issue of "user pays" where those who enjoy the benefits from vegetation of riparian zones are not necessarily the same people as those incurring the costs. The distribution of the costs and benefits associated with establishing vegetation in riparian areas is contentious.

The estimated cost of establishing vegetation in riparian zones
There are two primary sources of cost associated with the establishment of appropriate vegetation in riparian zones. The first is the cost of planting trees in these areas (assuming trees are appropriate). The second is the opportunity cost of the land. This cost is primarily on-farm loss of production as land is taken out of agricultural production (in the lower catchment this is assumed to be sugar cane production). Estimates of the cost of establishing vegetation in riparian zones require assumptions to be made about the extent to which an area requires re-establishment or rehabilitation. In particular, many riparian areas will require some level of restoration rather than complete revegetation.

A number of assumptions have been made to estimate the cost of establishing vegetation in a riparian area. In the interests of reasonable brevity, these assumptions are provided in Table 5. More detailed discussion about these assumptions is provided in Robinson *et al.* (1999). Estimation of the possible income loss to individual farmers as caneland is taken out of production, to establish riparian vegetation, highlights the possible disparity in the ability of growers to absorb the loss. The potential income loss and the ability of the grower to absorb the loss will impact on the willingness of a grower to engage in environmentally sustainable farm management practices.

Table 5. Assumptions underlying cost estimates for vegetating a riparian zone

Cost Component	Cost Assumption	Range of Estimate
Extent of Vegetation Required	a) Total re-vegetation (5,000 trees per ha)	3,000 – 5,000 trees per ha
	b) Some re-vegetation and Rehabilitation (2,000 trees per ha)	1,000 – 3,000 trees per ha
	c) Minor tree planing (500 trees per ha)	100 – 1,000 trees per ha
Cost of planting and maintaining trees	$3.00 per tree	$2 - $4 per tree
Width of buffer zone	40metres	15 - 40metres

The estimated income loss, expressed as a proportion of total income from the growing of sugar cane, across the entire cane growing district is relatively small (approximately 0.5 of one per cent per annum). However, if the income loss is expressed as a percentage of an individual farmer's total income, the loss can be shown to be significant. A number of scenarios have been developed to show the magnitude of the estimated relative income loss to cane farmers according to the size of their cane assignment. Three sizes of cane assignment have been considered distinguishing between cane farmers with an assignment which reflects the financial position of farmer who is marginally viable (40 ha assignment); secondly, a farmer who has a slightly larger assignment and is able to absorb some of the income loss (65ha assignment), and thirdly, a farmer who has a 100 ha assignment and is able to achieve economies of scale and where the income loss is likely to be absorbed. If these individual farmers had a one-kilometre length of their farm riparian to the Herbert River or Stone River and were required to vegetate a 40 metre zone which was currently under cane, they would incur a loss of their annual income. The results are provided in Table 6. Table 6 shows that if a cane farmer with a 40ha assignment to grow cane was to take 4ha out of production to revegetate a riparian zone, then his/her income loss would be 10 per cent of his/her total income from cane production per annum. On the other hand, a cane farmer with a 65 ha assignment would incur an income loss per annum of 6 per cent and for

a farmer with a 100 ha assignment, the per annum income loss is estimated to be 4 per cent of total income from cane. Thus the costs to farmers of taking the riparian zone out of cane (that is, the opportunity cost of the land) is not equitably distributed across all growers.

Table 6. Likely cost to cane farmers to revegetate a 4ha riparian zone

Size of Cane Assignment (ha)	Cost to Establish Vegetation ($)	Percentage annual Income Loss (%)
40	60,000	10
65	60,000	6
100	60,000	4

Summary of findings

For an individual cane farmer required to totally revegetate a 4ha riparian area and for whom the only benefit is a reduction in damage by rats, the return on his/her investment over a period of 20 years, using a discount rate of 6 per cent is estimated to be $206.00. This is not substantial. Indeed, it would take 20 years for the farmer to show a positive return. This situation has important implications for the HRCCC and for all organisations promoting the revegetation of riparian areas. The investment is not significantly attractive for farmers and additional incentives may need to be offered.

There are other benefits however, many of which are potentially enjoyed by the catchment community and society as a whole. These benefits include those associated with improved water quality, specifically an improvement in fish habitat and a reduction in the size and number of fish kills as well as the aesthetic improvement of water courses. Summary information about the magnitude of potential costs and benefits is provided in Table 7.

The implications arising from these estimates, which it is stressed are based on a number of simplifying assumptions, is that there are considerable costs associated with the establishment of vegetation in riparian zones. The cost to individual landowners is potentially significant. The benefits arising from re-vegetating these areas are not contained solely on an individual farm and an individual farmer cannot prevent others from enjoying the benefits from these areas. It would therefore appear to be appropriate for authorities wishing to encourage the establishment of vegetation in riparian zones to offer incentives to individual farmers.

Table 7. Summary estimates of potential costs and benefits of riparian vegetation

COSTS		**BENEFITS**	
Component of Cost	**Estimated Value**	**Identified Benefits**	**Estimated Value**
Re-vegetation (105 km)	$2,055,100	Integrated Pest Management – reduced rat damage to cane	$171,460 per annum
		Improved water quality – reduced fish kills	$19,500 per annum
Loss of cane production	$27,165per annum	Reduced cane loss from scouring	$97,200 (1:10 years)
		Reduced cane loss from weed inundation	$54,000 (1:7 years)
		Aesthetic benefits including increased owl population	Not valued

CONCLUSIONS

The principal challenge for the HRCCC has been to 'break down the fences' and facilitate a move toward a coordinated effort that extends across traditional land management decision-making boundaries so that the priority natural resource issues in the catchment can be addressed. The

community-based ICM process has revealed that although there is significant agreement amongst the diverse stakeholder interests in the catchment on the key issues that need to be addressed, understanding on the underlying causes and potential solutions vary considerably. The HRCCC has to-date largely focussed on issues for which in general there is much common ground on the way to proceed amongst stakeholder groups. It has yet to take a lead role, however, in progressing some of the more contentious resource management issues within the community (eg. drainage coordination, and fish kills in the lower floodplain adjacent to areas of intensive use). In an evaluation of the initial progress after four years of ICM in the Herbert, Bellamy and Johnson (1999) have identified the key HRCCC achievements as:

(i) Initiating a limited range of focussed land management projects to establish credibility and raise awareness of ICM process and natural resource management in general with the Herbert community (rather than focussing on issues of strategic importance to catchment management).
(ii) Gaining recognition as a legitimate community referral agency for the state and local government authorities on proposed developmental and infrastructure projects and other natural resource issues in the catchment.
(iii) Development of a Herbert River Catchment Management Plan that provides the essential elements of a 'sustainable' vision for the catchment.
(iv) Establishing a lead role within the Herbert River community as principal broker negotiating funding for industry and community groups to undertake natural resource management projects and activities in the catchment.
(v) Providing an effective community forum for discussing and progressing catchment issues, including revealing the range of different stakeholder perspectives on these issues as well as highlighting potential areas of community conflict.
(vi) Information provider and disseminator through HRCCC meetings providing a 'community forum', initiating focussed activities that locally have a relatively high profile, as well as through the existing communication networks of HRCCC member organisations.

Although progress may be perceived to be slow and limited to-date, these achievements indicate that significant improvements have occurred. These improvements are laying the foundation for a fundamental change in the attitudes and behaviours of key community leaders, as well as the overall approach to the management and planning of the catchment resources.

In summary, the Herbert River ICM process has revealed that the potential benefits from a community-based ICM approach to engaging stakeholders in ESD primarily relate to three key factors. The first relates to better coordination and communication in stakeholder planning processes. Improved coordination has a range of potential impacts including better identification of the underlying dimensions of natural resource problems, improved communication on natural resource issues amongst catchment stakeholders and better negotiation over ways of addressing problems. These in turn can potentially provide a basis for the avoidance of infrastructure damage and a reduction in downstream impacts of resource use. Secondly there is potential for a significant reduction in transaction costs with increased collaboration between catchment stakeholder groups. This will lead, for example, to greater exchange of information on natural resource issues and related decision-making through the HRCCC providing an effective community forum, as well as improved processes for negotiation over property rights leading to the potential avoidance of legal or regulatory action. In brief ICM can be regarded as a vehicle to reduce transaction costs which will in turn improve the allocation of resources. Finally, ICM has the potential to reduce uncertainty amongst stakeholders through, for example, raised awareness of others views, raised awareness of natural resource issues amongst stakeholders, better exchange of information, an improved technical knowledge base, and greater cooperation amongst catchment stakeholder groups. In this regard, information about the distribution of the

potential costs and benefits associated with activities to improve the condition of natural resources could assist ICM organisations to apply for funding to support or improve the uptake of on-farm natural resource management. As such, ICM can support the development of greater community trust in decision-making process. In conclusion, through fostering focussed activities, the ICM process has engaged the members of the Herbert community in practices, which if they continue to be more widely adopted will contribute significantly to a move toward ESD in the long term.

ACKNOWLEDGEMENTS

The authors wish to acknowledge the financial support of the Land and Water Resources Research and Development Corporation, which made this research possible.

The authors wish to express their extreme gratitude to all those people with have an interest or who are actively involved in the implementation of Integrated Catchment Management in Queensland and who gave time from their busy schedules to complete interviews or questionnaire survey forms that were fundamental to the success of many project activities. Of special note are the following people and agencies who willingly co-operated and provided valuable assistance to this five-year research project:

- The members of the Herbert River Catchment Coordinating Committee who actively participated and contributed their valuable time, views and knowledge.
- Dave Horsley, CSR Herbert River Mills, who was an invaluable source of information on natural resource management and related activities in the Herbert River catchment, provided substantial advice to the researchers and contributed actively to many of the research activities of this project.
- The Herbert River Catchment Coordinators, Rob Hunt and subsequently Andrew Petroeschevsky, who provided valuable comment and information as well as facilitating interactions with HRCCC members.
- Ray Quabba, Chair of the HRCCC, who gave his time, knowledge, invaluable assistance and encouragement to the researchers over the life of the project.
- Philip Rowland, Mike Merrin and Don Begbie, Department of Natural Resources, Queensland who have actively supported the project since its commencement and provided valuable assistance and access to information to the researchers involved.
- Luis Laredo, CSIRO Tropical Agriculture, Brisbane, who has provided valuable general computing assistance to the researchers involved and contributed actively to database development and management for some key research activities.
- Kathy Mitchell and Leesa Austin, CSIRO Tropical Agriculture Brisbane for invaluable assistance in the preparation of this publication.

INTRODUCTION

A new research project, based on a case study in the Herbert River catchment of north Queensland, is focussing on the development of an improved range of strategies for planning and implementing more effective catchment management programmes in Australia. The research is being jointly undertaken by: the CSIRO Division of Tropical Crops and Pastures; the CSIRO Division of Water Resources/Australian Research Centre for Water in Society (ARCWIS); the Department of Geographical Sciences and Planning, University of Queensland; and the Department of Primary Industries, Queensland. It is funded by these organisations with the support of the Land and Water Resources Research and Development Corporation (LWRRDC).

This report provides a summary of the outcomes of a workshop held on 7 April 1995 at the Mercure Inn, Townsville. The workshop involved a range of participants from within the Herbert community, industry, state and local government, and key research bodies, who had an interest in Integrated Catchment Management (ICM) in Queensland, and in the Herbert Catchment ICM process, in particular.

Workshop Aim

The principle aims of the workshop were to:

(i) Inform participants of the new research on ICM processes being undertaken in the Herbert catchment; and

(ii) Gain input from a diversity of stakeholders of ICM on what they consider are the most important factors for an effective ICM process.

Workshop Process

In order to gain an understanding of the breadth and diversity of perspective on ICM processes rather than a consensus view, participants were organised into four groups (see Appendix A) as broadly representative of:

1. Herbert River community/industry groups
2. State Government agencies
3. Research institutions
4. Herbert River constituency groups.

Three main workshop sessions were held during the course of the day (see Appendix B). At each session, a separate question was addressed by the four groups:

Session 1: Land and water management issues

In your opinion, what are the land and water management issues in the Herbert and why?

Session 2: Institutional issues

In your opinion, what are the government, industry and community organisational issues in successful ICM, and why?

Session 3: Moving forward

In your opinion, what issues are important in increasing effective government, industry and community involvement in ICM, and how?

At the end of each session, each participant group was asked to present to the full forum a summary of their discussions. A final session reviewed some key questions arising from the day's discussions.

SESSION 1: LAND AND WATER MANAGEMENT ISSUES

Participants were first asked to respond to the question, *"In your opinion, what are the land and water management issues in the Herbert and why?"*. This session sought to ascertain what the participants perceived to be the priority land and water management issues in the Herbert catchment at this time, and most importantly, the reasons why these issues were of importance or concern. The responses to these questions have been summarised under ten broad categories, which are not necessarily mutually exclusive but reflect the breadth of the key participant perspective presented at the workshop.

Note: the broad categories are not in any particular order of priority.

1. Lack of effective long term planning of water management with land development

Agricultural production and expansion, urban development, and tourist facilities influence/impact on:

(a) *water quality* in rivers/streams and groundwater systems, as well as offshore zones. For example, chemical pollution, increased nutrient loads in both surface and ground water resources, increased turbidity due to fertilisers, effluent, and "other" effluent from aquaculture and sugar mills lead to increased treatment costs, potential environmental problems (such as loss of river and coastal ecosystems, algal blooms, lowered water utility value), and impacts on vegetation and fauna (such as reduction in 'habitat' value).

(b) *quantity of water available* (e.g. inadequate surface supply, changed flooding patterns, increasing demand for irrigation of cane in dry cycles, and changed/reduced recharge rates for (deep) aquifers) which lead to social conflicts and consequent undesirable impacts including economic hardships, quality of life, and environmental problems.

The general view presented was that there is a need for the development of strategies for long term planning for improved water quality and quantity management with land use and development.

2. Lack of co-ordinated drainage strategies for the catchment

The lack of long term planning of drainage in a co-ordinated way within the catchment with the expansion of cane lands, development of forestry areas, and the building of levees has led to a range of land management problems related largely to altered flowpaths causing localised flooding and prolonged impounding of water. The impacts include:

- loss of crop production
- land degradation
- habitat destruction
- potential impacts on ground water resources/tables
- potential acid sulphate soil problems

A need was recognised for (a) the identification and management of detention areas or sumps, and (b) the development of co-ordinated "environmentally friendly" outlets through mangrove areas for drainage off adjacent canelands.

3. Flood protection

There is no general consensus on how much flood protection is required in the lower Herbert catchment. In general, there is: (a) a lack of resources to provide flood protection to many areas; and (b) unreasonable expectations by some members of the community re: the reality of what can be done to provide protection.

Primary causes of localised flooding are: (a) the construction of roads through farms which act as "defacto levees", and alter flow paths and/or impound water for a period of time; and (b) river aggradation (silting). In general it is a vicious cycle (e.g. altered flows cause flooding and vice versa; while aggradation increases the likelihood of further flooding).

The consequences of flood protection are: (a) inequitable flood patterns; and (b) social conflicts.

4. Riparian zone management

There is a need for flexibility in guidelines for managing the interface between "the farm" and the riparian zone. On the one hand, there is a need for retention and/or restoration of riparian vegetation to: (a) maintain/reduce loss of habitat and (b) provide stream bank stability. On the other hand, a number of trade-offs need to be taken into account: (a) riparian areas ultimately drain to a stream and the outlet has to be "agriculturally viable", and (b) pest management adjacent to riparian zones has to be balanced against the need for retention of vegetation to stabilise stream bank areas.

5. Habitat management and protection

A need was proposed for prevention of loss/modification and/or fragmentation of habitat, as well as the maintenance of corridors, for the protection and preservation of:

- rare and threatened species
- fisheries resource
- Wet tropics/world heritage areas (including the GBR)
- biodiversity
- system function
- amenity.

This issue arises because of, for example:

- increasing public pressure/expectations, particularly with the clearing of land
- differences in perception or opinion, in particular relating to rates of change
- differing perceptions of the role of the catchment, for example, a habitat or a base for production
- increasing alienation/fragmentation of land for other "productive" uses.

Another view expressed was that there is a lack of understanding within the community etc. of the full range of values of water courses, such as:

- drains
- fishing spots
- habitats
- water sources
- amenity areas
- recreation areas.

The need for maintenance of recreational use of land was seen to be threatened by: (a) the alienation of land for other uses, and (b) habitat modification. A need was therefore

recognised for all interests to get together to 'quantify' these values, so that everyone becomes aware of them. However, it was noted that not all these values are tangible. One view proposed that the River Trust should be 'facilitated' to manage the river in view of *all* of these values, and that the Trust needed to be "promoted to be publically accountable".

It was perceived that this issue could be addressed by ICM through the development of a 'Catchment Master Plan', i.e. through a land use planning process.

6. Increased soil erosion and sedimentation in river system

Soil erosion and particularly sedimentation in river systems is a major problem caused by, for example:

- lack of vegetation cover
- river bank collapse
- loss of riparian vegetation
- stock concentration along water courses/river banks in the upper catchment
- road construction
- old mining areas.

However, major slips in the gorge also contribute to sedimentation in the river and this begs the question of what is "normal" erosion.

The effects of increased soil erosion and sedimentation include:

- river aggradation (e.g. building of islands in the river)
- impacts on the hydraulic capacity of the river system
- "breakdowns" of river banks (which leads to land loss, infrastructure damage, economic loss)
- increased coastal ecosystem sedimentation (e.g. impact on reefs).

The residual effects of historical alluvial tin mining in the upper catchment are:

- increased river sedimentation downstream
- downstream/lower catchment impacts on water quality and in particular domestic/urban water supply.

7. Pest management planning

There is a State legislative requirement for the management of pests (i.e. plants and animals). The consequences of inadequate planning and management include:

- undesirable impacts on cane and pasture productivity
- environmental considerations.

Another view expressed was that pest management adjacent to riparian zones has to be balanced against the need for retention of vegetation to stabilise these areas.

8. Long term sustainability of agriculture

The loss of agricultural land (e.g. to urban use, tourism, parks), declining soil fertility, and fragmentation of agricultural lands are major land use 'conflict' that impacts on the long term sustainability of agriculture. The effects of loss of agricultural land include: (a) loss of production and consequently profitability; and (b) conservation losses.

Overgrazing by the pastoral industry particularly in the upper catchment was perceived by some to impact on the pastoral industry viability and land resource sustainability. In particular there is a need for better drought management strategies for the industry.

9. Land development/conservation conflicts

Caneland expansion and clearing for rural development purposes lead to:

- increased runoff
- increased flooding
- changes to drainage patterns
- loss of wetlands, sumps
- nutrients in runoff.

One view presented was the need for a cultural change in respect of agriculture from"every man for himself" to "regulation and polluter pays" principles. However there is: (a) a "lack of integration" of producers and consumers, and (b) a lack of "common interest" between rural and urban communities. Farmers however tend to carry the burden for environmental protection. Consumers do not "naturally" make the link between production and consumption. The impact of environmental controls must be on *all* communities, not only farmers.

Another view presented was that landholders may not be concerned with the "common resource", that is they do not often look beyond their own boundaries and therefore lose the bigger picture. This was considered to be in part due to inadequate understanding of the causes and consequences, such as, loss of aquatic habitat or biodiversity.

10. Community values and conflicts

One view expressed was that changing community goals as well as evolving value systems are a key influence on the degree and nature of conflict over land and water management issues in the Herbert River catchment.

SESSION 2: INSTITUTIONAL ISSUES

Participants responded to the Question: *In your opinion, what are the government, industry and community organisational issues in successful ICM and why?* This question sought to obtain participants' attitudes to the organisational constraints to achieving ICM in the Herbert River. This was interpreted widely to include the characteristics of the approach to ICM adopted in Queensland, as well as the attitudes and activities of the major stakeholders government and community. The workshop was not guided strongly in any direction but it was anticipated and hoped that the participants would touch on the identified elements of the evaluation framework including:

- the objectives of the ICM program
- financial resources and commitment
- coordination amongst implementing agencies
- policies, plans and decision rules of relevant agencies
- recruitment of staff
- opportunities for public involvement

The four focus groups attacked the problem in different ways and their responses have been summarised under three headings:

1. Attitudes and Perspective of Stakeholders
2. Commitment and Support for ICM
3. Coordination and Implementation

1. THE ATTITUDES AND PERSPECTIVE OF STAKEHOLDERS

1.1 General Issues

- there is a need to create a common understanding of ICM - understanding the big picture on all of this as to why ICM is needed
- by creating a better understanding of important community benefits from ICM, projects will help to unify community support and assist the development of projects which can be modified to obtain a win win outcome
- ICM should not be seen as a separate entity (i.e. process rather than institution), but as a "way of doing business"

1.2 Stakeholders

- who are the key stakeholders?
- have we clearly identified their responsibilities?
- there is significant variability between local governments in the region
- special interests groups have to be part of ICM, especially industry, as: (a) they are the users of land and natural resources, (b) they have specific interests which have broader implications, and (c) what they do impacts on others
- there is too much reliance now on the individual in the catchment
- it still boils down to personality/personal motivation - do the groups involved share a common vision?

1.3 Conflicts of interest

- between state government departments/agencies, e.g DPI - Forestry, Water Resources, Land Management
- in the community about development: ICM, growers, conservationists
- concern about international interest: exports, conservation agreements (such as the World Heritage Area)
- national - federal intervention and economic policy
- over land tenure and individual v's community rights
- there are also conflicts among "experts" about biophysical processes and also on which mechanisms to use (e.g. statutory, etc.)

2. COMMITMENT AND SUPPORT FOR ICM

2.1 General Issues

- the most essential task is to gain long term commitment to the process (i.e. in it for the long - haul)
- the (Qld ICM) model is expecting the local community to be able to do it all (pick up on all this information)
- there is the need for local government support because it is the most important action agency, and it has its own representation and structure
- need for federal and state governments to foster cooperation within the community on specific issues such as river management and wetlands retention
- need for community support for funding of projects
- the government requires support of at least 70 - 75% of the community to go ahead, so ICM won't help a divided community
- there is a lack of resources and the government is cutting back on their commitment ($s; employees)
- it seems that government is the hardest to get on side and committed to ICM (more so than agriculture industry and community)

- need support from local government agencies - problems with lack of local control, and authority always come form the top "Brisbane Boffins"
- there is not enough of an educational program within bureaucracy - how can we start to do this ?
- need commitment from the top officials of institutions to participate in order to make ICM work
- is "ICM" relevant to Joe Blow?
- need to ensure continuity of political commitment at local, state and federal levels
- clear "drive" from community level
- need for Valuer General recognition to provide rate relief

2.2 Commitment to Implementation

- there are problems with the voluntary Queensland approach to integrated catchment management, which currently is ad hoc and has only "advisory" status
- difficulty in reaching consensus in such an approach - how then to implement? to deal with peer pressure? to educate? That is compared with regulatory TCM in NSW, land use controls, the Environmental Protection Act, and planning schemes
- need political will to implement legislation
- need land tenure and use controls on leasehold lands (e.g. "lands" policy - freehold - use "rights")
- industry codes of practice as an offset to legislation

Causes of these problems include: lack of expertise; identified lines of communication; people only understand ICM from the issues that affect them; and the general lack of stakeholder's commitment, including government departments.

3. COORDINATION AND IMPLEMENTATION

3.1 Coordination

- there is an urgent need for co-ordination for efficient use of resources, i.e. achieving a movement in the same direction/to appreciate all aspects
- doing things in isolation (e.g. individual government agencies)
- are those on (the ICM) committee the right people (e.g. to link back to their organisation)? Are they legitimate representatives of their stakeholder group?
- local authority - should go back to local government
- need to co-ordinate land and water management controls
- provide community input through advisory groups

3.2 Means

- can ICM outcomes be put in a strategic plan? (statutory)
- identify the appropriate mechanisms for each ICM outcome
- use existing mechanisms wherever possible
- there is a problem of do they know when to use their mechanisms and when to influence? Need to identify who has the mechanisms and influences, and gain their support (re: when to use them - "empower" them)
- there is a question as to whether there should be a lead government agency (i.e. DPI in Qld), or a suite of collaborating agencies?
- the effectiveness of ICM depends on communication - "inter and intra"

3 3 Processes

- there is a need to establish the credibility of the process in the long term - monitoring assessment of ICM and effects (e.g. why do it if no identified outcomes?)

- who - administers? pays?
- there are equity questions - is compensation payable?
- who is responsible for the on-going management of the ICM program:
    - is there a lead agency? Is there structure?
    - does ICM process have credibility at: department level and community level?
    - are the resources available to effect action?
    - does ICM need legislative authority?
    - organisational politics influencing representation: following party lines
    - territoriality
    - ICM needs recognition as a "peak body"

3.4 Planning

- use shire planning - development controls
- impact on infrastructure on adjacent lands (eg. roads)

SESSION 3: MOVING FORWARD

After having discussed land and water management issues and organisational influences it was fitting to conclude the group sessions by focussing on factors considered influential in stimulating involvement in ICM. Hence, in Session 3, participants were asked the question: *In your opinion, what issues are important in increasing effective government, industry and community involvement in ICM, and how*? How to encourage the participation of different interests in a combined effort on a whole catchment scale certainly constitutes a burning question. To help prompt discussions, participants were asked to consider how to increase ICM's perceived significance and stakeholder motivation in the Herbert and, to do this, the four "Cs" of establishing *confidence, credibility, commitment and continuity* were highlighted.

Note: the following categories constitute broad groupings and are not mutually exclusive.

1. Establish confidence and credibility.

Important broad issues needing to be considered when attempting to increase involvement include ways to increase or secure:

- accountability
- clear identification of all stakeholders
- broad representation of stakeholders (not just the major vested interests), including support from community, industry and government
- defined responsibilities
- resources for concrete action

This will require being active/proactive in the community, using the media, and harnessing the talent and drive of those already committed to the ICM process. One specific suggestion for establishing credibility was to focus on (and aim to ensure) examples of effective ICM implementation are provided from within the catchment or elsewhere. One possible focus could be the establishment of a specific, measurable project within the catchment to highlight progress (eg. a flood plain level system).

Another example put forward was to highlight precursors to modern ICM (such as the local drainage boards) and to show how the situation *before* (eg. conflict, poor productivity) was less appealing than *after* their inception (eg. a "win-win" situation, improved production).

Other activities could include prioritising issues and subsequently convening community workshops on those deemed to be relevant (eg. levee banks), involving action/implementing agencies in the ICM process, and ensuring that *all* relevant industries (such as agriculture, tourism and other industries) are involved in examining strategic (long-term) water supply needs.

A related point here is that ICM denotes a "living process". While attending meetings is an important part of the overall process, there are many other activities and considerations (such as community workshops) which need to be entertained.

2. Foster and maintain commitment and motivation

Commitment and motivation to be involved in ICM can be enhanced by identifying the need for ICM; that is, by fully examining/uncovering local issues. Statutory bodies required to fulfil the aims of ICM should also be identified around this time.

The steering committee (CCC?) could be the main body to identify issues and to focus on key outcomes attainable through ICM. Efforts should be made to make the issues as transparent as possible in order to gain a common understanding for all.

At every stage, progress must be demonstrated to stakeholders at all levels of involvement. Commitment and motivation could also be enhanced by starting on and demonstrating an issue which is small, topical and measurable. An example is nutrient tracing through the catchment, which can essentially be a ? win-win? illustration. Thus, as with the means to achieve confidence and credibility noted above, results must be demonstrated.

Other suggestions include:

- setting up terms of reference for ICM (to be done by the CCC)
- gaining media (and other) publicity
- running awareness sessions
- providing the opportunity for local people/identities to address the CCC.

3. Ensure continuity

Such efforts need to cater for loss of motivation and burnout, and to adequately deal with related issues such as the fact that ICM is often (certainly in its initial stages) more process than product and may lack biophysical outcomes for a considerable time.

The fact that CCC members may have "too many hats" also needs to be resolved (eg. by efficient use of proxy). This is particularly the case when noting the recommendation that the CCC should meet regularly (in order to be effective). A further recommendation to help cater for over commitment is to (when possible) focus on doing small jobs one at a time.

One factor which needs consideration is the selection process of CCC members, with a recommended onus being on seeking people who are enthusiastic.

The role of the coordinator/facilitator clearly is vital in maintaining continuity (especially when considering the lack of any other DPI presence in Ingham). The position should be well-funded.

4. Promote education and awareness

Examples are to:

- publicise ICM goals and activities and "sell" ICM results (and praise)
- place an onus on achieving some visible outcomes (whether process or product)
- invite the media to ICM activities
- project ICM's role/responsibility to the community - emphasise that it is more that just "another committee" and aim to ensure ICM does have some use-value to those who seek advice
- set up a means for landholders and other stakeholders to obtain such advice
- use key individuals as a catalyst for change
- communicate that ICM does not signify "loss of power"
- participate in school projects (eg. via a CCC sub committee)
- aim to gain resources from the community, industry and government

5. Act to resolve conflict

One major point noted is that conflict resolution needs to be accepted as having a central role within ICM. Indeed, conflict is inevitable due to inherent tensions/ contradictions in ICM processes such as prioritisation and evaluation of issues/problems.

Ideas put forward here for lessening the need for "obtrusive" conflict resolution included increasing awareness, gaining accurate data and information early on, ensuring people go to the right information source, and carefully examining the consequences of management options.

Another group put forward the key to resolving/lessening conflict as the achievement of commitment to ICM by all participants. This could be realised by building trust between people, endeavouring to build a comfortable social group, finding common ground and components of community value, and identifying tradeoffs and incentives.

It was also noted that legislation and arbitration/mediation could be employed (only) as a final resolution for conflict.

6. Streamline technical support

This could possibly be achieved using GIS as a means for information coordination and for forming a land management database with sound information and data. A GIS users group could be formed to assist here.

7. **Achieve clear and measurable objectives** (including quantifiable benefits)

These should be concrete, have assigned responsibilities (eg. for monitoring), and contain defined milestones (eg. monitoring and evaluation dates).

Prospective benefits that are credible and can be assessed should be emphasised.

8. Investigate possible government mechanisms

For example, possibilities include using:

- Co-ordinator General
- local government strategic plans (while recognising possible limitations)
- catchments as units of regional planning
- voluntary contracts between local governments, Port Arthur, DEH, DPI
- Trunts inlet model

9. Develop industry codes of practice

Assess, for example, how ICM codes of practice may be related to those of the EPA and NRM (correct?).

10. Give due weight to all considerations (whether social, economic or environmental)

Most of these appear at least initially to apply to the operations of the CCC. For example, there is a need to:

- attach community and economic values to planning options
- recognise the influence of sugar prices
- consider the local politics and other contextual social influences inherent in all discussions (while, at the same time, attempting to keep things focussed)
- balance competing objectives
- account for issues in the upper catchment
- ensure local government talk on a catchment basis (as has happened)
- ensure administrative assistance
- share secretarial duties
- get information out to the wider community
- delegate responsibilities from CCC representatives (to members of their various bodies?)

assess the potential (via a state/national review of ICM) for setting up a whole-of-government advisory group .

APPENDIX A - WORKSHOP PARTICIPANTS

Group 1: Herbert Community and Industry Groups

Bill Barnes	Herbert River Catchment Co-ordinating Committee Herbert River Improvement Trust
Roy Pace	Cane Productivity Board CANEGROWERS
Ray Quabba	Herbert River Catchment Co-ordinating Committee CANEGROWERS Cane Productivity Board
Peter Sheedy	CANEGROWERS

Group 2: Government Agency Representatives

Steve Gilbert	Department of Lands, Townsville
Peter James	Department of Lands, Townsville
Peter Lindwall	Department of Housing, Local Government and Planning, Townsville
Lynn McTaggart	Department of Housing, Local Government and Planning, Townsville
Mike Merrin	ICM Co-ordinator, Johnstone River ICM

Group 3: Research Agencies

Jon Brodie	Great Barrier Reef Marine Park Authority, Townsville
Jeremy Conversi	Sinclair Kinglit Mertz, Townsville
John Taylor	CSIRO, Division of Tropical Crops and Pastures, Brisbane
Peter Zahnlieter	Sinclair Kinglit Mertz, Brisbane

Group 4: Herbert Catchment Constituency Groups

Alan Harvey	Hinchinbrook Shire Council, Ingham
Dave Horsley	Herbert River Catchment Co-ordinating Committee; CSR Pty. Ltd, Ingham.
Richard Humphries	Herbert River Catchment Co-ordinating Committee; Herberton Shire Council
Rob Hunt	ICM Co-ordinator, Herbert River ICM, Ingham

Project Researchers

Jenny Bellamy	CSIRO, Division of Tropical Crops and Pastures, Brisbane.
James Butterworth	CSIRO, Division of Water Resources, and Australian Research Centre for Water in Society, Perth
Andrew Johnson	CSIRO, Division of Tropical Crops and Pastures, Townsville
Geoff McDonald	Department of Geographical Sciences and Planning, University of Queensland, Brisbane
Geoff Syme	CSIRO, Division of Water Resources, and Australian Research Centre for Water in Society, Perth
Daniel Walker	CSIRO, Division of Tropical Crops and Pastures, Townsville

APPENDIX B:

APPENDIX 1: Questionnaire Form 92

EXECUTIVE SUMMARY

This study examined landholders' existing attitudes, beliefs and behaviours relating to land and water management in the Herbert River Catchment. The central aim was to provide an initial understanding of social factors with the potential to influence the implementation of Integrated Catchment Management (ICM), and whether and how such factors vary according to where people live and what their interests are.

A community survey formed the basis for the study. The survey was designed as a self-administered questionnaire and the mail-out method was the means of administration. Telephone contacts were also used to inform potential participants about the study and increase the response rate.

The questionnaire contained items concerning:

- levels of importance, perceived impacts, awareness and attitudes towards land and water management issues;
- perceived ability to control land and water management issues;
- tractability or "manageability" of potential issues;
- intentions to participate in relevant activities;
- awareness of government strategies;
- attitudes towards government's performance;
- use of information sources;
- group involvement.

The study area included the whole catchment. A range of landholders were contacted including those in the upper and lower catchment; in rural and urban areas; with different occupations including cane farming, grazing and mining; and with urban properties in eight settlements.

Most analyses were based on comparisons among four samples, namely upper rural, lower rural, upper urban and lower urban. These categories also collapsed into combined upper and lower, and rural and urban samples.

Of the 800 telephone calls made, 718 people agreed to take part. The number of returned and completed questionnaires was 477, providing an overall response rate of 66 percent.

Some main conclusions drawn from the study were as follows.

- Land degradation, water quantity problems, water quality problems and nature conservation issues were generally seen as highly important.
- Higher taxes and loss of confidence in the ability of government to manage natural resources were rated as high impacts. Other impacts included higher production costs, lower fish numbers and loss of environmental uses/benefits.
- Loss of farm productivity was considered a high impact by rural producers in the lower catchment.
- Any difficulty in managing land and water in the Herbert was considered to be related to the size and inability to travel throughout the catchment (between upper and lower areas), the fact that solutions are not easy and expensive, low trust of government programs, the wide variety of existing opinions, and insufficient understanding of problems.
- Most participants had heard most about Landcare, which was also the best-known government strategy. Those who had heard about ICM (more than 37 percent), and knew most about ICM were most likely to be rural producers in the lower catchment.
- Many agreed that things could and should be done to help improve the environment. However, action may be restricted by a widespread perception of lack of finances to plan more than a year ahead and the belief that locals do not have money available to spend on solutions.
- Many agreed that governments should work out better ways to fix land and water problems, and that incompetent government activities had been witnessed locally. Further, many could recall a government action that had damaged their livelihood.
- Many agreed they would be prepared to help in local projects, and that it was likely they would look into ways to improve the environmental condition of their properties.
- The likelihood of participating in land and water management activities appeared heightened by interest in local community issues and beliefs that: land degradation was important; thinking about issues for the Herbert was not too difficult; and government strategies (generally Landcare, and ICM) do have some personal use. More frequent use of the river/creeks, concern about the personal impacts of higher production costs and the rating of nature conservation issues as important were also related to intentions to participate.
- The most frequently used sources of information included the Herbert River Express, friends/colleagues, the local "grapevine", neighbours, and (the television program) Landline. Landline was considered the most reliable source.
- Compared with non-members, members of existing groups were more likely to consider constraints to

managing land and water in the Herbert to be the wide variety of local opinions, and the difficulty in thinking about issues for an area this size. Members were also more prepared to assist in local projects, and more likely to become (or stay) involved in a Landcare or catchment group and to see personal benefits accruing from group involvement.

Implications for ICM in the Herbert were drawn from study conclusions. For example, the low level of trust of government programs and the fact that many agreed that laws should be changed to ensure landholders become more responsible for their actions seem key issues facing ICM. Finally, the low level of perceived conflict in the Herbert appears to have positive implications for ICM.

1.0 INTRODUCTION

1.1 Evaluation of Integrated Catchment Management in a Wet Tropical Catchment

In 1994, the Land and Water Resources Research and Development Corporation (LWRRDC) funded research staff of the CSIRO Tropical Agriculture (in Brisbane and Townsville), CSIRO Land and Water (in Perth), and the University of Queensland, Department of Geographical Sciences and Planning to undertake research on Integrated Catchment Management (ICM) processes[1]. This longitudinal study over five-years is focussing the ICM program in the Herbert River catchment in North Queensland as a case study. The objectives of the investigation are.

1. Monitor and document the process of implementation of ICM in the Herbert River catchment and identify the social, economic and institutional factors that facilitate or hinder this process.
2. Evaluate key impacts of the implementation of the ICM process in terms of attitude and behaviour changes in the community and changes in the severity or tractability of the resource use conflicts for the catchment.
3. Assess the specific technical and related information needs that are relevant to an effective ICM implementation process in a wet tropical environment.
4. Develop a framework and related methods for evaluatig the process of ICM implementation that will facilitate the development of more effective catchment management programs in Australia.

The complexities of catchment management are such that longitudinal studies of processes are essential if the issues of catchment management are to be understood and appropriate lessons learned. The project acknowledges that, by its nature, ICM requires systematic evaluation. For example, ICM needs to take many (often conflicting) considerations into account, and operates in an environment where uncertainty is more often the rule than the exception. Moreover, indicators of progress are not easily defined and, to date, this area of investigation has largely been neglected.

In responding to these requirements, the project has adopted a multidisciplinary approach and draws on areas of expertise in natural resources sciences, social science, land use planning, economics, and media analysis.

The study reported here is the first stage of the community assessment component of the project.

1.2 Grounds for the Study

The impetus for this study comes from both ICM's focus on community involvement and an increasing emphasis on the need to evaluate effectiveness of this involvement within the ICM

[1] LWRRDC Project Reference: CTC7 - *Evaluation of Integrated Catchment Management in a wet tropical environment*

context. In other words, the key issues needing to be addressed are what ICM - as a largely community-based enterprise - delivers beyond isolated and 'unintegrated' resource management activities, and, as a result, what changes occur.

Like similar strategies in other States, Queensland ICM states that land and water management on a catchment basis needs to be community-driven with strong grounding at the local level. ICM objectives (particularly in non-statutory form) are generally considered achievable only to the extent that local communities have contributed to their development and are motivated to carry them out.

To date, ICM in Queensland is still in early stages of development. Most community-run catchment coordinating committees and other involved groups are yet to arrive at a position where progress can be adequately assessed. Community research is therefore required to assist the development of methods for evaluating effectiveness and, more generally, to help generate a better range of strategies for more effective catchment management programs throughout the country.

1.3 Objectives

A community survey of residents in rural and urban areas in the catchment formed the basis for the study. A questionnaire was developed to understand landholders' existing attitudes, beliefs and behaviours relating to land and water management in the catchment. The central aim was to provide an initial understanding of social factors with the potential to influence the implementation of ICM, and whether and how such factors vary according to where people live and what their interests are.

The study is longitudinal, with the findings reported here forming the Stage 1 baseline survey. A further survey will be undertaken before the completion of the project. To this end, the study (a) provides indications of existing community attitudes and behaviours, and (b) serves as a baseline to assess variation in attitudes and behaviours relating to the progress of ICM over time.

2.0 STUDY AREA

With a catchment area of more than 10,000 square kilometres, the Herbert River rises in the Great Dividing Range west of Innisfail and flows southeast to the sea to the south of Hinchinbrook Island. The upper catchment includes areas of tropical forest and grain cropping, a number of small active and inactive tin mines, but most of the area is devoted to grazing on native pastures. In the more populated lower catchment, sugar cane production is the dominant land use on the extensive alluvial and coastal plains. Completely dividing the upper and lower areas, approximately 15 percent of the catchment is in the Wet Tropics World Heritage Area. The catchment contains the shires of Herberton and Hinchinbrook and settlements including Ingham, Herberton, Allingham, Ravenshoe, Halifax, Lucinda, Taylors Beach, and Mount Garnet.

The upper and lower catchments are two distinctly different geographical areas. They also differ according to types of rural industry and the intensity of production, climatic and soil characteristics, and population size. As such, there are likely to be other distinctions, for example, along social, economic and recreational lines. Of course, this also applies for rural and urban areas.

2.1 ICM issues

The Herbert River Catchment Coordinating Committee was formed in 1993 on a voluntary basis by local community interests. The impetus for its formation was based on the recognition of the need for better community participation in decision-making relating to river management issues.

Before undertaking this study, the principal land and water management issue in the Herbert was identified as a lack of effective long-term planning and integration of water management with land development (Bellamy *et al.*, 1995). Consequently, prominent water quality problems include increased sedimentation, turbidity and nutrient loads in the river, and riparian zone management issues such as the need to improve riverbank stability and reduce loss of habitat. Water quantity concerns include inadequate or poor quality surface supply, increased demand for irrigation, flood protection, and changed flooding patterns. Additionally, a lack of coordinated drainage strategies has produced several impacts including loss of crop production and land degradation.

In consultation with landholders, agency personnel, and project team members, some more likely impediments to an effective ICM program were suggested as:

- differences between the upper and lower catchment;
- a lack of 'ownership' of the problem(s) (including public concern over perceived impacts of land use on the Great Barrier Reef; (rare) flora and fauna conservation issues such as biodiversity preservation and the mahogany glider);
- financial issues such as 'who pays for any required actions?';
- historical factors such as ad hoc land allocation and the fact that agencies had traditionally been concerned with land *use* rather than land *management*;
- community perceptions of (a) relevant government agencies as 'issue avoiders', and (b) of planning as interfering with the spirit of free enterprise, with ICM being viewed as a 'planning approach';

3.0 METHODOLOGY

3.1 The Mail-out Method

As mentioned, the intention of the survey was to gauge existing attitudes and behaviours, and serve as a benchmark for assessing any future attitude and behaviour change. Therefore, given the catchment's complexity (eg. geographical and social) and the number of required comparisons (between different populations in the catchment and across time), it was decided that the sample size should be as large as was feasible. Consequently, for logistic reasons, the survey was designed as a self-administered questionnaire and the mail-out method was selected as the means of administration.

At this benchmark stage, a further reason for preferring a mail-out survey over other approaches is that this method provides benefits such as better protection of anonymity. There is also less intrusion on those who may not be familiar with ICM and other land and water management issues.

Discussed below, the sampling framework also included (initial and follow-up) telephone contacts as a component of the mail-out method. This component was added to gauge willingness to participate, inform potential participants of the purpose of the study and increase the response rate (ie. the number of returned questionnaires).

3.2 Designing and Pretesting the Survey

To ensure that the major issues were addressed, a range of stakeholders were involved in defining the content of the questionnaire. This occurred primarily through interactions with members of the study team, most notably Dr Dan Shrubsole.

Through this input, a number of items from the recently conducted survey of Herbert River Catchment Coordinating Committee (HRCCC) members were included in the questionnaire. Comparisons between HRCCC members' opinions and those of the wider community will be detailed in a following publication.

In the last eighteen months, two community workshops held in Townsville and Ingham provided feedback and direction on the community assessment objectives, including the definition of relevant issues.

Pretests of the questionnaire were conducted in Perth. Draft versions of the survey were also sent for comment to a number of stakeholders, including residents in both the upper and lower catchment areas.

3.3 Survey Items

The final draft of the questionnaire contained items concerning:

- levels of importance, perceived impacts, awareness and attitudes towards various land and water management issues;
- perceived ability of landholders to control land and water management issues;
- tractability or "manageability" of potential issues;
- intentions to participate in land and water management and other group activities, and perceived impediments to participation;
- awareness of government strategies (including Property Management Planning, Landcare, ICM), and the HRCCC;
- attitudes towards government's performance regarding land and water management issues;
- use of information sources, including the media;
- group involvement, interest in community issues, and life satisfaction;
- demographic information.

The questionnaire is included in the report as Appendix 1.

3.4 Sampling Framework - Land use and Sample Locations

A range of landholders were contacted including those in the upper and lower catchment; in rural and urban areas; with different occupations including cane farming, grazing and mining; and with urban properties in eight settlements.

The maximum number of telephone contacts was set at 800. While this was also potentially the maximum sample size, a response rate of this size was unlikely given that some of those contacted would be unwilling to participate.

The sampling framework outlined below follows the logical order in which sample locations and sizes were selected.

3.4.1 Upper Catchment Rural

The upper catchment includes approximately 100 agricultural businesses and a much smaller number of mining enterprises. In addition to the main grazing industry, there is some dairy and small crops enterprises (mostly potatoes, corn etc.) and tree cropping.

Adhering to the approximate number of agricultural businesses (exact numbers could not be obtained), the maximum "upper rural" sample size was set as 100.

3.4.2 Upper Catchment Urban

The three selected settlements in the catchment were Herberton, Ravenshoe, and Mount Garnet. The main criterion for this sample was to gain sufficient data from each of the selected sites. Based on the criteria of population size (1991 Census), maximum "upper urban" sample numbers were set as:

- Herberton (about 1000 residents - sample 50);
- Ravenshoe (about 900 residents - sample 45);
- Mount Garnet (about 400 residents - sample 30).

3.4.3 Lower Catchment Urban

Following the sampling criterion of including settlements larger or equivalent in size to the towns surveyed in the upper catchment, the following five towns were surveyed. Based on population size, maximum "lower urban" sample numbers were set as

- Ingham (about 5100 residents - sample 100);
- Allingham (about 1000 residents - sample 50);
- Lucinda (about 800 residents - sample 40);
- Halifax (about 550 residents - sample 35);
- Taylor's Beach (about 400 residents - sample 30);

To be more representative, it was recognised that a greater number of people in Ingham ideally should complete the survey. While the designated figure could be as high as approximately 380, given other sample numbers, such a figure was considered unfeasible given available resources.

In sum, the total urban sample (across towns and both areas of the catchment) was set at 380.

3.4.4 Lower Catchment Rural

There are more than 850 cane growing businesses in the lower catchment. Other land uses include grazing (about 20 businesses) and some horticulture.

The first issue to be canvassed was the number of rural businesses to be contacted in the lower catchment. In line with the proportion of rural business aiming to be surveyed in the upper catchment (100), as one prerequisite, this figure could have varied between approximately 290 and 340 depending on whether the proportion against total shire numbers or the number of people living in the towns was selected. Of course, the main prerequisite was attaining the maximum sample size of 800 and, as such, achieving reasonable correspondence with the urban total of 380.

The selected figure of 320 corresponded with both prerequisites.

In sum, the total rural sample (across both areas of the catchment) was set at 420.

Finally, given the focus on land and water management issues, compared with urban sample numbers, the "over sampling" of the two rural areas was recognised as requirement of the survey.

3.5 Participant Selection

3.5.1 Increasing the Response Rate

In early July 1996, a CSIRO interview team was assembled in Perth. Interviewers contacted catchment residents by telephone, briefly discussed the purpose of the study and asked people if they were willing to participate. Those who agreed were subsequently mailed the questionnaire, while those who refused were asked if they would mind answering a few basic questions before hanging up (see section 4.1.1 below).

It was decided to use preliminary phone calls to help maximise the response rate to the mail-out questionnaire. In this way, the questionnaire could be mailed only to those who agreed to be involved and, rather than arriving unannounced, it was anticipated that personal contact would help to develop some familiarity with the aims of the study.

Additional means to heighten the response rate included announcing the study in a number of local newspapers before commencing the survey. Finally, reminder (follow-up) calls to participants who had not returned the questionnaire within the time designated were also included as a component of the sampling methodology.

The questionnaire was mailed along with a covering letter, a map of the catchment area and an information sheet titled, "Land and Water Management in the Tropics". The information sheet was developed by the study team as a further means to raise awareness of the overall study.

3.5.2 Contact Information

Contact information for catchment residents was obtained and collated from a number of sources, principally CSIRO Division of Tropical Crops and Pastures in Townsville, the Herberton Shire Council, the Department of Natural Resources in Mareeba, and Telstra White Pages (on CD ROM).

For each resident, information included telephone numbers, surname, first name or initials, street or postal address and, in some cases, title (Mr, Ms etc.).

Information was organised into four spreadsheets, one for each of the four samples noted above. Employing a random sampling procedure, interviewers selected residents to be contacted according to a designated number (eg. every fourth person). This was determined by the number of telephone contacts required compared with the entire sample pool (ie. the total number of residents listed on each spreadsheet). Residents were called up to three times if there was no answer.

Finally, the sampling strategy did not attempt to gain equal numbers of males and females. Given the questionnaire's focus, a sample selection favouring males appeared likely. It was notable, for example, that the clear majority of contact details in the lower rural sample were for men. Further, many women agreed to participate in the study but stated that they would ask their husbands to complete the questionnaire. The results section (4.11) shows that number of males and females did vary between samples, with the difference being greater for the two rural samples. Any differences were not considered problematic.

4.0 RESULTS

4.1 Final Sample Numbers

Of the 800 telephone calls made, those who agreed to take part numbered 718, while 82 refused. The refusal rate (around 10 percent) was low.

Compared with the original number proposed, the number of questionnaires mailed out for the four samples were:

- upper rural - 92 (100)
- lower rural - 282 (320)
- upper urban - 128 (125)
- lower urban - 216 (255)

The small discrepancy for the upper urban figures (ie. more were contacted than originally planned) was produced by transferring four potential contacts from Ingham to Mount Garnet. Contacting residents in Ingham proved more difficult than in the upper urban areas and, because of the set duration of the contact period, the two potential sample sizes were altered slightly during this period.

4.1.1 Refusals

If people declined to complete the questionnaire, there were asked if they would mind answering a few short questions before hanging up. Of the 31 people who agreed, many were elderly, retired/pensioners who felt they could not make any contribution to the study. It is likely that these factors influenced other refusal results below (eg. group membership, fishing frequency).

In brief, those who refused (and agreed to answer a few questions) had an average age of 63 years. Only 3 people were aged 30 or under, 18 people were aged 65 or above, and 23 were aged more than 50. In addition:

- most (26) stated they were not affected by any land and water management issues;
- most (26) did not belong to any local groups or associations;
- over half had not heard of the HRCCC;
- when asked "How often do you go fishing for recreation?", most (25) responded "Seldom" (4) or "Never" (21).

4.1.2 Returned Questionnaires

The number of returned and completed questionnaires was 477, providing an overall response rate of 66.4 percent (or 59.6 percent compared with the total number of telephone calls). Compared with average return rates on mail-out surveys (often as low as 20 percent), this rate was considered excellent.

In actuality, the number returned was 509. However, of these, 32 had not been completed. Various reasons were given, including only recently moving to the area, ill health, lack of time, no desire to participate, lack of knowledge, and not feeling capable of completing the task. One person noted that describing the situation in the upper catchment on the paper provided was impossible (stated problems included pest invasion, tree clearing, soil loss, and creek degradation).

In brief, it should also be noted that five of the questionnaires returned from the upper rural sample were from people who lived out of the catchment but who held property within the catchment area. Each of these participants had previously been asked to respond to the questionnaire in terms of their property. In addition, for some items relating to community

interest, the questionnaire was modified slightly so that responses were in terms of *that* community.

Questionnaires were returned from 145 and 332 people in the upper and lower catchment respectively (or 30.4 and 69.6 percent of the whole sample). Of these, 250 were classified as rural and 227 as urban (respectively, 52.4 percent and 47.6 percent of the whole sample). A breakdown of the number of questionnaires returned and response rates appears in the following table.

Catchment	Type of Holding	Number Returned	Response Rate (%)	Towns Surveyed	Number Returned	Response Rate (%)
UPPER	RURAL	59	64.1			
	URBAN	86	67.2	Herberton	38	76.0
				Mt Garnet	18	54.5
				Ravenshoe	30	66.7
LOWER	RURAL	191	67.7			
	URBAN	141	65.3	Allingham	28	60.1
				Ingham	45	61.6
				Halifax	17	54.8
				Lucinda	26	66.7
				Taylors Beach	24	88.9
TOTAL		**477**	**66.4**			

Among these figures, the very high return rate from Taylors Beach is notable (88.9 percent).

The table also shows that the number of returned questionnaires from the lower urban towns is one short of the total (141). This is explained by the fact that one resident from Cordelia expressed interest in participating in the study and was subsequently mailed the questionnaire.

4.2 Presentation of Findings

Results of the data analysis are presented here for each question in the survey. Results for the whole sample and cross comparisons (eg. between upper and lower catchment samples) are shown where relevant. The term, "whole sample" represents the total number of completed and returned questionnaires (477) and the number of people responding to a particular question (generally lower but close to 477).

The report extensively uses the term, **"the four samples"**, which - as used above - denotes the upper urban, upper rural, lower urban, and lower rural samples. Generally, each item in the questionnaire was first examined for any statistically significant response differences existed between these samples.

Responses to many following questions, were rated on 5-point scales. To present findings consistently, there are some modifications for response formats in this report. Unlike the questionnaire, for example, the scale of positive responses (such as very high, strongly agree) to negative responses (such as not at all useful, strongly disagree) is generally rated from 5 to 1 respectively. Where relevant, the presentation of results in the report may also differ from the items as they appear in the questionnaire.

In the following tables, the figure "**N**" denotes the number of responses given for a particular question. For any question, a number of people chose not to respond.

Finally, interviewees could provide up to three responses for open-ended questions. Therefore, percentages will not add to 100 but show the number of people giving a particular response (compared with the whole sample). For these questions, categories were also formed to maintain both detail and ease of presentation. Therefore, some categories may not be mutually exclusive.

4.2.1 Statistical tests

A number of statistical tests were used throughout the report. These included correlation analysis; appropriate analysis of variance for multiple group contrasts, paired samples t-tests (to compare mean scores); reliability, regression and factor analysis; cross tabulations (for categorical data such as group membership); and, where appropriate, non-parametric tests.

4.3 Advantages of, and key issues facing people, living in the Herbert River Catchment

Both following questions were open-ended, with each allowing up to three responses.

What do you think are the major advantages of living in the Herbert?

As stated, percentages will not add to 100 but show, compared with the total number of people who provided at least one response (431), how many gave a particular response. Some of the more prominent advantages are noted in the following table.

Advantages	N	Percent
Good climate	152	35.3
Lifestyle (stress free; country atmosphere)	138	32.1
Close access to many recreation sites (eg. beaches; rainforest)	83	19.3
Quality of the people (eg. caring, friendly, easy going, helping)	71	16.5
Healthy environment (eg. less pollution)	63	14.6
Personal safety / security (eg. better for children; low crime)	57	13.2
Small community / low population	56	13.0
Very quiet / peaceful	55	12.8
Good environment (unspoiled, natural, abundant wildlife)	54	12.5
Close to large centres (but also far enough away)	35	8.1
Good area for production (eg. sugar; soil; natural rainfall)	18	4.2
Good facilities	14	3.2
It's home	14	3.2
Good quality drinking water	11	2.6
Close knit community	10	2.3
Affordable land	7	1.6

In total, the sample provided 888 responses. 838 (or nearly 90 percent) are noted in the table.

The advantages clearly speak for themselves. In brief, the area offers a good climate, excellent recreation opportunities, and a relaxed and healthy rural lifestyle. Communities are friendly and cooperative and provide a safe environment. Other advantages include proximity to (and enough distance from) Townsville and Cairns, and the area's productive capacity.
Of interest, 16 of the 18 responses stating the area was good for production were from the lower catchment. Similarly, 11 of the 14 who saw good facilities as an advantage were from the lower catchment.

Generally, what do you think are some of the key issues facing people in the Herbert?

For this open-ended question, 409 people gave at least one response. More prominent key issues are noted in the following table.

Key Issues	N	Percent
Unemployment (particularly long term)	169	41.3
Clearing of marginal land/poor land management (including cane land expansion; tree clearing; "fauna versus farming")	60	14.7
Lack of diversity in industry/need for a new major industry (including over-reliance on sugar industry; economic downturn)	59	14.4
Water quantity (eg. Availability; lack of storage; lack of groundwater)	39	9.5
Lack, and need for improvement, of community services/facilities	38	9.3
Lack of opportunities for young people	31	7.6
Fishing issues (eg. overfishing, habitat loss, swamp drainage)	25	6.1
Pollution (water and air)	24	5.9
Flooding in the lower catchment	23	5.6
Lack of entertainment	21	5.1
Poor drinking water quality	20	4.9
Poor quality roads / poorly maintained roads	18	4.4
Tourism - lack of any tourism development	17	4.2
Drainage (eg. dissatisfaction with new proposals, run off too fast from new assignments)	13	3.2
Environmental issues (eg. affect lifestyle and potential for jobs)	11	2.7
Cane Prices	10	2.4
Conservationists/greenies ("ratbags")	10	2.4
Poor political representation	10	2.4
Continuous crushing of cane	10	2.4

In total, 786 responses were provided, of which 608 (more than 77 percent) appear in the table.

Unemployment was clearly the most pressing issue and, relatedly, opportunities for young people was the sixth most frequent response. Concerns about land management (primarily land clearing), lack of diversity and over-reliance on one industry, water availability and inadequate community services were also frequently mentioned.

Interestingly, for the issue regarding lack of diversity in industry, 54 of the 59 responses were from the lower catchment. Similarly, 12 of the 13 responses concerning drainage were from the lower catchment. Conversely, 24 of the 38 responses regarding community services, and 14 of the 18 responses regarding poor quality roads were from the upper catchment.

4.4 Issue Importance

For each of the four issues (below), ratings were gained for the importance felt personally and that perceived to be felt by others in the Herbert. A five-point scale ranging from very high to very low importance was used.
Both personal importance and importance to others were included to find any differences between samples and across issues. It was anticipated that the two ratings (self and others) may differ, and that knowledge of such differences would be important for establishing the importance of land and water management issues across the catchment. Future studies could also examine whether differential ratings for self and others highlight situations such as a "tolerance" for public policy and resource management approaches but a lack of willingness to be personally involved.

This and the following component of the questionnaire (Impacts of Issues, section 4.5) were derived from the survey of HRCCC members. Developed in consultation with catchment residents and other stakeholders, these items correspond with four general issues of importance (ie. land degradation, water quality problems, water quality problems, and nature conservation issues), and the potential influences of these issues on life in the Herbert. For the latter, fifteen impacts were generated, including high cost of water, loss of farm productivity, and poor drinking water quality.

In your opinion, how important are the following issues (1) to you personally, and (2) to people in the Herbert generally?

Land degradation

		importance to you personally		importance to people in the Herbert	
Response	**Rating**	**N (450)**	**Percent**	**N (438)**	**Percent**
very high importance	5	186	41.3	128	29.2
high	4	105	23.3	117	26.7
moderate	3	103	22.9	134	30.6
low	2	38	8.4	42	9.6
very low importance	1	18	4.0	17	3.9
		TOTAL 450	100.0	TOTAL 438	100.0
		Mean = 3.9		Mean = 3.7	

Both mean scores (3.9 and 3.7) indicate that land degradation was generally seen as highly important for both self and others. This was less so in terms of the importance for others in the Herbert, with moderate importance being chosen by more participants. Indeed, while the mean scores are similar, the importance of land degradation was seen as significantly lower for others than that attributed personally. On further scrutiny, this difference resulted entirely from the lower ratings of importance provided by many in the two rural samples. For example, whereas the ratings for both urban samples did not change, the mean for the upper rural sample dropped from 4.1 to 3.4. Consequently, ratings of the importance to others differed between the rural and urban samples.

There were no other significant differences between the samples.

Water Quantity Problems

		importance to you personally		importance to people in the Herbert	
Response	**Rating**	**N (456)**	**Percent**	**N (437)**	**Percent**
very high importance	5	226	49.6	190	43.5
high	4	89	19.5	99	22.7
moderate	3	86	18.9	97	22.2
low	2	27	5.9	32	7.3
very low importance	1	28	6.1	19	4.3
		TOTAL 456	100.0	TOTAL 437	100.0
		Mean = 4.0		Mean = 3.9	

Water quantity problems generally seen as high importance for both self and others (means 4.0 and 3.8). As for land degradation, compared with personal importance, the importance of water quantity problems for others was generally seen as different. Interestingly, mean scores dropped for both rural samples, and rose slightly for the upper urban sample (and was virtually unchanged for the lower urban sample). For example, the mean for the upper rural sample dropped from 4.3 to 3.9. Consequently, ratings of the importance to others differed between the rural and urban samples.

For personal importance, compared with both upper catchment samples, the lower rural sample was less likely to see water quantity problems as important (mean 3.8). Related to this finding, and as indicated by many responses to the question on key issues (page 10), such problems were generally viewed in terms of the availability and lack - rather than abundance - of water. However, people in the lower rural sample who noted that flooding and/or drainage were key issues (21 people or 11 percent of this sample) also tended to see water quantity problems as

having higher importance (mean 4.1, which was comparable with that of the combined upper catchment sample).

Water Quality Problems

		importance to you personally		importance to people in the Herbert	
Response	**Rating**	**N (462)**	**Percent**	**N (440)**	**Percent**
very high importance	5	250	54.1	204	46.4
high	4	103	22.3	109	24.8
moderate	3	61	13.2	77	17.5
low	2	30	6.5	40	9.1
very low importance	1	18	3.9	10	2.3
		TOTAL 462	100.0	TOTAL 440	100.0
		Mean = 4.2		Mean = 4.0	

Water quality problems were generally seen as highly important for both self and others (means 4.2 and 4.0). As for land degradation and water quantity, compared with personal importance, the importance of water quality problems was seen as significantly lower for others. However, unlike the previous findings, mean scores dropped for all four samples (rural and urban).

The same significant difference between the samples was found for personal importance and importance to others. Compared with the combined rural sample, those in the combined urban sample were more likely to place higher ratings of importance on the issue of water quality (means were between 4.1 and 4.3).

Nature Conservation Issues

		importance to you personally		importance to people in the Herbert	
Response	**Rating**	**N (450)**	**Percent**	**N (438)**	**Percent**
very high importance	5	147	32.7	84	19.3
high	4	104	23.1	83	19.0
moderate	3	141	31.3	173	39.7
low	2	38	8.4	67	15.4
very low importance	1	20	4.4	29	6.7
		TOTAL 450	100.0	TOTAL 438	100.0
		Mean = 3.7		Mean = 3.3	

Nature conservation issues were generally seen as having high to moderate importance for both self and others (means 3.7 and 3.3). As for the three previous issues, compared with personal importance, importance was generally seen as significantly lower for others. Mean scores dropped for all samples, particularly the upper rural and lower urban samples.

In terms of personal importance, compared with the lower rural sample, those in the lower urban sample were more likely to see nature conservation issues as important.
Unlike the three previous issues, there were no differences between the samples when examining importance to others. This occurred because, compared with personal importance, the mean score dropped most substantially for the lower urban sample, and was virtually identical with the lower rural sample.

In summary, the importance of land degradation, water quality problems, water quantity problems, and nature conservation issues were generally seen as high. For example, while the

lowest mean scores were for nature conservation issues, these were still on the high side of moderate. Finally, water quality problems were considered the most important issue.

4.5 Impacts of Issues

In your opinion, how much do each of the following impacts (1) affect you personally, and (2) affect people in the Herbert generally?

From high cost of water to loss of scenery, participants rated the following 15 impacts in terms of the degree to which they and others were affected. A five-point scale ranging from a very high to very low degree was used and, in addition, the response "not at all" was also included as an extra category. As the following tables indicate, this category was coded as zero and included in analysis of responses. As such, the midpoint of the scale is 2.5, or low to moderate.

High cost of water

		affects you personally		affects people in the Herbert	
Response	**Rating**	**N (462)**	**Percent**	**N (431)**	**Percent**
Very high degree	5	91	19.7	115	26.7
High	4	57	12.3	105	24.4
Moderate	3	91	19.7	122	28.3
Low	2	83	18.0	62	14.4
Very low degree	1	77	16.7	23	5.3
Not at all	0	63	13.6	4	.9
		TOTAL 462	100.0	TOTAL 431	100.0
		Mean = 2.6		Mean = 3.5	

In terms of personal effect, the frequencies and mean scores indicate a spread of scores across the scale. However, it is noticeable that (for this and many following issues) more participants were placed towards the high end of the scale when considering the impact on other people in the Herbert. Indeed, for the whole sample, the mean scores indicate that the effect of high water costs was seen as higher on others than that experienced personally (moderate to high compared with low to moderate).

This issue produced a number of significant differences. First, compared with the three other main samples, the lower urban sample was more likely to consider the cost of water as having an effect personally. Indeed, at 3.4, the mean score returned for this sample was between moderate and high which contrasts particularly with the upper and lower rural samples which returned means of 2.0 and 2.1 respectively. Second, compared with both rural samples, the upper urban sample (mean 2.8) was also more likely to consider the cost of water as having an effect personally. As these results suggest, compared with the combined rural sample, the combined urban sample was more likely to see the cost of water as having an effect personally.

In terms of the effect on others, those in the lower rural sample were less likely to see the cost of water as having an effect than both urban samples

The table shows that, in terms of personal effect, the mean score for the whole sample was moderate. However, with a mean of 3.7, the effect on the lower rural sample was closer to high and contrasts significantly with the three other samples, all of which were below 3. As expected, most of those not at all affected were from the urban sample (nearly 70 percent).

Loss of farm productivity

		affects you personally		affects people in the Herbert	
Response	**Rating**	**N (457)**	**Percent**	**N (437)**	**Percent**
very high degree	5	116	25.4	148	33.9
high	4	77	16.8	143	32.7
moderate	3	82	17.9	91	20.8
low	2	70	15.3	38	8.7
very low degree	1	65	14.2	14	3.2
not at all	0	47	10.3	3	.7
		TOTAL 457	100.0	TOTAL 437	100.0
		Mean = 2.9		Mean = 3.8	

Again, while a spread of scores was noticeable for personal impacts, for the impact on others, the frequencies and mean scores reveal that more respondents were placed towards the top end of the scale. As such, for the whole sample, the effect of lost farm productivity was considered higher on other people in the Herbert than that experienced personally. However, as was touched upon for the effects of water prices, this was not so for the lower rural sample which returned a similar mean score. Therefore, this group had more stability when rating impacts for self and others. This finding appears again for a number of the following items.

From this result it appears feasible that lost farm productivity is likely to be more of an issue for cane growers than other rural producers or urban residents in the catchment.

Finally, one interesting finding was that the lower urban sample was more likely than both rural samples to consider lost farm productivity as having an effect on others. In this way, a number of other findings below also suggest that, compared with the upper urban sample, the lower urban sample was the more "urban" of the two (ie. distinguishable as different to rural). For those in the upper urban sample, the effects of issues such as lost productivity more closely resembled those of the rural samples. Therefore, people living in Ravenshoe, Herberton and Mount Garnet may be more integrated with the rural community.

Higher production costs

		affects you personally		affects people in the Herbert	
Response	**Rating**	**N (455)**	**Percent**	**N (431)**	**Percent**
very high degree	5	160	35.2	182	42.2
high	4	108	23.7	152	35.3
moderate	3	65	14.3	71	16.5
low	2	44	9.7	17	3.9
very low degree	1	43	9.5	5	1.2
not at all	0	35	7.7	4	.9
		TOTAL 455	100.0	TOTAL 431	100.0
		Mean = 3.4		Mean = 4.1	

As might be expected, impacts of higher production costs were more likely to be personally experienced by participants in both rural samples, particularly those in the lower catchment. Indeed, for this sample, the mean (4.3) shows that - on average - these costs are felt from a high to very high degree. Conversely, as anticipated, most of those not at all affected were from the urban sample (more than 80 percent).

Frequencies and mean scores demonstrate that more participants were placed towards the top end of the scale for the impact on others. As such, for the whole sample, the effect of higher production costs was considered higher on others than that experienced personally (high, compared with moderate to high). Again, however, this was not the case for the lower rural sample which returned a similar mean score for both questions.

As for the issue of lost farm productivity, it appears that increased production costs are likely to be more of an issue for cane growers than others in the catchment.

Poor drinking water quality

		affects you personally		affects people in the Herbert	
Response	**Rating**	**N (467)**	**Percent**	**N (435)**	**Percent**
Very high degree	5	187	40.0	199	45.7
High	4	78	16.7	106	24.4
Moderate	3	49	10.5	73	16.8
Low	2	53	11.3	36	8.3
Very low degree	1	51	10.9	17	3.9
Not at all	0	49	10.5	4	.9
		TOTAL 467	100.0	TOTAL 435	100.0
		Mean = 3.3		Mean = 4.0	

With mean scores between moderate and high, both scales indicate that many participants considered the impacts of poor drinking water quality to be very high. However, one notable difference is the number of participants who did not consider they were personally affected (nearly 75 percent of whom were rural producers). In general, the impact was considered higher on others in the Herbert.

Significant differences between samples were in relation to personal impacts. While other samples returned more moderate mean scores, the mean for the lower urban sample was close to high (the difference between the rural and urban sample was also significant). In fact, those in Ingham rated the problem as high to very high. Therefore, urban residents in the lower catchment were more likely to be affected by poor drinking water. This finding provides an indication of why this sample gave high ratings for the importance of water quality problems (discussed earlier). This being noted, the poor quality of drinking water appears to be at least a moderate problem throughout the catchment.

Shortage of irrigation water

		affects you personally		affects people in the Herbert	
Response	**Rating**	**N (453)**	**Percent**	**N (431)**	**Percent**
Very high degree	5	104	23.0	129	29.9
High	4	54	11.9	95	22.0
Moderate	3	62	13.7	105	24.4
Low	2	66	14.6	56	13.0
Very low degree	1	90	19.9	39	9.0
Not at all	0	77	17.0	7	1.6
		TOTAL 453	100.0	TOTAL 431	100.0
		Mean = 2.5		Mean = 3.5	

As with previous issues, the first noticeable result for the impacts of irrigation water shortage is the significant difference between those experienced personally and by others. Mean scores for the whole sample were between low to moderate, and moderate to high respectively.

There were no differences among the four samples regarding personal impacts. However, for impacts on others, the upper urban sample had a significantly higher mean score than all other samples, particularly the lower rural sample (4.2 and 2.9 respectively).

Declining human health

		affects you personally		affects people in the Herbert	
Response	**Rating**	**N (452)**	**Percent**	**N (424)**	**Percent**
very high degree	5	143	31.6	122	28.8
high	4	63	13.9	72	17.0
moderate	3	94	20.8	113	26.7
low	2	55	12.2	64	15.1
very low degree	1	66	14.6	42	9.9
not at all	0	31	6.9	11	2.6
		TOTAL 452	100.0	TOTAL 424	100.0
		Mean = 3.2		Mean = 3.3	

For both personal impacts and those experienced by others, the means scores indicate declining human health to be considered as a moderate problem. The fact that more than 45 percent of the sample considered they and others were affected to a high or very high degree is also noteworthy. Notably, most of those not at all affected were from the urban sample (nearly 80 percent).

Interestingly, while the difference in mean scores appears negligible, it was statistically significant. This was due principally to a more marked increase in the mean scores between the two urban samples, while both rural samples tended to be more stable.

Next, compared with the upper rural sample, the two lower catchment samples were more likely to report being affected by declining health. This was also the case when comparing only the upper urban and lower urban samples. For effects on others, compared with the upper rural sample, those from the lower urban sample were more likely to consider these as high.

Loss of independence to make business decisions

		affects you personally		affects people in the Herbert	
Response	**Rating**	**N (444)**	**Percent**	**N (413)**	**Percent**
very high degree	5	117	26.4	108	26.2
high	4	71	16.0	102	24.7
moderate	3	76	17.1	108	26.2
low	2	60	13.5	48	11.6
very low degree	1	58	13.1	31	7.5
not at all	0	62	14.0	16	3.9
		TOTAL 444	100.0	TOTAL 413	100.0
		Mean = 2.9		Mean = 3.4	

On average, loss of independence was rated as having a moderate impact personally and a moderate to high impact on others. Once again, this difference was significant. However, as for preceding impacts there was no difference between means for the lower rural sample. While it might be anticipated that urban residents would be more likely to see loss of independence as having a greater impact on others (namely rural producers), this was also the case for the upper rural sample.

Following on from this finding, compared with all other samples, those in the lower rural sample were more likely to state loss of independence as a problem. The mean score for this sample was 3.4, with the three other means being below 3.

In terms of the impacts on others, no significant differences were evident.

Emotional stress

		affects you personally		affects people in the Herbert	
Response	**Rating**	**N (448)**	**Percent**	**N (411)**	**Percent**
Very high degree	5	87	19.4	77	18.7
High	4	69	15.4	77	18.7
Moderate	3	100	22.3	152	37.0
Low	2	85	19.0	73	17.8
Very low degree	1	64	14.3	21	5.1
Not at all	0	43	9.6	11	2.7
		TOTAL 448	100.0	TOTAL 411	100.0
		Mean = 2.8		Mean = 3.2	

Both mean scores for the impact of emotional stress were around the moderate mark, with the effect on others being significantly higher.

There was only one significant difference among the four samples. Compared with both upper catchment samples (mean scores both 2.4), the lower rural sample considered emotional stress to have more of a personal impact (mean 3.1). As previously, ratings for personal impacts and those on others were more uniform within the lower rural sample.

Conflicts with other local people

		affects you personally		affects people in the Herbert	
Response	**Rating**	**N (451)**	**Percent**	**N (413)**	**Percent**
Very high degree	5	47	10.4	54	13.1
High	4	34	7.5	49	11.9
Moderate	3	74	16.4	146	35.4
Low	2	110	24.4	93	22.5
Very low degree	1	120	26.6	60	14.5
Not at all	0	66	14.6	11	2.7
		TOTAL 451	100.0	TOTAL 413	100.0
		Mean = 2.1		Mean = 2.8	

The two mean scores for the impact of conflicts with other local people ranged roughly from low to moderate, with the effect on others being significantly higher. While the ranges for both rural samples tended to be smaller (when compared with the urban samples), the differences were significant.

For the four samples, the only difference in means was between the lower rural and upper urban samples. The lower sample was more likely to consider conflict as having a personal effect (although to only just over a low degree). This difference also translated into a distinction between the lower and upper catchments, with the former also being more likely to consider conflict as having a personal effect.

There were no other significant differences between samples.

Higher taxes

		affects you personally		affects people in the Herbert	
Response	**Rating**	**N (453)**	**Percent**	**N (425)**	**Percent**
very high degree	5	221	48.8	212	49.9
high	4	111	24.5	125	29.4
moderate	3	63	13.9	63	14.8
low	2	22	4.9	11	2.6
very low degree	1	23	5.1	8	1.9
not at all	0	13	2.9	6	1.4
		TOTAL 453	100.0	TOTAL 425	100.0
		Mean = 4.0		Mean = 4.2	

Compared with all other potential impacts put forward in the questionnaire, the effect of higher taxes (closely followed by loss of confidence in government to be discussed below) was considered to have the highest impact. This was around high for both mean scores and, despite their similarity, the effect on others was significantly higher. As for many previous issues, this occurred even though there was no difference between means for the lower rural sample.

Compared with both upper catchment samples, the lower rural sample was more likely to feel personally affected by higher taxes (the mean score for this sample was 4.3 and, for the lower urban sample, 4.0). There were no differences between samples for the effects of higher taxes on others.

Lower fish numbers

		affects you personally		affects people in the Herbert	
Response	**Rating**	**N (454)**	**Percent**	**N (429)**	**Percent**
very high degree	5	164	36.1	141	32.9
high	4	85	18.7	119	27.7
moderate	3	83	18.3	112	26.1
low	2	55	12.1	32	7.5
very low degree	1	32	7.0	20	4.7
not at all	0	35	7.7	5	1.2
		TOTAL 454	100.0	TOTAL 429	100.0
		Mean = 3.4		Mean = 3.7	

While both mean scores for the impact of lower fish numbers were similar and between moderate and high, the *perceived* impact on others was significantly higher. Again, there was only a slight (non-significant) difference between means for the lower rural sample.

Differences among the four samples were the same for personal impacts and for those on others. The major difference was seen by combining the samples into upper and lower groups, with the mean impact for those in the lower catchment approaching high and for the upper catchment slightly below moderate (means were 3.7 and 2.8 respectively). In particular, those living in Taylors Beach (and, to a lesser extent, Lucinda and Halifax) were likely to consider the impacts as high (mean 4.4).

Clearly, and not surprisingly, fishing appears to be more of a recreational activity in the lower catchment, especially for those living closer to the coast.

Loss of access to recreation

		affects you personally		affects people in the Herbert	
Response	**Rating**	**N (450)**	**Percent**	**N (429)**	**Percent**
Very high degree	5	140	31.1	137	31.9
High	4	100	22.2	108	25.2
Moderate	3	97	21.6	118	27.5
Low	2	42	9.3	35	8.2
Very low degree	1	38	8.4	20	4.7
Not at all	0	33	7.3	11	2.6
		TOTAL 450	100.0	TOTAL 429	100.0
		Mean = 3.4		Mean = 3.6	

For loss of access to recreation, more than 50 percent of the sample considered impacts experienced personally and by others as high or very high. Both mean scores were between moderate and high, with the latter being significantly higher. The means for all samples tended to rise.

The only significant difference concerned impacts on others. Lower urban participants considered the impacts of loss of access as higher than both upper catchment samples.

Loss of confidence in government's ability to manage land and water resources

		affects you personally		affects people in the Herbert	
Response	**Rating**	**N (453)**	**Percent**	**N (427)**	**Percent**
Very high degree	5	197	43.5	169	39.6
High	4	98	21.6	105	24.6
Moderate	3	112	24.7	114	26.7
Low	2	26	5.7	24	5.6
Very low degree	1	13	2.9	14	3.3
Not at all	0	7	1.5	1	.2
		TOTAL 453	100.0	TOTAL 427	100.0
		Mean = 3.9		Mean = 3.9	

As can be seen, both mean scores for the impact of loss of confidence in government were high and the same (to one decimal place), and there was no significant difference between them. Therefore, unlike previous impacts, loss of confidence in government was high in both rural and urban areas throughout the catchment.

All means for all samples centred around high (between 3.7 and 4.1). The means just noted provided the only difference between the samples, with the lower urban sample considering the impacts on others to be higher than the lower rural sample.

While both mean scores for the impact of loss of environmental uses/benefits were similar (generally moderate), the perceived impact on others was - unusually - significantly lower.

The only other differences were between the upper rural and lower urban sample, with the latter tending to rate the personal impact as higher (means were 3.1 and 3.7 respectively) and the impact on others also as higher (means were 3.0 and 3.5 respectively). In particular, those living in Taylors Beach (and, to a lesser extent, Halifax) rated the personal impact as higher (mean 4.3). The average rating provided by Ingham residents (3.2) was the second lowest of the 8 settlements (only Mount Garnet was lower).

Loss of environmental uses or benefits

		affects you personally		affects people in the Herbert	
Response	**Rating**	**N (450)**	**Percent**	**N (421)**	**Percent**
very high degree	5	128	28.4	86	20.4
high	4	89	19.8	73	17.3
moderate	3	124	27.6	163	38.7
low	2	58	12.9	66	15.7
very low degree	1	30	6.7	24	5.7
not at all	0	21	4.7	9	2.1
		TOTAL 450	100.0	TOTAL 421	100.0
		Mean = 3.4		Mean = 3.2	

Loss of scenery

		affects you personally		affects people in the Herbert	
Response	**Rating**	**N (449)**	**Percent**	**N (420)**	**Percent**
very high degree	5	114	25.4	71	16.9
high	4	76	16.9	55	13.1
moderate	3	116	25.8	154	36.7
low	2	52	11.6	66	15.7
very low degree	1	58	12.9	57	13.6
not at all	0	33	7.3	17	4.0
		TOTAL 449	100.0	TOTAL 420	100.0
		Mean = 3.1		Mean = 2.9	

Both mean scores for the impact of loss of scenery were similar (moderate) and, as for the impact of lost environmental uses, the perceived impact on others was also significantly lower. However, a drop in ratings was only apparent for the lower urban and, to a lesser extent, the upper rural sample.

For personal impacts, compared with the other three samples, the lower urban sample tended to rate loss of scenery as having a higher impact (mean 3.6). All other samples had mean scores of 3 or below. Again, of the lower urban sample locations, those living in Taylors Beach rated the impact as highest (mean 4.1).

For others, compared with the upper rural sample, the lower urban sample rated the impact as higher (means were 2.5 and 3.2 respectively).

4.5.6 Summary

For personal impacts, from highest to lowest, the seven highest impacts included higher taxes, loss of confidence in government's ability to manage land and water resources, higher production costs, lower fish numbers, loss of environmental uses/benefits, loss of access to recreation, and poor drinking water quality. In particular, higher taxes and loss of confidence in government were highly rated.

Loss of farm productivity was also considered a high impact for the lower rural sample. Interestingly, conflict with other local people was considered the lowest impact for the whole sample.

For impacts on others, from highest to lowest, the seven highest impacts included higher taxes, higher production costs, poor drinking water quality, loss of confidence in government, loss of

farm productivity, lower fish numbers, and loss of access to recreation. Higher taxes and higher production costs were the two issues with a mean score higher than 4.

4.6 Tractability

This component of the questionnaire examined how manageable (or practical) catchment management might be, given perceptions of possible impediments to effectively managing land and water in the catchment.

Participants were asked to rate how much they agreed or disagreed with a series of statements, with each underlining a potential obstacle to managing land and water. The fourteen statements are as follows.

Managing land and water in the Herbert is difficult because...

(1) problems aren't well understood

Response	Rating	N (458)	Percent
strongly agree	5	100	21.8
agree	4	224	48.9
neither agree nor disagree	3	71	15.5
disagree	2	48	10.5
strongly disagree	1	15	3.3
	TOTAL	458	100.0
Mean = 3.8			

The mean score (3.8) and the fact that nearly 50 percent of the whole sample agreed, shows general agreement with this statement. There was no significant difference among the four samples.

(2) solutions aren't easy

Response	Rating	N (463)	Percent
strongly agree	5	109	23.5
agree	4	265	57.2
neither agree nor disagree	3	36	7.8
disagree	2	45	9.7
strongly disagree	1	8	1.7
	TOTAL	463	100.0
Mean = 3.9			

The mean score (3.9) and the fact that more than 57 percent of the whole sample agreed, indicates general agreement with this statement. While there was no significant difference specifically among the four samples, compared with the upper catchment, those in the lower catchment sample were more likely to agree that solutions are not easy (means were 3.7 and 4 respectively).

(3) there aren't any problems that need urgent action

Response	Rating	N (458)	Percent
Strongly agree	5	14	3.1
Agree	4	29	6.3
Neither agree nor disagree	3	55	12.0
Disagree	2	209	45.6
Strongly disagree	1	151	33.0
	TOTAL	458	100.0
Mean = 2.0			

Notably, nearly 90 percent of the sample chose to disagree or strongly disagree that there are no problems requiring urgent action. No significant differences were evident for this statement, with all samples showing a large amount of disagreement.

(4) local people lack the money to spend on solutions

Response	Rating	N (463)	Percent
Strongly agree	5	79	17.1
Agree	4	211	45.6
Neither agree nor disagree	3	82	17.7
Disagree	2	64	13.8
Strongly disagree	1	27	5.8
	TOTAL	463	100.0
Mean = 3.5			

As the frequencies and mean score indicate, nearly 63 percent of the sample agreed or strongly agreed that local people lack money to spend on solutions.

There were a number of significant differences among the four samples. First, compared with the other three samples, participants in the lower urban sample were less likely to agree (the mean score was close to the midpoint of 3, while upper catchment means were both 3.9). In addition, the lower rural sample was also less likely to agree than both upper catchment samples, thus indicating a difference between the two catchments generally.

In review, while the lower urban sample was less likely to agree (including when compared with the lower rural sample), as a whole, lower catchment participants were significantly less likely to agree than those in the upper catchment. Put another way, those in the upper catchment were *more* likely to agree that local people lack money to spend on solutions. Of interest, this was particularly the case for Mount Garnet residents (mean 4.4).

(5) government strategies are a waste of time

Response	Rating	N (460)	Percent
strongly agree	5	62	13.5
agree	4	107	23.3
neither agree nor disagree	3	183	39.8
disagree	2	88	19.1
strongly disagree	1	20	4.3
	TOTAL	460	100.0
Mean = 3.2			

Nearly 40 percent of the sample chose to neither agree nor disagree with this statement, and there was also a reasonable spread of scores across the scale. There was no significant difference among the four samples. Therefore, throughout the catchment, the issue of whether government strategies are a waste of time is likely to bring out a broad range of responses, including many along the lines of neither agree nor disagree.

(6) solutions are expensive

Response	**Rating**	**N (463)**	**Percent**
strongly agree	5	104	22.5
agree	4	256	55.3
neither agree nor disagree	3	63	13.6
disagree	2	35	7.6
strongly disagree	1	5	1.1
	TOTAL	463	100.0

Mean = 3.9

The means score (3.9) and the fact that more than 55 percent of the whole sample chose to agree, indicates general agreement that solutions are expensive. There was no significant difference among the four samples. Perhaps of some note, the 5 people who chose to disagree strongly were from the urban samples.

(7) there are few benefits and many costs

Response	**Rating**	**N (459)**	**Percent**
strongly agree	5	45	9.8
agree	4	114	24.8
neither agree nor disagree	3	96	20.9
disagree	2	171	37.3
strongly disagree	1	33	7.2
	TOTAL	459	100.0

Mean = 2.9

The table shows that the whole sample appeared somewhat split between those who agreed and those who disagreed that there are few benefits and many costs. This being noted, the statement averaged out as one in which the whole sample neither agreed nor disagreed (mean 2.9). Finally, no significant difference was evident among the four samples. However, on a more specific level, residents of Ingham were more likely to agree than Ravenshoe residents.

(8) local people don't want to spend money on solutions

Response	**Rating**	**N (460)**	**Percent**
Strongly agree	5	47	10.2
Agree	4	172	37.4
Neither agree nor disagree	3	137	29.8
Disagree	2	93	20.2
Strongly disagree	1	11	2.4
	TOTAL	460	100.0

Mean = 3.3

There was a reasonable amount of agreement that local people do not want to spend money on solutions. However, the mean score and frequencies in the table indicate that, on average, participants tended to neither agree nor disagree. There were no significant differences between samples.

(9) the Herbert River catchment covers a large area

Response	Rating	N (461)	Percent
Strongly agree	5	142	30.8
Agree	4	272	59.0
Neither agree nor disagree	3	19	4.1
Disagree	2	24	5.2
Strongly disagree	1	4	.9
	TOTAL	461	100.0
Mean = 4.1			

As can be seen, there was very high agreement that the catchment covers a large area. Indeed, more than 60 percent of participants agreed and nearly 90 percent agreed or strongly agreed with this statement. There were no significant differences between samples.

(10) it's hard to get around the catchment (eg. from top to bottom)

Response	Rating	N (456)	Percent
Strongly agree	5	111	24.3
Agree	4	219	48.0
Neither agree nor disagree	3	79	17.3
Disagree	2	41	9.0
Strongly disagree	1	6	1.3
	TOTAL	456	100.0
Mean = 3.8			

The table indicates general acknowledgement of the difficulty of moving around the catchment (mean 3.8). No significant differences were evident among samples.

(11) people in the Herbert have a wide variety of opinions

Response	Rating	N (464)	Percent
strongly agree	5	79	17.0
agree	4	274	59.1
neither agree nor disagree	3	77	16.6
disagree	2	30	6.5
strongly disagree	1	4	.9
	TOTAL	464	100.0
Mean = 3.8			

The mean score and frequencies display general agreement that a wide variety of opinions exist in the Herbert (mean 3.8). There were no significant differences between samples.

An interesting comparison exists between the high level of agreement for this statement and the finding that conflict with other local people tended to be rated as a low impact. The two items

were not related. Therefore, while the existence of numerous opinions may impede land and water management in the Herbert, this may not, or has yet to, generate high levels of conflict among local people. From this, it might be suggested that, as a whole, the catchment community is likely to be resilient.

(12) local people don't trust government programs

Response	Rating	N (462)	Percent
strongly agree	5	111	24.0
agree	4	208	45.0
neither agree nor disagree	3	113	24.5
disagree	2	29	6.3
strongly disagree	1	1	.2
	TOTAL	462	100.0

Mean = 3.9

As above, the tendency was to agree with this statement (mean 3.9). There were no significant differences between samples. Across the board, level of trust in government therefore appears to be a key issue facing ICM in the Herbert.

(13) local people aren't that interested in community-type activities

Response	Rating	N (459)	Percent
strongly agree	5	24	5.2
agree	4	104	22.7
neither agree nor disagree	3	138	30.1
disagree	2	169	36.8
strongly disagree	1	24	5.2
	TOTAL	459	100.0

Mean = 2.9

While approximately 37 percent of the sample disagreed, this statement averaged out as one in which the whole sample neither agreed nor disagreed (mean 2.9). While no significant differences existed among the four samples, when comparing urban areas, Herberton residents were more likely to agree than those in Ingham (means 3.1 and 2.4 respectively).

(14) the government doesn't want to spend money on solutions

Response	Rating	N (463)	Percent
Strongly agree	5	100	21.6
Agree	4	174	37.6
Neither agree nor disagree	3	133	28.7
Disagree	2	52	11.2
Strongly disagree	1	4	.9
	TOTAL	463	100.0

Mean = 3.7

The mean score (3.7) and frequencies (more than 59 percent agreed or strongly agreed) indicate widespread agreement that the government does not want to spend money on solutions. There were no significant differences between samples.

4.6.5 Summary

In summary, from highest to lowest, the seven highest impediments to managing land and water in the Herbert were considered to be:

- the catchment's large area;
- a lack of easy solutions;
- the cost of solutions;
- low trust of government programs;
- the difficulty in moving around the catchment;
- the wide variety of opinions held by local people;
- insufficient understanding of relevant problems.

Also noteworthy, the three lowest potential impediments (all with mean scores below 3) included the statements "there are few benefits and many costs", "local people aren't that interested in community-type activities", and "there aren't any problems that need urgent action". In particular, participants tended to disagree most often with this final statement.

4.7 Knowledge of Government Strategies

Before we contacted you about this study, which of the following government strategies had you heard about?

		Property Management Planning (PMP)		Landcare		Integrated Catchment Management (ICM)	
Response	**Rating**	**N(475)**	**Percent**	**N(475)**	**Percent**	**N(475)**	**Percent**
Yes	1	123	25.9	406	85.5	178	37.5
No	2	352	74.1	69	14.5	297	62.5
TOTAL		475	100.0	475	100.0	475	100.0

The table shows that Landcare was by far the most familiar strategy to participants in the study. In brief, those who had not heard about Landcare were more likely to be in the urban samples, particularly the lower urban sample. Those who had heard about ICM and PMP were most likely to come from the lower rural sample (60 and 55 percent respectively).

Which strategy did you know most about?

Response	**Rating**	**N (453)**	**Percent**
PMP	1	12	2.6
Landcare	2	333	73.5
ICM	3	47	10.4
don't know of any	4	61	13.5
	TOTAL	453	100.0

As shown, the bulk of the sample (73.5 percent) knew most about Landcare.

Interestingly, 11 of the 12 people who knew most about PMP, and 42 of the 47 who knew most about ICM, resided in the lower catchment. Thus, the clear majority of people in the upper catchment (82.6 percent) knew most about Landcare.

Looking at differences between the rural and urban samples, for the latter, only 2 people, and 8 people knew most about PMP and ICM respectively. Of those who had not heard of any of the strategies, 40 of the 61 people were from the urban sample.

When thinking of the government strategy you know most about:

(1) how useful has this strategy been to you personally?

Response	Rating	N (380)	Percent
very useful	5	20	5.3
quite	4	36	9.5
moderately	3	102	26.8
not very	2	122	32.1
not at all useful	1	100	26.3
	TOTAL	380	100.0

Mean = 2.4

Only those who had heard of at least one of the strategies were asked to respond to this question. Notably, nearly 60 percent of the participants responded that the strategy had been not at all useful or not very useful. Looking at the results for PMP, Landcare and ICM separately, the mean responses were 3.0 (only 12 responses), 2.3 and 2.4 respectively (generally, moderately to not very useful).

For ICM, this figure may not be overly concerning given the fact that ICM in the Herbert is at an early stage of development. For Landcare, the lack of usefulness may be more of a concern given that it is a more established, localised and "hands on" approach than ICM. As noted below, however, very few of the sample were members of Landcare groups and this likely explains the figures in the above table.

(2) how effective has the strategy been in dealing with land and water issues in the Herbert?

Response	Rating	N (374)	Percent
Very effective	5	6	1.6
Fairly effective	4	100	26.7
Neither effective nor ineffective	3	130	34.8
Fairly ineffective	2	108	28.9
Very ineffective	1	30	8.0
	TOTAL	374	100.0

Mean = 2.9

Looking at the results for PMP, Landcare and ICM separately, the mean responses were 3.3 (only 12 responses), 2.8 and 2.8 respectively. Interestingly, when comparing the strategy's personal usefulness with their effectiveness generally, the mean scores were more positive and all increased significantly.

(3) how did you come to know of the strategy?

This was an open-ended question allowing up to two responses (for each strategy). Percentages show, for those providing at least one response (334), how many people gave a particular response. Some of the more prominent sources of knowledge about the three strategies are noted in the following table.

Sources of knowledge	N	Percent
Newspapers	79	23.7
Television / television advertisements	72	21.6
Media (in general)	44	13.2
Word of mouth	40	12.0
Meetings (in general)	31	9.3
Canegrowers meetings	22	6.6
Radio / radio talk shows	22	6.6
Reading	17	5.1
Advertisements (in general)	12	3.6
Canegrowers magazine	12	3.6
Local pamphlets	9	2.7
Personal experience	8	2.4
Landcare	6	1.8

In total, 429 responses were provided, of which 352 (more than 82 percent) appear in the table.

Notably, 67 percent of the responses could be classified as media sources (ie. a combination of the newspaper, television, media and radio responses).

Of those who knew most about PMP, the most common response was personal experience (4). For ICM, 15 people stated their sources to be meetings, while 7 people were more specific in stating canegrowers meetings. Other ways of knowing about ICM included newspapers (6), drainage boards (3), word of mouth (3), and the Canegrowers Magazine (2).

With approximately three quarters of this sample, Landcare accounted for the bulk of the responses. Most common were newspapers (72 of 79 in total), television (69 of 72), media (42 of 44), word of mouth (34 of 40), radio (22 of 22), and reading (15 of 17).

Have you heard of a group called the Herbert River Catchment Coordinating Committee?

Response	Rating	N (425)	Percent
Yes	1	93	21.9
Vaguely	2	86	20.2
No	3	246	57.9
	TOTAL	425	100.0

Interestingly, of those who had definitely heard about the Herbert River Catchment Coordinating Committee (HRCCC), 68 were from the lower rural sample (41 percent of this sample). Only 8 and 4 people had definitely heard about the HRCCC in the upper catchment rural and urban samples (14 and 5 percent of these samples) respectively. Thirteen people (10 percent) of the lower urban sample had heard of the HRCCC.

From lowest to highest, those who responded "Yes" or "Vaguely" comprised 17, 31, 34, and 65 percent of the upper urban, lower urban, upper rural and lower rural samples respectively. This result could have been expected, given that ICM may have more of a presence in the lower catchment and a greater focus on rural (rather than urban) resource management issues.

Of further interest, it is noteworthy that 179 people had heard of the HRCCC and 178 people had heard about ICM, with both figures being in the order of 40 percent. More than three quarters of those who had heard about ICM had heard of the HRCCC, while more than 21 percent of those who had not hear about ICM had at least vaguely heard about the HRCCC.

If YES or VAGUELY, what do you think the main purpose of this group is?

This was an open-ended question allowing up to two responses. Of these, a variety of responses were given. Some of the more prominent purposes of the HRCCC are summarised in the following table. The figures in the percent column are in relation to the total number of participants who provided at least one response (161).

Note that categories were formed to maintain detail and ease of presentation and, therefore, may not be mutually exclusive.

Purpose of HRCCC	**N**	**Percent**
Improve drainage systems (including in newly developed areas)	34	21.1
Preserve waterways (including land quality and river banks)	23	14.3
Conserve and manage water	21	13.0
Care for the catchment area	14	8.7
Coordinate river use	12	7.4
Control / mitigate flooding in the lower catchment (including a suggestion to dredge the Herbert River)	10	6.2
Raise awareness / inform the public of existing problems	8	5.0
Coordinate groups to discuss problems (such as drainage)	8	5.0
Calculate regular flood areas	7	4.3
Maintain flow in the Herbert River and creeks / keep it clean	7	4.3
Not sure / it has never been fully publicised locally	7	4.3
Form strategies to assist the community (eg. to help with drainage disputes)	6	3.7
Combine all drainage boards into one body (eg. to cut costs and improve effectiveness)	6	3.7
Dam the river	3	1.9
Monitor fertiliser runoff	3	1.9

In total, 196 responses were provided, of which 169 (more than 86 percent) appear in the table.

As can be seen, a variety of purposes were put forward. Most of the responses related primarily to water issues and many thought the purpose was fairly hands-on; for example, to improve drainage, control flooding, calculate flood areas, maintain river flow, and dam the river. Others, such as caring for the catchment area, raising awareness and forming strategies were more general.

4.8 Responsibility and Control, Views on Government, and Awareness and Intentions

In the next three sections, participants were asked to rate how much they agreed or disagreed with the following statements. The statements were organised into the three general areas of responsibility and control, views on government, and awareness and intentions. In brief, the perceived ability of residents to control land and water management issues, the assigned responsibility for dealing with such issues, views on government (including levels of trust and perceived competence), and levels of awareness and intentions (including preparedness to become involved in relevant activities) were all considered potential influences on the implementation of ICM.

In the tables below, means are only pertinent for issues considered applicable (which participants rated between 1 and 5). Thus, those who considered any issue not applicable were not included within analysis of that issue.

4.8.1 Responsibility and Control

There are things I can do personally to help improve the environment

Response	Rating	N (459)	Percent
strongly agree	5	77	16.8
agree	4	250	54.5
neither agree nor disagree	3	85	18.5
disagree	2	24	5.2
strongly disagree	1	7	1.5
not applicable		16	3.4
	TOTAL	459	100.0

Mean = 3.8

The mean score (3.8) and frequencies display widespread agreement with this statement. There were no significant differences between samples.

I don't usually have the finances available to plan more than a year ahead

Response	Rating	N (457)	Percent
Strongly agree	5	95	20.8
agree	4	197	43.1
neither agree nor disagree	3	68	14.9
disagree	2	59	12.9
strongly disagree	1	8	1.8
not applicable		30	6.6
	TOTAL	457	100.0

Mean = 3.7

The clear majority (nearly 64 percent) of the sample chose to agree or strongly agree with this statement. Therefore, the mean score (3.7) shows that lack of finances may be a hindrance to the establishment of more long-term planning time frames.

There was also a significant relationship between this item and levels of agreement that locals people lack the money to spend on solutions.

Concerning significant differences, while all four samples were likely to agree with the statement, compared with the two urban samples, those in the lower rural sample were less likely to agree (mean 3.5 compared with the upper urban mean of 4.1). Put another way, compared with the

lower rural sample, participants in the urban samples were more likely to agree they do not usually have the finances available to plan more than a year ahead. This was particularly evident for those living in Mount Garnet (mean 4.4).

While not significantly different, the mean score for the upper rural sample more closely matched those of the two urban samples.

Finally, of those who considered the statement as not applicable, 18 (60 percent) were from the lower urban sample.

The local community should take some responsibility for improving the environment

Response	**Rating**	**N (466)**	**Percent**
Strongly agree	5	113	24.2
agree	4	296	63.5
neither agree nor disagree	3	36	7.7
disagree	2	9	1.9
strongly disagree	1	8	1.7
not applicable		4	.9
TOTAL	466	100.0	

Mean = 4.1

The results in the table show that this was very much an "agree with" statement, with more than 87 percent of the sample choosing to agree or strongly agree. There were no significant differences between samples.

There are things local community groups can do to help improve the environment

Response	**Rating**	**N (458)**	**Percent**
strongly agree	5	78	17.0
agree	4	332	72.5
neither agree nor disagree	3	39	8.5
disagree	2	5	1.1
strongly disagree	1	2	.4
not applicable		2	.4
TOTAL		458	100.0

Mean = 4.0

As for the previous statement, there was widespread agreement that local community groups can undertake activities to help improve the environment. Nearly 90 percent of the sample agreed or strongly agreed with the statement, while only 7 people chose to disagree or strongly disagree (interestingly, of the latter, none were from the upper rural sample). Finally, there were no significant differences between samples.

Many environmental problems come from the way people manage their properties

Response	Rating	N (463)	Percent
strongly agree	5	101	21.8
agree	4	244	52.7
neither agree nor disagree	3	75	16.2
disagree	2	36	7.8
strongly disagree	1	5	1.1
not applicable		2	.4
	TOTAL	463	100.0

Mean = 3.9

Again, the mean score and frequencies in the table show widespread agreement. Indeed, nearly three quarters of the sample agreed or strongly agreed that many environmental problems come from the way people manage their properties.

Regarding any significant difference among the four samples, compared with upper rural and lower urban samples, the lower rural sample was less likely to agree with this statement (mean scores ranged from 3.7 to 4.1).

I can prevent any land and water problems from occurring on my property

Response	Rating	N (454)	Percent
strongly agree	5	47	10.4
agree	4	200	44.1
neither agree nor disagree	3	70	15.4
disagree	2	66	14.5
strongly disagree	1	22	4.8
not applicable		49	10.8
	TOTAL	454	100.0

Mean = 3.5

As expected, many participants did not consider this issue to apply to them. Of the 49 people who held this view, 43 were from the combined urban sample (88 percent) and, of these, 36 were from the lower urban sample (73 percent).

The table shows evidence of widespread agreement, and it is also noteworthy that less than 20 percent of the sample disagreed or strongly disagreed that land and water problems were preventable. The major difference between samples was between the upper and lower catchment sample. With means around 3.3, those in the lower catchment samples were less likely to agree with this statement. This distinction is likely to be related to differing environmental issues, the most prominent of which are incidences of periodic flooding, and some concerns regarding drainage.

Many participants also considered this issue as not applicable. Of the 42 people who held this view, 37 were from the combined urban sample (88 percent) and, of these, 30 were from the lower urban sample (71 percent). Much greater than any other sample, 23 percent of the lower urban sample regarded the issue as not applicable.

The mean score (2.9) resulted largely from a spread of ratings across the scale and, in particular, the frequencies revealed a division between those who agreed and disagreed.

I've complete control over what happens to the land and water on this property

Response	Rating	N (457)	Percent
Strongly agree	5	28	6.1
agree	4	144	31.5
neither agree nor disagree	3	68	14.9
disagree	2	129	28.2
strongly disagree	1	46	10.1
not applicable		42	9.2
	TOTAL	457	100.0
Mean = 2.9			

As they appear related, an interesting comparison exists between this statement and the statement, "I can prevent any land and water problems from occurring on my property". The latter provided a higher level of agreement (mean 3.5), while approximately twice as many participants chose to disagree or strongly disagree that they had complete control over land and water. A small number of participants who disagreed that they could prevent land and water problems from occurring agreed that they had complete control over land and water (although there was a strong tendency to disagree with both). On the other hand, 40 percent (70 people) of those who disagreed they had complete control agreed they could prevent problems from occurring.

Obviously prevention and complete control are similar although in many ways different notions. However, the relationship between the two statements was highly significant.

In terms of any significant differences between samples, compared with the lower rural sample, those in the lower urban sample were more likely to agree with this statement. This finding is notable when recalling that, for the issue regarding the prevention of land and water problems, the major difference between samples was between the upper and lower catchment. Indeed, in contrast, the difference between the combined rural and urban samples was also significant. In other words, those in urban areas generally felt they had more control over land and water on their properties.

This finding also indicates that the perceived ability to prevent and control land and water problems was lowest in the lower rural sample.

Laws should be changed to make landholders more responsible for the consequences of their activities

Response	Rating	N (456)	Percent
strongly agree	5	84	18.4
agree	4	179	39.3
neither agree nor disagree	3	116	25.4
disagree	2	50	11.0
strongly disagree	1	22	4.8
not applicable		5	1.1
	TOTAL	456	100.0
Mean = 3.6			

The mean score (3.6) and frequencies display a high level of agreement that laws should be changed to increase responsibility. Of the 72 people who disagreed or strongly disagreed, 45 (62

percent) were from the lower rural sample and 53 (74 percent) were from the combined rural sample.

In terms of significant differences between samples, compared with the two rural samples, those in the lower urban sample were more likely to agree with this statement (mean 4.0). Further, compared with the lower rural sample (which was the most ambivalent in responding to the statement), the upper urban sample was also more likely to agree (means 3.2 and 3.7 respectively). As such, the difference between the combined rural and urban samples was significant and, once again, the biggest difference was between the lower rural and lower urban samples.

It was also noted that the mean score for Ingham residents (3.6) was significantly lower than for the other four sample locations in the lower catchment (all other means were above 4.0 and for Halifax was 4.5)

It's too hard to think about land and water management issues for an area as big as the Herbert catchment

Response	Rating	N (462)	Percent
strongly agree	5	16	3.5
agree	4	47	10.2
neither agree nor disagree	3	70	15.2
disagree	2	223	48.3
strongly disagree	1	99	21.4
not applicable		7	1.5
	TOTAL	462	100.0
Mean = 2.2			

Interestingly, while the whole sample tended to agree that managing land and water in the Herbert may be difficult because of the catchment's large area, nearly 70 percent disagreed or strongly disagreed that thinking about relevant issues for an area this large is too hard. Thus, the general conclusion for the sample that might be drawn here is that while land and water management on a catchment basis is considered difficult, at the very least, conceptualising such issues is far from impossible.

Of further interest, there was one significant difference among the four samples. While all samples tended to disagree, compared with the lower rural sample, the upper rural sample was more likely to disagree (means 1.9 and 2.3 respectively).

While this difference is only in terms of degree, it is nonetheless an interesting finding given that the upper area of the Herbert occupies the largest part of the catchment.

4.8.2 Views on Government

Governments should work out better ways to fix land and water problems

Response	Rating	N (463)	Percent
Strongly agree	5	118	25.5
agree	4	243	52.5
neither agree nor disagree	3	76	16.4
disagree	2	16	3.5
strongly disagree	1	6	1.3
not applicable		4	.9
	TOTAL	463	100.0
Mean = 4.0			

The majority of the sample (78 percent) agreed or strongly agreed that governments should work out better ways to fix land and water problems. All four samples tended to agree with this statement and, as a result, no significant differences were evident.

I trust that public servants are working in my interest most of the time

Response	Rating	N (463)	Percent
Strongly agree	5	24	5.2
agree	4	159	34.3
neither agree nor disagree	3	125	27.0
disagree	2	88	19.0
strongly disagree	1	60	13.0
not applicable		7	1.5
	TOTAL	463	100.0
Mean = 3.0			

While there was some agreement with this statement, on average, the sample mean (3.0) was placed at the midpoint of the scale (neither agree nor disagree).

In terms of significant differences, compared with upper and lower rural samples, the upper urban sample was more likely to agree. Both rural samples returned mean scores below 3.

I've seen incompetent government activities in this part of the country

Response	Rating	N (455)	Percent
strongly agree	5	104	22.9
agree	4	207	45.5
neither agree nor disagree	3	89	19.6
disagree	2	30	6.6
strongly disagree	1	17	3.7
not applicable		8	1.8
	TOTAL	455	100.0
Mean = 3.8			

As with some previous issues, responses to this statement were markedly skewed to the top end of the scale. Nearly 70 percent of participants agreed or strongly agreed that they had witnessed government incompetence locally. Given ICM's need to establish a solid community profile, this strong level of agreement is clearly an important finding. There were no significant differences between samples.

Programs like Integrated Catchment Management interfere with people's rights to make their own decisions

Response	Rating	N (446)	Percent
strongly agree	5	17	3.8
agree	4	85	19.1
neither agree nor disagree	3	205	46.0
disagree	2	104	23.3
strongly disagree	1	22	4.9
not applicable		13	2.9
	TOTAL	446	100.0
Mean = 2.9			

A fairly even spread of ratings, and the fact that a large proportion of the sample (46 percent) chose to neither agree nor disagree acted to produce the mean score of 2.9. Hence, there was neither widespread agreement nor disagreement with this statement. Further, while those in the lower rural sample appeared most likely to agree, any differences between samples were not significant.

I am sure that our local views will be considered when planning for land and water management in this area

Response	Rating	N (461)	Percent
strongly agree	5	28	6.1
agree	4	152	33.0
neither agree nor disagree	3	144	31.2
disagree	2	101	21.9
strongly disagree	1	33	7.2
not applicable		3	.7
	TOTAL	461	100.0

Mean = 3.1

Ratings for this statement were reasonably spread, thus producing the mean score of 3.1 for the whole sample. There were no significant differences between samples.

I can recall at least one government action which has damaged my livelihood

Response	Rating	N (447)	Percent
Strongly agree	5	75	16.8
agree	4	117	26.2
neither agree nor disagree	3	100	22.4
disagree	2	69	15.4
strongly disagree	1	14	3.1
not applicable		72	16.1
	TOTAL	447	100.0

Mean = 3.5

Of the many who deemed this statement to be not applicable, 52 (72 percent) were from the urban sample.

The mean score (3.5) and frequencies in the table show that, compared with those who disagreed, more people agreed that they could recall a detrimental government action. Having the highest mean score (3.8), compared with the upper urban sample, the upper rural sample was more likely to agree with this statement.

4.8.3 Awareness and Intentions

Before discussing specific issues below, participants were asked three general questions concerning awareness and involvement in land and water issues in the Herbert. For these, note that the choice of responses differs from other statements in this category.

Generally speaking, what awareness do you think local people have about land and water issues in the Herbert?

Response	Rating	N (468)	Percent
very high awareness	5	63	13.5
high	4	123	26.3
moderate	3	164	35.0
low	2	95	20.3
very low awareness	1	23	4.9
TOTAL		468	100.0

Mean = 3.2

On average, the awareness of local people was considered moderate (mean 3.2). There was no significant difference among the four samples with mean scores ranging from 3.21 to 3.27 (to 2 decimal places).

How much do you think local people are prepared to become involved in land and water issues in the Herbert?

Response	Rating	N (467)	Percent
to a very high degree	5	32	6.9
high	4	104	22.3
moderate	3	199	42.6
low	2	116	24.8
very low degree	1	16	3.4
TOTAL	467	100.0	

Mean = 3.0

In all, preparedness to become involved in land and water issues was moderate (mean 3.0). No significant differences were evident among the four samples. However, while a comparison of the difference between ratings in the upper and lower catchments appeared slight, this was significant (means were 3.2 and 3.0 respectively). Essentially, compared with the lower catchment sample, those in the upper catchment were more likely to consider locals as prepared to become involved.

How much are you prepared to become involved in land and water issues in the Herbert?

Response	Rating	N (466)	Percent
to a very high degree	5	41	8.8
high	4	132	28.3
moderate	3	181	38.8
low	2	70	15.0
very low degree	1	42	9.0
TOTAL	466	100.0	

Mean = 3.1

Again, preparedness was moderate (mean 3.1). Of the four samples, the upper rural sample returned the highest mean score (3.4) which, when compared with the lower urban sample (mean 2.9), was significantly different. In addition, for the urban samples, residents in Mount Garnet were the most prepared (mean 3.6) compared with those in Ingham who were least prepared (mean 2.7).

The local environment is no worse off than it was when I first lived here

Response	Rating	N (459)	Percent
strongly agree	5	27	5.9
agree	4	129	28.1
neither agree nor disagree	3	81	17.6
disagree	2	151	32.9
strongly disagree	1	67	14.6
not applicable		4	.9
	TOTAL	459	100.0
Mean = 2.8			

As has occurred previously, for this statement the whole sample appeared somewhat divided between those who agreed and those who disagreed. Regarding any significant differences among the four samples, compared with the other 3 samples, the lower urban sample was more likely to disagree that the local environment is no worse off. In other words, this sample would be more likely to agree that the condition of the environment has deteriorated over time.

Interestingly, there appeared to be some relationship between this statement and levels of personal involvement in land and water management activities. More specifically, those who were more likely to become involved (eg. in local projects) were also less likely to agree that the condition of the local environment had not changed over time.

I would be prepared to assist in local projects such as riverbank stabilisation

Response	Rating	N (447)	Percent
strongly agree	5	32	7.2
agree	4	158	35.3
neither agree nor disagree	3	133	29.8
disagree	2	59	13.2
strongly disagree	1	9	2.0
not applicable		56	12.5
	TOTAL	447	100.0
Mean = 3.4			

The first result to note in the table is the large number of "not applicables", of which nearly 70 percent were from the urban samples.

The mean score (for those who considered the statement applicable) is less positive than the related statements which indicated widespread agreement that the local community should take some responsibility, and local community groups can undertake activities, for helping to improve the environment. However, it is situated on the positive side of the scale.

One significant difference existed among the four samples. Compared with the upper rural sample (who were most prepared), the lower urban sample was less prepared to assist in local projects (means ranged from 3.2 to 3.6). Significantly, within the lower urban sample, Ingham residents were the least prepared (mean 2.6), and notably less so than those living in Lucinda and Halifax (means both 3.7).

It is likely that I will become involved (or stay involved) with a Landcare or catchment group over the next year or two

Response	Rating	N (454)	Percent
strongly agree	5	15	3.3
agree	4	73	16.1
neither agree nor disagree	3	158	34.8
disagree	2	111	24.4
strongly disagree	1	26	5.7
not applicable		71	15.6
	TOTAL	454	100.0
Mean = 2.8			

Once again, many people considered this statement as not applicable. Of these nearly half were from the lower urban sample (and comprised 25 percent of that sample), and 20 percent were from the upper urban sample. 24 of the 71 people (34 percent) were from the rural samples and, of these, 18 were from the lower rural sample.

For the rest of the sample, the mean score is slightly below the mid point of the scale. The table also shows that more people chose to disagree than agree with the statement.

One significant difference existed among the four samples. As might be expected regarding rural-urban differences (and the perceived relevance of the statement), compared with the lower rural sample, those in the lower urban sample (particularly in Ingham) were less likely to become involved (mean scores ranged from 2.6 to 3.0).

It is likely that I will look into ways to improve the environmental condition of my property over the next year or two

Response	Rating	N (456)	Percent
strongly agree	5	47	10.3
agree	4	222	48.7
neither agree nor disagree	3	89	19.5
disagree	2	25	5.5
strongly disagree	1	11	2.4
not applicable		62	13.6
	TOTAL	456	100.0
Mean = 3.7			

As discussed a number times above, there were also many who considered this statement as not applicable. As expected, most of these participants (82 percent) were from the urban sample.

The mean score (3.7) and frequencies highlight the high level of agreement with this statement. Regarding differences among the four samples, while all samples tended to agree, compared with the other three samples, the lower urban sample was less likely to agree with this statement (mean 3.5, as compared with means between 3.7 and 3.8). This type of difference was expected given that the statement has more relevance to rural producers.

I could personally benefit from being involved in group activities to help manage land and water

Response	Rating	N (457)	Percent
strongly agree	5	18	3.9
agree	4	131	28.7
neither agree nor disagree	3	147	32.2
disagree	2	84	18.4
strongly disagree	1	18	3.9
not applicable		59	12.9
	TOTAL	457	100.0

Mean = 3.1

Participants who viewed this statement as not applicable included 45 (76 percent) from the urban sample. For the four samples, all mean scores centred around the mid point of the scale and were close to the sample mean (3.1). However, compared with the lower rural sample (mean 3.2), those in the lower urban sample were more likely to disagree with this statement (mean 2.9). Again, this finding was expected given the likely difference between rural and urban residents in the perceived relevance of the statement. As for a number of previous issues (including assessment of environmental change, likely involvement in planning and management, level of control), the fact that upper rural residents appeared more "rural" in their attitudes than lower urban residents is an interesting finding. In other words, for a number of statements, the lower urban sample appeared more likely to "stand out from the crowd".

Some people I know think that local groups are a good way to deal with many land and water management issues

Response	Rating	N (456)	Percent
strongly agree	5	29	6.4
agree	4	222	48.7
neither agree nor disagree	3	140	30.7
disagree	2	38	8.3
strongly disagree	1	9	2.0
not applicable		18	3.9
	TOTAL	456	100.0

Mean = 3.5

The mean score (3.5) and frequencies show a high level of agreement with this statement. For the four samples, all means scores were between 3.4 and 3.6 and, therefore, no significant differences were evident. This is noteworthy in that, given the nature of the statement, a difference between rural and urban samples may have been expected.

Section 5.7.1 discusses further investigation of items denoting intentions to participate in land and water management activities. A general measure named *Personal and Group Intentions* was formed and analyses were carried out to find out whether this measure was related to other items in the questionnaire.

4.9 Information Sources

Which of the following sources of information help you to keep informed about land and water management issues?

For this question, participants ticked as many boxes as were applicable. The figures in both percentage columns denote the proportion of people - compared with the whole sample - who use a particular source of information.

Information Source	Percent	Information Source	Percent
Neighbours	46.5	Telegraph Times	.2 (N=1)
A government agency	13.4	Herbert River Express	59.7
Industry groups	24.7	The Tablelander	27.3
Community groups	21.6	Tablelands Advertiser	23.9
Family members	34.2	Millstream Times	15.1
Friends/colleagues	53.9	Courier Mail	5.9
Personal experience	39.0	Magazines/journals	30.2
The local "grapevine"	48.4	Government newsletters	7.5
Public meetings	32.3	Country Hour (ABC radio)	28.3
The Australian newspaper	10.9	Landline (ABC television)	43.6
Cairns Post	16.8	None/I don't keep informed	2.5
Townsville Bulletin	30.6	Other	5.5

For the whole catchment, the ten most frequently used sources of information were - from highest to lowest - the Herbert River Express, friends/colleagues, the local "grapevine", neighbours, the television program "Landline", personal experience, family members, public meetings, the Townsville Bulletin, and magazines/journals. All of these sources were used by more than 30 percent of the sample.

Perhaps the most surprising findings were the fact that a local newspaper - the Herbert River Express - was used more frequently than more "traditional" sources of information such as friends/colleagues and personal experience. Second, also part of the media, "Landline" was a more often-used source than personal experience, family members and public meetings. Its use was as high as 53 percent in the upper catchment.

The primary position of the Herbert River Express is even more remarkable when noting that it is distributed principally in the lower catchment. For the lower catchment only, this paper was used by 84 percent of the sample.

Next, people who checked "a government agency", "industry groups", or "other" were asked to specify the particular source they had in mind.

Of the 15 specified government agencies, the Department of Primary Industries was noted for half the 68 entries (50 percent). CSIRO and Environment and Heritage were mentioned 3 times each and other agencies were noted on 2 or fewer occasions. These included Mines, Natural Resources, Lands, Water Resources, Forestry, the Irrigation and Water Supply Commission, and the National Wetlands Commission.

Of the 19 specified industry groups, Canegrowers was noted 75 times and formed the bulk of the 127 entries (59 percent). BSES (Bureau of Sugar Experimental Stations) was mentioned 19 (15 percent), the Cattleman's Union 7 (6 percent), and CSR and Drainage Boards 5 times (4 percent each). Other groups noted included the Queensland Commercial Fishing Organisation, Mining Companies, the Australian Cane Growers Association, and the Chamber of Commerce.

For other sources, local government, local government newsletters, universities, the Herbert River Improvement Trust, the Queensland Country Women's Association, the North Queensland Register, and radio and television in general were mentioned.

The above results were scrutinised to find any significant differences between samples.

First, obvious differences include use of various newspapers. As mentioned, the Herbert River Express is a lower catchment paper. In addition, the Townsville Bulletin was used virtually exclusively by lower catchment residents. 44 percent of the lower catchment sample used the Townsville Bulletin to keep informed about land and water management issues.

Similarly, the Tablelander, Tablelands Advertiser, and the Millstream Times are all distributed primarily in the upper catchment. For the upper catchment only, these papers were used as sources of information by 86, 75 and 49 percent respectively. The Cairns Post was also read almost exclusively in the upper catchment, with a readership of more than 50 percent. Interestingly, the Australian newspaper was also read by a larger proportion of people in this area (17 percent).

Briefly, a noticeable difference between the two catchment areas is found in the readership of the Townsville Bulletin (lower catchment) or the Cairns Post (upper catchment). Respectively, Townsville and Cairns are the closest major urban centres, and this is a clear example of the lack of integration between the two areas. Such separation might well produce many other differences than simply determining what newspaper is read.

There was no difference between samples regarding readership of the Courier Mail.

Other differences that may have been anticipated were those between the rural and urban samples. Compared with the urban sample, the rural sample was more likely to keep informed of land and water management issues by way of neighbours, industry groups, personal experience, public meetings, and government newsletters.

Additionally, magazines/journals were preferred by those in the rural sample, and particularly those in the lower rural sample (43 compared with 29 percent in the upper rural sample).

In contrast, the local "grapevine" was a preferred source of information in the upper catchment (59 compared with 44 percent). This was also the case for Landline (53 compared with 40 percent).

Significant differences between the lower rural and upper rural sample included the use of magazines/journals as mentioned, and (with the lower rural sample mentioned first) industry groups (52 compared with 5 percent), community groups (24 compared with 12 percent), and public meetings (46 compared with 25 percent).

Information sources that returned no differences between samples were family members, friends/colleagues, and the Country Hour.

Which two sources of information would you say were the most reliable for helping you to make decisions?

For the whole catchment, more than fifty separate sources were stated as the most reliable and, in all, 766 responses were provided. Comprising more than 90 percent of the total number of responses provided, the top twenty sources are presented in the following table. Note that the

figures in the percentage column show the proportion of people - compared with the whole sample (411) - who stated a certain source of information to be reliable.

Twenty most reliable information sources

Reliable Sources	**N**	**Percent**
Landline (ABC television)	88	21.4
Personal experience	82	20.0
Herbert River Express	74	18.0
Public meetings	51	12.4
The Country Hour (ABC Radio)	46	11.2
Canegrowers	44	10.7
Friends/colleagues	40	9.7
Neighbours	33	8.0
Industry Groups	31	7.5
Family members	28	6.8
The Tablelander	27	6.6
A government Agency	25	6.1
Magazines /Journals	24	5.8
The local "grapevine"	18	4.4
The Townsville Bulletin	17	4.1
Community groups	15	3.6
Newspapers (in general)	14	3.4
The Department of Primary Industries	13	3.2
The Cairns Post	12	2.9
BSES	12	2.9

A prominent and certainly unexpected finding, Landline was considered the most reliable source of information for helping participants to make decisions. This, in combination with the fact that Landline was fifth most used source of information highlights the potential influence this program has in conveying information to residents in the catchment.

It should also be noted that for the lower catchment sample only, Landline was the fourth most reliable source behind the Herbert River Express, public meetings, and personal experience. Therefore, in the upper catchment, Landline was considered by far to be the most reliable source (followed by personal experience, the Tablelander and the Country Hour).

Because of their reliability, these information sources, plus others noted in the table including Canegrowers and Industry groups, are clearly key areas for informing catchment residents about land and water management issues.

Further analysis was conducted to determine whether any differences existed between use of an information source and other items in the questionnaire. Numerous differences were evident and, once again, Landline figured prominently. The findings are as follows.

First, those used Landline as an information source were more likely to:
- agree there were things they could do to help improve the environment;
- agree they would become involved (or stay involved) with a Landcare or catchment group over the next year or two.

Those who kept informed of land and water management issues by talking to neighbours were more likely to have heard of ICM.

Participants used community groups were more likely to:
- have heard of PMP, and ICM;
- agree they would become involved (or stay involved) with a Landcare or catchment group;
- (as might be expected) agree they could personally benefit from being involved in group activities to help manage land and water.

Those used personal experience were more likely to:
- have heard of PMP, and ICM;
- agree they would become involved (or stay involved) with a Landcare or catchment group;
- agree that they would look into ways to improve the environmental condition of their property over the next year or two.

Those who used public meetings were more likely to:
- have heard of ICM;
- agree they would become involved (or stay involved) with a Landcare or catchment group;
- agree they could personally benefit from being involved in group activities to help manage land and water.

For the upper catchment only (no differences were found in the lower catchment), people who kept informed of land and water management issues by talking with family members were more likely to:
- have heard of Landcare;
- agree there were things they could do to help improve the environment.

People who kept informed by talking to friends/colleagues were more likely to have heard of Landcare.

Finally, for the lower catchment only, those who did not use the Herbert River Express as an information source were less likely to have heard of Landcare and ICM.

All significant differences noted above were evident even when looking at the rural sample only.

Does what you read in newspapers ever change your opinions about land and water management issues?

Response	Rating	N (447)	Percent
often	4	19	4.3
occasionally	3	254	56.8
seldom	2	137	30.6
never	1	37	8.3
	TOTAL	447	100.0
Mean = 2.6			

The mean score (2.6) indicates that, on average, the views of those in the sample change seldom to occasionally. There were no significant differences between the samples.

Does what you hear on the radio or see on TV ever change your opinions about land and water management issues?

Response	Rating	N (448)	Percent
often	4	49	10.9
occasionally	3	265	59.2
seldom	2	107	23.9
never	1	27	6.0
	TOTAL	448	100.0
Mean = 2.8			

For this question, the mean score (2.8) approached occasional opinion change. As the table shows, nearly 60 percent of the sample chose this response. Notably, the mean score was slightly, although significantly, higher than that for newspapers. However, it is noteworthy that the mean for the lower rural sample did not differ between the two questions.
Concerning other significant differences, compared with the lower rural sample, those in the upper rural sample were more likely to state that they occasionally changed their opinions when listening to radio or watching television. The greater watching of the television program Landline in the upper catchment may explain some of this difference.

How often do you discuss land and water management issues with your neighbours or others in this general area?

Response	Rating	N (453)	Percent
often	4	96	21.2
occasionally	3	213	47.0
seldom	2	121	26.7
never	1	23	5.1
	TOTAL	453	100.0
Mean = 2.8			

For this question, the mean score (2.8) approached occasional discussions with neighbours and other locals. As indicated, 47 percent of the sample chose this response.

As might be expected, compared with both urban samples (means 2.7), those in the lower rural sample were more likely to talk with their neighbours about land and water management issues (mean 3.0). While the mean score for the upper rural sample was also close to 3, there was no

significant difference (due to lower numbers in this sample). However, when combined, the difference between the rural and urban samples was significant.

4.10 Group Involvement

Are you a member of any regional, state or nationally-based groups or associations?
115 participants or exactly 25 percent of the whole sample (N=460) noted they were members of such groups. This level of membership ranged between (approximately) 17 percent for both urban samples, and 33 percent for the lower rural sample. Membership for the upper rural sample was 28 percent. From these figures, a test of the difference between rural and urban levels of membership was shown to be significant.

Are you a member of any local community groups or associations?
206 participants (44 percent of the whole sample, N=468) noted they were members of such groups. Included as members were 94 of the 115 people (or 82 percent) who indicated they were members of regional, state or nationally-based groups.

This level of membership ranged between (approximately) 50 percent for both rural samples, and 43 and 37 percent for the upper urban and lower urban samples respectively. From these figures, a test of the difference between rural and urban levels of membership was bordering on significant.

In total 236 participants (or nearly 50 percent of the whole sample) indicated membership in either local and/or regional/state/national groups.

Both of the above questions gave evidence of a higher level of group membership in rural landholders.

Analyses were conducted to determine whether any significant differences on items in the questionnaire existed between group members and non-members. For both members of regional/state/national and/or local groups a number of differences were evident. First, members were more likely to consider constraints to managing land and water in the Herbert to be the wide variety of opinions held by local people, and the difficulty in thinking about relevant issues for an area this size.

As might be expected, members were also more prepared to become involved in land and water issues, more prepared to assist in local projects such as riverbank stabilisation, more likely to become involved (or stay involved) in a Landcare or catchment group over the next year or two, and more likely to see personal benefits from involvement in group activities to manage land and water.

For regional/state/national groups only, members were less likely to agree that a constraint to managing land and water in the Herbert was that government strategies were a waste of time. They were, however, more likely to disagree with the statement "I trust that public servants are working in my interest most of the time".

For local groups only, members were more likely to agree that a constraint to managing land and water in the Herbert was that government does not to spend money on solutions.

Next, the questionnaire then asked those who were not members of any local community groups or associations were asked to state reasons for no involvement.

In all, 302 reasons were provided, with the ten most common appearing in the following table. These comprised more than 83 percent of the total number provided. The figures in the percentage column denote the proportion of a particular response, compared with the total number of people who provided at least one response (227).

Reasons for no involvement

Reason	**N**	**Percent**
Don't have the time / too busy / work commitments	151	66.5
Aged / too old	32	14.1
Not interested / apathetic	13	5.7
Poor health	10	4.4
No perceived need	10	4.4
Only recently arrived in the area	8	3.5
Dislike meetings / "not the type"	8	3.5
It is a "tight" community / not considered "local"	7	3.1
Too much travelling involved	7	3.1
Groups are all talk and not much action	7	3.1

Clearly, the bulk of the reasons given were related to lack of time, health and interest.

Next, those who were not members of any local community groups were asked whether they would ever consider joining a community group.

Of the sample of 237 (out of a possible 271), 21 percent stated "Yes", 32 percent "Don't Know" and 47 percent "No".

Those who responded "Yes" or "Don't Know" were asked to state their reasons for joining.

In all, 123 reasons were provided, with the nine most common appearing in the following table. These comprised more than 90 percent of the total number provided. The figures in the percentage column indicate the proportion of a particular response, compared with the number of people who gave at least one response (88).

Reasons for joining a community group

Reason	**N**	**Percent**
Interest in the topic/important focus	21	23.9
If I had a real chance to improve things (including betterment of the area)	20	22.7
Would depend on what the problem was	14	15.9
More time available	13	14.8
If I felt I had something to offer	12	13.6
If the issue affected me / my community	11	12.5

To gain personal fulfilment	8	9.1
To become better informed about an issue	6	6.8
Friendship and fellowship	6	6.8

Which of the following categories describe any of the groups you have some involvement with? This, and the following two questions, were answered only by those who were members of local and/or regional/state/national groups. As stated, this comprised 236 participants, of which 228 answered the question.

As shown in the following table, participants showed their involvement for a number of categories (or type of group), and ticked as many boxes as were applicable. The figures in both percentage columns indicate the proportion of people - compared with the whole sample of those involved in groups and who answered the question (228) - who were involved with a particular type of group.

Type of Group	Percent	Type of Group	Percent
Progress Association	10.1	Sporting Group	45.2
Rate Payers Association	5.7	Hobby/Craft Group	10.1
Professional Association	7.9	Community Action Group	10.1
Charity/Church/Welfare Group	28.9	Service Club (eg. Lions, Rotary)	18.9
Agriculture-related Organisation	28.5	Parents & Friends Association	25.0
Landcare, Conservation or similar Group	18.4	Other/s	19.3

The four separate samples were scrutinised to determine any differences in levels of involvement. Lower urban people were more likely to be involved with progress Associations and, as expected, the rural sample was more likely to be involved with an agriculture related organisation. However, within these figures, those in the lower rural sample were more likely to be involved than those in the upper sample.

Finally, compared with the other three samples, those in the lower rural sample were more likely to be involved with a parents and friends association.

Other groups written down by participants included ethnic/cultural, rural fire boards, a local ambulance committee, a traffic management committee, retired friends, political organisations, Masonic Lodge, Australian Volunteer Coast Guard, and the State Emergency Service.

Of the groups they were involved with, participants were next asked to designate the name of the group they considered as most important. For the 190 responses, and comprising almost 75 percent of this figure, most frequently mentioned were Sporting Groups (16.3 percent), Agriculture-related Organisations (14.7 percent), Charity/Church/Welfare Groups (12.6), Parents & Friends Groups (9.5 percent), Landcare, Conservation or similar Groups (8.4 percent), Service Clubs (6.8 percent), Progress Associations, and Hobby/Craft Groups (2.6 percent each).

Interestingly, approximately half of those who stated involvement with an Agriculture-related Organisation nominated this as the most important group. This was also the case for the "Landcare, Conservation or similar" category.

To complete this section of the questionnaire, participants were asked:

If you are involved in any groups in the "Landcare, Conservation or similar" category, please write down the name of the group that you are most involved with.
Of the 39 groups noted, over half (21) were Landcare groups. Other groups included Drainage Boards, Forestry, Hinchinbrook Citizens Association, Australian Conservation Foundation, Greenpeace, Queensland Commercial Fishing Organisation, Hinchinbrook Marine Resources Advisory Committee, Soil and Water Conservation Association of Australia, Herbert Cane Protection and Productivity Board, Warps Subdivision Working Group, and a local community rainforest reafforestation program.

4.10.1 Interest in Community Issues

Thinking of the local community where you live, please rate how much you agree or disagree with each of the following statements.
Participants used the following agree-disagree scale to respond to each statement. The statements and ordered mean scores appear in the table below.

1	2	3	4	5
strongly disagree	**disagree**	**neither agree nor disagree**	**agree**	**strongly agree**

Community issues

1.	Very few of my neighbours know me	2.0
2.	People in this community generally don't get along with each other	2.3
3.	I'm not very interested in local community issues	2.4
4.	The community is capable of getting things done without any outside help	2.6
5.	I don't really care what others in the community think of my actions	2.7
6.	I don't have the time to become involved in local community issues.	3.2
7.	I have almost no influence over what happens in this community	3.4
8.	I often think about local community issues	3.6
9.	It's very important to me to live in this particular community	3.7
10.	I want the same things from this community as other local people want	3.7
11.	I and many others in this community share similar values	3.8
12.	I feel quite comfortable in being a member of this local community	4.0
13.	I can recognise many of the people who live in this community	4.1
14.	I think this community is a good place to live	4.2
15.	I would like to remain living in this area for a long time	4.2

Considering mean scores of 4 or higher, most in the sample felt comfortable in being members of their local communities, could recognise many others, thought it was a good place to live, and would like to remain living in the Herbert for a long time.

As a rule of thumb, participants tended to disagree with negatively worded statements (ie. 1, 2, 3, 5) and agree with those worded positively. For the former, statements 6 and 7 are exceptions to

the rule, with mean scores lying on the agree side of the scale. For positively worded statements, only statement 4 stands out as lying on the disagree side of the scale.

In this regard, it was considered possible that statements 4 (community self-reliance) and 7 (personal influence) were possibly related. However, while many other statements were highly correlated, the relationship between these items was not significant.

Of the 15 statements, 7 revealed significant differences among the four samples. However, it should be noted that any differences were in terms of degree only and, as such, any conclusions need to be treated with caution. Noting that one sample was more interested in an issue than another does not imply that the latter was uninterested.

For statement 1, the lower rural sample was more likely to disagree agree than the upper urban sample. For statement 2, both lower catchment samples were more likely to disagree than the upper urban sample. For statement 4, the upper urban sample was more likely to disagree than the lower rural sample. For statement 5, the lower rural sample was more likely to disagree than the upper urban sample. For statement 9, the lower rural sample was more likely to agree than the three other samples. For statement 11, the lower rural sample was more likely to agree than the upper urban sample. Finally, for statement 15, the lower rural sample was more likely to agree than both urban samples.

It is notable that each of these results includes differences between the lower rural and upper urban samples. As a broad summary, compared mostly with the upper urban sample, the "community" as perceived by those within the lower rural sample appears more cooperative and self-reliant. Its members express more attachment to their area, are more concerned with how their actions are perceived by others, are likely to consider knowing more of their neighbours, and more likely to regard people in the community as sharing similar values.

4.10.2 Life Satisfaction

Please rate your level of satisfaction with the various aspects of your life at the moment. Participants used the following agree-disagree scale to respond to each statement. The statements and mean scores appear in the table below.

1	2	3	4	5
very dissatisfied	**moderately dissatisfied**	**neither satisfied nor dissatisfied**	**moderately satisfied**	**very satisfied**

Areas of Satisfaction	**Mean**
Your life in general	4.2
Your standard of living	4.1
Your personal health	4.1
The area where you live	4.3
The community in which you live	4.1
Existing community facilities and services	3.2

As can be seen, mean scores for the first five areas centred around moderate satisfaction. The exception was satisfaction with community facilities and services and, hence, this was the area that people were least satisfied with.

No significant differences existed among the four samples for the first four areas of satisfaction. For satisfaction with the community in which people live, the upper urban sample was less likely to be satisfied than the two lower catchment samples. Looking at particular areas, Herberton, Ravenshoe and Mount Garnet had the lowest mean scores. The difference between Mount Garnet (3.4) and Ingham (4.2) was the most prominent.

A similar difference among the four samples was also found for satisfaction with existing community facilities and services. While all tended to centre around "neither satisfied nor dissatisfied", the upper urban sample was more likely to be dissatisfied than the lower urban sample. This finding was highlighted earlier in responses to the question about key issues. In stating such issues, people in the upper catchment were more likely to note concerns such as lack of community services and access to those services, and also the poor quality of roads.

When thinking about your relationships with local people, how comfortable are you about living here?

This was the first of two final questions relating to community issues. Specifically, for these items, the degree of comfort people held with regard to their relationships with other local people was assessed.

Response	Rating	N (470)	Percent
very comfortable	5	227	48.3
quite	4	175	37.2
moderately	3	53	11.3
not very	2	11	2.3
not at all comfortable	1	4	.9
	TOTAL	470	100.0
Mean = 4.3			

Once again a matter of degree only, while all four samples centred around "quite comfortable", compared with both lower catchment samples, the upper urban sample had a lesser degree of comfort.

When thinking about how much interest local people have for your ideas and opinions, how comfortable are you about living here?

Response	Rating	N (454)	Percent
very comfortable	5	113	24.9
quite	4	177	39.0
moderately	3	125	27.5
not very	2	28	6.2
not at all comfortable	1	11	2.4
	TOTAL	454	100.0
Mean = 3.8			

Interestingly the only significant difference here was between the upper urban and the lower rural sample, with the latter indicating more comfort. However, all mean scores were between "moderately" and "quite" comfortable.

4.11 Demographic and Other Information

Age
Participants were aged between 17 (one person) and 91 years. The average age was 51.8 years. The mean ages for the four samples were very similar, ranging from 51.0 to 52.8 years.

Notably, with average ages of 55.7 and 56.8 respectively, the Lucinda and Taylors Beach samples appeared moderately older than other towns or the rural samples.

Gender
Of the 469 people who noted their gender, 293 were male (62.5 percent) and 176 female (37.5 percent). Notably, for the lower rural sample, more than 80 percent were male and, for the two urban samples around 47 percent were male (hence, more women than men answered the questionnaire in these samples). In the upper rural sample, 65 percent were male.

Country of Birth
Of the 462 people who noted their country of birth, 391 (84.6 percent) were born in Australia. Two other significant categories included 32 people born in "Europe" (6.9 percent) and 23 in "UK and Ireland" (5 percent).

Interestingly, only 65 percent of those in the upper urban sample were born in Australia. For this sample, and compared with the whole sample, other countries of birth included all of those born in New Zealand (5), and nearly half of those born in the UK and Ireland (11 of 23). Finally, none in the lower rural sample were born in the UK or Ireland, but included 14 of the 32 people born in Europe.

Marital Status
467 participants answered this question, of which 377 were married-defacto (80.7 percent), 35 widowed (7.5 percent), 34 never married/single (7.3 percent), and 21 divorced/separated (4.5 percent). The proportion of those married/defacto ranged from 88.3 percent (lower rural) to 70.6 percent (upper urban)

Do you have any family members living in the Herbert area other than those in your household?
331 of the 470 participants who answered this question (70.4 percent) responded positively.

Interestingly, for the upper urban and lower rural samples, this figure varied markedly between 44 and 87 percent respectively. At just over 52 percent, the upper rural sample was also a good deal lower than the average. Therefore, the conclusion drawn here is that, compared with the lower catchment, residents in the upper catchment are likely to have fewer familial ties beyond those in their household.

Main Occupation
Comprising more than 78 percent of the total number provided, the eleven most common occupations appear in the following table.

Occupation	N (463)	Percent
Cane Farmer	143	30.9
Home Duties	74	16.0
Retired	59	12.7
Grazier	22	4.8
Tradesman	20	4.3
School Teacher	11	2.4
General Farming (other than cane)	10	2.2
Nurse	8	1.7
Small Business	8	1.7
Retired Cane Farmer	4	.9
Community Worker	4	.9
Miner	3	.6

The reason that only three people stated their occupations as mining is related to the fact that, for those who hold mining leases, a large proportion will have other, "main" occupations.

How many years have you had this occupation?
There were 441 responses to this question. The range was from 1 to 72 years and the average length of time was 22 years.

Looking in particular at the dominant occupation provided, namely cane farming, the range was from 2 to 69 years and the average length of time was 29 years.

How long have you lived in the Herbert area?
Of the 467 responses to this question, the length of residence in the Herbert ranged from 1 to 89 years, with an average length of 34 years.

Looking again at the cane farming occupation only, the range was from 4 to 75 years and the average length of residence was 46 years.

For the four samples, there were also a number of differences between average length of residence. The range was from 18 years (upper urban) to 46 (lower rural). Again, the upper and lower samples differed significantly.

Is your property near to a river or creek which floods?
Of the 461 participants who answered this question 317 (68.8 percent) responded positively. 136 (29.3 percent) did not live, and 9 (2.0 percent) did not know whether they lived, near to a river or creek which floods.

As could be expected, 91 percent of the lower rural sample lived near to a river or creek which floods. However, this figure was as low as 47 percent for the lower urban sample. On closer inspection, this figure varied between 0 percent (Allingham) and 94 percent (Halifax). Within the

upper urban sample there was also variation between 29 percent (Mt Garnet) and 59 percent (both Herberton and Ravenshoe).

69 percent of the upper rural sample lived near to a river or creek which floods.

One interesting finding was that, compared with those who did not own or lease such property, those with property next to a river or creek which floods were less likely to agree that they had complete control over the land and water on their properties.

Thinking about where you live, what is the most important river or creek to you?
Comprising nearly 85 percent of the total number provided, the eleven most common rivers/creeks noted appear in the following table.

Important River / Creek	N (432)	Percent
Herbert River	192	44.4
Wild River	50	11.6
Millstream	30	6.9
Palm Creek	22	5.1
Stone River	21	4.9
Victoria Creek	15	3.5
Trebonne Creek	10	2.3
Cassady Creek	7	1.6
Vine Creek	7	1.6
Waterview Creek	6	1.4
Ripple Creek	5	1.2

How often do you use the river or creeks near where you live? (eg. for commercial, domestic or recreational purposes)

Response	Rating	N (469)	Percent
often	4	165	35.2
occasionally	3	136	29.0
seldom	2	89	19.0
never	1	79	16.8
TOTAL		469	100.0
Mean = 2.8			

While all means scores for the four samples were between 2.6 and 3.2 (centring around "occasionally"), the mean for the upper rural sample was the only one greater than 3. Therefore, people in this sample were the most likely to use the rivers or creeks near where they live (62 percent of this sample noted that they often use the river). In general, people in the upper catchment (rural and urban) were more likely to use rivers/creeks than those in the lower catchment.

For the lower urban sample, people in Halifax, Lucinda and Taylors Beach appeared to use rivers/creeks more regularly than those in Ingham and Allingham. The difference between

Ingham and Taylors Beach was significant (means were 3.2 and 2.3 respectively), with use by the latter sample being on par with that in the upper rural sample.

Of those who seldom or never use the rivers or creeks, respectively, 65 (73 percent) and 63 (80 percent) were from the lower catchment.

In addition, a number of significant differences were found between river use and other items in the questionnaire. Compared with those who never used the river, those who used the river often were:

- more likely to consider lower fish numbers as a personal impact;
- more likely to consider loss of access to recreation as a personal impact;
- more likely to have loss of confidence in government's ability to manage land and water resources;
- less likely to see programs such as ICM interfering with people's rights to make their own decisions;
- less likely to agree that the local environment had not deteriorated over time;
- more prepared to assist in local projects such as riverbank stabilisation;
- more likely to believe that many environmental problems come from the way people manage their properties;
- more likely to become involved (or stay involved) with a Landcare or catchment group in the next year or two;
- more likely to agree that there were personal benefits from being involved in group activities to help manage land and water.

How often do you go fishing for recreation?

Response	Rating	N (469)	Percent
often	4	77	16.4
occasionally	3	150	32.0
seldom	2	116	24.7
never	1	126	26.9
	TOTAL	469	100.0

Mean = 2.4

The mean score for this question shows that, for the whole sample, fishing for recreation was an activity tending to be carried out on a fairly infrequent basis. This figure, however, belies the fact that the mean scores of the four samples covered a wide range from 2.0 (upper rural) to 2.7 (lower urban). Generally, compared with the upper catchment samples, people in the lower catchment were likely to go fishing on a more regular basis.

Of the 77 participants who responded "often", 68 (88 percent) were from the lower catchment, and of the 150 who responded "occasionally", 111 (74 percent) were also from the lower catchment.

Within the lower urban sample, the likelihood of fishing more frequently was particularly evident for residents of Taylors Beach and Halifax (means 3.1 and 3.o respectively) Herberton provided the strongest difference (mean 1.9). However, it should also be noted that the mean score for Ingham was somewhat lower than that for Mount Garnet (means 2.3 and 2.5 respectively).

These findings correspond with the earlier item in which participants rated the degree of impact of lower fish numbers. For this item, Mount Garnet had the highest impact of the three upper urban samples, and had a similar mean score to that provided by Ingham.

Do you own or lease/rent a commercial rural, or rural property greater than 3 hectares (7.5 acres)?

Response	Rating	N (469)	Percent
yes -own	1	194	41.4
yes - lease/rent	2	25	5.3
yes – both	3	11	2.3
no	4	239	51.0
TOTAL		469	100.0

As the table indicates, 43.7 percent of the whole sample owned property greater than 3 hectares. Of those who owned such property, this figure was as high as 78 percent for the lower rural sample, followed by 60 percent for the upper rural sample. As expected, the rate of ownership of such property in the urban samples was low.

One unexpected result was that 13 participants in the upper rural sample did not own or lease/rent property above 3 hectares. On further investigation, the main occupations for these participants included home duties, tradesman, teacher and retired. One person also stated their occupation as mineral exploration.

Next, the original sample list was checked as a means to ensure that these properties were within the upper rural sample as had been specified. All were. 5 of the 13 properties were classified as mining-related and the remaining 8 as rural. Of the latter, it was confirmed that one participant owned stock, one resided on a rural residential block and one was a member of a Landcare group.

Which one of the following best describes your current use of this property?
Only those who owned or leased/rented rural property greater than 3 hectares were asked to complete this question. Results for the whole sample appear in the following table.

Current use of property

Use	Rating	N (228)	Percent
Cane farming	1	163	71.5
Grazing	2	41	18.0
Mining	3	3	1.3
Industrial	4	0	0
Other farming	5	12	5.3
Other	6	9	3.9
TOTAL		228	100.0

In brief, the majority of properties were used for cane faming. Most grazing activity occurred in the upper catchment (85 percent). The "other farming" category included goat and horse breeding, forestry, fruit growing, hay and maize production, potato farming, crayfish and rural residential subsistence. The "other" category included hobby farming and residential and minor stock use.

What is the size of your property?
For those who owned or leased/rented rural properties greater than 3 hectares, rounded to the nearest hectare, average property size was 6146 hectares in the upper catchment and 219 hectares in the lower catchment. To shed more light on property size, half the properties were 82 hectares or less. The average cane farm size was 145 hectares and grazing property, 6680 hectares.

Have you cleared any new land in the last twelve months?
30 people (12 percent of those owning property greater than 3 hectares) responded positively to this question. Of these, 24 (80 percent) were from the lower rural sample.

Those who had cleared new land were next asked to specify how much had been cleared. Results indicated a range from 1 to 162 hectares, with a mean score of 35 hectares and median of 18 hectares (ie. half the properties had cleared 18 hectares or less).

Would you be prepared to answer another shorter questionnaire if needed in a few months time?
284 participants, or 59.5 percent of the whole sample, were prepared to complete a further questionnaire. Surprisingly, compared with the lower catchment sample, more people were prepared to complete a further questionnaire in the upper catchment (73 percent as compared with 56 percent).

One interesting finding was that members of both local, and regional/state/national groups were more likely to agree to complete a further questionnaire. Of these, members involved with both Landcare, conservation or similar groups, and community action groups were more likely to agree.

5.0 SUMMARY AND CONCLUSIONS

This study aimed to understand landholders' existing attitudes, beliefs and behaviours relating to land and water management in the Herbert River catchment. The central aim was to provide an initial understanding of social factors with the potential to influence the implementation of ICM, and whether and how such factors vary according to where people live and what their interests are.

Some of the main conclusions provided by the research are noted as follows.

5.1 Issue Importance

Land degradation, water quantity problems, water quality problems and nature conservation issues were generally seen as highly important. The two latter issues yielded the highest and lowest means scores respectively. It was also observed that the lower urban sample was likely to place higher ratings of importance for these two issues.

Water quantity problems were largely viewed in terms of the lack - rather than abundance - of water and, as such, appeared to be of less importance in the lower catchment. Based on current perceptions, one difference between the two catchment areas appears to be that one does not have enough, and the other has too much water.

A clear finding was the difference in the ratings of importance to others and impacts on others. Essentially, one can consider an issue as important without being affected by it. More specifically, results showed that one's ratings of importance tended to be less for others than those felt personally. This occurred largely due to lower importance ratings being provided by the

rural samples. This makes intuitive sense given that the perception of "others" in the Herbert may include urban residents who may be less affected by problems such as land degradation.

It was interesting to note that where lower ratings (for others) were also provided by the urban sample, this was for issues more likely to be considered personally important (namely water quality and nature conservation issues). For water quality problems, the knowledge that such problems were isolated to certain areas (or less severe in other areas) of the catchment may have helped to lower importance ratings. Conceivably, "others" when thinking of nature conservation issues may have included rural producers and a perception that such people generally regard these issues as less important.

Possibly relating to this observation, a common finding in the literature is for people to underestimate others' feelings about the importance of prosocial behaviours (for example, the view that one's neighbours are less environmentally responsible).

5.2 Impacts

Regarding possible impacts of environmental and other pressures felt by people living in the Herbert, in particular, higher taxes and loss of confidence in the ability of government to manage natural resources were rated as high. Other impacts rated moderate to high included higher production costs, lower fish numbers and loss of environmental uses/benefits. Further, reduced farm productivity was a high impact for rural producers in the lower catchment. The low level of perceived conflict in the Herbert was also a noteworthy finding.

High impacts on others included higher taxes, higher production costs, loss of confidence in government, poor drinking water quality and loss of farm productivity.

As discussed, compared with impacts felt personally, impacts on others tended to be significantly higher. Also noted, compared with urban residents, the ratings for respondents in the two rural samples, and particularly the lower rural sample, were less liable to change (ie. more uniform). Therefore, the higher ratings for others generally came from participants in the urban samples, who were less likely to be personally affected by issues including higher production costs, loss of independence to make business decisions, and higher taxes.

As suggested, people in the lower urban sample appeared more "urban" than the upper urban sample in their views about certain issues. From this, it was suggested that the two upper catchment samples are more like-minded than their lower catchment counterparts.

This was evident, for example, for the impacts of loss of access to recreation, loss of environmental uses or benefits, and loss of scenery. As the lower urban sample was most likely to consider these impacts as high (and most likely to agree with other statements, including the need to change laws to increase landholder responsibility for actions undertaken), more "urban" may also equate with more "green". This particularly appeared to be the case for those living in Taylors Beach, whereas the views of those living in Ingham were not as conspicuous.

Interestingly, those in the lower urban sample were also generally less likely to become personally involved in land and water management activities (see below).

5.3 Tractability

For the broad issue of tractability, managing land and water in the Herbert was considered to be made most difficult by the catchment's large area, the fact that solutions are not easy, the expense required to put solutions in place, low trust of government programs, the difficulty of moving around the catchment, the wide variety of existing opinions, and insufficient understanding of problems.

In particular, and certainly from the point of view of perceived credibility, the low level of trust of government programs appears to be a key issue facing ICM in the Herbert.

On the upside of the scale, according to the bulk of those surveyed, the management of land and water would not be impeded by any lack of interest in community-type activities, the existence of more costs than benefits, or a lack of problems apparently requiring urgent action.

5.4 Awareness of Government Strategies

Of the three government strategies put forward, participants had heard most about Landcare (more than 85 percent) which, not surprisingly, was also the best-known strategy. Those who had heard about ICM (more than 37 percent), and knew most about ICM were most likely to be rural producers in the lower catchment.

Generally, knowledge of PMP, Landcare and ICM was greater in the rural samples. Knowledge about the strategies came most often from media sources while for ICM, meetings were also frequently mentioned.

As suggested above, while the widespread lack of perceived use-value and clear effectiveness of ICM and Landcare can be partially explained by low levels of membership in such groups (or, alternatively, may explain the low level of membership), this is still a finding that should warrant close attention.

Around three quarters of those who had definitely or vaguely heard of the Herbert River Catchment Coordinating Committee were rural producers in the lower catchment. Therefore, compared with this sample, all other samples were much less likely to have heard of the HRCCC.

5.5 Responsibility and Control

The first point of note was the widespread agreement by participants that there were things that they as individuals and as a community could do to help improve the environment, and that the local community should take some responsibility for doing this. Another potential spur to action was the high level of agreement that many environmental problems come from the way people manage their properties.

While there was agreement with these issues, any action may be hampered by an equally widespread perception of lack of finances to plan more than a year ahead (although less prevalent in the lower rural sample).

Next, many agreed they could prevent the occurrence of land and water problems on their properties. However, there was less agreement with this issue in the lower catchment (which was possibly related to flooding and drainage concerns being more prevalent).

Compared with the ability to prevent problems, less people agreed that they had complete control over the land and water on their properties. Interestingly, for prevention, distinctions were between the upper and lower catchment whereas for control, these were along rural-urban lines. As might be predicted, those in urban areas (and, therefore, with smaller properties and less direct use of their land) felt they had more control.

In brief, many agreed that laws should be changed to ensure landholders become more responsible for their actions. Once again, those in the lower urban sample (with the exception of Ingham) were more likely to agree and, compared with the lower rural sample, the upper urban sample was also more likely to agree. Lastly, the majority of the sample disagreed that thinking about land and water management for an area the size of the Herbert was too hard. One conclusion drawn from this was that, while managing land and water on a catchment basis was generally considered difficult, thinking about such issues was by no means viewed as impossible.

5.6 Views on Government

This component of the questionnaire highlighted widespread agreement that governments should work out better ways to fix land and water problems, and that incompetent government activities had been witnessed locally. Further, many people could recall a government action that had damaged their livelihood.

The upper urban sample was more likely to trust that public servants worked in their interests most of the time. In general, many others also agreed with this statement. However, as the direction of the mean score for this positively worded statement was less forceful than for the negatively worded statements mentioned above, some relationship between these issues and levels of trust was anticipated. In short, those who agreed they had witnessed incompetent government activities were less likely to trust that public servants worked in their interests.

Similar findings were evident for the statements, "I am sure that our local views will be considered when planning for land and water management in this area", and "Programs like Integrated Catchment Management interfere with people's rights to make their own decisions". Respectively, those who had witnessed government incompetence were less and more likely to agree with these statements.

5.7 Awareness and Intentions

In general awareness of, and preparedness (both personally and for others) to become involved in land and water management activities were viewed as moderate. Preparedness was generally rated as higher in the upper catchment.

In addition, many agreed they would be prepared to assist in local projects such as riverbank stabilisation. Once again this was more evident in the upper catchment.

Compared with this issue, less people thought it likely they would become involved or stay involved with a Landcare or catchment group over the next year or two. Similarly, less believed they could personally benefit from being involved in group activities. In addition, like all issues focussed on personal involvement, significant numbers responded that such issues were not applicable. Generally, the majority of these responses were from people in urban areas.

Many (close to 60 percent) agreed it was likely that they would look into ways to improve the environmental condition of their properties. Further, many agreed that they knew people who considered local groups to be a good way to deal with many land and water management issues.

Finally, again highlighting the distinction between other samples and the lower urban sample, the latter was more likely to disagree that the statement, "the local environment is no worse off than when I first lived here". For all samples, while more chose to disagree, there were also many who agreed. Some relationship also existed between this statement and the item, "how much are you prepared to become involved in land and water issues in the Herbert?". Those who were more likely to become involved were also less likely to agree that the condition of the local environment had not changed over time.

5.7.1 Influences on Involvement

Further analysis was carried out on the items denoting intentions to participate in land and water management activities. Of these, four items formed a reliable scale (0.8) and single intention component (or factor). These were then combined into a composite measure of behavioural intention by adding and dividing the ratings for each participant by four (the number of items). The items selected were:

- *How much are you prepared to become involved in land and water issues in the Herbert?;*
- *I would be prepared to assist in local projects such as riverbank stabilisation;*
- *It is likely that I will become involved (or stay involved) with a Landcare or catchment group over the next year or two;*
- *I can personally benefit from being involved in group activities to help manage land and water.*

The composite item concerns preparedness to become involved, both in a local and group context (specifically concerning land and water management), and relates group involvement to the achievement of personal benefits. A general name for this factor is *Personal and Group Intentions*.

Analyses were carried out to establish whether this intention measure was related to other items in the questionnaire. Using regression analyses, the capacity of other items to influence (predict) Personal and Group Intentions was then investigated.

For the whole sample (and in order of significance), Personal and Group Intentions were influenced by interest in local community issues, one's rating of the personal importance of land degradation, beliefs concerning the difficulty of thinking about an area the size of the Herbert, and the personal usefulness of the nominated government strategy (ie. the strategy known most about). Use of the river/creeks (note that one item within the intention factor related to riverbank stabilisation), the personal impact of higher production costs, and the personal importance of nature conservation issues also influenced intentions.

In summary, the likelihood of participating in land and water management activities appeared to be heightened by:

- a strong interest in local community issues;
- a belief that land degradation was personally important;
- a belief that thinking about land and water issues for an area as big as the Herbert was not too difficult;
- the opinion that government strategies (generally Landcare, and ICM) do have some personal use.

In addition, more frequent use of the river/creeks, concern about the personal impacts of higher production costs and the rating of nature conservation issues as important also related positively to Personal and Group Intentions.

It is noteworthy that, while trust of government programs was stated above as a key issue facing ICM in the Herbert, this was not related to Personal and Group Intentions. However, trust in public servants was to a small degree.

For the rural sample only (upper and lower catchment), influences on intentions were similar and also included the ability to prevent land and water problems from occurring at the property level.

For the urban sample, Personal and Group Intentions were best predicted by the personal importance of nature conservation issues, interest in community issues and the belief that many environmental problems come from the way people manage their properties. Loss of confidence in government's ability to manage land and water resources also influenced intentions.

5.8 Information Sources

The most frequently used sources of information included the Herbert River Express, friends/colleagues, the local "grapevine", neighbours, "Landline", personal experience, and family members.

One of the more notable findings was that the Herbert River Express was used more frequently than more "traditional" sources such as friends and personal experience. Second, "Landline" was used more frequently than personal experience, family members and public meetings. Its use was particularly high in the upper catchment.

Certainly an unexpected finding, Landline was considered the most reliable source. Clearly, Landline is an influential program in conveying information to catchment residents.

On this point, it was noted that the local "grapevine" was also a preferred source of information in the upper catchment, whereas sources including industry groups and public meetings were used more frequently in the lower catchment. This finding therefore suggests that ways to disseminate information about land and water management activities (including ICM) may need to be tailored to the two catchment areas.

The Herbert River Express, public meetings, personal experience, the Country Hour, and Canegrowers were also frequently noted as reliable sources.

Briefly, a clear example of the lack of integration between the upper and lower catchment areas was found in the readership of the Townsville Bulletin (lower catchment) and the Cairns Post (upper catchment).

Further analysis revealed a number of differences between the use of particular information sources and other questionnaire items. Many of these were related to the use of Landline, neighbours, community groups, personal experience and public meetings. For example, compared with non-use, use of these sources was related to more awareness of government strategies (PMP, Landcare, ICM), more agreement that things could be done personally to help improve the environment, and stronger intentions of becoming (or staying) involved in a Landcare or catchment group.

5.9 Group Involvement

One quarter of the whole sample were members of regional/state/national groups, while 44 percent were members of local groups. Many were members of each, and nearly 50 percent were members of either type of group. Rural producers, in particular, had high levels of group membership.

Compared with non-members, members were, for example, more likely to consider constraints to managing land and water to be the wide variety of opinions held by local people, and the difficulty in thinking about relevant issues for an area this size. Members were also more prepared to become involved in land and water issues and to assist in local projects such as riverbank stabilisation, and more likely to become (or stay) involved in a Landcare or catchment group and to see personal benefits accruing from involvement in group activities.

Some of the more prominent groups participants were involved with included sporting groups, Charity/church/welfare groups, agriculture related organisations, and Parents and Friends Associations. Groups considered most important also generally followed this order.

Lastly, approximately half of those who stated involvement with an Agriculture-related Organisation nominated this as the most important group. This was also the case for the "Landcare, Conservation or similar" category.

5.10 Interest in Community Issues

This component of the questionnaire indicated that most people were comfortable in being members of their local communities, thought it was a good place to live, could recognise many other local people, and would like to remain living in the Herbert for a long time.

Next, it was noted that any differences between samples on any of the items all included differences between the lower rural and upper urban samples. From this, it was broadly summarised that, compared mostly with the upper urban sample, the "community" as perceived by those within the lower rural sample appears more cooperative and self-reliant. However, as a word of caution, the differences appeared slight and any conclusions should not be drawn without further analysis.

For life satisfaction, all but one of the mean scores centred around moderate satisfaction. The exception was satisfaction with community facilities and services, with this being the area that people were least satisfied with. In particular, people in the upper urban sample was more likely to register dissatisfaction.

In a similar manner, for satisfaction with the community in which people live, people in the upper urban sample were less likely to be satisfied than those in the lower catchment.

The upper urban sample also responded less positively to the statements, "When thinking about your relationships with local people, how comfortable are you about living here?", and, "When thinking about how much interest local people have for your ideas and opinions, how comfortable are you about living here?".

5.11 Other Information

In brief, other findings included the following.

- Residents in the upper catchment had fewer familial ties beyond those in their household.
- People with property next to a river or creek which floods were less likely to agree that they had complete control over the land and water on their properties.
- Generally, people in the upper catchment were more likely to use rivers/creeks than those in the lower catchment.

Finally, compared with those who never used the river, those who used the river often provided significantly different ratings on a number of items. For example, the latter were:

- more likely to consider lower fish numbers and loss of access to recreation as personal impacts;
- more likely to have loss of confidence in government's ability to manage land and water resources;
- less likely to see programs such as ICM interfering with people's rights to make their own decisions.

Those who used the river often were also more prepared to be involved in land and water management activities and to see the benefits from such involvement.

6.0 IMPLICATIONS FOR ICM

Within the assessment of existing community behaviours and attitudes towards land and water management issues, a number of findings were considered to have implications for the progress of ICM in the Herbert River Catchment.

The first relevant finding was that the four principal issues (ie. land degradation, water quality problems, water quantity problems and nature conservation issues) were generally viewed as highly important. In brief, while some differences were evident between samples (eg. lower urban residents were more likely to rate the importance of water quality and nature conservation issues as high), the general importance of these issues to residents implies that ICM has the scope to plan and implement actions along a number of fronts. This could be done according to different areas of importance and, discussed below, where perceived impacts are seen to be high.

As was the case for issue importance, a number of influences on life in the Herbert were viewed as high impact, in particular, higher taxes and lost confidence in the ability of government to manage natural resources. Other notable impacts included higher production costs, lower fish numbers and loss of environmental uses/benefits.

Notably, the potentially wide scope for ICM was again emphasised by the fact that (a) several impacts were seen as high and (b) many impacts were seen as higher on others in the community than that experienced personally. That is, some issues were less important personally, but were still rated as having high impacts on others. These included the high cost of water, loss of farm productivity, and higher production costs.

On average, the awareness of land and water management issues held by local people was considered moderate. In conjunction with high ratings of personal impacts and those on others, this also demonstrates that ICM can have inroads into a number of important areas. As stated below, compared with "others", personal importance/impacts appeared more likely to influence intentions to participate in land and water management activities. However, knowledge that

certain impacts on others in the Herbert are generally seen as high (or low) can help to guide planning and action.

While awareness of land and water management issues held by local people was considered moderate, many agreed that problems are not well understood. Therefore, awareness of problems does not appear to be related to understanding.

Continuing with knowledge and awareness issues, Landcare was clearly the best-known government strategy, and knowledge of the three government strategies was generally higher in the rural samples. Those who had heard about ICM and the HRCCC and (of the three strategies) knew most about ICM were most likely to be rural producers in the lower catchment.

ICM in the Herbert is at an early stage of development. However, while noting that there appears to be a fair degree of awareness of relevant issues (at least as defined within the questionnaire), the widespread lack of knowledge and perceived effectiveness of ICM may require close attention. Further, target areas for increasing awareness of ICM include all urban settlements and the upper catchment generally.

Additionally, it is noteworthy that approximately 40 percent of the sample had heard of ICM and the HRCCC. Due to a lack of comparative results from other areas, it is difficult to say whether this level of awareness is excellent or mediocre (or somewhere in between).

In one study in the Blackwood Catchment in Western Australia (Butterworth & Carr, 1996), it is notable that similar questions returned 40 percent for ICM and 81 percent for the local coordinating group (BCCG).

A possible reason for this figure is that the BCCG has long had a reasonably solid public profile (eg. via local press) and, perhaps more significant, has had a "shop front" by way of a regional office in a prominent location in the catchment. A similar example closer to the Herbert, the Johnstone River Catchment Centre is located in the centre of Innisfail. This has helped ICM in the Johnstone to gain both a public profile and customer focus (Syme, Butterworth & Nancarrow, 1993).

From their findings, Butterworth and Carr (1996) suggested that the profile of ICM needed to be raised as the foundation underpinning the aims and activities of the BCCG. For example, within an information strategy, differences between ICM and Landcare as well as existing or needed coordination on areas of overlap could be highlighted.

For the issue of tractability, managing land and water was considered to be made most difficult by the large area and difficulty in moving around the catchment, the fact that solutions are not easy and expensive, low trust of government programs, the wide variety of existing opinions, and insufficient understanding of problems.

Results also showed that land and water management would not be obstructed by any lack of interest in community-type activities, the existence of more costs than benefits, or lack of problems requiring action. Within an ICM information strategy, for example, it may be advantageous to highlight factors such as the importance of land degradation and impacts associated with higher production costs, rather than emphasising the benefits of land and water management and the urgency of some problems.

Furthermore, the low level of perceived conflict in the Herbert contrasts with the view that the wide variety of existing opinions is a potential obstacle to managing land and water. This clearly has positive implications for ICM.

Another set of relevant findings for ICM included the analysis of behavioural intentions and subsequent formation of the combined measure "Personal and Group Intentions". In brief, those prepared to participate in land and water management activities were likely to:

- be interested in local community issues;
- believe that land degradation was personally important;
- believe that thinking about land and water issues for an area as big as the Herbert was not too difficult;
- hold that government strategies (generally Landcare, and ICM) do have some personal use.

More frequent use of the river/creeks, concern about the personal impacts of higher production costs and the rating of nature conservation issues as important also related positively to Personal and Group Intentions.

Assuming a causal relationship exists between the above influences and intentions, such influences could be the focus for arousing interest in ICM. Broadly, for example, the importance of land degradation throughout the catchment, the usefulness of ICM and Landcare, and the significance of catchment identity could all be promoted.

Regarding views on ability and responsibility to manage land and water, widespread agreement that actions could and should be undertaken as individuals and as a community provides another positive implication for ICM. However, noted above, any action may be restricted by an equally widespread perception of lack of finances to plan more than a year ahead and the related belief that locals do not have money available to spend on solutions (particularly in the upper catchment).

Many people also agreed that laws should be changed to ensure landholders become more responsible for their actions (although those in the lower rural sample were more ambivalent towards this statement). The majority also disagreed that thinking about relevant issues for the whole catchment was too hard. Consequently, it appeared that many may hold that managing land and water on a catchment basis may be a difficult, but certainly not futile exercise.

Views on government revealed a high level of agreement that governments should develop improved methods for addressing land and water problems, and that incompetent government activities within the catchment had been witnessed. Further, many stated they could recall a government action that had damaged their livelihood. People who agreed they had seen government incompetence were less likely to trust public servants and more likely to agree that programs like ICM interfere with the right of landholders to make their own decisions.

In particular, the low level of trust of government programs and public servants seem prominent issues facing ICM in the Herbert. Trust of public servants, for example, had a significant (although not highly predictive) relationship with the measure of intentions. In this instance, lower levels of trust of public servants were related to increased willingness to participate in land and water management activities.

One suggestion is proposed for dealing with the issue of low government credibility and trust. In conjunction with catchment residents, appropriate roles for public servants could be defined in

order to gain successful and ongoing relationships between the community and government in key areas.

These conclusions carry a number of implications for those selecting ICM planning and implementation processes. It is therefore proposed that a greater understanding of catchment management processes could be gained by investigating what these implications actually entail. As a result, there appears to be several avenues for future research by the study team. For example, comparisons could be made with property rights issues emerging from a study on institutional decision making for land and water allocation in the Shire of Gingin in Western Australia (McCreddin & Syme, 1996).

Finally, to mention two other findings that may have relevance for ICM, members of groups were more prepared to become involved in land and water management activities (including assisting in local projects), more likely to become (or stay) involved in a Landcare or catchment group, and more likely to assume there are personal benefits from involvement in group activities. Second, proximity to, and use of, the river/creeks provided some notable findings. For example, those with property next to a river or creek which floods agreed less that they had complete control over land and water, while those who used the river often were also more prepared to be involved in relevant activities and to see the benefits from such involvement.

Consequently, positive aspects and experiences related to group membership and involvement generally could also be used as promotional tools within an ICM information/communication strategy.

APPENDIX 1

Land and Water Management in the Herbert River Catchment Questionnaire

1. Using the scale below please rate your level of satisfaction with the various aspects of your life at the moment. *(please write your chosen number from the scale next to each item).*

Scale:

1	2	3	4	5
very dissatisfied	**moderately dissatisfied**	**neither satisfied nor dissatisfied**	**moderately satisfied**	**very satisfied**

Your life in general _____

Your standard of living _____

Your personal health _____

The area where you live _____

The community in which you live _____

Existing community facilities and services _____

2. What do you think are the major advantages of living in the Herbert?

_____

_____

_____

_____

3. Generally, what do you think are some of the key issues facing people in the Herbert?

_____

_____

_____

_____

4. In your opinion, how important are the following issues **(1) to you personally**, and **(2) to people in the Herbert generally**? *(using the following scale, please write your chosen number/s in the two boxes next to each issue).*

Scale:

1	2	3	4	5
very high importance	**high**	**moderate**	**low**	**very low importance**

	importance to you personally	importance to people in the Herbert
Land degradation		
Water quality problems		
Water quantity problems		
Nature conservation issues (eg. loss of wildlife habitat, management of state forests)		

5. Following are a list of issues which **some people** think have an impact on life in the Herbert. In **your opinion**, how much do each of the following impacts **(1) affect you personally**, and **(2) affect people in the Herbert generally**? *(using the following scale, please write your chosen number/s in the two boxes next to each impact).*

Scale:

1	2	3	4	5
very high degree	**high**	**moderate**	**low**	**very low degree**

OR **8** **not at all**

Possible Impacts	affects you personally	affects people in the Herbert
High cost of water		
Loss of farm productivity		
Higher production costs		
Poor drinking water quality		
Shortage of irrigation water		
Declining human health		
Loss of independence to make business decisions		
Emotional stress		
Conflicts with other local people		
Higher taxes		
Lower fish numbers		
Loss of access to recreation		
Loss of confidence in government's ability to manage land and water resources		
Loss of environmental uses or benefits (eg. wildlife habitat)		
Loss of scenery		

6. Generally speaking, what **awareness** do you think local people have about land and water issues in the Herbert? *(please circle one number only)*

1	2	3	4	5
very high awareness	**high**	**moderate**	**low**	**very low awareness**

7. How much do you think **local people** are prepared to become involved in land and water issues in the Herbert? *(circle one number only)*

1	2	3	4	5
to a very high degree	**high**	**moderate**	**low**	**very low degree**

8. How much are **you** prepared to become involved in land and water issues in the Herbert? *(circle <u>one</u> number only)*

1	2	3	4	5
to a very high degree	**high**	**moderate**	**low**	**very low degree**

9. Using the scale below please rate how much you agree or disagree with the following statements. *(please write your chosen number from the scale next to each statement).*

<u>Scale:</u>

1	2	3	4	5
strongly disagree	**disagree**	**neither agree nor disagree**	**agree**	**strongly agree**

Managing land and water in the Herbert is difficult because...

problems aren't well understood. _____

solutions aren't easy. _____

there aren't any problems that need urgent action. _____

local people lack the money to spend on solutions. _____

government strategies are a waste of time. _____

solutions are expensive. _____

there are few benefits and many costs. _____

local people don't want to spend money on solutions. _____

the Herbert River catchment covers a large area. _____

it's hard to get around the catchment (eg. from top to bottom). _____

people in the Herbert have a wide variety of opinions. _____

local people don't trust government programs. _____

local people aren't that interested in community-type activities. _____

the government doesn't want to spend money on solutions. _____

10. Before we contacted you about this study, which of the government strategies in the box below had you heard about and which one did you know most about?

STRATEGY	**HAD YOU HEARD OF THIS?** *(please tick as many boxes as apply)* ↓	**WHICH DID YOU KNOW MOST ABOUT?** *(tick <u>one</u> box only)* ↓
Property Management Planning or "PMP"	?	?
Landcare	?	?
Integrated Catchment Management or "ICM"	?	?

☞*If you haven't heard of any of these government strategies, please go to question* **12.**

11. When thinking of the government strategy you know most about:

A. how useful has this strategy been to you personally? *(please circle <u>one</u> number only)*

1	2	3	4	5
not at all useful	**not very**	**moderately**	**quite**	**very useful**

B. how effective has the strategy been in dealing with land and water issues in the Herbert? *(circle <u>one</u> number only)*

1	2	3	4	5
very effective	**fairly effective**	**neither effective nor ineffective**	**fairly ineffective**	**very ineffective**

C. how did you come to know of the strategy?

_____

_____

12. Have you heard of a group called the Herbert River Catchment Coordinating Committee?

YES .... 1 **VAGUELY .... 2** **NO .... 3** ☞*please go to question* **13.**

↓ ↓

If YES or VAGUELY, what do you think the main purpose of this group is?

_____

_____

13. Using the scale below please rate how much you agree or disagree with the following statements. *(write your chosen number from the scale next to each statement).*

<u>Scale:</u>

1	2	3	4	5	**<u>OR</u>**	8
strongly disagree	**disagree**	**neither agree nor disagree**	**agree**	**strongly agree**		**not applicable**

Governments should work out better ways to fix land and water problems. _____

There are things I can do personally to help improve the environment. _____

It's too hard to think about land and water management issues for an area as big as the Herbert catchment. _____

I don't usually have the finances available to plan more than a year ahead. _____

I trust that public servants are working in my interest most of the time. _____

I've seen incompetent government activities in this part of the country. _____

The local community should take some responsibility for improving the environment. _____

Programs like Integrated Catchment Management interfere with people's rights to make their own decisions. _____

There are things local community groups can do to help improve the environment. _____

I am sure that our local views will be considered when planning for land and water management in this area. _____

The local environment is no worse off than it was when I first lived here. _____

I would be prepared to assist in local projects such as riverbank stabilisation. _____

Many environmental problems come from the way people manage their properties. _____

I can prevent any land and water problems from occurring on my property. _____

It is likely that I will become involved (or stay involved) with a Landcare or catchment group over the next year or two. _____

I've complete control over what happens to the land and water on this property. _____

It is likely that I will look into ways to improve the environmental condition of my property over the next year or two. _____

I can recall at least one government action which has damaged my livelihood. _____

I could personally benefit from being involved in group activities to help manage land and water. _____

Laws should be changed to make landholders more responsible for the consequences of their activities. _____

Some people I know think that local groups are a good way to deal with many land and water management issues. _____

14. Which of the following sources of information help you to **keep informed** about land and water management issues? *(tick as many boxes as apply)*

Neighbours	☐	The Australian newspaper	☐
A government agency (please specify)	☐	Cairns Post	☐
_____		Townsville Bulletin	☐
_____		Telegraph Times	☐
Industry groups (please specify	☐	Herbert River Express	☐
_____		The Tablelander	☐
_____		Tablelands Advertiser	☐
Community Groups	☐	Millstream Times	☐
Family members	☐	Courier Mail	☐
Friends/colleagues	☐	Magazines/journals	☐
Personal experience	☐	Government newsletters	☐
The local "grapevine"	☐	The Country Hour (ABC radio)	☐
Public meetings	☐	Landline (ABC television)	☐
Other (please specify)	☐		
_____		None/I don't keep informed	☐
_____		☞ *please go to question* **19**.	

15. In the above box, which two sources of information would you say were the most **reliable** for helping you to make decisions?

- (1)
- (2)

16. Does what you read in newspapers ever change your opinions about land and water management issues? *(please circle <u>one</u> number only)*

1	2	3	4
often	**occasionally**	**seldom**	**never**

17. Does what you hear on the radio or see on TV ever change your opinions about land and water management issues? *(please circle <u>one</u> number only)*

1	2	3	4
often	**occasionally**	**seldom**	**never**

18. How often do you discuss land and water management issues with your neighbours or others in this general area? *(circle <u>one</u> number only)*

1	2	3	4
often	**occasionally**	**seldom**	**never**

19. When thinking about your **relationships with local people**, how comfortable are you about living here? *(circle <u>one</u> number only)*

1	2	3	4	5
not at all comfortable	**not very**	**moderately**	**quite**	**very comfortable**

20. When thinking about how much **interest local people have for your ideas and opinions**, how comfortable are you about living here? *(circle <u>one</u> number only)*

1	2	3	4	5
not at all comfortable	**not very**	**moderately**	**quite**	**very comfortable**

21. Are you a member of any regional, state or nationally-based groups or associations? *(please circle <u>one</u> number only)*

YES .... 1 **NO 2**

22. Are you a member of any local community groups or associations? *(circle <u>one</u> number only)*

YES .... 1 ☞ *please go to question* **25**.

or

NO 2

↓

23. Generally, what are some of your reasons for not being involved in any community groups?

_____

_____

_____

_____

24. Would you ever consider joining a community group? *(circle <u>one</u> number only)*

YES .... 1 **DON'T KNOW .... 2** **NO 3**

↓ ↓

For what reasons would you join? _____

_____

_____

_____

☞ *If you answered* **NO to question 21** *and* **NO to question 22**, *please go to question* **28**.

25. Which of the following categories describe *any* of the groups you have some involvement with? *(please tick as many boxes as apply)*

Progress Association	☐	Sporting Group	☐
Rate Payers Association	☐	Hobby/Craft Group	☐
Professional Association	☐	Community Action Group	☐
Charity/Church/Welfare Group	☐	Service Club (eg Lions, Rotary)	☐
Agriculture-related Organisation	☐	Parents & Friends Association	☐
Landcare, Conservation or similar Group	☐	Other/s (*please explain*)	☐
		_____	
		_____	

26. Of the groups you are involved with, please write down the name of the group that is **most important** to you.

- **Important group:** _____

27. If you are involved in any groups in the "Landcare, Conservation or similar" category, please write down the name of the group that you are **most involved** with. This may or may not be the same as the group that is the most important to you.

- **Landcare, Conservation or similar group:** _____

_____

28. Thinking of the local community where you live, please rate how much you agree or disagree with each of the following statements. *(using the scale below, write your chosen number from the scale next to each statement).*

Scale:

1	2	3	4	5
strongly disagree	**disagree**	**neither agree nor disagree**	**agree**	**strongly agree**

I'm not very interested in local community issues. _____

I feel quite comfortable in being a member of this local community. _____

The community is capable of getting things done without any outside help. _____

I would like to remain living in this area for a long time. _____

I have almost no influence over what happens in this community. _____

It's very important to me to live in this particular community. _____

People in this community generally don't get along with each other. _____

I don't really care what others in the community think of my actions. _____

Very few of my neighbours know me. _____

I often think about local community issues. _____

I want the same things from this community as other local people want. _____

I and many others in this community share similar values. _____

I think this community is a good place to live. _____

I can recognise many of the people who live in this community. _____

I. don't have the time to become involved in local community issues _____

OTHER INFORMATION

29. How old are you? _____ **years**

30. What is your gender? *(please circle a number)*

MALE .... 1 FEMALE 2

31. Which country were you born in? _____

32. What is your marital status? *(circle the most appropriate number)*

Married/Defacto	**.... 1**	Divorced/Separated	**.... 2**
Never Married/Single	**.... 3**	Widowed	**.... 4**

33. Do you have any family members living in the Herbert area other than those in your household? *(circle <u>one</u> number only)*

YES .... 1 NO 2

34. What is your main occupation? _____

35. How many years have you had this occupation? _____ **years**

36. How long have you lived in the Herbert area? _____ **years**

37. Is your property near to a river or creek which floods?

YES .... 1 **NO .... 2** **DON'T KNOW 3**

38. Thinking about where you live, what is the most important river or creek to you?

_____

39. How often do you use the river or creeks near where you live? (eg. for commercial, domestic or recreational purposes) *(please circle <u>one</u> number only)*

1	**2**	**3**	**4**
often	**occasionally**	**seldom**	**never**

40. How often do you go fishing for recreation? *(circle <u>one</u> number only)*

1	**2**	**3**	**4**
often	**occasionally**	**seldom**	**never**

41. Do you own or lease/rent a commercial rural, or rural property greater than 3 hectares (7.5 acres)? (*please circle <u>one</u> number only)*

YES **NO .... 3** ☞ *please go to question* **45.**

↓

OWN .... 1 or LEASE/RENT 2

42. Which one of the following best describes your current use of this property? *(circle <u>one</u> number only)*

Cane farming **.... 1** Grazing **.... 2** Mining **.... 3** Industrial **.... 4**

Other farming **.... 5** *(please specify)* _____

Other **.... 6** *(please specify)* _____

43. What is the size of your property? _____ **hectares** *<u>or</u>* _____ **acres**

44. Have you cleared any new land in the last twelve months?

YES .... 1 **NO .... 2** ☞ *please go to question* **45.**

↓

If YES, how much new land have you cleared? _____ **hectares** *<u>or</u>* _____ **acres**

45. Would you be prepared to answer another shorter questionnaire if needed in a few months time?

YES .... 1 **NO 2**

Chapter 3

Land and Water Management in the Herbert River Catchment: A Survey of Rural and Urban Residents

Summary Report to the Herbert River Catchment Coordinating Committee

James E. Butterworth, Geoffrey J. Syme, Blair E. Nancarrow

Butterworth, J.E., Syme, G.J., and Nancarrow, B.E. (1997). Land and Water Management in the Herbert River Catchment: A Survey of Rural and Urban Residents. *Summary Report to the Herbert River Catchment Coordinating Committee.*

This study forms the community assessment component of CSIRO-led research evaluating the implementation of Integrated Catchment Management (ICM) in the Herbert River Catchment. The study is supported by the Land and Water Resources Research and Development Corporation (LWRRDC).

THE STUDY

This study examined landholders' behaviours and attitudes towards land and water management in the Herbert River Catchment. The aim was to provide an understanding of the sorts of issues that might affect the performance of Integrated Catchment Management (ICM) in the Herbert, and how these might vary according to where people live and what their interests are.

The basis of the study was a community survey, and this was designed as a questionnaire to be filled out by those agreeing to take part (see Appendix 1). Telephone calls were used to inform people about the study, and those willing to be involved were then mailed the survey.

The questionnaire contained items including landholders':

- level of importance, perceived impacts/effects, awareness and attitudes and attitudes towards various land and water management issues;
- perceived ability to control land and water management issues;
- tractability or "manageability" of potential issues;
- intentions to participate in relevant activities;
- awareness of government strategies;
- attitudes towards government's performance;
- use of information sources;
- group involvement.

The study area included the whole catchment. A range of landholders were contacted, including those in the upper and lower catchment; in rural and urban areas; and with different occupations including cane farming, grazing and mining.

In all, 800 telephone calls were made and 718 people agreed to take part. The number of returned and completed questionnaires was 477, providing an overall return rate of 66%.

A breakdown of the number of questionnaires returned and response rates appears in the following table.

Catchment	Type of Holding	Number Returned	Response Rate (%)	Towns surveyed	Number Returned	Response Rate (%)
UPPER	RURAL	59	64.1			
	URBAN	86	67.2	Herberton	38	76.0
				Mt Garnet	18	54.5
				Ravenshoe	30	66.7
LOWER	RURAL	191	67.7			
	URBAN	141	65.3	Allingham	28	60.1
				Ingham	45	61.6
				Halifax	17	54.8
				Lucinda	26	66.7
				Taylors Beach	24	88.9
TOTAL		**477**	**66.4**			

RESULTS

Some of the main conclusions of the research are discussed below. Most results are based on comparisons among four samples: *upper rural, lower rural, upper urban* and *lower urban*. When appropriate, these categories were also combined into more general *upper* and *lower*, and *rural* and *urban* samples.

Issue Importance

For the whole sample, land degradation, water quantity problems, water quality problems and nature conservation issues were generally seen as highly important. The last two issues produced the highest and lowest ratings (average or mean scores) respectively. The lower urban sample was likely to place higher ratings of importance for these two issues.

Water quantity problems were largely viewed in terms of the lack – rather than abundance – of water and, as such, appeared to be less important in the lower catchment. Based on current views, one difference between the two catchment areas might be that one does not have enough, and the other has too much water.

Results also showed that ratings of importance tended to be less for others than those felt personally. This occurred largely due to lower importance ratings being provided by the rural samples. This makes sense in that the perception of "others" in the Herbert may include urban residents who may be less affected by problems such as land degradation.

It was interesting that where lower importance ratings (for others) were also provided by the urban sample, this occurred when issues were more likely to be considered personally important (namely water quality and nature conservation issues). Also, for water quality problems, the knowledge that such problems were isolated to certain areas (or less severe in other areas) of the catchment may have helped to lower importance ratings.

Impacts

In terms of the effects of various issues on people personally, higher taxes and loss of confidence in the ability of government to manage natural resources were rated highly. Other impacts rated moderate to high included higher production costs, lower fish numbers and loss of environmental uses/benefits. For rural producers in the lower catchment, reduced farm productivity was a high impact.

High impacts on others included higher taxes, higher production costs, loss of confidence in government, poor drinking water quality and loss of farm productivity.

Compared with impacts felt personally, impacts on others tended to be significantly higher. Also, compared with urban residents, the ratings from people in the two rural samples, and particularly the lower rural sample, were less liable to change (when comparing self with others). Therefore, the higher ratings for others generally came from people in the urban samples, who were less likely to be personally affected by issues including higher production costs, loss of independence to make business decisions, and higher taxes.

As discussed in the full report, people in the lower urban sample appeared more "urban" than the upper urban sample in their views about certain issues. From this, it was suggested that the two upper catchment samples may be more like-minded than those in the lower catchment.

As examples, this was the case for the impacts of loss of: access to recreation, environmental uses or benefits, and scenery. As the lower urban sample was most likely to consier these impacts as high (and most likely to agree with other statements, including the need to change laws to increase landholders' responsibility for their actions), more "urban" may also stand for more "green". (Or – at least at this time – more concerned with such issues). This particularly seemed the case for those living in Taylors Beach, whereas the views of those living in Ingham were not as pronounced.

Interestingly, those in the lower urban sample were also generally less likely to become personally involved in land and water management activities (see below).

Tractability

For the issue of tractability (or manageability), managing land and water was thought to be made most difficult by the catchment's large areas, the fact that solutions are not easy, the expense required to put solutions in place, low trust of government programs, the difficulty of moving around the catchment, the wide variety of existing opinions, and insufficient understanding of problems.

Certainly from the point of view of perceived credibility, the low level of trust of government programs appears to be a key issue facing ICM in the Herbert.

On the upside of the scale, according to most, land and water management would not be impeded by any lack of interest in community-type activities, the existence of more costs than benefits, or a lack of problems apparently requiring urgent action.

Awareness of Government Strategies

Of the three government strategies put forward (ICM, Landcare and Property Management Planning), participants had heard most about Landcare (more than 85%) which, not surprisingly, was also the best-known strategy. Those who had heard about ICM (more than 37%), and knew most about ICM were most likely to be rural producers in the lower catchment.

Interestingly, 11 of the 12 people who knew most about PMP, and 42 of the 47 who knew most about ICM, resided in the lower catchment. Thus, the clear majority of people in the upper catchment (82.6%) knew most about Landcare.

Results appear in the following tables. Please note that the figure "**N**" in the tables shows the number of responses to a particular question. For any question, at least a few people chose not to respond.

		Property Management Planning (PMP		Landcare		Integrated Catchment Management (ICM)	
Response	**Rating**	**N(475)**	**Percent**	**N(475)**	**Percent**	**N(475)**	**Percent**
Heard about	1	123	25.9	406	85.5	178	37.5
Not heard about	2	352	74.1	69	14.5	297	62.5
TOTAL		475	100.0	475	100.0	475	100.0

Strategy known most about

Response	**Rating**	**N(453)**	**Percent**
PMP	1	12	2.6
Landcare	2	333	73.5
ICM	3	47	10.4
don't know of any	4	61	13.5
TOTAL		453	100.0

Usefulness of the strategy known most about

Response	**Rating**	**N(380)**	**Percent**
very useful	5	20	5.3
quite	4	36	9.5
moderately	3	102	26.8
not very	2	122	32.1
not at all useful	1	100	26.3
TOTAL		380	100.0
Mean = 2.4			

For this issue, nearly 60% of the participants responded that the strategy had been not at all useful or not very useful. Looking at the results for PMP, Landcare and ICM separately, the average ratings were 3.0 (only 12 responses), 2.3 and 2.4 respectively (generally, moderately to not very useful).

For ICM, this figure may not be too concerning since ICM in the Herbert is at a fairly early stage of development. For Landcare, the lack of usefulness may be more of a concern given that it is a more established, locally-based and "hands on" approach than ICM. As noted below, however, very few of the samples were members of Landcare groups and this likely explains the figures in the above table.

Response	Rating	N(380)	Percent
very effective	5	6	1.6
fairly effective	4	100	26.7
neither effective nor	3	130	34.8
ineffective	2	108	28.9
fairly ineffective	1	30	8.0
very ineffective			
		374	100.0
TOTAL			
Mean = 2.9			

Looking at the results for PMP, Landcare and ICM separately, the average ratings were 3.3 (only 12 responses), 2.8 and 2.8 respectively. Interestingly, when comparing the strategy's personal usefulness with their general effectiveness, the ratings all increased significantly.

While there were widespread views that ICM and Landcare lacked use-value and clear effectiveness, this might be partially explained by low membership numbers in such groups (or, alternatively, may explain the low level of membership). Nevertheless, it is a finding that should warrant close attention.

Sources of knowledge	N	Percent
Newspapers	79	23.7
Television/television advertisements	72	21.6
Media (in general)	44	13.2
Word of mouth	40	12.0
Meetings (in general)	31	9.3
Canegrowers meetings	22	6.6
Radio/radio talk shows	22	6.6
Reading	17	5.1
Advertisements (in general)	12	3.6
Canegrowers magazine	12	3.6
Local pamphlets	9	2.7
Personal experience	8	2.4
Landcare	6	1.8

67% of the responses could be classified as media sources (ie. a combination of the newspaper, television, media and radio responses).

With approximately three-quarters of this sample, Landcare accounted for the bulk of the responses. Most common were newspapers (72 of 79 in total), television (69 of 72), media (42 of 444), word of mouth (34 of 40), radio (22 of 22), and reading (15 of 17).

For ICM, 15 people stated their sources to be meetings, while 7 people were more specific in stating canegrowers meetings. Other sources included newspapers (6), drainage boards (3), word of mouth (3), and the Canegrowers Magazine (2).

The next question asked people whether they had heard of the Herbert River Catchment Coordinating Committee.

Response	Rating	N(425)	Percent
Yes	1	93	21.9
Vaguely	2	86	20.2
No	3	246	57.9
TOTAL		425	100.0

Interestingly, of those who had definitely heard about the HRCCC, 68 were from the lower rural sample (41% of this sample). Only 8 and 4 people had definitely heard about the HRCCC in the upper catchment rural and urban samples (14 and 5 % of these samples) respectively. Thirteen people (10%) of the lower urban sample had heard of the HRCCC.

Around three quarters of those who had definitely or vaguely heard of the Herbert River Catchment Coordinating Committee were rural producers in the lower catchment. Therefore, compared with this sample, all other samples were much less likely to have heard of the HRCCC.

From lowest to highest, those who responded "Yes" or "Vaguely" comprised 17, 31, 34, and 65% of the upper urban, lower urban, upper rural and lower rural samples respectively. This result could have been expected, given that ICM may have more of a presence in the lower catchment and a greater focus on rural (rather than urban) resource management issues.

Of further interest, it is noteworthy that 179 people had heard of the HRCCC and 178 people had heard about ICM, with both figures being in the order of 40%. More than three quarters of those who had heard about ICM had heard of the HRCCC, while more than 21% of those who had not heard about ICM had at least vaguely heard about the HRCCC.

Participants were then asked to state what they believed to be the main purpose of the HRCCC. Some of the more prominent purposes of the HRCCC are summarised in the following table. The figures in the percent column related to the total number of people who gave at least one response (161).

Purpose of HRCCC	N	Percent
Preserve waterways (including land quality and river banks)	23	14.3
Conserve and manage water	21	13.0
Care for the catchment area	14	8.7
Coordinate river use	12	7.4
Control/mitigate flooding in the lower catchment (including a suggestion to dredge the Herbert River)	10	6.2
Raise awareness/inform the public of existing problems	8	5.0
Coordinate groups to discuss problems (such as drainage)	8	5.0
Calculate regular flood areas	7	4.3
Maintain flow in the Herbert River and creeks/keep it clean	7	4.3
Not sure/it has never been fully publicised locally	7	4.3
Form strategies to assist the community (eg. to help with drainage disputes)	6	3.7
Combine all drainage boards into one body (eg. to cut costs and improve effectiveness)	6	3.7
Dam the river	3	1.9
Monitor fertiliser runoff	3	1.9

As can be seen, a variety of purposes were put forward. Most related mainly to water issues and many were fairly hands-on; for example, to improve drainage, control flooding, calculate flood areas, maintain river flow, and dam the river.

Responsibility and Control

For these questions, a clear finding was the widespread agreement by participants that (a) there were things that they as individuals and as a community could do to help improve the environment, and (b) the local community should take some responsibility for doing this. Another potential influence to action was the high level of agreement that many environmental problems come from the way people manage their properties.

While there was agreement with these issues, any action to improve the environment may be limited by an equally widespread view that finances are lacking to plan more than a year ahead (although less prevalent in the lower rural sample).

Next, many agreed they could prevent land and water problems on their properties. However, there was less agreement with this issue in the lower catchment (which was possibly related to flooding and drainage concerns being more widespread).

Compared with the ability to prevent problems, fewer people agreed that they had complete control over the land and water on their properties. Interestingly, for the issue of prevention, distinctions were between the upper and lower catchment (with those in the lower catchment believing they had less ability) whereas for control, these were along rural-urban lines. As might be predicted, those in urban areas (and, therefore, with smaller properties and less direct use of their land) felt they had more control.

In brief, many agreed that laws should be changed to ensure landholders become more responsible for their actions. Again, those in the lower urban sample (with the exception of Ingham) were more likely to agree and, compared with the lower rural sample, the upper urban sample was also more likely to agree. Lastly, most of the sample disagreed that thinking about land and water management for an area the size of the Herbert was too hard. One conclusion drawn from this was that, while managing land and water on a catchment basis was generally considered difficult, thinking about such issues was by no means viewed as impossible.

Views on Government

This part of the questionnaire showed a high level of agreement that governments should work out better ways to fix land and water problems, and that incompetent government activities had been seen locally. Many people also felt they could recall a government action that had damaged their livelihood.

The upper urban sample was more likely to trust that public servants worked in their interests most of the time, although, in general, many others also agreed public servants were trustworthy. Those who agreed they had seen government incompetence, however, were less likely to trust that public servants worked in their interests.

There were similar findings for the statements, *I am sure that our local views will be considered when planning for land and water management in this area*, and *Programs like Integrated Catchment Management interfere with people's rights to make their own decisions*. Those who noted they had seen government incompetence were less and more likely to agree with these statements respectively.

Awareness and Intentions

In general, awareness of, and willingness to become involved in land and water management activities were viewed as moderate. Willingness was generally rated as higher in the upper catchment.

Also, may agreed they would be prepared to assist in local projects such as riverbank stabilisation. Again, this was more evident in the upper catchment.

Compared with this issues, fewer people thought it likely they would become involved or stay involved with a Landcare or catchment group. Similarly, less believed they could personally benefit from being involved in group activities.

Like all issues concerning personal involvement, many people felt that such issues did not apply to them. Generally, the majority of these were from people living in urban areas.

Many (nearly 60%) agreed it was likely that they would look into ways to improve the environmental condition of their properties. Many (more than 50%) also agreed that they knew people who considered local groups to be a good way to deal with many land and water management issues.

To highlight again the distinction between other samples and the lower urban sample, the latter was more likely to disagree that the statement, *the local environment is no worse off than when I first lived here*. For all samples, while more chose to disagree, there were also many who agreed. There was also

some relationship between this statement and the item, *how much are you prepared to become involved in land and water issues in the Herbert?*. Those who were more likely to become involved were also more likely to disagree that the local environment had not deteriorated over time.

Influences on Involvement

Further scrutiny was made of the items relating to intentions to participate in land and water management activities. Of these, four items were combined into a single measure of intention. The items selected were:

- *How much are you prepared to become involved in land and water issues in the Herbert?*
- *I would be prepared to assist in local projects such as riverbank stabilisation;*
- *It is likely that I will become involved (or stay involved) with a Landcare or catchment group over the next year or two;*
- *I can personally benefit from being involved in group activities to help manage land and water.*

The combined measure concerns preparedness to become involved, both in a local and group context (specifically concerning land and water management), and relates group involvement to personal benefits. This measure was called *Personal and Group Intentions*.

Next, an attempt was made to find out whether this measure was related to other items in the questionnaire. In other words, other items were looked at to see if they could influence (predict) Personal and Group Intentions.

For the whole sample (and in order of significance), Personal and Group Intentions were influenced by interest in local community issues, the personal importance of land degradation, beliefs about the difficulty of thinking about an area the size of the Herbert, and the personal usefulness of the specified government strategy (ie. the strategy known most about). Use of the river/creeks, the personal effects of higher production costs, and the importance of nature conservation issues also influenced intentions.

In summary, the likelihood of participating in land and water management activities appeared to be influenced by:

- a strong interest in local community issues;
- a belief that land degradation was personally important;
- a belief that thinking about land and water issues for an area as big as the Herbert was not too difficult;
- the opinion that government strategies (generally Landcare, and ICM) do have some personal use.

Also, more frequent use of the river/creeks, concern about the personal effects of higher production costs and the rating of nature conservation issues as important, also related positively to Personal and Group Intentions.

It is important to note that, while trust of government programs was considered a key issue facing ICM in the Herbert, this was not related to Personal and Group Intentions. However, trust in public servants was to a small degree.

For the rural sample only (upper and lower catchment), influences on intentions were similar and also included the ability to prevent land and water problems from occurring at the property level.

For the urban sample, Personal and Group Intentions were best predicted by the personal importance of nature conservation issues, interest in community issues and the belief that many environmental problems come from the way people manage their properties. Loss of confidence in the ability of government to manage land and water resources was also influential.

Information Sources

Participants were asked, *Which of the following sources of information help you to keep informed about land and water management issues?*

In the following table, the figures in both percentage columns show the proportion of people – compared with the whole sample – who use a particular source of information.

Information Source	**Percent**	**Information Source**	**Percent**
Neighbours	46.5		.2 (N=1)
A government agency	13.4		59.7
Industry groups	24.7		27.3
Community groups	21.6		23.9
Family members	34.2		15.1
Friends/colleagues	53.9		5.9
Personal experience	39.0		30.2
The local "grapevine"	48.4		7.5
Public meeting	32.3		28.3
The Australian newspaper	10.9		43.6
Cairns Post	16.8		2.5
Townsville Bulletin	30.6		5.5

In brief, the most frequently used sources of information included the Herbert River Express, friends/colleagues, the local "grapevine", neighbours, "Landline", personal experience, and family members.

One of the more notable findings was that the Herbert River Express was used more frequently than more "traditional" sources such as friends and personal experience.

Second, "Landline" was used more frequently than personal experience, family members and public meetings. Its use was particularly high in the upper catchment.

Certainly an unexpected finding, "Landline" was considered the most reliable source. Clearly, "Landline" is an influential program in passing on information to catchment residents.

On this point, it was noted that the local "grapevine" was also a preferred source of information in the upper catchment, whereas sources including industry groups and public meetings were used more frequently in the lower catchment. This finding therefore suggests that ways to provide

information about land and water management activities (including ICM) may need to be tailored to the two catchment areas.

The Herbert River Express, public meetings, personal experience, the Country Hour, and Canegrowers were also frequently noted as reliable sources.

Briefly, a clear example of the lack of integration between the upper and lower catchment areas was found in the readership of the Townsville Bulletin (lower catchment) and the Cairns Post (upper catchment).

Further analysis revealed a number of differences between the use of particular information sources and other questionnaire items. Many of these were related to the use of Landline, neighbours, community groups, personal experience and public meetings. For example, compared with non-use, use of these sources was related to more awareness of government strategies (PMP, Landcare, ICM), more agreement that things could be done personally to help improve the environment, and stronger intentions of becoming (or staying) involved in a Landcare or catchment group.

Group Involvement

One quarter of the whole sample were members of regional/state/national groups, while 44% were members of local groups. Many were members of each, and nearly 50% were members of either type of group. Rural producers, in particular, had high levels of group membership.

Compared with non-members, members were, for example, more likely to consider constraints to managing land and water to be the wide variety of opinions held by local people, and the difficulty in thinking about relevant issues for an area this size. Members were also more prepared to become involved in land and water issues and to assist in local projects such as riverbank stabilisation, and more likely to become (or stay) involved in Landcare or catchment groups and to see the personal benefits of involvement in group activities.

Some of the more prominent groups included sporting groups, charity/church/welfare groups, agriculture related organisations, and Parents and Friends Associations.

Lastly, approximately half of those who stated involvement with an agriculture-related organisation nominated this as the most important group. This was also the case for the "Landcare, Conservation or similar" category.

Interest in Community Issues

This part of the questionnaire showed that most people were comfortable in being members of their local communities, thought it was a good place to live, could recognise many other local people, and would like to remain living in the Herbert for a long time.

Next, it was noted that any difference on the items all included differences between the lower rural and upper urban samples. From this, it was broadly summarised that, compared mostly with the upper urban sample, the "community" as perceived by those within the lower rural sample appears more cooperative and self-reliant. However, as a word of caution, the differences to appear slight.

For life satisfaction, all but one of the average ratings centred around moderate. The exception was satisfaction with community facilities and services, with this being the area that people were the least satisfied. In particular, people in the upper urban sample were more likely to register dissatisfaction.

Similarly, for satisfaction with the community in which people live, people in the upper urban sample were less likely to be satisfied than those in the lower catchment.

The upper urban sample also responded less positively to the statements, *When thinking about your relationships with local people, how comfortable are you about living here?*, and, *When thinking about how much interest local people have for your ideas and opinions, how comfortable are you about living here?*

Other Information

In brief, other findings included the following:
- Residents in the upper catchment had fewer familial ties beyond those in their household;
- People with property next to a river or creek which floods were less likely to agree that they had complete control over the land and water on their properties;
- Generally, people in the upper catchment were more likely to use rivers/creeks than those in the lower catchment.

Finally, compared with those who never used the river, those who used the river often gave different ratings on a number of items. For example, these people were:
- more likely to consider lower fish numbers and loss of access to recreation as personal impacts;
- more likely to have loss of confidence in government's ability to manage land and water resources;
- less likely to see programs such as ICM interfering with people's rights to make their own decisions.

Those who used the river often were also more prepared to be involved in land and water management activities and to see the benefits from such involvement.

Implications for ICM

A number of findings were considered to have implications for the progress of ICM in the Herbert.

The first relevant finding was that the four principal issues (ie. land degradation, water quality problems, water quantity problems and nature conservation issues) were generally viewed as highly important. In brief, while there were some differences between samples (eg. lower urban residents were more likely to rate the importance of water quality and nature conservation issues as high), the general importance of these issues to residents implies that ICM has the scope to plan and carry out actions along a number of fronts. This could be done according to different areas of importance and, discussed below, where perceived impacts are seen to be high.

As was the case for issue importance, a number of influences on life in the Herbert were viewed as having a high impact, in particular, higher taxes and lost confidence in the ability of government to manage natural resources. Other notable impacts included higher production costs, lower fish numbers and loss of environmental uses/benefits.

The potentially wide scope for ICM was emphasised by the fact that (a) several impacts were seen as high and (b) many impacts were seen as higher on others in the community than that experienced personally. That is, some issues were less important personally, but were still rated as having high impacts on others. These included the high cost of water, loss of farm productivity, and higher production costs.

On average, the awareness of land and water management issues held by local people was considered moderate. Along with high ratings of personal impacts and those on others, this also shows that ICM can have inroads into a number of important areas. As stated below, compared with "others", personal importance/impacts appeared more likely to influence intentions to participate in land and water management activities. However, knowledge that certain impacts on others in the Herbert are generally seen as high (or low) can help to guide planning and action.

While awareness of land and water management issues held by local people was considered moderate, many agreed that problems are not well understood. Therefore, awareness of problems does not appear to be related to understanding.

Continuing with knowledge and awareness issues, Landcare was clearly the best-known government strategy, and knowledge of the three government strategies was generally higher in the rural samples. Those who had heard about ICM and the HRCCC and (of the three strategies) knew most about ICM were most likely to be rural producers in the lower catchment.

ICM in the Herbert is at an early stage of development. However, while noting that there appears to be a fair degree of awareness of relevant issues (at least as defined within the questionnaire), the widespread lack of knowledge and perceived effectiveness of ICM may require close attention. Further, target areas for increasing awareness of ICM include all urban settlements and the upper catchment generally.

In addition, it is noteworthy that approximately 40% of the sample had heard of ICM and the HRCCC. Due to a lack of comparable results from other areas, it is difficult to say whether this level of awareness is excellent, mediocre, or somewhere in between.

In one study in the Blackwood Catchment in Western Australia (Butterworth & Carr, 1996), it is notable that similar questions returned 40% for ICM and 81% for the local coordinating group (BCCG).

A possible reason for this figure is that the BCCG has long had a solid public profile (eg. via local press) and, perhaps more significant, has had a "shop front" by way of a regional office in a prominent location in the catchment. A similar example closer to the Herbert, the Johnstone River Catchment Centre is located in the centre of Innisfail. This has helped ICM in the Johnstone to gain both a public profile and customer focus (Syme, Butterworth & Nancarrow, 1993).

From their findings, Butterworth and Carr (1996) suggested that the profile of ICM in the Blackwood needed to be raised as the basis of the aims and activities of the BCCG. For example, within an information strategy, differences between ICM and Landcare, as well as existing or needed coordination on areas of overlap, could be highlighted.

For the issues of tractability, managing land and water was considered to be made most difficult by the large area and difficulty in moving around the catchment, the fact that solutions are not easy and expensive, low trust of government programs, the wide variety of existing opinions, and insufficient understanding of problems.

Results also showed that land and water management would not be obstructed by any lack of interest in community-type activities, the existence of more costs than benefits, or lack of problems requiring action. Within an ICM information strategy, for example, it may be useful to highlight factors such as the importance of land degradation and impacts associated with higher production costs, rather than emphasising the benefits of land and water management and the urgency of some problems.

Next, the low level of perceived conflict in the Herbert (at least at the time of the survey) contrasts with the view that the wide variety of existing opinions is a potential obstacle to managing land and water. While this appears to have positive implications for ICM, it understood that "hot:" issues may occasionally occur in the Herbert and these may increase the potential for conflict. Therefore, further research would be needed to clarify the degree to which perceived conflict is stable or varies over time.

Another set of relevant findings for ICM included the analysis of people's intentions and formation of the measure *Personal and Group Intentions*. In brief, those prepared to participate in land and water management activities were likely to:

- be interested in local community issues;
- believe that land degradation was personally important;
- believe that thinking about land and water issues for an area as big as the Herbert was not too difficult;
- hold that government strategies (generally Landcare and ICM) do have some personal use.

More frequent use of the river/creeks, concern about the personal impacts of higher production costs and the rating of nature conservation issues as important also related to intentions to participate.

Assuming a "causal" relationship exists between the above influences and intentions, such influences could be the focus for arousing interest in ICM. Broadly, for example, the importance of land degradation throughout the catchment, the usefulness of ICM and Landcare, and the significance of catchment identity could all be promoted.

Regarding views on ability and responsibility to manage land and water, the widespread agreement that actions could and should be undertaken as individuals and as a community is another positive implication for ICM. However, any action may be restricted by an equally widespread perception of lack of finances to plan more than a year ahead and the related belief that locals do not have money available to spend on solutions (particularly in the upper catchment).

Many people also agreed that laws should be changed to ensure landholders become more responsible for their actions (although those in the lower rural sample had more mixed views towards this statement). The majority also disagreed that thinking about relevant issues for the whole catchment was too hard. As such, it appeared that many may think that managing land and water on a catchment basis may be a difficult, but certainly not futile exercise.

Views on government revealed a high level of agreement that governments should develop improved methods for addressing land and water problems, and that there had been incompetent government activities within the catchment. Further, many stated they could recall a government action that had damaged their livelihood. People who agreed they had seen government incompetence were less likely to trust public servants and more likely to agree that programs like ICM interfere with the right of landholders to make their own decisions.

In particular, the low level of trust of government programs and public servants seem prominent issues facing ICM in the Herbert. To this end, one suggestion is proposed for dealing with low government credibility and trust. In conjunction with catchment residents, appropriate roles for public servants could be defined as a way to gain successful and ongoing relationships between the community and government in key areas.

Finally, to mention tow other findings that may have relevance for ICM, members of groups were more prepared to become involved in land and water management activities (including assisting in local projects), more likely to become (or stay) involved in a Landcare or catchment group, and more likely to assume there are personal benefits from involvement in group activities. Second, proximity to, and use of, the river/creeks provided some notable findings. For example, those with property next to a river or creek which floods agreed less that they had complete control over land and water, while those who used the river often were also more prepared to be involved in relevant activities and to see the benefits from such involvement.

Consequently, positive aspects and experiences related to group membership and involvement generally could also be used as promotional tools within an ICM information/communication strategy.

1.0 Introduction

This study follows a survey performed in 1996 (Butterworth, Syme and Nancarrow, 1997) examining landholders' attitudes, beliefs and behaviours relating to land and water management in the Herbert River Catchment in north Queensland. The two surveys form the community assessment component of research evaluating the implementation of Integrated Catchment Management (ICM) in the Herbert River Catchment.

The original survey (see Appendix 1) covered:

- levels of importance, perceived impacts, awareness and attitudes towards various land and water management issues;
- perceived ability to control land and water management issues;
- tractability or "manageability" of potential issues;
- intentions to participate in relevant activities;
- attitudes towards government's performance;
- use of information sources; and
- group involvement.

The 1998 survey (see Appendix 2) covered the above items and those listed below:

- importance of various activities for ICM;
- awareness and opinions of the Herbert River Catchment Coordinating Committee's (HRCCC's) activities;
- awareness of information resources for the catchment;
- perceptions of current and preferred monetary contributions to Landcare and ICM; and
- the relationship between local government and ICM.

Survey 1 respondents who agreed they would be involved in a similar survey in the future were contacted by telephone along with a random selection of additional landholders. The response rates are shown in the table below.

Catchment	Type of holding	Number returned	Response Rate (%)	Towns Surveyed	Number Returned	Response Rate (%)
Upper	Rural	47	47.0			
	Urban	70	55.1	Herberton	33	71.7
				Mt Garnet	18	60.0
				Ravenshoe	19	45.2
Lower	Rural	141	44.1			
	Urban	143	55.9	Allingham	38	71.7
				Ingham	40	42.6
				Halifax	19	55.9
				Lucinda	26	72.2
				Taylors Beach	20	74.1
TOTAL		401	49.9			

A comparison of the results for the upper and lower catchment is provided in the following table. The final section explains the implications of the results for ICM.

2.0 Comparison of Results for the Upper and Lower Catchment

	Upper Catchment	Lower Catchment
Response Rate		
Overall	51.5%	49.3%
Urban	Herberton 71.7% Mount Garnet 60.0% Ravenshoe 45.2%	Taylor's Beach 74.1% Lucinda 72.2% Allingham 71.7% Halifax 55.9% Ingham 42.6%
Rural	47.0%	44.1%
Repeat	65.7%	62.1%
New	40.0%	43.8%
Demographics		
Age	Median age 40 to 55 years.	Median age 40 to 55 years.
Gender	60% male and 40% female.	62% male and 38% female.
Main occupations	Retired, home duties, grazier.	Cane farmer, home duties, retired, education, or a trade.
Lived in Herbert	Average of 14.5 years. Average of 17.2 years.	Average of 24.4 years. Average of 38.2 years.
Rural Properties		
Rural properties over 3 hectares	53% did not own or lease/rent 37% owned 10% leased or rented	50% did not own or lease/rent 45% owned 4% leased or rented 2% owned & leased/rented
Average size	6258 hectares	202 hectares
Clearing	Very few who owned/leased/rented such properties had cleared in the last 12 months.	Very few who owned/leased/rented such properties had cleared in the last 12 months.
Farming	Mainly used for grazing. Other farming included maize, corn, avocadoes, navy beans, trees, vegetables, fruit, potatoes, goat and horse breeding, hay, hobby farming, grain, grapes, small crops and poultry.	Mainly used for cane farming. Other farming included grazing, trees, pharmaceutical drugs, and aquaculture.
Other uses	Mainly residential, wildlife, subdivision or idle.	Mainly residential, mixed grazing and cane, or subdivision.
Life Satisfaction	Moderate satisfaction with: life in general, standard of living, personal health, where they lived and their community. Lower satisfaction with community facilities or services.	Moderate satisfaction with: life in general, standard of living, personal health, where they lived and their community. Lower satisfaction with community facilities or services.

Main advantages of the Herbert River Catchment	Healthy environment, great climate, unspoiled natural environment, good quality drinking water.	Personal safety, close access to recreation, closeness to large centres, close knit community.
Key Issues	Unemployment, water quantity issues, lack of opportunities for young people.	Lack of diversity in industry, unemployment, lack of opportunities for young people, flooding, weather/changing weather patterns, fishing issues.
Importance of Issues High personal importance	Water quality problems, land degradation, water quantity problems, nature conservation, and loss of biodiversity.	Water quality problems, land degradation, vegetation on river banks, flooding, nature conservation, wetlands and loss of biodiversity.
Moderate to high personal importance	Vegetation on river banks, wetlands.	Water quantity problems.
High importance to the Herbert	Water quantity problems, water quality problems.	Flooding, water quality problems.
Moderate to high importance to the Herbert	Land degradation, flooding, vegetation on river banks, wetlands, loss of biodiversity, and nature conservation.	Land degradation, water quantity, vegetation on river banks, wetlands, loss of biodiversity, and nature conservation.
Impacts of Issues		
Overall	Where there was a difference between the upper and lower catchment, the upper catchment indicated lower impacts.	Where there was a difference between the upper and lower catchment, the lower catchment indicated higher impacts.
Personal impacts	Most issues had a moderate to high impact.	All issues had a moderate to high impact.
Highest impacts	1. Loss of confidence in government's ability to manage land and water resources. 2. Higher taxes (higher for rural). 3. Poor drinking water quality.	1. Higher taxes (higher for lower rural than other respondents). 2. Loss of confidence in government's ability to manage land and water resources. 3. Poor drinking water quality. lower fish numbers, 4. Loss of environmental uses. 5. Loss of farm productivity (higher for rural respondents). 6. Higher production costs (higher for lower rural than other respondents).
Lowest impacts	1. Loss of farm productivity. 2. Emotional stress.	Emotional stress.
Impacts on the Herbert	All of the issues were rated between moderate and high.	All of the issues were rated between moderate and very high.
Highest impacts	1. Higher production costs. 2. Higher taxes. 3. Loss of confidence in government's ability to manage land and water	1. Higher taxes, 2. Loss of farm productivity. 3. Higher production costs. 4. Poor water quality.

	resources. 4. Loss of productivity. 5. Lower fish numbers.	5. Loss of confidence in government's ability to manage land and water resources. 6. Lower fish numbers.
Lowest impacts	1. Emotional stress (higher for rural than urban respondents). 2. Loss of environmental uses. 3. Loss of access to recreation.	1. Emotional stress (higher for rural than urban respondents). 2. Loss of environmental uses.
Tractability		
Greatest impediments	1. Slow government strategies. 2. The catchment's size. 3. Slow reactions by government to new problems. 4. Cost of solutions. 5. Lack of easy solutions. 6. Low trust of government programs. 7. Insufficient understanding of relevant problems.	1. Slow government strategies. 2. The catchment's size. 3. Slow reactions by government to new problems. 4. Cost of solutions. 5. Lack of easy solutions. 6. Low trust of government programs. 7. Insufficient understanding of relevant problems.
Lowest impediments	1. There are few benefits and many costs. 2. Local people aren't that interested in community-type activities.	1. There are few benefits and many costs. 2. Local people aren't that interested in community-type activities.
Differences	Of the eleven impediments only *local people lack the money to spend on solutions* was rated differently in the upper and lower catchment – upper agreed more strongly.	Of the eleven impediments only *local people lack the money to spend on solutions* was rated differently in the upper and lower catchment – lower agreed less strongly.
Government Strategies		
Most familiar	93% had heard of Landcare 47% had heard of ICM 22% had heard of PMP Knowledge highest for Landcare.	89% had heard of Landcare 51% had heard of ICM 33% had heard of PMP More awareness in lower rural. Knowledge highest for Landcare.
Personal usefulness	Most familiar strategy rated as moderate to not very useful.	Most familiar strategy rated as moderate to not very useful.
Effectiveness in dealing with land and water issues	Landcare rated as fairly effective overall. ICM rated as fairly effective.	Landcare rated as fairly effective overall. ICM rated as fairly effective.
Sources of information	Heard of most familiar strategy mainly through newspapers, TV/TV advertisements, the media, or by word of mouth.	Heard of most familiar strategy mainly through newspapers, TV/TV advertisements, the media, or by word of mouth.
Other programs	One fifth were aware of other government funded programs on wider environmental matters.	One fifth were aware of other government funded programs on wider environmental matters.
Main comments	It lacked knowledge of the local situation, was poorly organised, dealt with reforestation, worked well, was not consulting locals.	It lacked knowledge of the local situation, was poorly organised, dealt with reforestation, worked well, was not consulting locals.

Activities for ICM		
Overall	All eleven activities were rated well over moderately important.	All eleven activities were rated well over moderately important.
Most important	1. Develop solutions for and better understanding of environmental problems in the Herbert catchment. 2. Raise the level of local awareness and knowledge of environmental management issues. 3. Encourage local government to take an active role in environmental management issues. 4. Encourage joint projects between community, industry and state and local government. 5. Encourage research.	1. Develop solutions for and better understanding of environmental problems in the Herbert catchment. 2. Raise the level of local awareness and knowledge of environmental management issues. 3. Encourage local government to take an active role in environmental management issues. 4. Encourage joint projects between community, industry and state and local government. 5. Encourage research.
Differences	Rural sample: upper catchment more strongly supported: 1. Encouraging coordinating of state government programs. 2. Separate ICM programs for the upper and lower catchments.	Rural sample: lower catchment less strongly supported: 1. Encouraging coordinating of state government programs. 2. Separate ICM programs for the upper and lower catchments.
The HRCCC		
ICM and HRCCC	21% of those who had not heard about ICM (earlier in the questionnaire) had at least vaguely heard of the HRCCC.	21% of those who had not heard about ICM (earlier in the questionnaire) had at least vaguely heard of the HRCCC.
Awareness	35.7% had heard of the HRCCC at least vaguely. Most rural respondents had heard of the HRCCC (less in the upper catchment).	48.1% had heard of the HRCCC at least vaguely. Most rural respondents had heard of the HRCCC (more in the lower catchment).
Perceived purposes	Most frequent responses: care for the catchment, conserve & manage water, preserve waterways, raise awareness/inform the public of existing programs. 10% were not sure or said that the purpose had not been fully publicised locally.	Most frequent responses: care for the catchment, conserve & manage water, preserve waterways, raise awareness/inform the public of existing programs. 10% were not sure or said that the purpose had not been fully publicised locally.
Effectiveness	Most of those who responded believed that the HRCCC had been effective in achieving its goals and purposes to some extent.	Most of those who responded believed that the HRCCC had been effective in achieving its goals and purposes to some extent.
Specific activities	Over one fifth were unaware of any of the specific activities of the HRCCC. (Low response rate may indicate an even higher percentage).	Over one fifth were unaware of any of the specific activities of the HRCCC. (Low response rate may indicate an even higher percentage).
Progress	Half responded that the HRCCC was progressing quickly enough, at least to some extent. The majority felt that they were heading in the right direction at least to some extent.	Half responded that the HRCCC was progressing quickly enough, at least to some extent. The majority felt that they were heading in the right direction at least to some extent.

Resources		
Herbert Resource Information Centre	2% had visited the HRIC.	28% had visited the HRIC.
Herbert River Catchment Atlas	30% had seen the Atlas.	33% had seen the Atlas.
HRCCC Catchment Management Strategy	6% had seen the Strategy.	10% had seen the Strategy.
Responsibility		
General agreement	Many environmental problems come from the way people manage their properties (upper rural higher than lower rural).	Many environmental problems come from the way people manage their properties (lower rural lower than upper rural).
Divided opinion regarding ICM	1. It should be paid for and run by the government. 2. It should remain a voluntary activity. 3. The government expects too much from local communities. 4. Laws should be changed to make landholders more responsible for consequences of their activities.	1. It should be paid for and run by the government. 2. It should remain a voluntary activity. 3. The government expects too much from local communities. 4. Laws should be changed to make landholders more responsible for consequences of their activities.
Control		
High agreement	There are things local community groups can do to help improve the environment (higher in the upper catchment).	There are things local community groups can do to help improve the environment (lower in the lower catchment).
General agreement	1. There are things I can do personally to help improve the environment. 2. I don't usually have the finances available to plan more than a year ahead.	1. There are things I can do personally to help improve the environment. 2. I don't usually have the finances available to plan more than a year ahead.
General disagreement	It is too hard to think about land and water management issues for an area as big as the Herbert catchment.	It is too hard to think about land and water management issues for an area as big as the Herbert catchment.
Government		
High agreement	Need better incentives for landholders to address environmental issues/problems.	Need better incentives for landholders to address environmental issues/problems.
General agreement	1. The government needs to give more resources to voluntary groups. 2. Different government agencies often give conflicting information on land and water management issues.	1. The government needs to give more resources to voluntary groups. 2. Different government agencies often give conflicting information on land and water management issues.
Split opinion	1. Programs like ICM interfere with people's rights to make their own decisions. 2. ICM programs should have legislative backing. 3. The government gives plenty of resources to voluntary groups.	1. Programs like ICM interfere with people's rights to make their own decisions. 2. ICM programs should have legislative backing. 3. The government gives plenty of resources to voluntary groups.

Awareness		
Local people	Moderate degree of awareness about land and water management issues (lower than lower catchment).	Moderate degree of awareness about land and water management issues (higher than upper catchment).
General agreement	There are problems that need urgent action (upper rural more than lower rural).	There are problems that need urgent action (lower rural less than upper rural).
Split opinion	Local environment is no worse off than when I first lived here.	Local environment is no worse off than when I first lived here.
Intentions		
Local people	Would be prepared to become involved in land and water issues to a moderate degree.	Would be prepared to become involved in land and water issues to a moderate degree.
Respondents	Prepared to be involved to a moderate/high degree.	Prepared to be involved to a moderate/high degree.
Split opinion	1. Preparedness to assist in local projects such as riverbank stabilisation (upper rural agreed more than lower rural). 2. Likelihood of becoming (or staying) involved with a Landcare or catchment group over the next year or two. 3. Personal benefits of being involved in group activities to help manage land and water.	1. Preparedness to assist in local projects such as riverbank stabilisation (lower rural agreed less than lower rural). 2. Likelihood of becoming (or staying) involved with a Landcare or catchment group over the next year or two. 3. Personal benefits of being involved in group activities to help manage land and water.
Involvement in Groups		
Local community groups	42% had been involved in local community groups or associations over the last 12 months.	28% had been involved in local community group or associations over the last 12 months.
Main groups	Landcare, conservation, etc, charity/church/welfare, agriculture related, service club, parents and friends, sporting group.	Landcare, conservation, etc, charity/church/welfare, agriculture related, service club, parents and friends, sporting group.
Landcare, conservation or similar groups	Few responses, however, most frequent were Landcare groups.	Few responses, however, most frequent were Landcare groups.
Local Community		
General agreement	1. It is a good place to live. 2. They recognise many of the people. 3. They feel quite comfortable there. 4. Interest in local issues. 5. They shared similar values with others. 6. It's important to live there (lower agreement in the upper catchment).	1. It is a good place to live. 2. They recognise many of the people. 3. They feel quite comfortable there. 4. Interest in local issues. 5. They shared similar values with others. 6. It's important to live there (higher agreement in the lower catchment).
Split opinion	1. Influence over what happens (less agreement in the upper catchment). 2. People in their community don't generally get along. 3. Often think about local community	1. Influence over what happens (more agreement in the lower catchment). 2. People in their community don't generally get along. 3. Often think about local community

	issues. 4. Having the time to become involved in local community issues.	issues. 4. Having the time to become involved in local community issues.
ICM and Local Government	90% believed that local government should have a role in ICM. The main reasons were: - knowledge of the local environment - more resources and information - responsible for building and maintaining infrastructure - within its region. 96% responded that local government planning should take ICM into account. The main reasons were: - benefit the community - responsible for building and maintaining infrastructure - knowledge of local environment - provide better management for the future.	88% believed that local government should have a role in ICM. The main reasons were: - knowledge of the local environment - more resources and information - representation of local people and views - better able to obtain funds. 93% responded that local government planning should take ICM into account. The main reasons were: - benefit the community - uniformity of approach - stop development in the wrong areas.
Funding		
Amounts being contributed by the different sections	Commonwealth gov $35.51** Queensland gov $32.57 Local government $14.79 Industry $4.91 ** Farmers $11.85 ** Significant difference between the upper and lower catchment.	Commonwealth gov $26.77 ** Queensland gov $28.29 Local government $19.35 Industry $11.89 ** Farmers $12.47 ** Significant difference between the upper and lower catchment.
Amounts that should be contributed by the different sections	Commonwealth gov $39.03 Queensland gov $29.82 Local government $12.11 ** Industry $10.23 Farmers $8.55 It was thought that industry should be contributing more than they were at the time.	Commonwealth gov $34.94 Queensland gov $26.26 Local government $16.94 ** Industry $11.53 Farmers $10.23 It was thought that the Commonwealth government should be contributing more than they were at the time.

3.0 Implications of the Findings for ICM

This section outlines consistent and important findings across Survey 2 and their implications for ICM.

There was very strong stability of opinions between 1996 and 1998.

- Prompted and unprompted responses displayed relatively few differences and differences that did exist were by a matter of degree.

For ICM, the stability of the results suggests that opinions and priorities do remain fairly stable over time, and that any changes in awareness or behaviour related to land and water management, are likely to take longer than two years to occur, given the resources available.

There was a fairly high degree of satisfaction with living in the Herbert.

- There was moderate satisfaction with life in general, standard of living, personal health, the area where respondents lived and the community in which they lived.
- Respondents generally agreed that it is a good place to live, they felt quite comfortable living there, recognised many of the people in their local community, shared similar values with others and felt it was important to live in that particular community.
- Respondents reported many advantages of the Herbert.

The finding that there was general satisfaction with many aspects of living in the Herbert River catchment suggests that most people would not support any changes that would threaten these aspects of their community.

The most important issues to respondents when not prompted were related to employment, in other words, life issues:

- unemployment;
- a lack of opportunities for young people; and
- a lack of diversity in industry.

Following these were issues related to land and water management and the environment:

- clearing of marginal land;
- flooding;
- drainage;
- water quantity issues;
- fishing issues;
- the impact of weather and changing weather conditions on primary industry; and
- environmental issues in general.

When prompted on land and water management issues, many respondents found them to be important:

- most issues were more important personally than to the Herbert in general;
- respondents generally agreed that there were problems that needed urgent action;
- however, opinion was divided on whether or not the environment had worsened since respondents first lived in the Herbert;
- high ratings of personal importance, and importance for the Herbert, of water quality problems, land degradation, water quantity problems and nature conservation;
- moderate to high ratings of importance of flooding, wetlands, vegetation on riverbanks and loss of biodiversity.

When asked about the personal impact, and the impact on the Herbert, of various issues:

- there were few differences over time;
- the personal impact of loss of farm productivity, poor drinking water quality and loss of environmental uses/benefits increased over time;
- for the Herbert, the impact of loss of farm productivity was seen to have increased since Survey 1 and the impact of lower fish numbers was perceived to have decreased;
- there was a high impact on respondents of poor drinking water quality and loss of environmental uses; and

- respondents perceived the largest impacts on the Herbert to be from loss of farm productivity and poor drinking water quality.

There was community awareness and interest in the Herbert issues, most respondents:
- were interested in local issues; and
- local awareness about land and water issues was considered to be moderate, as in Survey 1.

There is awareness of problems and the perception that land and water issues are important, both personally and on a catchment scale. This signifies general support for ICM to tackle land and water management on a number of fronts. However, land and water management issues were not uppermost in people's minds, which suggests that there needs to be awareness and acknowledgment by ICM that while people may support land and water management of various kinds, their first priorities lie with 'life issues'.

Opinions were divided about:
- the degree of influence respondents felt over what happened in their communities;
- whether or not people in their community generally got along; and
- whether or not respondents often thought about local community issues.

While there was community interest in issues for the Herbert, the influence people felt was not particularly high, it appeared that there may be some conflict and not all respondents often thought about local community issues. These factors may hinder community participation in ICM.

The community displayed a high sense of self-responsibility:
- many environmental problems come from the way people manage their properties;
- laws should be changed to make landholders more responsible for the consequences of their activities (more respondents agreed than disagreed, but generally divided).

While a high sense of self-responsibility in the community for dealing with land and water management issues is an advantage for ICM in gaining community participation, it will be very important for ICM to recognise this in working with the community and in the types of policies that are promoted.

There was a high sense of control over the community's ability to deal with land and water management, illustrated by agreement that:
- it was not too hard to think about land and water management issues for an area as big as the Herbert catchment;
- there were things they could do personally to help improve the environment; and
- there were things local community groups could do to help improve the environment.

A high sense of community control over dealing with land and water management issues is a very positive result for ICM.

The high sense of control may be hindered by a perceived lack of resources, for example:
- many didn't usually have the finances available to plan more than one year ahead;
- respondents tended to disagree that the government gives plenty of resources to voluntary groups;
- respondents reported a high personal impact of higher taxes;

- a high perceived impact on the Herbert of higher taxes, a loss of farm productivity, and higher production costs;
- many agreed the government needs to give more resources to voluntary groups; and
- support for government incentives for landholders to address environmental issues.

Many community members feel that individual landholders have a role to play in land and water management and see that there are ways they and their local communities can assist. To do this, they may need assistance from the government in terms of resources and government incentives.

In addition, there were perceived to be a number of impediments to effectively managing land and water in the catchment, the greatest impediments were seen to be:

- slow government strategies;
- slow reactions of government to new problems;
- the catchment's large area;
- the cost of solutions;
- a lack of easy solutions;
- low trust of government programs; and
- insufficient understanding of relevant problems.

It will be important for ICM to address these perceptions of impediments, perhaps by:

- encouraging timely responses from government;
- encouraging financial support for ICM;
- developing and promoting solutions;
- encouraging improved formal and informal communication between the government and the community; and
- improving understanding of land and water management problems.

While the catchment's large area was seen to be a difficulty, it was not considered to be insurmountable earlier in the survey.

Awareness of government strategies and resources was varied:

- Landcare was the most familiar strategy: most respondents had heard of Landcare and the majority knew more about it than ICM and Property Management Planning;
- one third had heard of PMP;
- half had heard of ICM;
- a higher proportion of cane farmers and graziers had heard of ICM than any of the other main occupations (home duties, trade, retired, education and general farming);
- a higher percentage of repeat respondents had heard of ICM than new respondents;
- those who had heard about ICM and (of the three strategies) knew most about ICM were most likely to be rural producers in the lower catchment, ie. cane farmer;
- only 2% of upper catchment respondents had visited the Herbert Resource Information Centre, compared with 28% from the lower catchment;
- approximately 30% had seen the Herbert River Catchment Atlas; and
- approximately 10% had seen the HRCCC Catchment Management Strategy.

Although the awareness levels of ICM are encouraging, they could be improved, particularly in urban areas and the upper catchment generally, which will be assisted by the efforts of the new upper catchment committee. The low percentage of upper catchment respondents who had visited the Herbert Resource Information Centre highlights a need for more information in the upper catchment.

The main sources of information regarding government strategies were:

- newspapers;
- television and television advertisements;
- the media in general; and
- general meetings or Canegrowers Association meetings (for ICM specifically).

Informing the community of broad scale government strategies will be most effective through newspapers, and if possible, television or the general media, whereas more localised information about ICM may be more effective through meetings.

Perceptions of government management of land and water were as follows:

- 60% of respondents felt that the most familiar government strategy was either not very useful or not at all useful to them personally.
- Comments on other government funded programs included that they lacked knowledge of the local situation, did not consult local people, did not use the best or most recent information, worked well or that it was a good idea.
- There was general agreement that different government departments often give conflicting information regarding land and water management issues.

The perceived personal usefulness of government strategies may need to be improved. It will be important for the government to respond to community perceptions regarding the importance of local knowledge, consulting local people, using the best quality information and giving consistent information to the community. Providing consistent feedback as to the positive outcomes of government programs would be useful.

Perceptions of the HRCC

- About 44% had heard of the HRCCC, at least vaguely (very similar to Survey 1).
- Its main purposes were perceived to be care for the catchment, conserving and managing water, preserving waterways, raising awareness and improving drainage.
- Very few people were aware of its specific activities.
- Most of those who had heard of the HRCCC felt that it had been effective to some extent in achieving its goals and purposes.
- About half thought that the group was progressing quickly enough.
- The majority thought they were generally heading in the right direction.
- 21% of those who had not heard about ICM had at least vaguely heard of the HRCCC.

Although the level of community awareness of the HRCCC was encouraging, it had not increased in the two years since Survey 1 was conducted. Awareness could be improved, particularly regarding the specific activities of the HRCCC. The majority of those who were aware of the committee supported its general direction and effectiveness and were fairly satisfied with the speed of its progress.

The main priorities for the direction of ICM were as follows:

- 90% of respondents felt that local government should have a role in ICM;
- 95% of respondents felt that local government planning should take ICM into account;
- encouraging joint projects between different parties;
- raising local awareness;
- developing solutions for, and better understanding of, environmental problems;
- encouraging research; and
- encouraging local government involvement.

Still highly important for ICM, but lowest in priority were:

- understanding specific on-ground projects;
- separate ICM programs for the upper and lower catchments;
- providing a continuing source of advice to local government on catchment issues; and
- encouraging discussion between community interest groups.

Continuing close involvement with local government, and reporting on this involvement to the community, will be very important for ICM in the future. In addition, key priorities for ICM are:

- encouraging joint projects;
- raising local awareness;
- gaining a better understanding of environmental problems;
- developing solutions for environmental problems;
- encouraging research; and
- communicating on this work to the community.

There were split opinions regarding community and government roles in ICM, for example, whether or not:

- ICM should remain a voluntary activity by community members;
- government expectations of the community in ICM were too high;
- the government should pay for and run ICM; and
- programs like ICM interfere with people's rights to make their own decisions.

In terms of funding contributions by government, industry and the community:

- the Commonwealth Government was perceived to be contributing more funding than the Queensland Government, Local Government, industry or farmers;
- upper catchment respondents thought that industry should be contributing more than they were, whereas lower catchment respondents thought that the Commonwealth Government should be contributing more than they were; and
- while industry was perceived to be contributing the least at the time of Survey 2, in general, respondents thought that farmers should contribute the least amount of funding of the five parties.

Overall, the differences between perceptions of current funding contributions and perceptions of how much government, industry and farmers should be contributing were quite small. This indicates that the overall system was perceived to be reasonably fair and indicates a preference for fairly even monetary contributions from various parties. In addition, various results show an overall preference for a partnership approach between government, industry and the community, rather than the responsibility going primarily either to the government or the community.

Involvement in groups

- there were divided opinions about whether or not respondents had the time to become involved in local community issues;
- 42% of upper catchment respondents and 28% of lower catchment respondents had been involved in local community groups or associations in the past years; and
- the main categories were Landcare, conservation, etc.; charity, church or welfare; agriculture related groups; and service clubs.

There were divided opinions regarding information to become involved:

- perceived preparedness of local people to become involved in land and water issues had decreased from Survey 1 (close to moderate in both);

- preparedness of respondents to become involved in land and water issues had increased since Survey 1 (again close to moderate in both) and was higher in rural respondents;
- preparedness to assist in local projects;
- likelihood of respondents becoming or staying involved with a Landcare or catchment management group over the next .year; and
- the degree of personal benefit to be gained from involvement in group activities to help manage land and water

Involvement in other local community groups and associations may prevent some people from becoming active in ICM groups due to their time commitments, particularly in the upper catchment. In addition, the split opinions regarding intentions to become or stay involved in land and water management indicate that there are some people who are unlikely to become involved in ICM. This does not mean that people will not be able to remain or become interested in ICM activities or carry out activities promoted by ICM. It does mean that the HRCCC should be careful to ensure maximised benefits for the time expended by the community on ICM related activities.

Finally, the questionnaire may have raised expectations in the community, and it will be important for the HRCCC to respond to the issues found to be important to respondents.

LAND & WATER MANAGEMENT
ISSUES FOR THE HERBERT RIVER CATCHMENT
SURVEY QUESTIONNAIRE
July 1996

LOCATION:	Upper Catchment	…. 1	Lower Catchment	…. 2
LANDUSE:	Rural	…. 1		
	Urban			
	Herberton	…. 2	Allingham	…. 5
	Mt Garnet	…. 3	Ingham	…. 6
	Ravenshoe	…. 4	Halifax	…. 7
			Lucinda	…. 8
			Taylors Beach	…. 9

1. Using the scale below please rate your level of satisfaction with the various aspects of your life at the moment. *(please write your chosen number from the scale next to each item)*

Scale:

1	2	3	4	5
very dissatisfied	**moderately dissatisfied**	**neither satisfied nor dissatisfied**	**moderately satisfied**	**very satisfied**

Your life in general _____

Your standard of living _____

Your personal health _____

The area where you live _____

The community in which you live _____

Existing community facilities and services _____

2. What do you think are the major advantages of living in the Herbert?

_____

_____

_____

_____

3. Generally, what do you think are some of the key issues facing people in the Herbert?

_____

_____

_____

_____

4. How important are the following issues **(1) to you personally, and (2) to people in the Herbert generally**? *(using the following scale, please write your chosen number/s in the two boxes next to each issue)*

Scale:

1	2	3	4	5
very high importance	**high**	**moderate**	**low**	**very low importance**

	importance to you personally	**importance to people in the Herbert**
Land degradation		
Water quality problems		
Water quantity problems		
Nature conservation issues ..... (eg. loss of wildlife habitat, management of world heritage areas)		

5. Following are a list of issues which **some people** think have an impact on life in the Herbert. In **your opinion**, how much do each of the following impacts **(1) affect you personally**, and **(2) affect people in the Herbert generally**? *(using the following scale, please write your chosen number/s in the two boxes next to each impact)*

Scale:

1 very high degree — **2** high — **3** moderate — **4** low — **5** very low degree **OR** **8** not at all

Possible Impacts	affects you personally	affects people in the Herbert
High cost of water		
Loss of farm productivity		
Higher production costs		
Poor drinking water quality		
Shortage of irrigation water		
Declining human health		
Loss of independence to make business decisions		
Emotional stress		
Conflicts with other local people		
Higher taxes		
Lower fish numbers		
Loss of access to recreation		
Loss of confidence in government's ability to manage land and water resources		
Loss of environmental uses or benefits (eg. wildlife habitat)		
Loss of scenery		

6. Generally speaking, what **awareness** do you think local people have about land and water issues in the Herbert? *(please circle <u>one</u> number only)*

1 very high awareness — **2** high — **3** moderate — **4** low — **5** very low awareness

7. How much do you think **local people** are prepared to become involved in land and water issues in the Herbert? *(circle <u>one</u> number only)*

1 to a very high degree — **2** high — **3** moderate — **4** low — **5** very low degree

8. How much are **you** prepared to become involved in land and water issues in the Herbert? *(circle <u>one</u> number only)*

1	2	3	4	5
to a very high degree	**high**	**moderate**	**low**	**very low degree**

9. Using the scale below please rate how much you agree or disagree with the following statements. *(please write your chosen number from the scale next to each statement)*

<u>Scale:</u>

1	2	3	4	5
strongly disagree	**disagree**	**neither agree nor disagree**	**agree**	**strongly agree**

Managing land and water in the Herbert is difficult because...

problems aren't well understood _____

solutions aren't easy _____

there aren't any problems that need urgent action _____

local people lack the money to spend on solutions _____

government strategies are a waste of time _____

solutions are expensive _____

there are few benefits and many costs _____

local people don't want to spend money on solutions _____

the Herbert River catchment covers a large area _____

it's hard to get around the catchment (eg from top to bottom) _____

people in the Herbert have a wide variety of opinions _____

local people don't trust government programs _____

local people aren't that interested in community-type activities _____

the government doesn't want to spend money on solutions _____

10. Before we contacted you about this study, which of the government strategies in the box below had you heard about and which one did you know most about?

STRATEGY	**HAD YOU HEARD OF THIS?** *(please tick as many boxes as apply)* ↓	**WHICH DID YOU KNOW MOST ABOUT?** *(circle <u>one</u> number only)* ↓
Property Management Planning or "PMP"	☐	1
Landcare	☐	2
Integrated Catchment Management or "ICM"	☐	3

☞ *If you haven't heard of any of these government strategies, please go to question* **12.**

11. When thinking of the government strategy you know most about:
A. how useful has this strategy been to you personally? *(please circle <u>one</u> number only)*

1	2	3	4	5
not at all useful	**not very**	**moderately**	**quite**	**very useful**

B. how effective has the strategy been in dealing with land and water issues in the Herbert? *(circle <u>one</u> number only)*

1	2	3	4	5
very effective	**fairly effective**	**neither effective nor ineffective**	**fairly ineffective**	**very ineffective**

C. how did you come to know of the strategy?

_____

_____

_____

12. Have you heard of a group called the Herbert River Catchment Coordinating Committee?

YES …. 1 **VAGUELY …. 2** **NO …. 3** ☞ *please go to question* **13**

If YES or VAGUELY, what do you think the main purpose of this group is?

_____

_____

13. Using the scale below, please rate how much you agree or disagree with the following statements. (*Write your chosen number from the scale next to each statement).*

<u>Scale:</u>

1	2	3	4	5		
strongly disagree	**disagree**	**neither agree nor disagree**	**agree**	**strongly agree**	**<u>OR</u>**	**8 not applicable**

Governments should work out better ways to fix land and water problems	_____	_____
There are things I can do personally to help improve the environment	_____	_____
It's too hard to think about land and water management issues for an areas as big as the Herbert catchment	_____	_____
I don't usually have the finances available to plan more than a year ahead	_____	_____
I trust that public servants are working in my interest most of the time	_____	_____
I've seen incompetent government activities in this part of the courntry	_____	_____
The local community should take some responsibility for improving the environment	_____	_____
Programs like Integrated Catchment Management interfere with people's Rights to make their own decisions	_____	_____

There are things local community groups can do to help improve the environment	_____	_____
I am sure that our local views will be considered when planning for land and water management in this area	_____	_____
The local environment is no worse off than it was when I first lived here	_____	_____
I would be prepared to assist in local projects such as riverbank stabilisation	_____	_____
Many environmental problems come from the way people manage their properties	_____	_____
I can prevent any land and water problems from occurring on my property	_____	_____
It is likely that I will become involved (or stay involved) with a Landcare or catchment group over the next year or two	_____	_____
I've complete control over what happens to the land and water on this property	_____	_____
It is likely that I will look into ways to improve the environmental condition of my property over the next year or two	_____	_____
I can recall at least 1 government action which has damaged my livelihood	_____	_____
I could personally benefit from being involved in group activities to help manage land and water	_____	_____
Laws should be changed to make landholders more responsible for the consequences of their activities	_____	_____
Some people I know think that local groups are a good way to deal with many land and water management issues	_____	_____

14. Which of the following sources of information help you to **keep informed** about land and water management issues? (*tick as many boxes as apply*)

Neighbours	☐	The Australian newspaper	☐
A government agency (please specify)	☐	Cairns Post	☐
_____		Townsville Bulletin	☐
_____		Telegraph Times	☐
Industry groups (please specify)	☐	Herbert River Express	☐
_____	☐	The Tablelander	☐
_____	☐	Tablelands Advertiser	☐
Community groups	☐	Millstream Times	☐
Family members	☐	Courier Mail	☐
Friends/colleagues	☐	Magazines/journals	☐
Personal experience	☐	Government newsletters	☐
The local "grapevine"	☐	The Country Hour (ABC radio)	☐
Public meetings	☐	Landline (ABC television)	☐
Other (please specify)	☐		
_____		None/I don't keep informed	☐
_____		☞ please go to question **19**	

19. In the box above, which two sources of information would you say were the most **reliable** for helping you to make decisions?

1. _____

2. _____

16. Does what you read in newspapers ever change your opinions about land and water management issues? (*please circle <u>one</u> number only*)

1	2	3	4
often	**occasionally**	**seldom**	**never**

17. Does what you hear on the radio or see on TV ever change your opinions about land and water management issues? (*please circle <u>one</u> number only*)

1	2	3	4
often	**occasionally**	**seldom**	**never**

18. How often do you discuss land and water management issues with your neighbours or others in this general area? (*please circle <u>one</u> number only*)

1	2	3	4
often	**occasionally**	**seldom**	**never**

19. When thinking about your **relationships with local people**, how comfortable are you about living here? (*please circle <u>one</u> number only*)

1	2	3	4	5
not at all comfortable	**not very**	**moderately**	**quite**	**very comfortable**

20. When thinking about how much **interest local people have for your ideas and opinions**, how comfortable are you about living here? (*please circle <u>one</u> number only*)

1	2	3	4	5
not at all comfortable	**not very**	**moderately**	**quite**	**very comfortable**

21. Are you a member of any regional, state or nationally-based groups or associations? (*please circle <u>one</u> number only*)

YES …. 1 **NO …. 2**

22. Are you a member of any local community groups or associations? (*circle <u>one</u> number only*)

YES …. 1 ☞ *please go to question* **25**

or

NO …. 2
↓

23. Generally, what are some of your reasons for not being involved in any community groups?

_____

_____

_____

_____

24. Would you ever consider joining a community group? (*circle <u>one</u> number only*)

YES …. 1 **DON'T KNOW …. 2** **NO …. 2**

↓ ↓

For what reasons would you join? _____

_____

_____

_____

☞ If you answered **NO to question 21** and **NO to question 22**, please go to question **28**

25. Which of the following categories describe *any* of the groups you have some involvement with? (*please tick as many boxes as apply*)

Progress Assoc.	☐	Sporting Group	☐
Rate Payers Assoc.	☐	Hobby/Craft Group	☐
Professional Assoc.	☐	Community Action Group	☐
Charity/Church/Welfare Group	☐	Service Club (eg. Lions, Rotary)	☐
Agriculture-related Organisation	☐	Parents & Friends Assoc.	☐
Landcare, Conservation or similar group	☐	Other/s (*please explain*)	☐
		_____	
		_____	

26. Of the groups you are involved with, please write down the name of the group that is **most important** to you.

- **Important group**_____

27. If you are involved in any groups in the "Landcare, Conservation or similar" category, please write down the name of the group that you are **most involved** with. This may not be the same as the group that is the most important to you.

- **Landcare, Conservation or similar group:**_____

_____

28. Thinking of the local community where you live, please rate how much you agree or disagree with each of the following statements. *(using the scale below, write your chosen number from the scale next to each statement)*

Scale:

1	2	3	4	5
strongly disagree	**disagree**	**neither agree nor disagree**	**agree**	**strongly agree**

I'm not very interested in local community issues _____

I feel quite comfortable in being a member of this local community _____

The community is capable of getting things done without any outside help _____

I would like to remain living in this area for a long time _____

I have almost no influence over what happens in this community _____

It's very important to me to live in this particular community _____

People in this community generally don't get along with each other _____

I don't really care what others in the community think of my actions _____

Very few of my neighbours know me _____

I often think about local community issues _____

I and many others in this community share similar values _____

I think this community is a good place to live _____

I can recognise many of the people who live in this community _____

I don't have the time to become involved in local community issues _____

OTHER INFORMATION

29. How old are you? _____ **years**

30. What is your gender? *(please circle the number)*

MALE .... 1 **FEMALE 2**

31. Which country were you born in? _____

32. What is your marital status? (*circle the most appropriate number*)

Married/De facto	…. 1	Divorced/Separated	…. 2
Never Married/Single	…. 3	Widowed	…. 4

33. Do you have any family members living in the Herbert area other than those in your household? (*circle <u>one</u> number only*)

YES …. 1 **NO …. 2**

34. What is your main occupation? _____

35. How many years have you had this occupation? _____ **years**

36. How long have you lived in the Herbert area? _____ **years**

37. Is your property near to a river or creek which floods?

YES …. 1 NO …. 2 DON'T KNOW …. 3

38. Thinking about where you live, what is the most important river or creek to you?

_____

39. How often do you use the river or creek near where you live? (eg. for commercial, domestic or recreational purposes) (*please circle <u>one</u> number only*)

1	2	3	4
often	**occasionally**	**seldom**	**never**

40. How often do you go fishing for recreation? (*circle <u>one</u> number only*)

1	2	3	4
often	**occasionally**	**seldom**	**never**

41. Do you own or lease/rent a commercial rural, or rural property greater than 3 hectares (7.5 acres)? *(please circle <u>one</u> number only)*

YES **NO …. 3** ☞ *please go to question* **45**

↓

OWN .... 1 or LEASE/RENT 2

42. Which one of the following best describes your current use of this property? *(circle <u>one</u> number only)*

Cane farming **.... 1** Grazing **.... 2** Mining **.... 3** Industrial **.... 4**

Other farming **.... 5** *(please specify)*_____

Other **.... 6** *(please specify)*_____

43. What is the size of your property? _____ **hectares** *<u>or</u>* _____ **acres**

44. Have you cleared any new land in the last twelve months?

YES .... 1 NO .... 2 ☞ *please go to question* **45**

↓

If YES, how much new land have you cleared? _____ **hectares** *<u>or</u>* _____ **acres**

45. Would you be prepared to answer another shorter questionnaire if needed in a few months time?

YES .... 1 NO 2

If YES, please write your name, postal address and phone number in the space provided.

Your Name:

Postal Address:

Phone number:

Thank you very much for your time.

Are there any comments you would like to add?

			Lucinda	…. 8
			Taylors Beach	…. 9

1. Using the scale below please rate your level of satisfaction with the various aspects of your life at the moment. *(please write your chosen number from the scale next to each item)*

Scale:

1	2	3	4	5
very dissatisfied	**moderately dissatisfied**	**neither satisfied nor dissatisfied**	**moderately satisfied**	**very satisfied**

Your life in general _____

Your standard of living _____

Your personal health _____

The area where you live _____

The community in which you live _____

Existing community facilities and services _____

2. What do you think are the major advantages of living in the Herbert?

_____

_____

_____

_____

3. Generally, what do you think are some of the key issues facing people in the Herbert?

_____

_____

_____

_____

4. How important are the following issues **(1) to you personally, and (2) to people in the Herbert generally**? *(using the following scale, please write your chosen number/s in the two boxes next to each issue)*

Scale:

1	2	3	4	5
very high importance	**high**	**moderate**	**low**	**very low importance**

	importance to you personally	**importance to people in the Herbert**
Land degradation		
Water quality problems		
Water quantity problems		
Nature conservation issues ..... (eg. loss of wildlife habitat, management of world heritage areas)		

Flooding		
Wetlands.....		
Vegetation on river banks		
Loss of biodiversity (numbers of different species).....		

5. Following are a list of issues which **some people** think have an impact on life in the Herbert. In **your opinion**, how much do each of the following impacts **(1) affect you personally**, and **(2) affect people in the Herbert generally**? *(using the following scale, please write your chosen number/s in the two boxes next to each impact)*

Scale:

1 very high degree — **2** high — **3** moderate — **4** low — **5** very low degree **OR** **8** not at all

Possible Impacts	**affects you personally**	**affects people in the Herbert**
Loss of farm productivity.....		
Higher production costs.....		
Poor drinking water quality.....		
Emotional stress		
Higher taxes.....		
Lower fish numbers		
Loss of access to recreation		
Loss of confidence in government's ability to manage land and water resources		
Loss of environmental uses or benefits (eg. wildlife habitat)		

6. Generally speaking, what **awareness** do you think local people have about land and water issues in the Herbert? *(please circle <u>one</u> number only)*

1 very high awareness — **2** high — **3** moderate — **4** low — **5** very low awareness

7. How much do you think **local people** are prepared to become involved in land and water issues in the Herbert? *(circle <u>one</u> number only)*

1 to a very high degree — **2** high — **3** moderate — **4** low — **5** very low degree

8. How much are **you** prepared to become involved in land and water issues in the Herbert? *(circle <u>one</u> number only)*

1 to a very high degree — **2** high — **3** moderate — **4** low — **5** very low degree

9. Using the scale below please rate how much you agree or disagree with the following statements. *(please write your chosen number from the scale next to each statement)*

Scale:

1	2	3	4	5
strongly disagree	**disagree**	**neither agree nor disagree**	**agree**	**strongly agree**

Managing land and water in the Herbert is difficult because...

problems aren't well understood _____

solutions aren't easy _____

local people lack the money to spend on solutions _____

government strategies are too slow _____

solutions are expensive _____

there are few benefits and many costs _____

local people don't want to spend money on solutions _____

the Herbert River catchment covers a large area _____

local people don't trust government programs _____

local people aren't that interested in community-type activities _____

the government doesn't want to spend money on solutions _____

government departments and other agencies are too slow to react to new issues or problems _____

10. Before we contacted you about this study, which of the government strategies in the box below had you heard about and which one did you know most about?

STRATEGY	**HAD YOU HEARD OF THIS?** *(please tick as many boxes as apply)* ↓	**WHICH DID YOU KNOW MOST ABOUT?** *(circle one number only)* ↓
Property Management Planning or "PMP"	☐	1
Landcare	☐	2
Integrated Catchment Management or "ICM"	☐	3
		N/A

☞ *If you haven't heard of any of these government strategies, please go to question* **12.**

11. When thinking of the government strategy you know most about:
A. how useful has this strategy been to you personally? *(please circle one number only)*

1	2	3	4	5
not at all useful	**not very**	**moderately**	**quite**	**very useful**

B. how effective has the strategy been in dealing with land and water issues in the Herbert? *(circle <u>one</u> number only)*

1	2	3	4	5
very effective	**fairly effective**	**neither effective nor ineffective**	**fairly ineffective**	**very ineffective**

C. how did you come to know of the strategy?

_____

_____

_____

12. Are you aware of any other Government Funded programs on wider environmental matters in the Herbert catchment?

YES …. 1 ↓ **NO …. 2** ☞ *please go to question* **13**

If YES, please write down any comments you have on them.

_____

_____

_____

13. How important is it to you that the following activities are part of Integrated Catchment Management? *(Using the following scale, please write your chosen number next to each issue).* **Then…** please rank the three most important activities to you: 1 is most important.

<u>Scale:</u>

1	2	3	4	5
very high importance	**high**	**moderate**	**low**	**very low importance**

	Scale	Rank 1 to 3 ↓
Encourage community <u>action</u> at a catchment level.	____	____
Raise the level of local awareness and knowledge of environmental issues on the catchment.	____	____
Encourage Local Government to take an active role in environmental management issues.	____	____
Encourage coordination of state government programs.	____	____
Undertake specific on ground projects with other bodies.	____	____
Provide a continuing source of advice to local government on catchment issues.	____	____

Encourage research. _____ _____

Develop solutions for and better understanding of environmental problems in the Herbert catchment. _____ _____

Encourage discussion between community interest groups on environmental issues. _____ _____

Separate ICM programs for the Upper and Lower Herbert catchments. _____ _____

Encourage joint projects between community, industry and state and local government. _____ _____

14. Have you heard of a group called the Herbert River Catchment Coordinating Committee?

YES .... 1 **VAGUELY .... 2** **NO .... 3** ☞ *please go to question* **19**

If YES or VAGUELY, what do you think the main purpose of this group is?

_____

_____

15. Has the group been effective in achieving its goals and purpose?

YES …. 1 **TO SOME EXTENT …. 2** **NO …. 3**

16. Are there any specific things that you know they have done?

Please describe

_____

_____

_____

17. In your opinion, are they progressing quickly enough?

YES …. 1 **TO SOME EXTENT …. 2 NO …. 3**

18. In your opinion, are they heading in the right direction?

YES …. 1 **TO SOME EXTENT …. 2 NO …. 3**

19. Using the scale below please rate how much you agree or disagree with the following statements. *(write your chosen number from the scale next to each statement)*

Scale:

1	2	3	4	5	**OR** 8
strongly **disagree**	disagree	neither agree **nor disagree**	agree	strongly **agree**	not applicable

There are things I can do personally to help improve the environment. _____

It's too hard to think about land and water management issues for an area as big as the Herbert catchment. _____

I don't usually have the finances available to plan more than a year ahead. _____

The government needs to give more resources to voluntary groups. _____

Programs like Integrated Catchment Management interfere with people's rights to make their own decisions. _____

There are things local community groups can do to help improve the environment. _____

Catchment management should be paid for and run by the government. _____

The local environment is no worse off than it was when I first lived here. _____

ICM should remain a voluntary activity by community members. _____

I would be prepared to assist in local projects such as riverbank stabilisation. _____

Scale:

1	**2**	**3**	**4**	**5**	**OR**	**8**
strongly **disagree**	disagree	neither agree **nor disagree**	agree	strongly **agree**	not applicable	

Many environmental problems come from the way people manage their properties. _____

It is likely that I will become involved (or stay involved) with a Landcare or catchment group over the next year or two. _____

I could personally benefit from being involved in group activities to help manage land and water. _____

The government expects too much from local communities in catchment management. _____

Laws should be changed to make landholders more responsible for the consequences of their activities. _____

Different government agencies often give conflicting information on land and water management issues. _____

There should be better government incentives for landholders to address environmental issues/problems. _____

There aren't any environmental problems that need urgent action. _____

ICM programs should have legislative backing. _____

The government gives plenty of resources to voluntary groups. _____

20. Over the last 12 months, have you been involved in any local community groups or associations?

YES …. 1 **NO …. 2** ? *please go to question* **22**

If YES, which groups or associations were they?

_____

_____

_____

21. If you were involved in any Landcare, conservation or similar types of group, please write down the name of the group that you were **most involved** with.

_____

22. Thinking of the local community where you live, please rate how much you agree or disagree with each of the following statements. *(using the scale below, write your chosen number from the scale next to each statement)*

Scale:

1	2	3	4	5
strongly disagree	**disagree**	**neither agree nor disagree**	**agree**	**strongly agree**

I'm not very interested in local community issues. _____

I feel quite comfortable in being a member of this local community. _____

I have almost no influence over what happens in this community. _____

It's very important to me to live in this particular community. _____

People in this community generally don't get along with each other. _____

I often think about local community issues. _____

I and many others in this community share similar values. _____

I think this community is a good place to live. _____

I can recognise many of the people who live in this community. _____

I don't have the time to become involved in local community issues. _____

23. Should Local Government **have a role** in Integrated Catchment Management?

YES …. 1 **NO …. 2**

Please give reasons

_____

_____

_____

24. Should Local Government Planning sometimes **take into account** Integrated Catchment Management?

YES …. 1 **NO …. 2**

Please give reasons

_____

_____

_____

25. For every $100 spent on catchment management and landcare,

A. how much of it do you think **IS** being contributed by:
(please write the amount in the space provided)

The Commonwealth Government?		$_____
The Queensland Government?		$_____
Local Government on the Herbert Catchment?		$_____
Industry?		$_____
Individual farmers?		$_____
	TOTAL	**$ 100**

B. how much of it do you think **SHOULD** be contributed by:

The Commonwealth Government?		$_____
The Queensland Government?		$_____
Local Government on the Herbert Catchment?		$_____
Industry?		$_____
Individual farmers?		$_____
	TOTAL	**$ 100**

Please comment on why you have chosen the amounts for part B.

_____

_____

_____

26. Have you visited the Herbert Resource Information Centre in Ingham?

YES …. 1 **NO …. 2**

27. Have you seen the Herbert River Catchment Atlas?

YES …. 1 NO …. 2

28. Have you seen the Herbert River Catchment Coordinating Committee's Catchment Management Strategy?

YES …. 1 NO …. 2

OTHER INFORMATION

29. Show which category best describes your age. *(please circle one number only)*

Less than 24 years	**……..**	**1**
24 to 39 years	**……..**	**2**
40 to 55 years	**……..**	**3**
56 to 65 years	**……..**	**4**
66 to 75 years	**……..**	**5**
More than 75 years	**……..**	**6**

30. What is your gender? *(please circle the number)*

MALE .... 1 FEMALE 2

31. What is your main occupation? _____

32. How many years have you had this occupation? _____ **years**

33. How long have you lived in the Herbert area? _____ **years**

34. How often do you go fishing for recreation? *(circle <u>one</u> number only)*

1	2	3	4
often	**occasionally**	**seldom**	**never**

35. Do you own or lease/rent a commercial rural, or rural property greater than 3 hectares (7.5 acres)? *(please circle <u>one</u> number only)*

YES: OWN .... 1 or LEASE/RENT 2

NO .... 3 ☞ *if you have any further comments, please use the back page.*

36. Which one of the following <u>best</u> describes your <u>current</u> use of this property? *(circle <u>one</u> number only)*

Cane farming **.... 1** Grazing **.... 2** Mining **.... 3** Industrial **.... 4**

Other farming **.... 5** *(please specify)*_____

Other **.... 6** *(please specify)*_____

37. What is the size of your property? _____ **hectares** *or* _____ **acres**

38. Have you cleared any new land in the last twelve months?

YES .... 1 **NO 2**

If YES, how much new land have you cleared? _____ **hectares** *or* _____ **acres**

Thank you very much for your time. Please use the back page for any additional comments.

Chapter 5

Land and Water Management in the Herbert River Catchment:

A Longitudinal Study of Community Views

Executive Summary:

Implications of the Findings for ICM

This section outlines consistent and important findings across Survey 2 and their implications for ICM.

There was very strong stability of opinions between 1996 and 1998.

- Prompted and unprompted responses displayed relatively few differences and differences that did exist were by a matter of degree.

For ICM, the stability of the results suggests that opinions and priorities do remain fairly stable over time and that any changes in awareness or behaviour related to land and water management are likely take longer than two years to occur given the resources available.

There was a fairly high degree of satisfaction with living in the Herbert.

- There was moderate satisfaction with life in general, standard of living, personal health, the area where respondents lived and the community in which they lived.
- Respondents generally agreed that it is a good place to live, they felt quite comfortable living there, recognised many of the people in their local community, shared similar values with others and felt it was important to live in that particular community.
- Respondents reported many advantages of the Herbert.

The finding that there was general satisfaction with many aspects of living in the Herbert River catchment suggests that most people would not support any changes that would threaten these aspects of their community.

The most important issues to respondents when not prompted were related to employment, in other words, life issues:

- unemployment;
- a lack of opportunities for young people; and
- a lack of diversity in industry.

Following these were issues related to land and water management and the environment:

- clearing of marginal land;
- flooding;
- drainage;
- water quantity issues;
- fishing issues;
- the impact of weather and changing weather conditions on primary industry; and
- environmental issues in general.

When prompted on land and water management issues, many respondents found them to be important:

- most issues were more important personally than to the Herbert in general;
- respondents generally agreed that there were problems that needed urgent action;
- however opinion was divided on whether or not the environment had worsened since respondents first lived in the Herbert;
- high ratings of personal importance, and importance for the Herbert, of water quality problems, land degradation, water quantity problems and nature conservation;
- moderate to high ratings of importance of flooding, wetlands, vegetation on riverbanks and loss of biodiversity.

When asked about the personal impact, and the impact on the Herbert, of various issues:

- there were few differences over time;
- the personal impact of loss of farm productivity, poor drinking water quality and loss of environmental uses/benefits increased over time;
- for the Herbert, the impact of loss of farm productivity was seen to have increased since Survey 1 and the impact of lower fish numbers was perceived to have decreased;
- there was a high impact on respondents of poor drinking water quality and loss of environmental uses; and
- respondents perceived the largest impacts on the Herbert to be from loss of farm productivity and poor drinking water quality.

There was community awareness and interest in Herbert issues, most respondents:

- were interested in local issues; and
- local awareness about land and water issues was considered to be moderate, as in Survey 1.

There is awareness of problems and the perception that land and water issues are important, both personally and on a catchment scale. This signifies general support for ICM to tackle land and water management on a number of fronts. However, land and water management issues were not uppermost in people's minds which suggests that there needs to be awareness and acknowledgment by ICM that while people may support land and water management of various kinds, their first priorities lie with 'life issues'.

Opinions were divided about:

- the degree of influence respondents felt over what happened in their communities;
- whether or not people in their community generally got along; and
- whether or not respondents often thought about local community issues.

While there was community interest in issues for the Herbert, the influence people felt was not particularly high, it appeared that there may be some conflict and not all respondents often thought about local community issues. These factors may hinder community participation in ICM.

The community displayed a high sense of self responsibility:

- many environmental problems come from the way people manage their properties;
- laws should be changed to make landholders more responsible for the consequences of their activities (more respondents agreed than disagreed but generally divided).

While a high sense of self responsibility in the community for dealing with land and water management issues is an advantage for ICM in gaining community participation, it will be very important for ICM to recognise this in working with the community and in the types of policies that are promoted.

There was a high sense of control over the community's ability to deal with land and water management, illustrated by agreement that:

- it was not too hard to think about land and water management issues for an area as big as the Herbert catchment;
- there were things they could do personally to help improve the environment; and
- there were things local community groups could do to help improve the environment.

A high sense of community control over dealing with land and water management issues is a very positive result for ICM.

The high sense of control may be hindered by a perceived lack of resources, for example:

- many didn't usually have the finances available to plan more than one year ahead;
- respondents tended to disagree that the government gives plenty of resources to voluntary groups;
- respondents reported a high personal impact of higher taxes;
- a high perceived impact on the Herbert of higher taxes, a loss of farm productivity, and higher production costs;
- many agreed the government needs to give more resources to voluntary groups; and
- support for government incentives for landholders to address environmental issues.

Many community members feel that individual landholders have a role to play in land and water management and see that there are ways they and their local communities can assist. To do this, they may need assistance from the government in terms of resources and government incentives.

In addition, there were perceived to be a number of impediments to effectively managing land and water in the catchment, the greatest impediments were seen to be:

- slow government strategies;
- slow reactions of government to new problems;
- the catchment's large area;
- the cost of solutions;
- a lack of easy solutions;
- low trust of government programs; and
- insufficient understanding of relevant problems.

It will be important for ICM to address these perceptions of impediments, perhaps by:

- encouraging timely responses from government;
- encouraging financial support for ICM;
- developing and promoting solutions;
- encouraging improved formal and informal communication between the government and the community; and
- improving understanding of land and water management problems.

While the catchment's large area was seen to be a difficulty, it was not considered to be insurmountable earlier in the survey.

Awareness of government strategies and resources was varied:

- Landcare was the most familiar strategy: most respondents had heard of Landcare and the majority knew more about it than ICM and Property Management Planning;
- one third had heard of PMP;
- half had heard of ICM;
- a higher proportion of cane farmers and graziers had heard of ICM than any of the other main occupations (home duties, trade, retired, education and general farming);
- a higher percentage of repeat respondents had heard of ICM than new respondents;
- those who had heard about ICM and (of the three strategies) knew most about ICM were most likely to be rural producers in the lower catchment, ie. cane farmers;
- only 2% of upper catchment respondents had visited the Herbert Resource Information Centre, compared with 28% from the lower catchment;
- approximately 30% had seen the Herbert River Catchment Atlas; and
- approximately 10% had seen the HRCCC Catchment Management Strategy.

Although the awareness levels of ICM are encouraging, they could be improved, particularly in urban areas and the upper catchment generally, which will be assisted by the efforts of the new upper catchment committee. The low percentage of upper catchment respondents who had visited the Herbert Resource Information Centre highlights a need for more information in the upper catchment.

The main sources of information regarding government strategies were:

- newspapers;
- television and television advertisements;
- the media in general; and
- general meetings or Canegrowers Association meetings (for ICM specifically).

Informing the community of broad scale government strategies will be most effective through newspapers and if possible television or the general media whereas more localised information about ICM may be more effective through meetings.

Perceptions of government management of land and water were as follows:

- 60% of respondents felt that the most familiar government strategy was either not very useful or not at all useful to them personally.
- Comments on other government funded programs included that they lacked knowledge of the local situation, did not consult local people, did not use the best or most recent information, worked well or that it was good idea.
- There was general agreement that different government departments often give conflicting information regarding land and water management issues.

The perceived personal usefulness of government strategies may need to be improved. It will be important for the government to respond to community perceptions regarding the importance of local knowledge, consulting local people, using the best quality information and giving consistent information to the community. Providing consistent feedback as to the positive outcomes of government programs would be useful.

Perceptions of the HRCCC

- About 44% had heard of the HRCCC at least vaguely (very similar to Survey 1).
- Its main purposes were perceived to be care for the catchment, conserving and managing water, preserving waterways, raising awareness and improving drainage.
- Very few people were aware of its specific activities.
- Most of those who had heard of the HRCCC felt that it had been effective to some extent in achieving its goals and purposes.

- About half thought that the group was progressing quickly enough.
- The majority thought they were generally heading in the right direction.
- 21% of those who had not heard about ICM had at least vaguely heard of the HRCCC.

Although the level of community awareness of the HRCCC was encouraging, it had not increased in the two years since Survey 1 was conducted. Awareness could be improved, particularly regarding the specific activities of the HRCCC. The majority of those who were aware of the committee supported its general direction and effectiveness and were fairly satisfied with the speed of its progress.

The main priorities for the direction of ICM were as follows:

- 90% of respondents felt that local government should have a role in ICM;
- 95% of respondents felt that local government planning should take ICM into account;
- encouraging joint projects between different parties;
- raising local awareness;
- developing solutions for, and better understanding of, environmental problems;
- encouraging research; and
- encouraging local government involvement.

Still highly important for ICM but lowest in priority were:

- undertaking specific on ground projects;
- separate ICM programs for the upper and lower catchments;
- providing a continuing source of advice to local government on catchment issues; and
- encouraging discussion between community interest groups.

Continuing close involvement with local government, and reporting on this involvement to the community, will be very important for ICM in the future. In addition, key priorities for ICM are:

- encouraging joint projects;
- raising local awareness;
- gaining a better understanding of environmental problems;
- developing solutions for environmental problems;
- encouraging research; and
- communicating on this work to the community.

There were split opinions regarding community and government roles in ICM, for example, whether or not:

- ICM should remain a voluntary activity by community members.
- government expectations of the community in ICM were too high;
- the government should pay for and run ICM; and
- programs like ICM interfere with people's rights to make their own decisions.

In terms of funding contributions by government, industry and the community:

- the Commonwealth Government was perceived to be contributing more funding than the Queensland government, local government, industry or farmers;
- upper catchment respondents thought that industry should be contributing more than they were whereas lower catchment respondents thought that the Commonwealth Government should be contributing more than they were; and
- while industry was perceived to be contributing the least at the time of Survey 2, in general, respondents thought that farmers should contribute the least amount of funding of the five parties.

Overall, the differences between perceptions of current funding contributions and perceptions of how much government, industry and farmers should be contributing were quite small. This indicates that the overall system was perceived to be reasonably fair and indicates a preference for fairly even monetary contributions from various parties. In addition, various results show an overall preference for a partnership approach between government, industry and the community rather the responsibility going primarily either to the government or the community.

Involvement in groups

- there were divided opinions about whether or not respondents had the time to become involved in local community issues;
- 42% of upper catchment respondents and 28% of lower catchment respondents had been involved in local community groups or associations in the past year; and

- the main categories were Landcare, conservation, etc; charity, church or welfare; agriculture related groups; and service clubs.

There were divided opinions regarding intentions to become involved:

- perceived preparedness of local people to become involved in land and water issues had decreased from Survey 1 (close to moderate in both);
- preparedness of respondents to become involved in land and water issues had increased since Survey 1 (again close to moderate in both) and was higher in rural respondents;
- preparedness to assist in local projects;
- likelihood of respondents becoming or staying involved with a Landcare or catchment management group over the next year; and
- the degree of personal benefit to be gained from involvement in group activities to help manage land and water.

Involvement in other local community groups and associations may prevent some people from becoming active in ICM groups due to their time commitments, particularly in the upper catchment. In addition, the split opinions regarding intentions to become or stay involved in land and water management indicate that there are some people who are unlikely to become involved in ICM. This does not mean that people will not be able to remain or become interested in ICM activities or carry out activities promoted by ICM. It does mean that the HRCCC should be careful to ensure maximised benefits for the time expended by the community on ICM related activities.

Finally, the questionnaire may have raised expectations in the community and it will be important for the HRCCC to respond to the issues found to be important to respondents.

1.0 INTRODUCTION

This study follows a survey performed in 1996 (Butterworth, Syme & Nancarrow, 1997) examining landholders' attitudes, beliefs and behaviours relating to land and water management in the Herbert River Catchment in north Queensland. Together, the two surveys form the community assessment component of research, led by CSIRO, evaluating the implementation of Integrated Catchment Management (ICM) in the Herbert River Catchment. The aims of the community assessment component were as follows.

1. *To examine, longitudinally, landholders' behaviours and attitudes towards land and water management in the Herbert River Catchment.*

As it was a longitudinal study, the second survey was conducted to assess variation in attitudes and behaviours over time. In addition, the two surveys will serve as a benchmark against which and attitude and behaviour change relating to the progress of ICM in the Herbert River Catchment in particular and in Queensland generally can be assessed.

2. *More specifically, to provide an understanding of social factors that might influence the implementation of ICM in the Herbert.*

The original impetus for the study evolved from ICM's focus on community involvement and an increasing emphasis on the need to evaluate effectiveness of this involvement. In other words, what does ICM deliver beyond isolated and "unintegrated" resource management activities, and, as a result, what changes occur? The results will provide key baselines for the assessment of factors that hinder or foster an effective ICM process in the Herbert.

3. *Relatedly, to provide an understanding of whether and how such factors vary according to where people live and what their interests are.*

The study focused on individuals in both rural and urban areas of the catchment and with a wide variety of occupations and interests.

2.0 STUDY AREA

With a catchment area of more than 10,000 square kilometres, the Herbert River rises in the Great Dividing Range west of Innisfail and flows south east to the sea to the south of Hinchinbrook Island. The upper catchment consists of tropical forest, a number of small active and inactive tin mines, and most of this area is devoted to grazing. In the more populated lower catchment, sugar cane production is the dominant land use on the lower river flats and coastal plain. Completely dividing the upper and lower areas, is the Wet Tropics World Heritage Area, which makes up approximately 15 percent of the catchment. The catchment contains the shires of Herberton and Hinchinbrook and the main settlements are Ingham, Herberton, Allingham, Ravenshoe, Halifax, Lucinda, Taylors Beach and Mount Garnet.

The upper and lower catchments are two distinctly different geographical areas. They also differ according to types of rural industry and the intensity of production, climatic and soil characteristics, and population size. As such, there are likely to be other distinctions, for example, along social, economic and recreational lines. Of course, this also applies for rural and urban areas.

3.0 METHODOLOGY

3.1 The Questionnaires

The original 1996 questionnaire (see Appendix 1) contained items concerning:

- levels of importance, perceived impacts, awareness and attitudes towards various land and water management issues;
- perceived ability of landholders to control land and water management issues;
- tractability or "manageability" of potential issues;
- intentions to participate in land and water management and other group activities, and perceived impediments to participation;
- awareness of government strategies (including Property Management Planning, Landcare, ICM), and the HRCCC;
- attitudes towards government's performance regarding land and water management issues;
- use of information sources, including the media;
- group involvement, interest in community issues, and life satisfaction;
- demographic information.

The 1998 questionnaire (see Appendix 2) contained all but the "use of information sources" item. Additional questions included:

- awareness of other government funded programs on wider environmental matters in the Herbert catchment;
- importance of various activities as part of ICM;
- effectiveness of the HRCCC in achieving its goals;
- awareness of HRCCC activities;
- opinions on the speed of their progress;
- opinions on the direction they are taking;
- whether local government should have a role in ICM;
- whether local government should take into account ICM;
- how much money is being contributed by the levels of government, industry and farmers to catchment management and landcare;
- how much money should be contributed by the levels of government, industry and farmers to catchment management and landcare;
- whether respondents had visited the Herbert Resource Information Centre in Ingham;
- whether respondents had seen the Herbert River Catchment Atlas; and
- whether respondents had seen the Herbert River Catchment Coordinating Committee's Catchment Management Strategy.

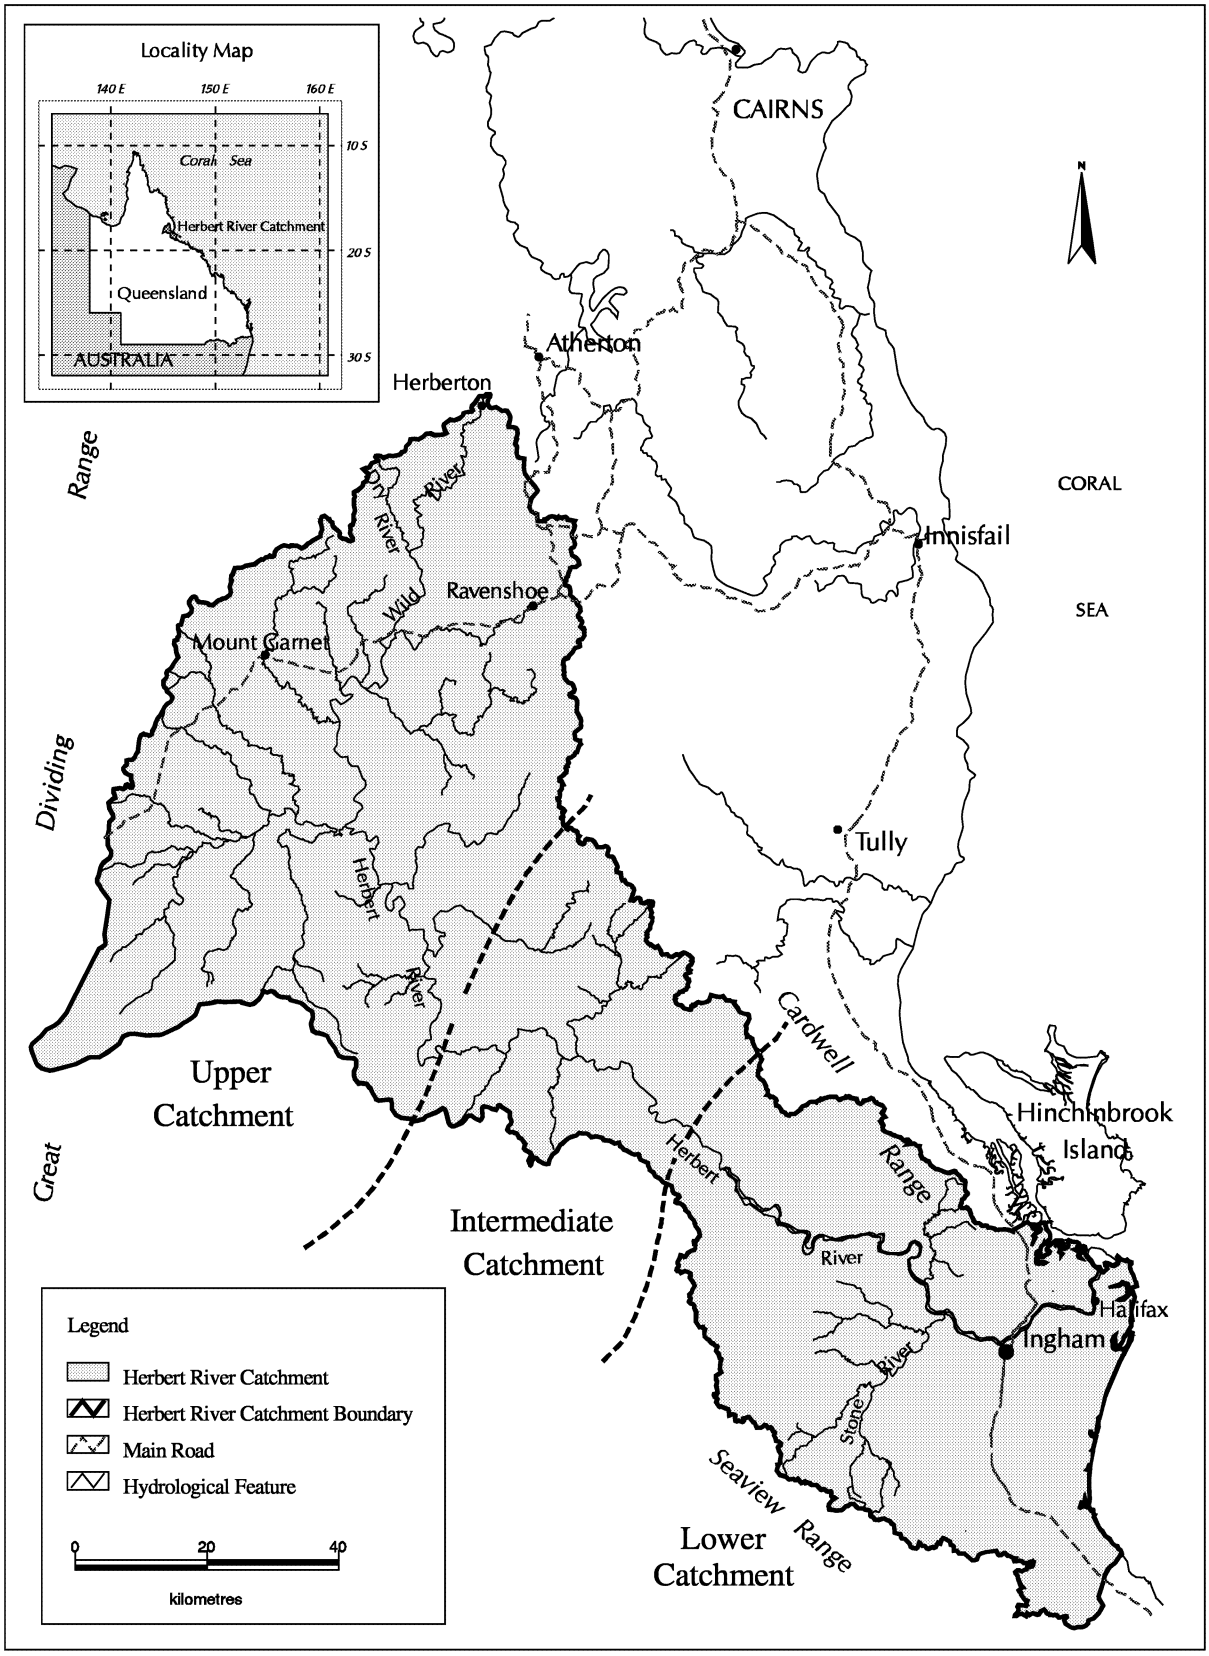

Figure 1. Herbert River Catchment.

3.2 The Sample

The same sampling procedure was used for Survey 2 (1998) and Survey 1 (1996). Due to the complexity of the catchment (eg. geographical and social) and the number of required comparisons (between different populations in the catchment and across time) the sample size for both surveys needed to be as large as feasible. Consequently, for logistic reasons, the surveys were designed as self-administered questionnaires and the mail-out method was selected as the means of administration. This method also provided better protection of anonymity and less intrusion on those who may not be familiar with ICM and other land and water management issues.

The sample was randomly selected and was proportionally sampled from ten locations in the catchment. In the upper catchment: rural areas and urban areas (Herberton, Mount Garnet and Ravenshoe) and in the lower catchment: rural areas and urban areas (Allingham, Ingham, Halifax, Lucinda, and Taylors Beach).

For both surveys, the sampling framework included telephone contacts as a component of the mail-out method. This was added to gauge willingness to participate, inform potential participants of the purpose of the study and increase the response rate (ie. the number of returned questionnaires). In Survey 1 reminder telephone calls were made to those people who had not returned the questionnaire by the specified due date. Reminder notes were used in Survey 2.

A range of landholders were contacted including those in the upper and lower catchment; in rural and urban areas; with different occupations including cane farming, grazing and mining; and with urban properties in eight settlements.

The maximum number of telephone contacts was set at 800. While this was also potentially the maximum sample size, a response rate of this size was unlikely given that some of those contacted would be unwilling to participate.

All Survey 1 respondents were asked whether they would be prepared to answer another questionnaire in the future. Those who replied yes, they would be involved again, were contacted first in Survey 2 (the 'repeat' sample). The samples for each location were then completed with randomly selected names from the list of residents obtained in Survey 1 (the 'new' sample). Due to the stability of the population in the intervening years, the same list was thought to be adequate for use in Survey 2.

To inform the general community that the repeat survey was being conducted, and why, and to give some brief information on the overall study, a short notice was placed in "The Herbert River Express" prior to the initial telephone calls (see Appendix 3 for the wording of the notice).

All of those people who agreed to participate were sent a copy of the questionnaire, a letter thanking them for their involvement and providing more details of the study, a map of the Herbert River Catchment, and a pamphlet explaining the study (see Appendix 4).

3.3 Returned Questionnaires

To provide a comparison of response rates for the two surveys, the two tables below show the number of people telephoned, the number who agreed to participate and the number of completed questionnaires returned.

1996 Survey

Catchment	Type of Holding	Calls	Sent	Returns	% of calls	Towns Surveyed	Returns	%
UPPER	Rural	100	92	59	59.0			
	Urban	125	128	86	68.8	Herberton Mt Garnet Ravenshoe	38 18 30	76.0 54.5 66.7
LOWER	Rural	320	282	191	59.7			
	Urban	255	216	141	55.3	Allingham Ingham Halifax Lucinda Taylors Beach	28 45 17 26 24	60.1 61.6 54.8 66.7 88.9
TOTAL		800	718	477	59.6			

59.6% response rate

1998 Survey

Catchment	Type of Holding	Calls	Sent	Returns	% of calls	Towns Surveyed	Returns	%
UPPER	Rural	100	76	47	47.0

	Sub-totals	576	508	284	49.3			
TOTALS		276 rep 527 new 803	237 rep 466 new 703	175 rep 226 new 401	63.4 42.9 49.9			

Refusals

Those who declined to complete the questionnaire were asked if they would answer a few short questions (Appendix 5). Of the 43 who did, 18 stated that their main occupation was home duties and 10 that they were retired or pensioners. Two thirds were female and the average age was 56. Briefly, most (29) were not affected by any land or water management issues and those who were mainly mentioned rain/flooding and drinking water quality. Most (40) did not belong

to any local groups or associations. Most never went fishing for recreation and 58% had at least vaguely heard of the HRCCC.

4.0 PRESENTATION OF FINDINGS

Results of the data analysis are presented for each question in the survey and results for the whole sample are shown. Where there were significant differences between different groups, cross comparisons are shown (eg. between upper and lower catchment samples or between Survey 1 and Survey 2. The term, 'whole sample' represents the total number of completed and returned questionnaires (401). The number of people responding to a particular question (generally lower but close to 401) is always listed. In the tables that follow, "N" denotes the number of responses given for a particular question.

Most items in the questionnaire was examined for any statistically significant response differences between the upper and lower catchment samples or between the urban and rural samples; and any significant interactions between the two. Survey 1 results were however examined for statistically significant differences between the responses of the 'four samples', ie. the upper urban, upper rural, lower urban, and lower rural samples.

Responses to many questions, were rated on 5-point scales so for consistency, these have been re-coded in presenting the results. Unlike the questionnaire, for example, the scale of positive responses (such as very high or strongly agree) to negative responses (such as not at all useful or strongly disagree) is generally rated from 5 to 1 respectively.

Finally, respondents could provide up to two or three responses for open-ended questions so percentages will not add to 100. The number of people stating a particular response is shown along with a percentage comparing this with the overall number of respondents to that question. For these questions, categories were also formed to maintain both detail and ease of presentation. Therefore, some categories may not be mutually exclusive.

Extra comments made in the body of the questionnaire are included in the report. Additional comments were invited at the end of the questionnaire and these can found in Appendix 6. As such a large amount of input was gained from this exercise, a summary of the issues mentioned is also provided.

4.1 Statistical Tests

A number of statistical tests were used throughout the report. These included correlation analysis; appropriate analysis of variance for multiple group contrasts, paired samples t-tests and independent samples t-tests (to compare mean scores); reliability, regression and factor analysis; cross tabulations (for categorical data such as group membership); and, where appropriate, non-parametric tests.

4.2 Life Satisfaction

Please rate your level of satisfaction with the various aspects of your life at the moment. Participants were asked to use the following scale to respond to each statement. The statements and mean scores appear in the table below.

1	2	3	4	5
very dissatisfied	moderately dissatisfied	neither satisfied nor dissatisfied	moderately satisfied	very satisfied

Areas of Satisfaction	Survey 2 Mean	Survey 1 Mean
Your life in general	4.1	4.2
Your standard of living	4.0	4.1
Your personal health	4.0	4.1
The area where you live	4.2	4.3
The community in which you live	4.1	4.1
Existing community facilities and services	3.3	3.2

In Survey 2, mean ratings for the first five areas centred around moderate satisfaction but satisfaction was slightly lower with existing community facilities and services, close to neither satisfied nor dissatisfied.

Comparing the mean ratings of those people who were involved in both Surveys, their ratings of satisfaction with their life in general and with their standard of living were still close to moderately satisfied in Survey 2 but significantly lower in Survey 2.

A two way analysis of variance revealed that lower catchment respondents were more satisfied (mean = 3.4) with existing community facilities and services than upper catchment respondents (mean = 3.15). In Survey 1, lower urban respondents were more likely to be satisfied than upper urban respondents.

4.3 Advantages of Living in the Herbert River Catchment

The table lists prominent responses from Survey 1 and the percentage of respondents that offered each answer in Survey 2. There were four additional prominent responses for Survey 2. A total of 817 responses were stated by the sample and 778 of these (95 per cent) are noted in the table.

The main advantages experienced by respondents in Survey 2 were very similar to those mentioned in Survey 1. The area was said to offer a relaxed rural lifestyle, with a good climate, unspoiled, healthy and natural environment and excellent recreation opportunities. It was described as a small, safe, friendly, close knit community which is also close to large centres. Of the prominent responses, lower catchment respondents mentioned personal safety, close access to recreation, closeness to large centres and close knit community to a larger extent than upper catchment respondents. Upper catchment respondents mentioned healthy environment, best climate, unspoiled environment and good quality drinking water more frequently than lower catchment respondents.

What do you think are the major advantages of living in the Herbert?

Advantages	Survey 2 N = 372		Survey 1 N = 431	
	N	%	N	%
Lifestyle (stress free; country atmosphere)	121	32.5	138	32.1
Good climate	106	28.5	152	35.3
Close access to many recreation sites (eg. beaches; rainforest)	93	25.0	83	19.3
Small community / low population	58	15.6	56	13.0
Close to large centres (but also far enough away)	56	15.1	35	8.1
Good environment (unspoiled, natural, abundant wildlife)	53	14.2	54	12.5
Personal safety / security (eg. better for children; low crime)	52	14.0	57	13.2
Close knit community	50	13.4	10	2.3
Healthy environment (eg. less pollution)	42	11.3	63	14.6
Very quiet/peaceful	35	9.4	55	12.8
Quality of the people (eg. caring, friendly, easy going, helping)	33	8.9	71	16.5
Good quality drinking water	18	4.8	11	2.6
Good area for production (eg. sugar; soil; natural rainfall)	14	3.8	18	4.2
Good facilities	11	3.0	14	3.2
Farming *	9	2.4	-	-
Scenery *	8	2.2	-	-
Work *	7	1.9	-	-
Water available for irrigation **	6	1.6	-	-
It's home	4	1.1	14	3.2
Affordable land	2	0.5	7	1.6

* Not a prominent response in Survey 1 ** New category in Survey 2
NB: percentages do not add to 100 as up to three responses were allowed

4.4 Key Issues

Generally, what do you think are some of the key issues facing people in the Herbert?
The most frequent responses from Surveys 1 and 2 (1998) are listed in the table below.

Key issues	Survey 2 N = 359		Survey 1 N = 409	
	N	%	N	%
Unemployment (particularly long term)	97	27.0	169	41.3
Lack of diversity in industry/need for a new major industry (including overreliance on sugar industry; economic down turn)	90	25.1	59	14.4
Lack of opportunities for young people	67	18.7	31	7.6
Flooding in the lower catchment	57	15.9	23	5.6
Lack, and need for improvement, of community services/facilities	42	11.7	38	9.3
Weather, and changing weather patterns, affects primary industry *	28	7.8	-	-
Water quantity (eg availability; lack of storage; lack of groundwater)	27	7.5	39	9.5
Fishing issues (eg. Overfishing, habitat loss, swamp drainage)	27	7.5	25	6.1
Environmental issues (eg. Affect lifestyle and potential for jobs)	27	7.5	11	2.7
Clearing of marginal land/poor land management (including cane land expansion; tree clearing; "fauna versus farming'	24	6.7	60	14.7
Pollution (water and air)	21	5.8	24	5.9
Poor drinking water quality	15	4.2	201	4.9
Drainage (eg. Dissatisfaction with new proposals, run off too fast from new assignments)	15	4.2	13	3.2
High costs of living *	14	3.9	-	-
Lack of funds (eg. for creating jobs, from council) **	10	2.8	-	-
Poorly quality roads/poorly maintained roads	10	2.8	18	4.4
Tourism – lack of any tourism development	9	2.5	17	4.2
Cane prices	9	2.5	10	2.4
Weed degradation *	8	2.5	-	-
Ageing population *	8	2.2	-	-
Government interference in all aspects of life *	8	2.2	-	-
Lack of growth and progress **	8	2.2	-	-
Lack of entertainment	7	1.9	21	5.1
Conservationists/greenies ("ratbags")	6	1.7	10	2.4

* Not a prominent response in Survey 1 ** New category in Survey 2

A total of 762 responses were mentioned by the 359 respondents to this question. The most frequent responses are shown in the table and provide more than 83 per cent of the total number of responses. A comparison is made with the prominent responses in the 1996 Survey.

Unemployment was the most frequent response in both surveys but was mentioned by a lower percentage of respondents in Survey 2 (27.0%) than in Survey 1 (41.3%), reflecting an actual decrease in unemployment in that time period (Australian Bureau of Statistics, 1999). Related to this, a lack of opportunities for young people was mentioned more frequently in Survey 2 (18.7%) than Survey 1 (7.6%) and was mentioned more frequently by lower catchment respondents (57 of 67 responses).

While clearing of marginal land was the second most frequent response in Survey 1 (14.7%), in Survey 2 it appeared to be less important to respondents (6.7%). It was mainly of concern to lower catchment respondents (21 of 24 responses) in Survey 2.

Lack of diversity in industry was mentioned by a higher percentage of respondents in Survey 2 (25.1%) than in Survey 1 (14.4%) and was mentioned by lower catchment respondents in 73 of the 77 responses.

A higher percentage of respondents were concerned about flooding in Survey 2 (15.9%) than Survey 1 (5.6%) and this was predominantly a concern of lower catchment respondents (54 of the 57 responses). Drainage was mentioned by lower catchment respondents in 14 of the 15 responses.

Water quantity issues were mentioned by upper catchment respondents in 23 of the 27 cases. Fishing issues and weather conditions were only mentioned by lower catchment respondents and environmental issues were mentioned by lower catchment respondents in 21 of the 27 responses.

4.5 Issue Importance

This section asked for importance ratings of eight issues, both for respondents personally and for the people of the Herbert. Four issues were repeated from Survey 1 and four issues were added in Survey 2 to gain feedback from the community on their importance.

It was anticipated in Survey 1 that the two ratings (for self and others) may differ, and that knowledge of such differences would be important for establishing the importance of land and water management issues across the catchment.

How important are the following issues (1) to you personally, and (2) to people in the Herbert in general?

1. Land degradation (repeat)

		importance to you personally		importance to people in the Herbert	
Response	**Rating**	**N (385)**	**Percent**	**N (372)**	**Percent**
very high importance	5	193	50.1	139	37.4
high	4	106	27.5	102	27.4
moderate	3	65	16.9	91	24.5
low	2	14	3.6	36	9.7
very low importance	1	7	1.8	4	1.1
		TOTAL 385	100.0	TOTAL 372	100.0
		Mean = 4.2		Mean = 3.9	

Land degradation was generally seen as highly important for both self and others (the means were 4.2 and 3.9 respectively). It was seen to be significantly more important to respondents personally than they perceived it to be to others in the Herbert.

Overall, land degradation was found to be more important to respondents in Survey 2 than in Survey 1. It was significantly more important to respondents in Survey 2 than in Survey 1 (means 4.2 and 3.9) and it was perceived to be significantly more important to others in the Herbert in Survey 2 than in Survey 1 (means 3.9 and 3.7).

Similarly, those respondents who completed both Surveys found land degradation to be significantly more important in Survey 2 than Survey 1 (means 4.2 and 3.9) and also significantly more important to others in Survey 2 than Survey 1 (means 3.8 and 3.7).

2. Water quality problems (repeat)

		importance to you personally		importance to people in the Herbert	
Response	**Rating**	**N (394)**	**Percent**	**N (379)**	**Percent**
very high importance	5	232	58.9	192	50.7
high	4	93	23.6	101	26.6
moderate	3	41	10.4	62	16.4
low	2	23	5.8	21	5.5
very low importance	1	5	1.3	3	0.8
		TOTAL 394	100.0	TOTAL 379	100.0
		Mean = 4.3		Mean = 4.2	

Water quality problems were generally reported to be highly important to respondents and perceived to be highly important to others in the Herbert (means 4.3 and 4.2 respectively). Water quality problems were significantly more important to respondents personally than they perceived them to be to others in the Herbert.

Water quality was of higher importance to respondents in Survey 2 than to respondents in Survey 1 (4.3 and 4.2) and perceived to be more important to others in the Herbert in Survey 2 than in Survey 1 (means 4.2 and 4.0). It also increased significantly in importance to those respondents who participated in both Surveys, who rated water quality problems as significantly more important in Survey 2 (mean of 4.2 in Survey 1 and 4.4 in Survey 2).

3. Water quantity problems (repeat)

		importance to you personally		importance to people in the Herbert	
Response	**Rating**	**N (387)**	**Percent**	**N (374)**	**Percent**
very high importance	5	166	42.9	150	40.1
high	4	74	19.1	83	22.2
moderate	3	75	19.4	80	21.4
low	2	47	12.1	42	11.2
very low importance	1	25	6.5	19	5.1
		TOTAL 387	100.0	TOTAL 374	100.0
		Mean = 3.8		Mean = 3.8	

Water quantity problems were generally reported as having moderate to high importance by both respondents personally and to others (both means 3.8).

Different to the previous issues, water quantity problems were less important to Survey 2 respondents than Survey 1 respondents (means 3.8 and 4.0 respectively) and perceived to be less important to others in the Herbert in Survey 2 than Survey 1 (means 3.8 and 3.9 respectively).

In addition, water quantity problems decreased significantly in importance for repeat participants, rating it as highly important in Survey 1 and moderately to highly important in Survey 2 (4.0 and 3.8).

Using a two way analysis of variance, it was shown that there was a significant difference between the upper and lower catchments for the personal importance – more upper catchment

respondents found this issue to be important (means upper 4.2, lower 3.6). There was no significant difference between urban and rural respondents and no significant interaction between urban versus rural and upper catchment versus lower catchment.

Examining the perceptions of importance of water quantity to others in the Herbert in the same way, a similar effect was found. Water quantity was perceived to be more important to the Herbert by upper catchment respondents (4.35) than lower catchment respondents (3.6). There was no significant difference between urban and rural respondents and no significant interaction between upper versus lower catchment and urban versus rural respondents.

4. Nature conservation issues (repeat)

		importance to you personally		importance to people in the Herbert	
Response	**Rating**	**N (387)**	**Percent**	**N (370)**	**Percent**
very high importance	5	158	40.8	81	21.9
high	4	109	28.2	106	28.6
moderate	3	91	23.5	128	34.6
low	2	24	6.2	40	10.8
very low importance	1	5	1.3	15	4.1
		TOTAL 387	100.0	TOTAL 370	100.0
		Mean = 4.0		Mean = 3.5	

Nature conservation was of high importance to respondents personally and perceived to be of moderate to high importance by others in the Herbert. This was a significant difference.

Nature conservation was more important to Survey 2 respondents than to respondents in Survey 1 (4.0 and 3.7) and perceived to be more important to others in the Herbert in Survey 2 than it was in Survey 1 (3.5 and 3.3).

Those respondents who participated in both Surveys rated nature conservation as significantly more important in Survey 2 (mean 4.1) than Survey 1 (3.7).

Using a two way analysis of variance, it was shown that nature conservation was more important to urban respondents (4.2) than to rural respondents (3.8).

5. Flooding (new)

		importance to you personally		importance to people in the Herbert	
Response	**Rating**	**N (396)**	**Percent**	**N (376)**	**Percent**
very high importance	5	177	44.7	201	53.5
high	4	72	18.2	96	25.5
moderate	3	58	14.6	53	14.1
low	2	51	12.9	18	4.8
very low importance	1	38	9.6	8	2.1
		TOTAL396	100.0	TOTAL376	100.0
		Mean = 3.8		Mean = 4.2	

Flooding was of high importance to respondents and to others in the Herbert overall. It was, however, perceived to be significantly more important to other people in the Herbert than it was to respondents personally.

The results of a two way analysis of variance to examine the impact of catchment and urban versus rural were not surprising. Flooding was more important to lower catchment respondents

(mean 4.1) than to upper catchment respondents (2.8). In addition, it was found to be more important to rural respondents (4.0) than to urban respondents (3.5).

Again, a similar result was found for respondents' perceptions of the importance of flooding to others in the Herbert. Flooding was perceived to be more important to people in the Herbert by lower catchment respondents (4.4) than to upper catchment respondents (3.6).

6. Wetlands (new)

		importance to you personally		importance to people in the Herbert	
Response	**Rating**	**N (383)**	**Percent**	**N (369)**	**Percent**
very high importance	5	134	35.0	82	22.2
high	4	108	28.2	84	22.8
moderate	3	85	22.2	128	34.7
low	2	38	9.9	52	14.1
very low importance	1	18	4.7	23	6.2
		TOTAL 383	100.0	TOTAL369	100.0
		Mean = 3.8		Mean = 3.4	

Wetlands were of moderate to high importance to Survey 2 respondents who rated the importance as significantly higher to themselves than the importance to others in the Herbert.

Wetlands were more important, personally, to lower catchment respondents (4.0) than to upper catchment respondents (3.3) and more important to urban respondents (3.9) than to rural respondents (3.6).

7. Vegetation on river banks (new)

		importance to you personally		importance to people in the Herbert	
Response	**Rating**	**N (391)**	**Percent**	**N (372)**	**Percent**
very high importance	5	176	45.0	107	28.8
high	4	104	26.6	86	23.1
moderate	3	77	19.7	117	31.5
low	2	27	6.9	44	11.8
very low importance	1	7	1.8	18	4.8
		TOTAL391	100.0	TOTAL372	100.0
		Mean = 4.1		Mean = 3.6	

Vegetation on river banks was highly important to respondents and perceived to be significantly less important to others in the Herbert (means 4.1 and 3.6).

Vegetation on river banks was found to be more important to lower catchment respondents (4.2) than to upper catchment respondents (3.8) in a two way analysis of variance comparing respondents from the upper and lower catchments and urban and rural respondents.

8. Loss of biodiversity (new)

Response	Rating	importance to you personally N (387)	Percent	importance to people in the Herbert N (370)	Percent
very high importance	5	152	39.3	81	21.9
high	4	104	26.9	89	24.1
moderate	3	89	23.0	122	33.0
low	2	34	8.8	57	15.4
very low importance	1	8	2.1	21	5.7
		TOTAL 387	100.0	TOTAL370	100.0
		Mean = 3.9		Mean = 3.4	

Loss of biodiversity was of high importance to respondents and seen to be of moderate to high importance to others in the Herbert, which was a significant difference.

In a two way analysis of variance, urban respondents were found to have rated loss of biodiversity as more important than rural respondents.

Discussion

In summary, all eight issues were at least moderately important to respondents. Ranking the mean importance ratings (below), water quality was most important overall and land degradation was ranked second overall. Of interest is the finding that flooding was ranked equal first in its importance to people in the Herbert and ranked equal last in personal importance. This may be because while flooding doesn't affect a large proportion of people in the catchment, many were aware of its impact on those who do experience flooding.

Ranking of mean ratings	Importance to you personally	Importance to people in the Herbert
Land degradation	2	2
Water quality problems	1	1
Water quantity problems	6	3
Nature conservation issues	4	5
Flooding	6	1
Wetlands	6	6
Vegetation on river banks	3	4
Loss of biodiversity	5	6

Many of the issues were rated as more important personally than for the Herbert. Exceptions were flooding, as highlighted above, and water quantity, which was rated as equally important personally and for the Herbert.

Repeat issues

Land degradation, water quality and nature conservation were rated as more important personally, and to others in the Herbert, in Survey 2.

Respondents involved in both Surveys rated water quality and land degradation as more important in Survey 2, personally and for the Herbert, reflecting the overall samples. Nature conservation was only found to be more important personally in Survey 2 by repeat respondents and equally important in both surveys for others in the Herbert.

Water quantity problems decreased in importance from Survey 1 to Survey 2, both personally and for the Herbert in the overall comparison but only personally for those people who participated in both surveys.

For Survey 2, only a couple of differences were found between the upper and lower catchment or between rural and urban respondents for these repeat questions. Water quantity problems were rated as more important by upper catchment respondents, both personally and to others in the Herbert. Nature conservation was more important personally to urban respondents than to rural respondents.

New issues
Wetlands, vegetation on river banks and flooding were all found to be more important to respondents (personally) in the lower catchment. Flooding was also rated higher by lower catchment respondents in its importance to people in the Herbert.

In terms of personal importance, wetlands and loss of biodiversity were rated higher by urban respondents and flooding was rated higher by rural respondents.

4.6 Impacts of Issues

The seven issues with the highest personal impact in Survey 1 were used is Survey 2, ie. higher taxes, loss of confidence in government's ability to manage land and water resources, higher production costs, lower fish numbers, loss of environmental uses/benefits, loss of access to recreation and poor drinking water quality.

In addition, loss of farm productivity was also used in Survey 2 as it was among the seven issues reported to have the highest impact on people in the Herbert (loss of environmental uses/benefits was not among these seven issues). In addition, it was considered to be important to compare the impact of emotional stress on participants over time and this issue was therefore included in Survey 2.

In your opinion, how much do each of the following impacts (1) affect you personally, and (2) affect people in the Herbert generally?

1. Loss of farm productivity

		affects you personally		affects people in the Herbert	
Response	**Rating**	**N (392)**	**Percent**	**N (376)**	**Percent**
very high degree	5	145	37.0	184	48.9
high	4	66	16.8	122	32.4
moderate	3	63	16.1	49	13.0
low	2	49	12.5	11	2.9
very low degree	1	38	9.7	8	2.1
not at all	0	31	7.9	2	0.5
		TOTAL 392	100.0	TOTAL376	100.0
		Mean = 3.3		Mean = 4.2	

While 53.8% of the sample felt that loss of farm productivity affected them personally to at least a high degree, 81.3% felt that it affected people in the Herbert generally to at least a high degree. There was a significantly greater impact reported for people in the Herbert compared to the personal impact reported by respondents. This finding was the same as in Survey 1. Also similar to Survey 1, the majority of those not at all affected were from the urban sample (90%).

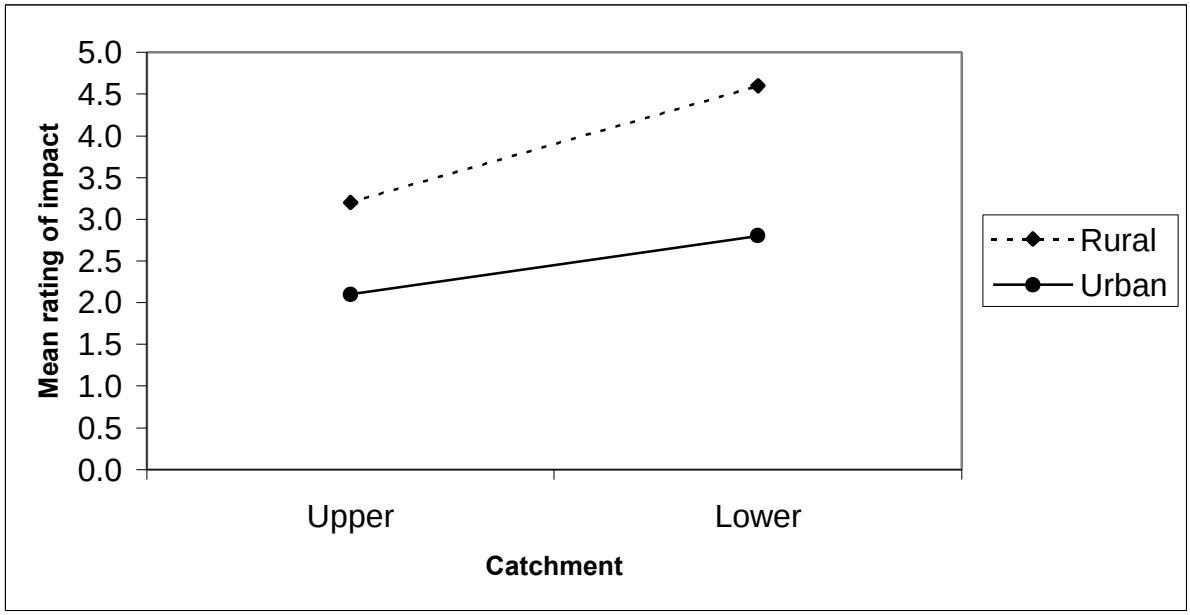
The impact of a loss of farm productivity had more effect on respondents in Survey 2 than in Survey 1 (3.3 and 2.9) and a higher perceived effect on others in Survey 2 (4.2 and 3.8). Similarly, for those respondents who completed both Surveys, the personal effect and the perceived effect

on others was higher in Survey 2 than Survey 1 (personal means 3.3 and 2.9; Herbert means 4.1 and 3.8).

A two way analysis of variance revealed a significant difference between upper and lower catchment respondents; between rural and urban respondents; and a significant interaction between the two, as shown above. It can be seen that loss of farm productivity impacted on lower rural respondents to the greatest degree, which was also found to be the case in Survey 1.

In terms of the impact on others, lower catchment respondents rated the impact on others higher than upper catchment respondents, similar to Survey 1 in which the lower urban sample was more likely than both rural samples to consider loss of farm productivity as having an effect on others.

To summarise these results, respondents perceived loss of farm productivity to have a strong impact on the Herbert Catchment and while still high, a significantly lower effect on them personally. The impact had become stronger in all ways since Survey 1, for those involved in both surveys and for the overall samples, and both personal impact and for the Herbert as a whole.



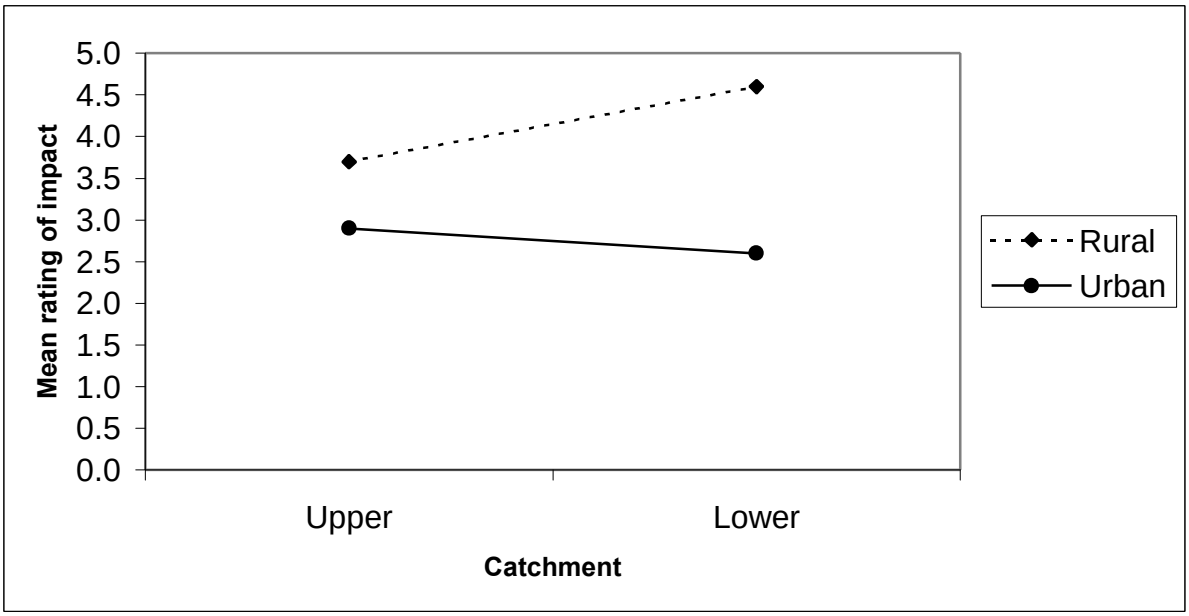
Not surprisingly, the impact was higher for rural respondents. It was also higher for lower catchment respondents. These trends suggest that the impact of a loss of farm productivity affected cane farmers more than other groups of people, as in Survey 1.

Lower catchment respondents felt it had a higher impact on others than upper catchment respondents, perhaps being aware of the higher impact that others in the lower catchment also felt from this issue.

2. Higher production costs

Response	Rating	affects you personally N (393)	Percent	affects people in the Herbert N (378)	Percent
very high degree	5	157	39.9	169	44.7
high	4	81	20.6	130	34.4
moderate	3	51	13.0	60	15.9
low	2	37	9.4	15	4.0
very low degree	1	39	9.9	3	0.8
not at all	0	28	7.1	1	0.3
		TOTAL393	100.0	TOTAL378	100.0
		Mean = 3.5		Mean = 4.2	

While 60.5% felt that higher production costs affected them personally to a high degree, 79.1% felt that it affected others in the Herbert to a high degree. The difference between the mean ratings of the effect on respondents compared to the perceived effect on other people in the Herbert was significant, repeating a finding from Survey 1. Similar to Survey 1, in Survey 2 all of those not at all affected were from the urban sample.



A two way analysis of variance was conducted to examine any differences between the upper and lower catchment and urban and rural respondents. It showed a significant main affect for urban versus rural respondents and a significant interaction between upper and lower catchment versus urban and rural residents for the personal impact. Higher production costs impacted on lower rural respondents to the highest degree.

The impact on people in the Herbert was rated higher by urban respondents (mean 4.3) than by rural respondents (mean 4.0). Both of these results were similar to the findings of Survey 1.
In summary, higher production costs was perceived to have a higher impact on the Herbert in general than respondents reported on themselves. There was consistency between the two Surveys. As in Survey 1, this issue affected rural respondents more than urban respondents. Urban and rural location versus upper and lower catchment interacted to influence the personal ratings. Lower rural respondents were affected the most and lower urban the least, suggesting, as in Survey 1, that cane farmers were affected more than other groups by higher production costs. The impact on the Herbert was rated higher by urban respondents than rural, illustrating an awareness of the impact this issue had on others in the catchment.

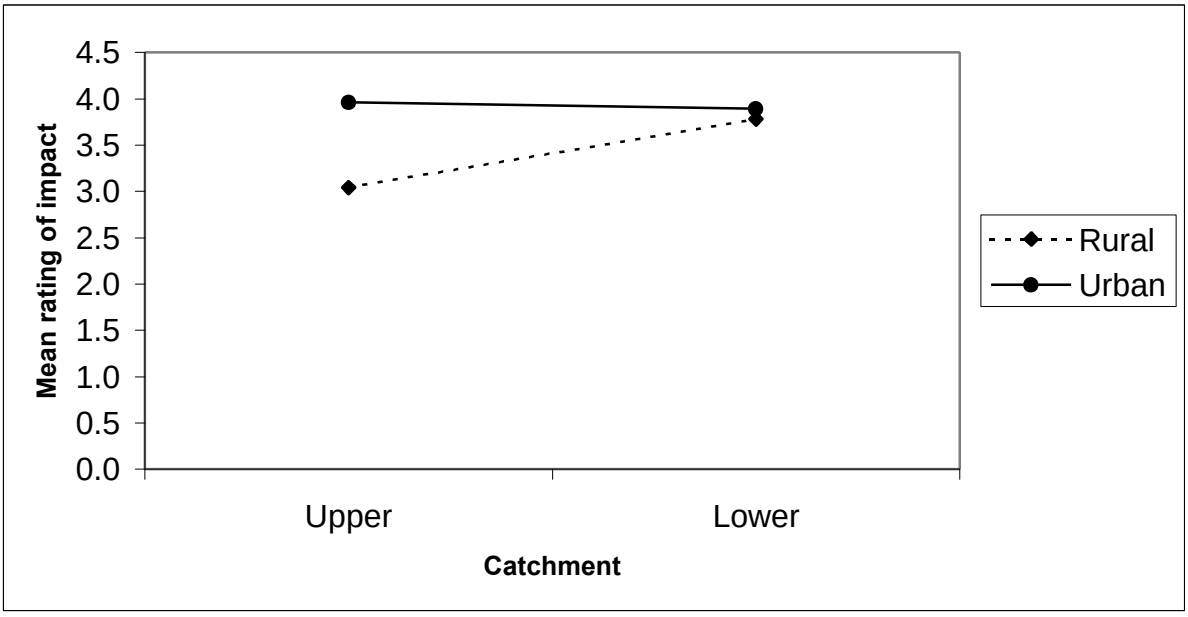
3. Poor drinking water quality

Response	Rating	affects you personally N (395)	Percent	affects people in the Herbert N (376)	Percent
very high degree	5	187	47.3	180	47.9
high	4	68	17.2	84	22.3
moderate	3	58	14.7	80	21.3
low	2	39	9.9	20	5.3
very low degree	1	26	6.6	11	2.9
not at all	0	17	4.3	1	0.3
		TOTAL395 Mean = 3.8	100.0	TOTAL376 Mean = 4.1	100.0

A large percentage (64.5%) felt that poor drinking water quality affected them to a high or very high degree and an even higher percentage (70.2%) felt that it affected others to a high or very high degree. This was a significant difference as it was in Survey 1.

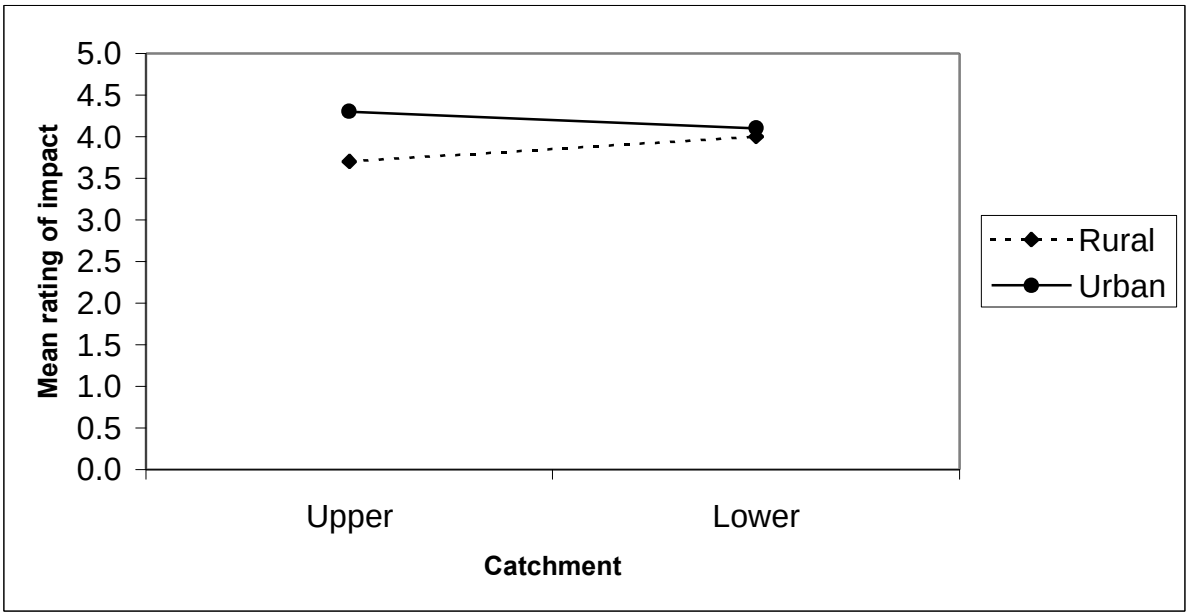
Poor drinking water quality had significantly more effect for respondents in Survey 2 than in Survey 1 (3.8 and 3.3) but there was no significant difference between the two Surveys for the perceived effect on others.

Very similar results were found for repeat participants: poor drinking water quality was reported to have a greater effect on respondents in Survey 2 than Survey 1 (3.7 and 3.3) but no significant difference for the perceived effect on others in the Herbert.



There was a significant difference between the upper and lower catchment; between the urban and rural respondents; and a significant interaction between the two. Lower catchment respondents rated the personal impact of poor drinking water quality higher than upper catchment respondents and urban respondents rated the personal impact higher than rural respondents. In Survey 1, however, lower urban respondents rated the impact significantly higher than the other samples. Upper rural respondents stood out as being least affected by poor drinking water quality, although still rated by them as moderate. As in Survey 1, poor drinking water quality was rated to have at least a moderate impact on all four samples of the catchment.

While there were no differences between the four samples in Survey 1, a number of differences were found between them in Survey 2. The impact on people in the Herbert of poor drinking water quality was rated significantly higher by urban respondents (mean 4.3) than by rural respondents (mean 3.7) when looking at upper catchment respondents. The figure above illustrates the significant interaction between upper and lower catchment versus and urban and rural location. The impact on people in the Herbert in general was rated highest by upper urban respondents and lowest by upper rural respondents.



Overall, poor drinking water quality had a high impact on people. Respondents reported a larger impact on people in the Herbert in general than the personal impact they felt. The impact on respondents was stronger in Survey 2 than Survey 1, both for the overall samples and for repeat respondents.

There was a significant interaction in examining urban and rural residents versus upper and lower catchments. For the upper catchment, urban respondents reported a higher personal impact than rural respondents. For those in rural areas, lower catchment respondents reported a higher personal impact than upper catchment respondents.

Upper rural respondents were affected the least by poor drinking water quality although they still reported a moderate impact.

Among upper catchment respondents, urban respondents reported a higher perceived impact on the Herbert in general than rural respondents.

4. Emotional stress

Response	Rating	affects you personally N (391)	Percent	affects people in the Herbert N (359)	Percent
very high degree	5	74	18.9	58	16.2
high	4	62	15.9	81	22.6
moderate	3	94	24.0	156	43.5
low	2	84	21.5	43	12.0
very low degree	1	53	13.6	16	4.5
not at all	0	24	6.1	5	1.4
		TOTAL391	100.0	TOTAL359	100.0
		Mean = 2.9		Mean = 3.3	

One fifth of respondents (19.7%) felt that emotional stress affected them personally to a very low degree or not at all. A higher percentage (34.8%) felt that emotional stress affected them personally to a high or very high degree.

A similar percentage (38.8%) felt that emotional stress affected other people in the Herbert to a high or very high degree, while the largest percentage (43.5%) felt that it affected other people to a moderate degree and only 5.9% felt that it affected others to a low degree or not at all. The mean scores were near the moderate mark, the same as in Survey 1.

There was a significant difference between the effect emotional stress had on respondents and the perceived effect it had on others in the Herbert, the same result as in Survey 1.

A two way analysis of variance examining upper and lower catchments and urban and rural locations revealed that there was a significant difference between urban and rural respondents: the impact of emotional stress was reported by urban respondents (mean 2.5) to be lower than for rural respondents (mean 3.3). Of those respondents who reported no impact at all, 70.8% were from the urban sample. A difference was also found between upper and lower catchments: upper catchment respondents reported a lower degree of impact on them (mean 2.3) than lower catchment respondents (mean 3.1). This reflects the results of Survey 1 in which lower rural respondents experienced more personal impact than upper catchment respondents.

The impact of emotional stress on people in the Herbert was rated significantly higher by lower catchment respondents (mean 3.4) than by upper catchment respondents (mean 3.1).

Thus, emotional stress was reported to have a moderate impact on respondents and on people in the Herbert but a significantly larger impact on the Herbert. These impacts had remained static from Survey 1. Emotional stress had a higher impact on rural respondents than urban and a lower impact on the upper catchment than the lower catchment.

It was perceived to have a larger impact on people in the Herbert by rural respondents than by urban respondents. Presumably, as emotional stress had a higher impact on rural respondents, they also perceived it to have a large impact on others.

5. Higher taxes

Response	Rating	affects you personally N (396)	Percent	affects people in the Herbert N (374)	Percent
very high degree	5	206	52.0	185	49.5
high	4	87	22.0	116	31.0
moderate	3	47	11.9	57	15.2
low	2	27	6.8	9	2.4
very low degree	1	18	4.5	6	1.6
not at all	0	11	2.8	1	0.3
		TOTAL396 Mean = 4.0	100.0	TOTAL374 Mean = 4.2	100.0

A large percentage of respondents reported that higher taxes had a high or very high degree of impact on them (74%) and an even larger percentage (80.5%) reported a high or very high degree of impact on other people in the Herbert. Higher taxes had the largest impact of all nine issues, in both Surveys. The mean scores were exactly the same for both surveys.

The issue of higher taxes was reported to affect respondents and others in the Herbert to a high degree but it was perceived to have a significantly higher effect on others in the Herbert, despite the similarity in the mean ratings.

A two way analysis of variance was conducted to examine any differences between the upper and lower catchment and rural and urban respondents. Lower catchment respondents reported a greater impact of higher taxes (mean 4.1) than upper catchment respondents (mean 3.7) and rural respondents reported a greater impact (mean 4.3) than urban respondents (mean 3.7). Of the eleven respondents who felt that higher taxes had no impact at all on people in the Herbert, ten were from the urban sample. Lower catchment respondents also reported a greater degree of impact on others of higher taxes (mean 4.3) than upper catchment respondents (mean 4.0). This was similar to Survey 1 in which lower rural respondents rated the impact of higher taxes significantly higher than the other three samples.

Higher taxes was reported to have a higher impact personally and on the Herbert, by lower catchment respondents than by upper catchment respondents and rural respondents reported a higher personal impact than urban respondents. These are similar results to Survey 1, in which the lower rural sample was more likely to feel personally affected by higher taxes compared with both upper catchment samples. However, there were no differences between samples for the effect on others.

6. Lower fish numbers

Response	Rating	affects you personally N (390)	Percent	affects people in the Herbert N (374)	Percent
very high degree	5	131	33.6	107	28.6
high	4	100	25.6	112	29.9
moderate	3	77	19.7	114	30.5
low	2	32	8.2	24	6.4
very low degree	1	28	7.2	15	4.0
not at all	0	22	5.6	2	0.5
		TOTAL390 Mean = 3.5	100.0	TOTAL 374 Mean = 3.7	100.0

The majority of respondents to this question rated the personal impact of lower fish numbers as high or very high (59.2%) and a similar percentage rated the impact in this way for people in the Herbert (58.5%).

Lower fish numbers was reported to have a moderate to high effect on both respondents and others in the Herbert but a significantly higher effect on other people in the Herbert, the same result as in Survey 1. In addition, comparing those people who participated in both Surveys, lower fish numbers was perceived to have decreased in its effect on people in the Herbert from Survey 1 to Survey 2 (means 3.7 and 3.5).

A two way analysis of variance conducted to examine differences between the upper and lower catchments and urban and rural locations showed that lower catchment respondents reported a significantly greater degree of impact of lower fish numbers (mean 3.8) than upper catchment respondents (mean 2.9), the same result as Survey 1, including very similar means. Urban respondents reported a significantly greater degree of impact (mean 3.7) than rural respondents (mean 3.4). Lower catchment respondents also reported a significantly greater degree of impact of lower fish numbers on people in the Herbert in general (mean 3.8) than upper catchment respondents (mean 3.5), the same as in Survey 1.
Overall, lower fish numbers had a moderate to high impact but a significantly higher impact on the Herbert than on respondents. Repeat respondents reported a decreased impact on the Herbert since Survey 1.

Lower fish numbers had a greater personal impact on lower catchment respondents, and they reported a greater impact on the Herbert, than upper catchment respondents. Urban respondents reported a greater personal impact than rural respondents. As in Survey 1, fishing appears to be more a recreational activity for those people living in the lower catchment, which is not at all surprising.

7. Loss of access to recreation

		affects you personally		affects people in the Herbert	
Response	**Rating**	**N (393)**	**Percent**	**N (373)**	**Percent**
very high degree	5	110	28.0	92	24.7
high	4	96	24.4	111	29.8
moderate	3	97	24.7	117	31.4
low	2	43	10.9	32	8.6
very low degree	1	28	7.1	16	4.3
not at all	0	19	4.8	5	1.3
		TOTAL 393	100.0	TOTAL 373	100.0
		Mean = 3.4		Mean = 3.6	

As in Survey 1, more than 50 per cent of the sample considered impacts experienced personally and by others to be high or very high and the mean scores (equal to Survey 1) were between moderate and high with a significantly higher impact on others in the Herbert.

The two way analysis of variance conducted to examine differences between the upper and lower catchment and urban and rural locations showed a significant difference between the upper and lower catchment. Lower catchment respondents rated the impact of the loss of access to recreation (mean 3.5) significantly higher than upper catchment respondents (mean 3.1).

No significant difference was found between the upper and lower catchment or between urban and rural respondents for the impact on people in the Herbert in general, whereas in Survey 1,

lower urban participants considered general Herbert impacts of a loss of recreation to be significantly higher than both upper catchment samples.

In summary, loss of access to recreation had a moderate to high impact overall but a higher impact was reported on the Herbert, repeating the results of Survey 1. The lower catchment was impacted more by a loss of access to recreation than the upper catchment.

The results of Survey 2 were very similar to the results of Survey 1. The majority of respondents rated the impact of loss of confidence in government's ability to manage land and water resources as high or higher, 68.4% for the personal impacts and 65.1% for the impact on others.

Loss of confidence in government's ability to manage land and water resources was reported to have a high effect on respondents and for others. Despite the similarity in the means, the personal impact was significantly higher than on others in the Herbert, the same as in Survey 1.

8. Loss of confidence in government's ability to manage land and water resources

		affects you personally		affects people in the Herbert	
Response	**Rating**	**N (395)**	**Percent**	**N (375)**	**Percent**
very high degree	5	154	39.0	130	34.7
high	4	118	29.4	114	30.4
moderate	3	93	23.2	97	25.9
low	2	17	4.3	26	6.9
very low degree	1	6	1.5	5	1.3
not at all	0	7	1.8	3	0.8
		TOTAL 395	100.0	TOTAL 375	100.0
		Mean = 4.0		Mean = 3.9	

The two way analysis of variance conducted to examine differences between the upper and lower catchment and urban and rural locations showed no significant differences or interaction, either for personal effect or effect on people in the Herbert in general. This was different to Survey 1 in which the lower urban sample rated the impact on the Herbert in general as higher than the lower rural sample.

In summary, loss of confidence in government's ability to manage land and water resources was rated as high overall and significantly higher on respondents themselves as opposed to the Herbert in general. No differences between the two Surveys were found nor any differences between catchments or between urban and rural respondents.

9. Loss of environmental uses or benefits (eg. wildlife habitat)

		affects you personally		affects people in the Herbert	
Response	**Rating**	**N (392)**	**Percent**	**N (372)**	**Percent**
very high degree	5	115	29.3	72	19.4
high	4	106	27.0	84	22.6
moderate	3	114	29.1	143	38.4
low	2	36	9.2	59	15.9
very low degree	1	11	2.8	11	3.0
not at all	0	10	2.6	3	0.8
		TOTAL 392	100.0	TOTAL 372	100.0
		Mean = 3.6		Mean = 3.4	

Loss of environmental uses or benefits was reported to have a moderate to high impact on respondents and others but a significantly higher effect on respondents, the same results as found in Survey 1.

Both the effect on respondents, and perceived effect on others, of a loss of environmental uses or benefits were reported to be significantly higher in Survey 2 than in Survey 1 (means 3.6 and 3.4; 3.4 and 3.2). Similarly, respondents who completed both Surveys reported an increase in the effect of a loss of environmental uses or benefits (Survey 1 Mean = 3.4; Survey 2 Mean = 3.7).

A two way analysis of variance was conducted to examine differences between the upper and lower catchment and urban and rural respondents. Lower catchment respondents were found to be impacted to a greater degree by loss of environmental uses or benefits (mean 3.7) than upper catchment respondents (mean 3.4). Urban respondents rated the impact higher (mean 3.8) than rural respondents (mean 3.5). These results are similar to the results of Survey 1 in which lower urban respondents rated the personal impact and impact on the Herbert as significantly higher than the upper rural sample. In Survey 2, however, no differences were found for the impact on people in the Herbert in general.

Overall, loss of environmental uses or benefits had a moderate to high impact and a higher personal impact. The personal impact had increased since Survey 1, both for the overall sample and for repeat respondents. Lower catchment respondents reported a higher impact than in the upper catchment and urban respondents more than rural respondents.

Discussion

Throughout this question, less participants responded to the section regarding the impact on people in the Herbert. This may be a result of more people feeling comfortable to respond about their own opinions than on behalf of others. In addition, fewer participants responded that there was no impact at all on people in the Herbert, presumably because fewer were willing to assume that there would be no-one who was affected by the issue.

Overall, comparing the mean responses for the entire sample, the four issues reported to have the highest impact on respondents were:

- higher taxes;
- loss of confidence in the government's ability to manage land and water resources;
- poor drinking water quality; and
- loss of environmental uses or benefits.

In Survey 1, the issues with the highest impact were (for repeat respondents only):

- loss of confidence in the government's ability to manage land and water resources;
- higher taxes;
- loss of farm productivity; and
- lower fish numbers.

In Survey 2, the four issues reported to have the highest impact on people in the Herbert were:

- higher taxes;
- loss of farm productivity;
- higher production costs; and
- poor drinking water quality.

In Survey 1, the four issues reported to have the highest impact were (for repeat respondents only):

- higher taxes;

- higher production costs;
- poor drinking water quality; and
- loss of confidence in the government's ability to manage land and water resources;

The stability of community opinions over the two years between the surveys was quite strong. However, there were some differences, listed below, between the two surveys.

- The impact of 'loss of farm productivity' increased, both in terms of the personal impact and the impact on the Herbert and for both the overall samples and for repeat respondents.
- The personal impact of 'poor drinking water quality' increased, both for the overall samples and for repeat respondents.
- In Survey 2, upper urban respondents rated the impact on the Herbert of 'poor drinking water quality' significantly higher than upper rural respondents whereas there was no difference between samples in Survey 1.
- In Survey 2, the impact of 'emotional stress' on the Herbert was rated higher by lower catchment respondents than upper catchment respondents but there was no difference between catchments in Survey 1.
- The impact of 'lower fish numbers' was rated significantly lower by repeat respondents for the Herbert in Survey 2 than in Survey 1.
- The personal impact of 'lower fish numbers' was rated higher by urban respondents than rural respondents in Survey 2 whereas there were no significant differences between them in Survey 1.
- 'Loss of access to recreation' was rated higher by lower catchment respondents than upper catchment respondents in terms of personal impact but there was no difference in Survey 1.
- The impact of 'loss of access to recreation' on the Herbert was rated higher by the lower urban sample than upper catchment respondents in Survey 1 but no difference was displayed between catchments or locations in Survey 2.
- While the impact of a 'loss of confidence in government's ability to manage land and water resources' on the Herbert was rated higher by the lower urban sample than the lower rural sample in Survey 1, there were no such differences in Survey 2.
- The only issue for which there agreement between the upper and lower catchment and rural and urban respondents was 'loss of confidence in government's ability to manage land and water resources'.
- 'Loss of environmental uses/benefits' increased in its impact, both personally and for the Herbert, both between the overall survey samples and for repeat respondents.
- The impact of 'loss of environmental uses/benefits' on the Herbert was rated higher by lower urban respondents than upper rural respondents in Survey 1 but no differences were displayed in Survey 2 between catchments or locations.

4.7 Awareness and Intentions

As in Survey 1, three general questions were asked concerning awareness and involvement in land and water issues in the Herbert.

Generally speaking, what awareness do you think local people have about land and water issues in the Herbert?

Response	Rating	N (392)	Percent
very high awareness	5	41	10.5
high	4	99	25.3
moderate	3	169	43.1
low	2	70	17.9
very low awareness	1	13	3.3
TOTAL		392	100.0
Mean = 3.1			

Awareness of local people about land and water issues in the Herbert was perceived to be moderate overall. Lower catchment respondents rated this item significantly higher than upper catchment respondents (means 3.3 and 3.0). There were no differences between the surveys.

How much do you think local people are prepared to become involved in land and water issues in the Herbert?

Response	Rating	N (394)	Percent
very high degree	5	15	3.8
high	4	72	18.3
moderate	3	195	49.5
low	2	94	23.9
very low degree	1	18	4.6
TOTAL		394	100.0
Mean = 2.9			

Respondents perceived that local people would be prepared to become involved in land and water issues in the Herbert to a moderate degree overall. The degree to which it was thought local people would become involved had significantly decreased from Survey 1 to Survey 2 (means 3.0 and 2.9) although the ratings were very close. Similarly, respondents who participated in both surveys gave a significantly lower response in Survey 2 than in Survey 1 (means 3.0 and 2.9).

How much are you prepared to become involved in land and water issues in the Herbert?

Response	Rating	N (389)	Percent
very high degree	5	40	10.3
high	4	118	30.3
moderate	3	154	39.6
low	2	50	12.9
very low degree	1	27	6.9
TOTAL		389	100.0
Mean = 3.3			

Respondents indicated that overall they would be prepared to become involved in land and water issues in the Herbert to a moderate/high degree. From Survey 1 to Survey 2 the degree to which respondents were prepared to become involved in land and water issues had increased significantly (means 3.1 and 3.2). In addition, from Survey 1 to Survey 2, repeat respondents were significantly more prepared to become involved (means 3.1 and 3.3).

In Survey 2, rural respondents rated this higher than urban respondents (means 3.4 and 3.1).

Discussion
Overall, local awareness about land and water issues was considered to be moderate, as it was in Survey 1.

Interestingly, while the perceived preparedness of local people to become involved in land and water issues had decreased from Survey 1, both overall and for repeat respondents, the actual preparedness of respondents themselves to become involved had increased both overall and for repeat respondents.

It would be useful to determine whether or not these two items are related, it may be that the decreased perception that local people were prepared to become involved contributed to the preparedness of respondents to become involved themselves.

4.8 Tractability

This section of the questionnaire was repeated from Survey 1. It examined how manageable (or practical) catchment management might be, given perceptions of possible impediments to effectively managing land and water in the catchment.

Participants were asked to rate how much they agreed or disagreed with the statements, each underlining a particular obstacle to managing land and water. Ten of the fourteen statements from Survey 1 were used in Survey 2 and two additional statements were used as they had become important issues since Survey 1 was conducted.

Managing land and water in the Herbert is difficult because…
1. problems aren't well understood (repeat)

Response	Rating	N (389)	Percent
strongly agree	5	66	17.0
agree	4	229	58.9
neither agree nor disagree	3	49	12.6
disagree	2	37	9.5
strongly disagree	1	8	2.1
TOTAL		389	100.0
Mean = 3.8			

The majority of respondents (75.9%) agreed or strongly agreed that managing land and water was difficult because problems were not well understood. This is a very similar result as Survey 1, in which the mean score was exactly the same. There were no significant differences between the four samples, as in Survey 1.

2. solutions aren't easy (repeat)

Response	Rating	N (392)	Percent
strongly agree	5	88	22.4
agree	4	224	57.1
neither agree nor disagree	3	35	8.9
disagree	2	36	9.2
strongly disagree	1	9	2.3
TOTAL		392	100.0
Mean = 3.9			

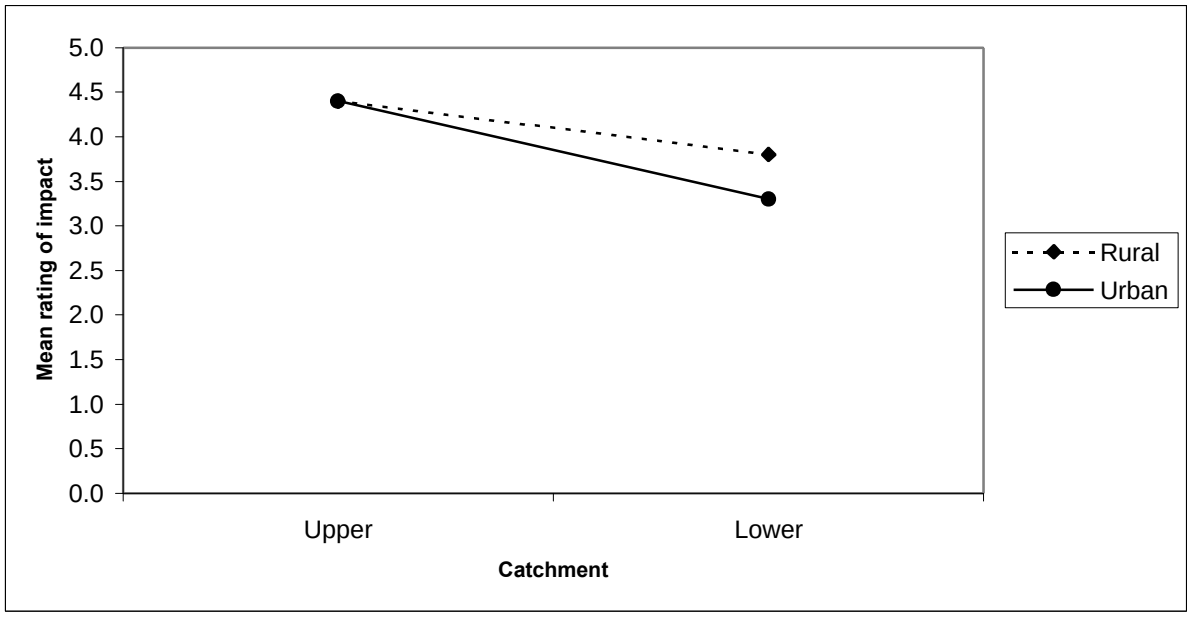
As in Survey 1, the majority of respondents agreed or strongly agreed (79.5%) that solutions were not easy, making land and water management difficult. There were no differences between any of the samples in Survey 2, whereas in Survey 1 lower catchment respondents were more likely to agree that solutions were not easy.

3. local people lack the money to spend on solutions (repeat)

Response	Rating	N (393)	Percent
strongly agree	5	121	30.8
agree	4	148	37.7
neither agree nor disagree	3	68	17.3
disagree	2	43	10.9
strongly disagree	1	13	3.3
TOTAL		393	100.0
Mean = 3.8			

Nearly 70% agreed or strongly agreed that local people lack the money to spend on solutions, making managing land and water difficult. There was a significant difference between the overall responses in Survey 1 and 2 with the mean being higher in Survey 2 than in Survey 1 (3.8 and 3.5). There was also a significant difference between the responses of those people who completed both Surveys, agreeing more strongly that local people lack the money to spend on solutions in the later Survey (Survey 1 mean = 3.5; Survey 2 mean = 4.0). This was the only significant difference for repeat respondents for this list of statements.

In addition, a two way analysis of variance showed that upper catchment respondents (mean 4.4) agreed more strongly than lower catchment respondents (mean 3.6), and rural respondents (mean 4.0) agreed more strongly than urban respondents (mean 3.7), that local people lack the money to spend on solutions. There was also an interaction between upper and lower catchment versus urban and rural location, as shown below. The Survey 1 results were similar: the lower urban sample was less likely to agree with the statement and the lower rural sample was less likely to agree with the statement than both upper catchment samples.



4. government strategies are too slow (new)

Response	Rating	N (391)	Percent
strongly agree	5	179	45.8
agree	4	152	38.9
neither agree nor disagree	3	50	12.8
disagree	2	7	1.8
strongly disagree	1	3	0.8
TOTAL		391	100.0
Mean = 4.3			

Most respondents (84.7%) agreed that government strategies are too slow. There were no differences between samples, either in Survey 1 or 2.

5. solutions are expensive (repeat)

Response	Rating	N (391)	Percent
strongly agree	5	143	36.6
agree	4	165	42.2
neither agree nor disagree	3	46	11.8
disagree	2	33	8.4
strongly disagree	1	4	1.0
TOTAL		391	100.0
Mean = 4.0			

The majority of respondents (78.8%) agreed or strongly agreed that solutions are expensive, making managing land and water difficult. The mean was significantly higher for Survey 2 than Survey 1 respondents overall (means 4.0 and 3.9). There were no differences between samples in Survey 1 or 2.

6. there are few benefits and many costs (repeat)

Response	Rating	N (392)	Percent
strongly agree	5	49	12.5
agree	4	113	28.8
neither agree nor disagree	3	84	21.4
disagree	2	102	26.0
strongly disagree	1	44	11.2
TOTAL		392	100.0
Mean = 3.0			

Opinions on this item were split, with 41.3% agreeing to some degree and 37.2% disagreeing to some degree. There was quite a high percentage who neither agreed nor disagreed with the statement (21.4%). The split of opinion was highlighted by the overall mean of 3.0, neither agree no disagree. While the overall means for Survey 1 and Survey 2 appeared similar, they were significantly different, with agreement higher in Survey 2 than in Survey 1 (3.0 and 2.9). There were no differences among the samples in either survey.

7. local people don't want to spend money on solutions (repeat)

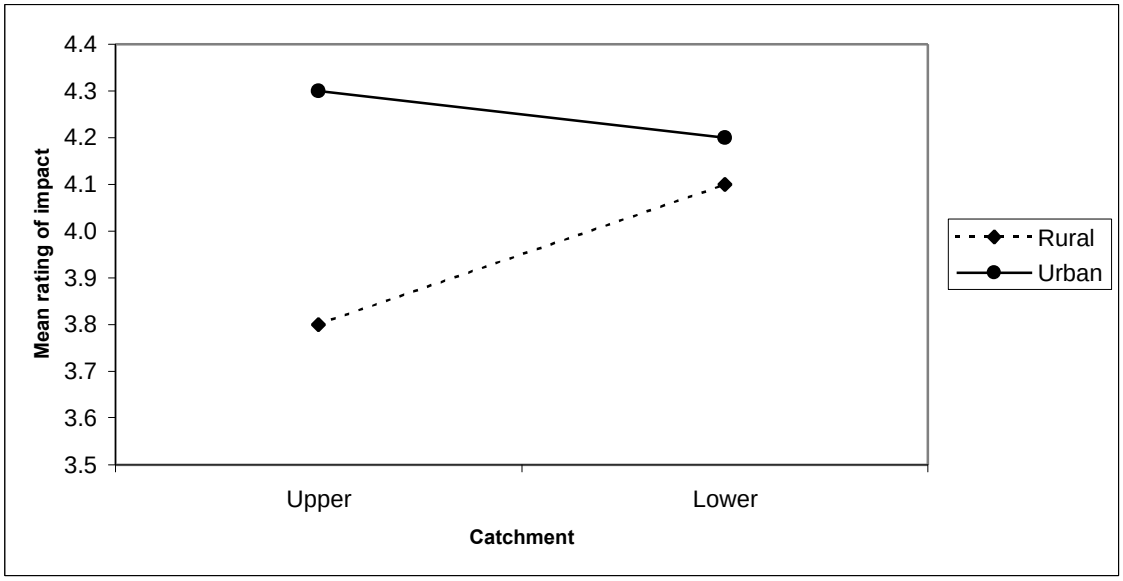
Response	Rating	N (392)	Percent
strongly agree	5	50	12.8
agree	4	150	38.3
neither agree nor disagree	3	102	26.0
disagree	2	81	20.7
strongly disagree	1	9	2.3
TOTAL		392	100.0
Mean = 3.4			

Half of the respondents agreed that local people don't want to spend money on solutions and a quarter neither agreed nor disagreed. The mean, however, as in Survey 1, indicated that on average, participants tended to neither agree nor disagree. There were no significant differences between the two Surveys and no differences between the samples in either survey.

8. the Herbert River Catchment covers a large area (repeat)

Response	Rating	N (388)	Percent
strongly agree	5	131	33.8
agree	4	207	53.4
neither agree nor disagree	3	27	7.0
disagree	2	16	4.1
strongly disagree	1	7	1.8
TOTAL		388	100.0
Mean = 4.1			

As in Survey 1, a very large percentage of respondents (87.2%) agreed or strongly agreed that land and water management are difficult because the Herbert River Catchment covers a large area. Rural respondents were more likely than urban respondents, in Survey 2, to agree that the large area of the Herbert River Catchment made land and water management difficult (means 4.0 and 3.7). There was also a two way interaction between catchment and location, as shown in the figure below. The direction of the difference between the two catchments was different depending on respondents' urban or rural location. There were no differences between samples in Survey 1.



9. local people don't trust government programs (repeat)

Response	Rating	N (393)	Percent
strongly agree	5	107	27.2
agree	4	155	39.4
neither agree nor disagree	3	99	25.2
disagree	2	23	5.9
strongly disagree	1	9	2.3
TOTAL		393	100.0
Mean = 3.8			

A much larger percentage of respondents agreed that local people don't trust government programs (66.6%) than disagreed (8.1%). In addition, approximately one quarter neither agreed nor disagreed. There were no differences between the two surveys nor between samples in either survey. Level of trust in government appears to be a key issue facing ICM in the Herbert.

A very low percentage strongly agreed or disagreed with the statement that local people aren't that interested in community-type activities. Responses were split between agreement, disagreement and neither. The mean of 2.9, as in Survey 1, highlights that, on average, the sample neither agreed nor disagreed that local people are not that interested in community-type activities. There were no differences between samples in either survey.

10. local people aren't that interested in community-type activities (repeat)

Response	Rating	N (392)	Percent
strongly agree	5	23	5.9
agree	4	106	27.0
neither agree nor disagree	3	112	28.6
disagree	2	130	33.2
strongly disagree	1	21	5.4
TOTAL		392	100.0
Mean = 2.9			

11. the government doesn't want to spend money on solutions (repeat)

Response	Rating	N (392)	Percent
strongly agree	5	79	20.2
agree	4	160	40.8
neither agree nor disagree	3	114	29.1
disagree	2	35	8.9
strongly disagree	1	4	1.0
TOTAL		392	100.0
Mean = 3.7			

A large percentage of respondents (61%) agreed that the government doesn't want to spend money on solutions making land and water management difficult. Nearly thirty per cent neither agreed nor disagreed. The mean score was the same as in Survey 1 and there were no differences between samples in either Survey 1 or Survey 2.

12. government departments and other agencies are too slow to react to new issues or problems (new)

Response	Rating	N (392)	Percent
strongly agree	5	144	36.7
agree	4	180	45.9
neither agree nor disagree	3	52	13.3
disagree	2	12	3.1
strongly disagree	1	4	1.0
TOTAL		392	100.0
Mean = 4.1			

Most respondents (82.6%) agreed that government departments and other agencies are too slow to react to new issues or problems and again there were no differences between samples.

Discussion

The greatest impediments to managing land and water in the Herbert were the same in both surveys, despite different orders and significant differences between some of the means. The highest impediments and their means, were:

Impediment	Survey 2	Survey 1
the catchment's large area	4.1	4.1
a lack of easy solutions	3.9	3.9
the cost of solutions	4.0	3.9
low trust of government programs	3.8	3.9
the difficulty of moving around the catchment	n/a	3.8
the wide variety of opinions held by local people	n/a	3.8
insufficient understanding of relevant problems	3.8	3.8
slow government strategies (new)	4.3	n/a
slow reactions by government to new problems (new)	4.1	n/a

It can be seen that the two additional items in Survey 2, *government strategies are too slow* and *government departments and other agencies are too slow to react to new issues or problems,* scored highest overall.

In Survey 1, the three lowest potential impediments (all with mean scores below 3) were *there are few benefits and many costs, local people aren't that interested* and *there aren't any problems that need urgent action.* In Survey 2, the latter item was not repeated but the other items were the lowest scoring items once again, with mean scores of 3 or less. They therefore constitute very little impediment to managing land and water in the Herbert. In other words, by implication, respondents did see there to be benefits of managing land and water in the Herbert and perceived local people to be interested in managing land and water.

There were very few differences between mean scores in comparing the two surveys, comparing catchments or comparing rural and urban samples. The only significant differences between the means of the two surveys were for the following three items: *local people lack the money to spend on solutions; solutions are expensive;* and *there are few benefits and many costs* were all agreed to more by respondents in Survey 2 than in Survey 1.

The only difference in Survey 2 between the four samples was that rural respondents agreed more than urban respondents that the catchment's large area was an impediment to managing land and water in the Herbert.

This may suggest that the issue of how manageable or practical catchment management might be are relatively stable across time and the location of residents in the Herbert Catchment.

4.9 Knowledge of Government Strategies

Before we contacted you about this study, which of the government strategies had you heard about …

		Property Management Planning (PMP)		Landcare		Integrated Catchment Management (ICM)	
Response	Rating	N	Percent	N	Percent	N	Percent
Survey 2							
Yes	1	118	29.9	357	90.2	196	49.5
No	2	277	70.1	39	9.8	200	50.5
	TOTAL	395	100.0	396	100.0	396	100.0
Survey 1							
Yes	1	123	25.9	406	85.5	178	37.5
No	2	352	74.1	69	14.5	297	62.5
	TOTAL	475	100.0	475	100.0	475	100.0

As for Survey 1, Landcare was the most familiar strategy to respondents. A slightly higher percentage had heard of all three strategies in Survey 2 than had in Survey 1. In Survey 2, approximately 90% had heard of Landcare, approximately 50% had heard of Integrated Catchment Management and 30% had heard of Property Management Planning. In Survey 2, a significantly higher percentage of repeat respondents had heard of ICM (58%) than new respondents (43%).

A higher percentage of respondents in the lower catchment had heard of Property Management Planning than in the upper catchment (33% and 22%). As in Survey 1, those who had heard about each of the strategies were more likely to come from the lower rural sample and less likely to come from the lower urban sample than to be expected.

… and which one did you know most about?

	Survey 2		Survey 1	
Response	**N(363)**	**Percent**	**N(453)**	**Percent**
PMP	14	3.9	12	2.6
Landcare	279	76.9	333	73.5
ICM	35	9.6	47	10.4
Don't know of any	35	9.6	61	13.5
TOTAL	363	100.0	453	100.0

The majority of respondents (76.9%) in Survey 2 knew most about Landcare and a very similar percentage in Survey 1 knew most about Landcare (73.5%).

When thinking of the government strategy you know most about:

1. how useful has this strategy been to you personally?

Response	Rating	N (322)	Percent
very useful	5	14	4.3
quite	4	30	9.3
moderately	3	91	28.3
not very	2	104	32.3
not at all useful	1	83	25.8
TOTAL		322	100.0
Mean = 2.3			

As in Survey 1, only those who had heard of at least one of the strategies were asked to respond to this question.

Again, as in Survey 1, nearly 60% of the participants responded that the government strategy had either been not at all useful or not very useful (58.1%). Upper catchment respondents reported the strategy they knew most about to be significantly less useful to them than was reported by lower catchment respondents (means 2.1 and 2.4 respectively). There was no significant difference between repeat respondents, or the overall samples, in Survey 1 and Survey 2. Looking at the results for PMP, Landcare and ICM separately, the mean scores were 2.6 (only 14 responses), 2.3, and 2.6, generally moderate to not very useful, similar to Survey 1.

2. how effective has the strategy been in dealing with land and water issues in the Herbert?

Response	Rating	N (310)	Percent
very effective	5	4	1.3
fairly effective	4	98	31.6
neither effective nor ineffective	3	97	31.3
fairly ineffective	2	81	26.1
very ineffective	1	30	9.7
TOTAL		310	100.0
Mean = 2.9			

Looking at the results for PMP, Landcare and ICM separately, the mean responses were 2.5 (only 13 responses), 2.9, and 2.9, similar to Survey 1 means, which were 3.3 (only 12 responses), 2.8, and 2.8.

3. how did you come to know of the strategy?

This was an open-ended question which allowed up to two responses. The table below shows the percentage of respondents for each different source of knowledge as a proportion of the number of respondents who gave at least one response (299). The most prominent responses are shown, with a total of 386 (or 92%) of the responses included.

Sources of knowledge	Survey 2 N = 299		Survey 1 N = 334	
	N	%	N	%
Newspapers	85	28.4	79	23.7
Television/television advertisements	58	19.4	72	21.6
Media (in general)	50	16.7	44	13.2
Word of mouth	34	11.4	40	12.0
Personal experience	29	9.7	8	2.4
Meetings (in general)	25	8.4	31	9.3
Canegrowers magazine	17	5.7	12	3.6
Radio/radio talk shows	13	4.3	22	6.6
Canegrowers meetings	11	3.7	22	6.6
Advertisements (in general)	10	3.3	12	3.6
Landcare	10	3.3	6	1.8
Reading	9	3.0	17	5.1
Local pamphlets	8	2.7	9	2.7
Publications **	8	2.7	-	-
Visual **	8	2.7	-	-
ICM delegate **	6	2.0	-	-
Department of Primary Industry **	5	1.7	-	-

** New category in Survey 2

A notable difference is that a higher percentage of respondents in Survey 2 had heard of the strategy they knew most about through personal experience than in Survey 1 (9.7% versus 2.4%).

While in Survey 1, 67% of the responses could be classified as media sources (ie. a combination of the newspaper, television, media and radio responses) only 49% percent of the responses were to do with the media in Survey 2.

Of those who knew most about PMP, the most common response was word of mouth (3 responses) as opposed to personal experience in Survey 1. For both surveys, the most frequent way for people to hear about ICM was through meetings, in Survey 2, 8 people stated their source to be meetings in general, while 5 were more specific in stating canegrowers meetings. Other ways for people to hear about ICM in Survey 2 were the newspapers (6), through their ICM delegate (6), and through the media in general (4).

Landcare accounted for 83% of the responses. The most common responses for Landcare were newspapers (71 of 79 in total), television/television advertisements (54 of 54 in total) media in general (45 of 49 in total), word of mouth (25 of 31), Canegrowers magazine (14 of 17), and personal experience (14 of 18).

Are you aware of any other Government Funded programs on wider environmental matters in the Herbert catchment?

This question was added in Survey 2 to gain some understanding of community awareness of other Government Funded programs on wider environmental matters in the Herbert catchment.

Response	N (369)	Percent
Yes	72	19.5
No	297	80.5
TOTAL	369	100.0

The majority of respondents (80.5%) to this question were not aware of any other Government Funded programs on wider environmental matters in the Herbert catchment.

Please write down any comments you have on them.
Sixty of those who were aware of other Government Funded programs on wider environmental matters gave 88 comments on those programs, 76 (86%) of which are listed below.

Comment	N (60)	Percent
Lack knowledge of the local situation	12	20.0
Poorly organised	10	16.7
Reforestation	9	15.0
Works well	7	11.7
Not consulting local people	6	10.0
Good idea	5	8.3
No benefit to the environment/no impact on environment	5	8.3
Not using best/most recent information	4	6.7
Need more funds	3	5.0
Token measures to suggest something is done	3	5.0
Government departments avoid difficult decisions	3	5.0
Blame others when problems arise	3	5.0
Fish kills in creeks	3	5.0
Lack of publicity	3	5.0

The most frequent comment on the program was that those conducting it did not have enough information on the local situation. Related to this were comments that the program was not using the best or most recent information or was not consulting local people. One sixth of the respondents felt that the program they knew most about was poorly organised. Positive comments included that the program works well (11.7%) or that it was a good idea (8.3%).

Discussion
Landcare was the most familiar government strategy to respondents: the majority of respondents stated that they had heard about Landcare. Half of the respondents had heard of ICM and nearly one third had heard of PMP. These were very similar results to Survey 1.

A greater proportion of respondents in the lower catchment had heard of PMP than in the upper catchment. Similar to Survey 1, those who had heard about the strategies were more likely to come from the lower rural sample.

In both surveys, the majority of respondents knew most about Landcare compared to the other two strategies.

As in Survey 1, nearly 60% of respondents felt that the government strategy they knew most about had either been not at all useful or not very useful to them personally. There was consistency across the surveys and the four samples. Mean ratings were *moderate* to *not very useful.*

Respondents felt that the strategy they knew most about was neither effective nor ineffective in dealing with land and water issues on average, which indicates either that respondents were unaware of the effectiveness of the strategy or were undecided.

When respondents were asked how they came to know of the strategy, newspapers were the most frequent source, followed by television/television advertisements and the media in general. The order of responses was very similar in both surveys considering the time span between surveys, slightly different samples, and open-ended nature of the question. However, a higher percentage of respondents reported hearing of the strategy through personal experience in Survey 2.

In both surveys, the most frequent way for respondents to hear about ICM was through meetings, in general or canegrowers meetings specifically.

Respondents were asked if they were aware of any other government funded programs on wider environmental matters in the Herbert catchment. One fifth of respondents to this question were aware of other programs. Rather than ask to specify the programs, the study concentrated on respondents' opinions of these programs. The main comment was that it *lacked knowledge of the local situation.* Related to this were the comments *not consulting local people* and *not using best or most recent information.* While most of the prominent comments were negative, amongst them were the comments *it works well* and *good idea.*.

4.10 Activities of Integrated Catchment Management

This question was added to Survey 2 to gain input from the community on the most important activities for ICM. Respondents were asked to rate how important each activity was and then to rank from one to three the most important of the list of 11 activities.

How important is it to you that the following activities are part of Integrated Catchment Management?

1. Encourage community action at a catchment level.

Response	Rating	N (367)	Percent
very high importance	5	103	28.1
high	4	161	43.9
moderate	3	84	22.9
low	2	15	4.1
very low importance	1	4	1.1
TOTAL		367	100.0
Mean = 3.9			

The majority of respondents gave this activity a rating of high or very high importance (72%) and the mean score was high.

2. Raise the level of local awareness and knowledge of environmental management issues.

Response	Rating	N (368)	Percent
very high importance	5	125	34.0
high	4	166	45.1
moderate	3	62	16.8
low	2	10	2.7
very low importance	1	5	1.4
TOTAL		368	100.0
Mean = 4.1			

The majority of respondents gave *raising the level of local awareness and knowledge of environmental issues* a rating of very high or high importance (79.1%) and the mean score was high.

3. Encourage Local Government to take an active role in environmental management issues.

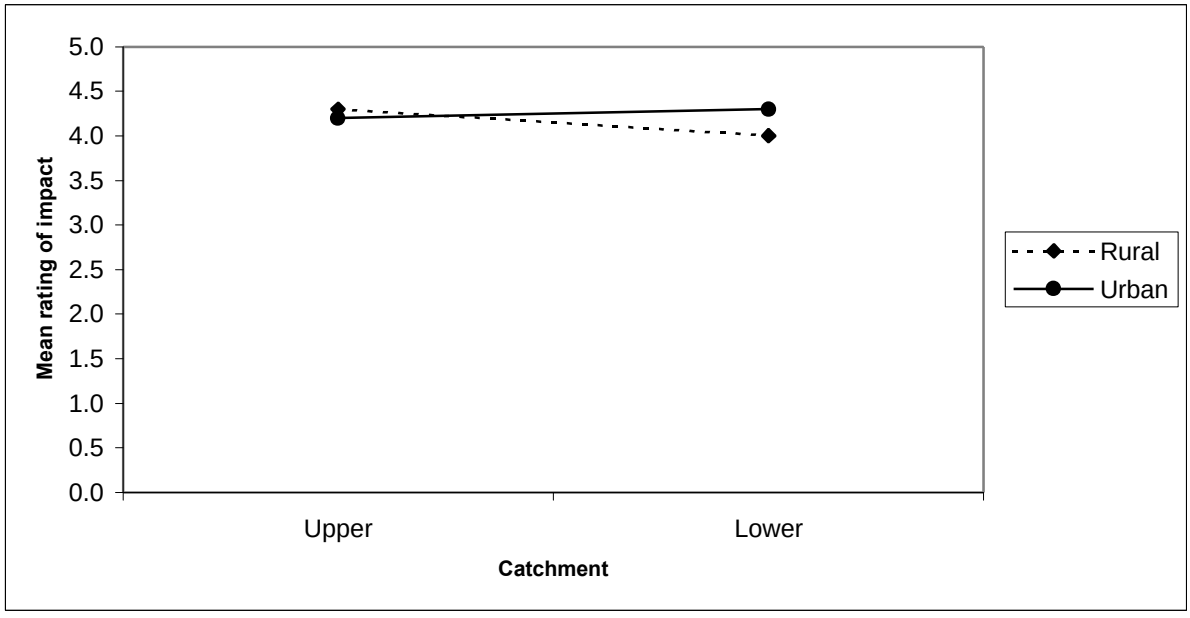
Response	Rating	N (368)	Percent
very high importance	5	161	43.8
high	4	143	38.9
moderate	3	49	13.3
low	2	6	1.6
very low importance	1	9	2.4
TOTAL		368	100.0
Mean = 4.2			

The overwhelming majority gave this activity a rating of very high or high importance (82.7%) and the mean was a little above high.

4. Encourage coordination of state government programs.

Response	Rating	N (371)	Percent
very high importance	5	148	39.9
high	4	155	41.8
moderate	3	52	14.0
low	2	14	3.8
very low importance	1	2	0.5
TOTAL		371	100.0
Mean = 4.2			

The majority (81.7%) rated this as high or very high. There was a significant two way interaction between upper and lower catchment versus urban and rural location, (below).



Within the rural sample, upper catchment respondents rated this activity significantly higher than lower catchment respondents (means 4.3 and 4.0) and within the lower catchment sample, urban respondents rated this activity significantly higher than rural respondents (means 4.3 and 4.0).

5. Undertake specific on ground projects with other bodies.

Response	Rating	N (362)	Percent
very high importance	5	87	24.0
high	4	173	47.8
moderate	3	83	22.9
low	2	14	3.9
very low importance	1	5	1.4
TOTAL		362	100.0
Mean = 3.9			

A large percentage of respondents to this question rated *undertaking specific on ground projects with other bodies* as very high or highly important (71.8%) and the mean was high.

6. Provide a continuing source of advice to local government on catchment issues.

Response	Rating	N (367)	Percent
very high importance	5	128	34.9
high	4	172	46.9
moderate	3	52	14.2
low	2	9	2.5
very low importance	1	6	1.6
TOTAL		367	100.0
Mean = 4.1			

Once again, the majority of respondents rated this activity as very high or highly important (81.8%) and the mean was high.

7. Encourage research.

Response	Rating	N (367)	Percent
very high importance	5	163	44.4
high	4	145	39.5
moderate	3	49	13.4
low	2	6	1.6
very low importance	1	4	1.1
TOTAL		367	100.0
Mean = 4.2			

The majority of respondents rated *encouraging research* as a highly important or very highly important activity (83.9%) and the mean response was high.

8. Develop solutions for and better understanding of environmental problems in the Herbert catchment.

Response	Rating	N (369)	Percent
very high importance	5	172	46.6
high	4	151	40.9
moderate	3	37	10.0
low	2	7	1.9
very low importance	1	2	0.5
TOTAL		369	100.0
Mean = 4.3			

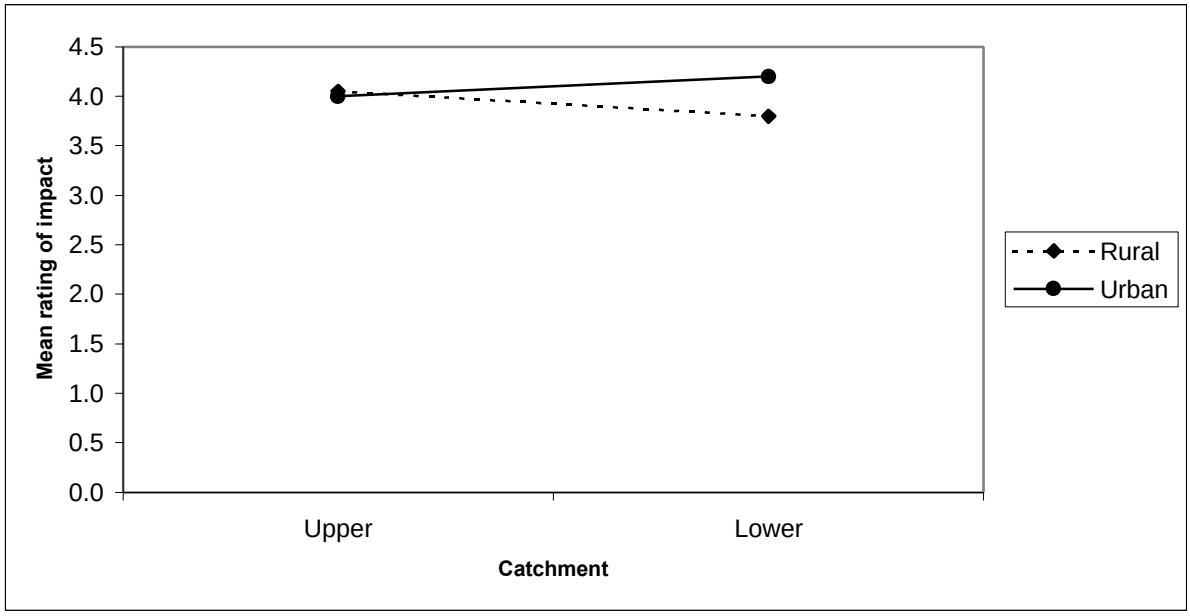
Most respondents rated this activity as very high or highly important (87.5%) and the mean was between high and very high.

9. Encourage discussion between community interest groups on environmental issues.

Response	Rating	N (366)	Percent
very high importance	5	109	29.8
high	4	165	45.1
moderate	3	73	19.9
low	2	14	3.8
very low importance	1	5	1.4
TOTAL		366	100.0
Mean = 4.0			

The majority of respondents rated *encouraging discussion between community interest groups on environmental issues* as very high or highly important (74.9%) and the mean response was high.

There was a significant two way interaction between the upper and lower catchment versus urban and rural location, as shown below. For the lower catchment sample, urban respondents rated this activity as more important than rural respondents (means 4.2 and 3.8).

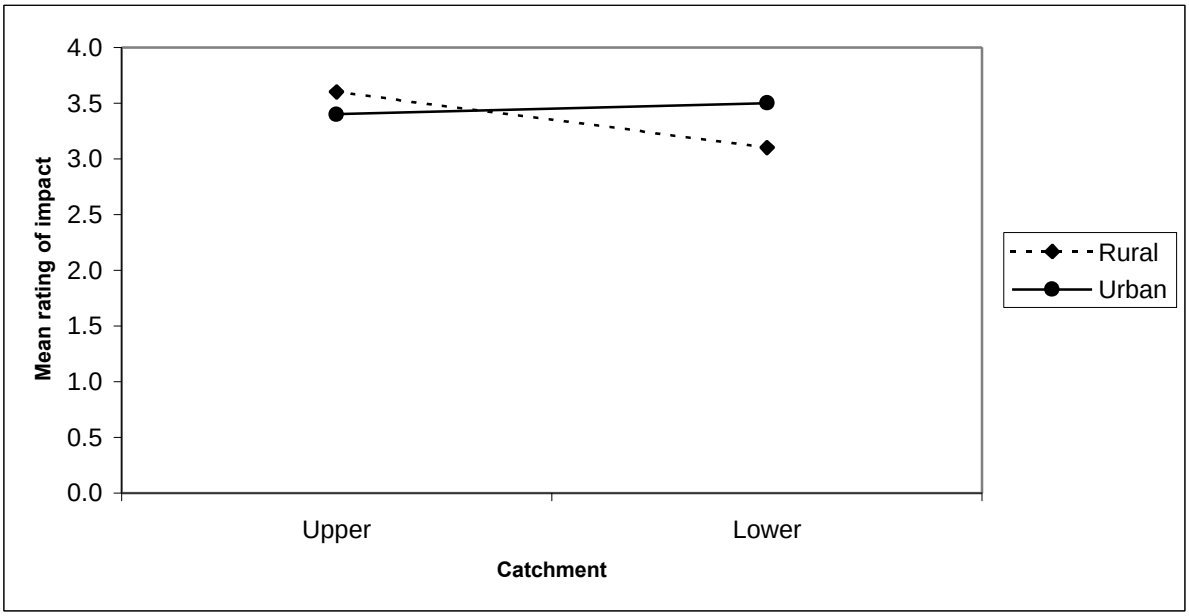


10. Separate ICM programs for the Upper and Lower Herbert catchments.

Response	Rating	N (351)	Percent
very high importance	5	68	19.4
high	4	100	28.5
moderate	3	91	25.9
low	2	58	16.5
very low importance	1	34	9.7
TOTAL		351	100.0
Mean = 3.3			

Nearly half of the sample rated this as important or highly important (47.9%). Approximately one quarter of the sample rated it as moderately important and another quarter as low or very low importance. The mean score of 3.3 was the lowest of the eleven possible activities for ICM.

There was a significant two way interaction as shown below. Within the lower catchment, urban respondents rated this activity as more important than rural respondents (means 3.5 and 3.0). Within the rural sample, upper catchment respondents rated this activity higher than lower catchment respondents (means 3.6 and 3.0).



11. Encourage joint projects between community, industry and state and local government.

Response	Rating	N (368)	Percent
very high importance	5	160	43.5
high	4	142	38.6
moderate	3	50	13.6
low	2	12	3.3
very low importance	1	4	1.1
TOTAL		368	100.0
Mean = 4.2			

A large percentage of respondents rated this activity as very high or highly important (82.1%) and the mean response was high.

And please rank the three most important activities to you: 1 is most important.
1. Encourage community action at a catchment level.

Ranking	N (244)	Percent
First	24	9.8
Second	23	9.4
Third	20	8.2
No rank	177	72.5
TOTAL	244	100.0

2. Raise the level of local awareness and knowledge of environmental management issues.

Ranking	N (244)	Percent
First	36	14.7
Second	31	12.7
Third	38	15.6
No rank	139	57.0
TOTAL	244	100.0

3. Encourage Local Government to take an active role in environmental management issues.

Ranking	N (241)	Percent
First	33	13.7
Second	31	12.9
Third	21	8.7
No rank	156	64.7
TOTAL	241	100.0

4. Encourage coordination of state government programs.

Ranking	N (244)	Percent
First	18	7.4
Second	24	9.8
Third	16	6.6
No rank	186	76.2
TOTAL	244	100.0

5. Undertake specific on ground projects with other bodies.

Ranking	N (241)	Percent
First	4	1.6
Second	12	5.0
Third	6	2.5
No rank	219	90.9
TOTAL	241	100.0

6. Provide a continuing source of advice to local government on catchment issues.

Ranking	N (243)	Percent
First	7	2.9
Second	8	3.3
Third	13	5.3
No rank	215	88.5
TOTAL	243	100.0

7. Encourage research.

Ranking	N (243)	Percent
First	32	13.2
Second	34	14.0
Third	25	10.3
No rank	152	62.5
TOTAL	243	100.0

8. Develop solutions for and better understanding of environmental problems in the Herbert catchment.

Ranking	N (243)	Percent
First	40	16.5
Second	43	17.7
Third	21	8.6
No rank	139	57.2
TOTAL	243	100.0

9. Encourage discussion between community interest groups on environmental issues.

Ranking	N (242)	Percent
First	5	2.1
Second	12	4.9
Third	17	7.0
No rank	208	86.0
TOTAL	242	100.0

10. Separate ICM programs for the Upper and Lower Herbert catchments.

Ranking	N (242)	Percent
First	12	4.9
Second	7	2.9
Third	6	2.5
No rank	217	89.7
TOTAL	242	100.0

11. Encourage joint projects between community, industry and state and local government.

Ranking	N (242)	Percent
First	33	13.6
Second	26	10.7
Third	49	20.3
No rank	134	55.4
TOTAL	242	100.0

The eleven activities were examined in terms of the percentage of respondents who gave each a ranking of first and the percentage of respondents who gave each a ranking in the top three. As there were slight differences in the overall ranking, both are shown in the table below.

In either list, however, the five most important activities for ICM were:

- encourage joint projects between community, industry and state and local government;
- raise the level of local awareness and knowledge of environmental management issues;
- develop solutions for and better understanding of environmental problems in the Herbert catchment;
- encourage research; and
- encourage Local Government to take an active role in environmental management issues.

Activity	**Ranking of percentages (1st)**	**Ranking of percentages (1st, 2nd or 3rd)**
Encourage joint projects between community, industry and state and local government.	1	4
Raise the level of local awareness and knowledge of environmental management issues.	2	2
Develop solutions for and better understanding of environmental problems in the Herbert catchment.	3	1
Encourage research.	4	5
Encourage Local Government to take an active role in environmental management issues.	5	3
Encourage community action at a catchment level.	6	6
Encourage coordination of state government programs.	7	7
Encourage discussion between community interest groups on environmental issues.	8	10
Provide a continuing source of advice to local government on catchment issues.	9	9
Separate ICM programs for the Upper and Lower Herbert catchments.	10	8
Undertake specific on ground projects with other bodies.	11	11

Discussion

Overall, most of the eleven activities were rated as very high or highly important. The only activity rated as moderately important was *separate ICM programs for the Upper and Lower catchments,* which, in addition, was not ranked in the top three activities by 90% of respondents to the question.

While most activities were important for ICM to undertake, by examining the importance of the activities to respondents in comparison to each other, it can be seen that the most important activities were related to developing solutions, raising awareness, and encouraging Local Government involvement, research and joint projects between different parties. The least

important activities, compared to others, were separate ICM programs for the upper and lower catchments, providing advice to local government, encouraging discussion, and undertaking specific on ground projects.

4.11 The Herbert River Catchment Coordinating Committee

Have you heard of a group called the Herbert River Catchment Coordinating Committee?

	Survey 2		Survey 1	
Response	**N (376)**	**Percent**	**N (425)**	**Percent**
Yes	90	23.9	93	21.9
Vaguely	77	20.5	86	20.2
No	209	55.6	246	57.9
TOTAL	376	100.0	425	100.0

In Survey 2, a little over half of the respondents had not heard of the Herbert River Catchment Coordinating Committee while a little less than half had heard of the group, either definitely (23.9%) or vaguely (20.5%). These were very similar results to Survey 1.

Of those who had definitely heard of the HRCCC, 58% were from the lower rural sample which was more than the proportion of lower rural respondents in the overall sample. Only 9% were from the upper urban sample, less than to be expected and 12% were from the upper rural sample, similar to the number expected. From the lower urban sample, less than would be expected (21%) had heard of the HRCCC.

From highest to lowest, those who responded "Yes" or "Vaguely" comprised 61%, 54%, 35%, and 23% of the lower rural, upper rural, lower urban and upper urban samples respectively, the same order as in Survey 1. As ICM often has more of a presence in the lower catchment and a greater focus in rural rather than urban areas, this result was to be expected.

In Survey 1, it was found that a very similar percentage had heard of ICM and the HRCCC. In Survey 2, the result was the same: while 49.5% of respondents to the appropriate question had heard of ICM, 44.4% had at least vaguely heard of the HRCCC. In Survey 1, more than three quarters of those who had heard of ICM had heard of the HRCCC at least vaguely and in Survey 2, this was slightly lower, 68%. In addition, in both surveys, 21% of those who had not heard about ICM had at least vaguely heard of the HRCCC.

If yes or vaguely, what do you think the main purpose of the group is?
Of the 167 participants who responded that they had heard of the HRCCC, vaguely or otherwise, 156 gave 200 responses to this question (two responses were permitted). The frequency of responses is shown below, compared to the most prominent responses from Survey 1. This represents 172 (or 86%) of the total number of responses.

Purpose of HRCCC	Survey 2 N = 156		Survey 1 N = 161	
	N	%	N	%
Care for the catchment area	28	17.9	14	8.7
Conserve and manage water	19	12.2	21	13.0
Not sure/it has never been fully publicised locally	18	11.5	7	4.3
Preserve waterways (including land quality and river banks)	15	9.6	23	14.3
Raise awareness/inform the public of existing problems	14	9.0	8	5.0
Improve drainage systems (including in newly developed areas)	12	7.7	34	21.1
Coordinate groups to discuss problems (such as drainage)	10	6.4	8	5.0
Ensure water availability, cost and quality *	7	4.5	-	-
Control/mitigate flooding in the lower catchment (including a suggestion to dredge the Herbert River)	6	3.8	10	6.2
Form strategies to assist the community (eg to help with drainage disputes)	6	3.8	6	3.7
Set guidelines for development to care for use of land and water*	6	3.8	-	-
Research into problems of the catchment area **	6	3.8	-	-
Coordinate river use	5	3.2	12	7.4
Best management practice catchment management program in partnership with the community *	5	3.2	-	-
Programs to prevent environmental problems **	4	2.6	-	-
Manage water supply in the best way, for all users	4	2.6	3	1.9
Discuss degradation *	4	2.6	-	-
Maintain flow in the Herbert River and creeks/keep it clean	1	0.6	7	4.3
Combine all drainage board into one body (eg to cut costs and improve effectiveness)	1	0.6	6	3.7
Monitor fertiliser runoff	1	0.6	3	1.9
Dam the river	0	0	3	1.9
Calculate regular flood areas	0	0	7	4.3

* Not a prominent response in Survey 1 ** New category in Survey 2

Noticeably more prominent in Survey 2 were the perceived purpose to *care for the catchment area* and the response *not sure/it has never been fully publicised locally.*

Additional responses in Survey 2 were *research into problems of the catchment area* and *programs to prevent environmental problems.* Some responses were mentioned by very few people in Survey 1 and were more prominent in Survey 2: *ensure water availability, cost and quality; set guidelines for development to care for use of land and water; best management practice catchment management program in partnership with community;* and *discuss degradation.* Less prominent responses in Survey 2 than in Survey 1 were *preserve waterways* and *improve drainage systems*.

Has the group been effective in achieving its goals and purpose?
This question, new to Survey 2, was asked of those 167 respondents who had heard of the HRCCC.

Response	N (148)	Percent
Yes	6	4.1
To some extent	110	74.3
No	32	21.6
TOTAL	148	100.0

The majority (74%) of the 148 respondents to this question indicated that they believed that the HRCCC was effective in achieving its goals and purposes to some extent.

Are there any specific things that you know they have done? Please describe.
This question was also new to Survey 2 and was asked to gain some understanding of the level of community awareness of HRCCC activities. Three responses were permitted to this question. Of those 167 respondents who had heard of the HRCCC, 89 answered this question (53.3%) and provided 122 responses, of which 89 (or 73%) are listed in the table.

Specific activities	N (89)	Percent
Unaware/don't know	20	22.5
Tree planting on riverbanks (eg to prevent destruction of river banks)	15	16.9
Survey water availability and quality	8	9.0
Work on the banks of the Herbert River	7	7.9
Erecting owl boxes and perches	7	7.9
Weed control	7	7.9
Formation of water drainage	6	6.7
Remove flood gates	4	4.5
Acid sulphate soils workshop	3	3.4
Work on the banks of the Annabranch River	3	3.4
Identify sites suitable for dams	3	3.4
Research into catchment area	3	3.4
Rock walling at Long Pocket	3	3.4

A large percentage responded that they were *unaware or didn't know* of any specific activities of the HRCCC. Considering the large percentage of those who had heard of the HRCCC and did not respond to this question, the percentage of respondents who were unaware of the specific activities of the HRCCC may be much larger. A large proportion mentioned *tree planting on riverbanks* and related to this were the responses: *work on the banks of the Herbert River* or *work on the banks of the Annabranch River*.

In your opinion, are they progressing quickly enough?
The 167 respondents who had heard of the HRCCC were asked whether the HRCCC was progressing quickly enough, a new question in Survey 2. Of those respondents, 147 answered this question (88%). The majority of responses were split between *no* (49%) and *to some extent* (46.3%) as shown in the table below.

Response	N (147)	Percent
Yes	7	4.8
To some extent	68	46.3
No	72	49.0
TOTAL	147	100.0

In your opinion, are they heading in the right direction?
Those who had heard of the HRCCC were also asked whether they were heading in the right direction, again a new question in Survey 2. A much larger percentage of respondents to this question believed that the HRCCC were heading in the right direction at least to some extent (approximately 90%).

Response	N (144)	Percent
Yes	42	29.2
To some extent	88	61.1
No	14	9.7
TOTAL	144	100.0

Discussion

Slightly less than half of the respondents had heard of the HRCCC, either definitely or vaguely, a very similar percentage to Survey 1. A higher proportion of people in the lower rural sample had heard of the HRCCC than from the other samples. As was to be expected, the order of the samples was the same as in Survey 1: lower rural, upper rural, lower urban and upper urban samples.

Those who had heard of the HRCCC were asked what they perceived to be the main purpose of the group. The most prominent responses were slightly different to Survey 1: *care for the catchment area*; *conserve and manage water*; and *not sure/it has never been fully publicised.* The first and third statement were more prominent in Survey 2. Less prominent in Survey 2 were: *preserve waterways* and *improve drainage systems.*

Survey 2 also asked those respondents who had heard of the HRCCC about the effectiveness, speed of progress, specific activities and direction of the HRCCC. The majority believed that the group had been effective in achieving its goals and purposes to some extent. Half felt that it was not progressing quickly enough and a little less than half felt that it was to some extent.

The most prominent response to the question about the HRCCC's perceived activities was *unaware/don't know.* The low response rate to the question may mean that the actual proportion may be much higher. There was, however, awareness of many different activities.

4.12 Responsibility and Control, Views on Government, Awareness and Intentions

Participants were asked to rate how much they agreed or disagreed with the following statements about responsibility and control, views on government, and awareness and intentions. 'Responsibility and control' includes the perceived ability of residents to control land and water management issues and the assigned responsibility for dealing with such issues. 'Views on government' includes levels of trust and perceived competence and 'awareness and intentions' includes levels of awareness and preparedness to become involved in relevant activities. These were all considered to be potential influences on the implementation of ICM. Those who considered any issues not applicable were presented but not included within mean scores and subsequent analyses.

4.12.1 Responsibility and Control

There are things I can do personally to help improve the environment. (Repeat)

Response	Rating	N (388)	Percent
strongly agree	5	72	18.6
agree	4	225	58.0
neither agree nor disagree	3	54	13.9
disagree	2	14	3.6
strongly disagree	1	7	1.8
not applicable		16	4.1
TOTAL		388	100.0
Mean = 3.9			

The majority (76.6%) of respondents agreed or strongly agreed with this statement. There was no difference between the surveys for those respondents involved in both surveys. For the overall samples, agreement was higher in Survey 2 than in Survey 1 (means 3.9 and 3.8). Comparing the urban and rural samples and upper and lower catchment samples, upper catchment respondents were more likely to agree than lower catchment respondents (means 4.1 and 3.9) whereas in Survey 1 there were no differences between samples.

It's too hard to think about land and water management issues for an area as big as the Herbert catchment. (Repeat)

Response	Rating	N (387)	Percent
strongly agree	5	5	1.3
agree	4	33	8.5
neither agree nor disagree	3	63	16.3
disagree	2	192	49.6
strongly disagree	1	84	21.7
not applicable		10	2.6
TOTAL		387	100.0
Mean = 2.2			

There was general disagreement with this statement: 71.3% disagreed or strongly disagreed and the mean score was very close to disagreement. There were no significant differences between the mean scores in both surveys, either for the overall samples or for those who participated in both surveys.

Rural respondents more likely to disagree that *it's too hard to think about land and water management issues for an area as big as the Herbert catchment* than rural respondents (means 2.1 and 2.2).

There were no differences between the upper and lower catchment whereas in Survey 1 there was one difference among the four samples. Compared with the lower rural sample, the upper rural sample was more likely to disagree with the statement. While the difference was only in terms of degree, it was nonetheless interesting given that the upper area of the Herbert occupies the largest part of the catchment.

As in Survey 1, most participants in Survey 2 also agreed that managing land and water in the Herbert is difficult because the Herbert catchment covers a large area (see Section 4.6). Once again it is of interest that despite this widespread opinion, there was general disagreement in both surveys that it is too hard to think about land and water management issues for an area as big as the Herbert catchment. Thus while land and water management in the Herbert may be difficult, it is definitely not viewed as impossible despite the size of the catchment.

I don't usually have the finances available to plan more than a year ahead. (Repeat)

Response	Rating	N (386)	Percent
strongly agree	5	91	23.6
agree	4	167	43.3
neither agree nor disagree	3	56	14.5
disagree	2	32	8.3
strongly disagree	1	9	2.3
not applicable		31	8.0
TOTAL		386	100.0
Mean = 3.8			

The majority of respondents (66.9%) agreed or strongly agreed with the statement *I don't usually have the finances available to plan more than a year ahead.* Repeat respondents more strongly agreed with this statement in Survey 2 than in Survey 1 (means 3.8 and 3.5) and overall, respondents more strongly agreed in Survey 2 than in Survey 1 (means 3.8 and 3.7).

There were no significant differences between the urban and rural samples or between the upper and lower catchment samples. This was different to Survey 1 in which those in the lower rural sample were less likely to agree compared with the two urban samples.

There are things local community groups can do to help improve the environment. (Repeat)

Response	Rating	N (388)	Percent
strongly agree	5	74	19.0
agree	4	273	70.2
neither agree nor disagree	3	29	7.5
disagree	2	6	1.5
strongly disagree	1	4	1.0
not applicable		3	0.8
TOTAL		388	100.0
Mean = 4.0			

The vast majority of respondents (89.2%) either agreed or strongly agreed that *there are things local community groups can do to help improve the environment,* a very similar result to Survey 1. Very few respondents disagreed or felt that it was not applicable.

There was consistency between the four samples as in Survey 1.

Catchment management should be paid for and run by the government. (New)

Response	Rating	N (388)	Percent
strongly agree	5	70	18.0
agree	4	138	35.6
neither agree nor disagree	3	123	31.7
disagree	2	46	11.9
strongly disagree	1	8	2.1
not applicable		3	0.8
TOTAL		388	100.0
Mean = 3.6			

A little over half (53.6%) of the respondents to this question agreed or strongly agreed that *catchment management should be paid for and run by the government*, a relatively large percentage neither agreed nor disagreed and very few respondents felt that this was not applicable.

There was consistency between the four samples.

ICM should remain a voluntary activity by community members. (New)

Response	Rating	N (388)	Percent
strongly agree	5	19	5.0
agree	4	90	23.7
neither agree nor disagree	3	128	33.8
disagree	2	104	27.4
strongly disagree	1	21	5.5
not applicable		17	4.5
TOTAL			100.0
Mean = 2.9			

Respondents were relatively indecisive about this issue, with 33.8% stating that they neither agreed nor disagreed and opinions were fairly evenly split between agreement (28.7%) and disagreement (32.9%).

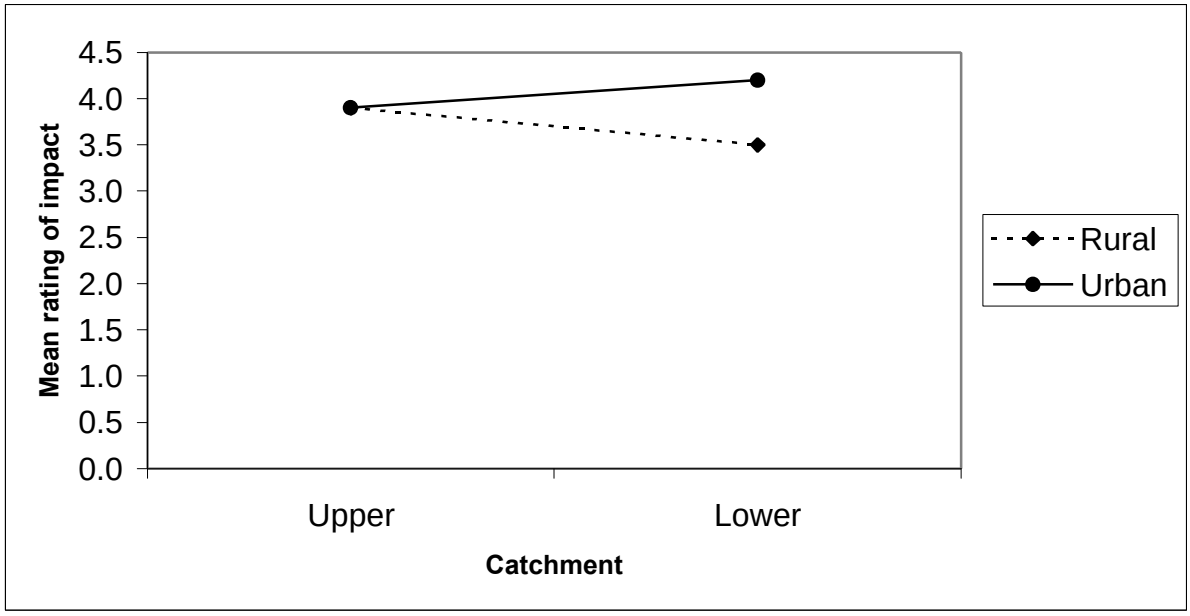
Rural respondents were more likely to agree with this statement than urban respondents (means 3.1 and 2.8).

Many environmental problems come from the way people manage their properties. (Repeat)

Response	Rating	N (388)	Percent
strongly agree	5	94	24.2
agree	4	193	49.7
neither agree nor disagree	3	65	16.8
disagree	2	24	6.2
strongly disagree	1	10	2.6
not applicable		2	0.5
TOTAL			100.0
Mean = 3.9			

A large percentage (73.9%) agreed or strongly agreed that *many environmental problems come from the way people manage their properties,* a very similar result to Survey 1. A low percentage disagreed or stated that it was not applicable.

There was consistency between the two surveys, both for repeat respondents and for the overall samples. In comparing the four samples, urban respondents more strongly agreed than rural respondents (means 4.1 and 3.6) and there was a significant two way interaction, as shown below.



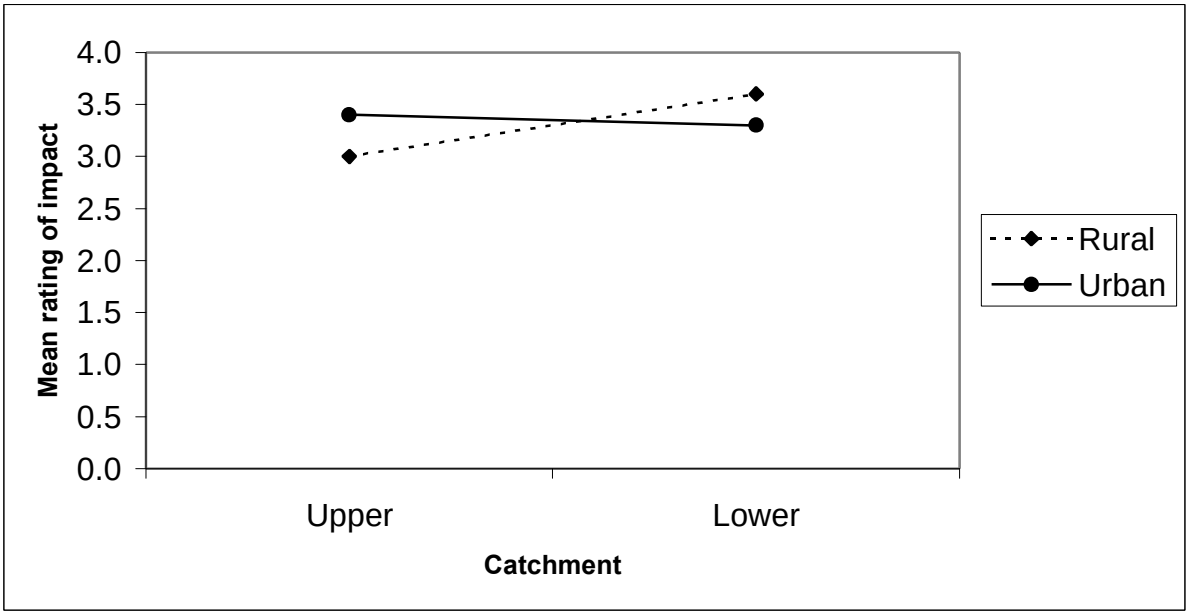
Within the lower catchment sample, urban respondents more strongly agreed with the statement than rural respondents. Within the rural sample, upper catchment respondents more strongly agreed than lower catchment respondents and within the urban sample, lower catchment respondents more strongly agreed than upper catchment respondents. These are very similar results to Survey 1 in which lower rural respondents were less likely to agree with the statement than upper rural and lower urban respondents.

The government expects too much from local communities in catchment management. (New)

Response	Rating	N (388)	Percent
strongly agree	5	39	10.1
agree	4	134	34.8
neither agree nor disagree	3	151	39.2
disagree	2	50	13.0
strongly disagree	1	6	1.6
not applicable		5	1.3
TOTAL			100.0
Mean = 3.4			

A larger percentage of respondents agreed or strongly agreed that *the government expects too much from local communities in catchment management* (44.9%) than disagreed or strongly disagreed (14.6%). A large percentage (39.2%), however, neither agreed nor disagreed with the statement. Very few felt that it was not applicable.

There was a significant difference between catchment samples: lower catchment respondents more strongly agreed than upper catchment respondents (means 3.5 and 3.2), and there was a significant two way interaction between upper and lower catchment versus urban and rural locations, as shown below.



Within the lower catchment sample, rural respondents more strongly agreed than urban respondents and within the rural sample, lower catchment respondents more strongly agreed than upper catchment respondents.

Laws should be changed to make landholders more responsible for the consequences of their activities. (Repeat)

Response	Rating	N (388)	Percent
strongly agree	5	86	22.1
agree	4	140	36.0
neither agree nor disagree	3	92	23.7
disagree	2	46	11.8
strongly disagree	1	23	5.9
not applicable		2	0.5
TOTAL			100.0
Mean = 3.6			

Many respondents (58.1%) agreed or strongly agreed that *laws should be changed to make landholders more responsible for the consequences of their activities*. A relatively large percentage (23.7%) neither agreed nor disagreed with this statement.

There was no significant difference between the ratings provided by respondents involved in both surveys or for the overall samples.

There was, however, a significant difference between urban and rural respondents: urban respondents were more likely to agree with the statement than rural respondents (means 4.0 and 3.2). In Survey 1, however, there were further differences. Lower urban respondents were more likely to agree than both rural samples and upper urban respondents were more likely to agree than lower rural respondents.

4.12.2 Views on Government

Programs like Integrated Catchment Management interfere with people's rights to make their own decisions. (Repeat)

Response	Rating	N (384)	Percent
strongly agree	5	19	4.9
agree	4	59	15.4
neither agree nor disagree	3	144	37.5
disagree	2	107	27.9
strongly disagree	1	39	10.2
not applicable		16	4.2
TOTAL		384	100.0
Mean = 2.8			

Nearly 40% neither agreed nor disagreed with this statement and the mean reflected this result. There was a great deal of consistency between the two surveys, for both repeat respondents and the overall samples, and consistency between the upper and lower catchment and urban and rural respondents. This was similar to Survey 1 in which there were no significant differences, despite a trend for those in the lower rural sample to be more likely to agree.

The government needs to give more resources to voluntary groups. (New)

Response	Rating	N (388)	Percent
strongly agree	5	83	21.4
agree	4	189	48.7
neither agree nor disagree	3	77	19.8
disagree	2	23	5.9
strongly disagree	1	11	2.8
not applicable		5	1.3
TOTAL		388	100.0
Mean = 3.8			

The majority of respondents (70.1%) agreed or strongly agreed that *the government needs to give more resources to voluntary groups* and very few disagreed or felt that it was not applicable.

No significant differences were found between the upper and lower catchment samples or between the urban and rural samples.

Different government agencies often give conflicting information on land and water management issues. (New)

Response	Rating	N (388)	Percent
strongly agree	5	75	19.4
agree	4	206	53.2
neither agree nor disagree	3	89	23.0
disagree	2	5	1.3
strongly disagree	1	1	0.3
not applicable		11	2.8
TOTAL			100.0
Mean = 3.9			

The majority (72.6%) of respondents agreed or strongly agreed that *different government agencies often give conflicting information on land and water management issues.* Nearly all of the remaining respondents neither agreed nor disagreed (23%).

There was consistency between the upper and lower catchment and urban and rural respondents.

There should be better government incentives for landholders to address environmental issues/problems. (New)

Response	Rating	N (388)	Percent
strongly agree	5	133	34.5
agree	4	197	51.0
neither agree nor disagree	3	34	8.8
disagree	2	14	3.6
strongly disagree	1	4	1.0
not applicable		4	1.0
TOTAL			100.0
Mean = 4.1			

The majority of respondents (85.5%) agreed or strongly agreed that *there should be better government incentives for landholders to address environmental issues/problems.*

A significant difference was found between the urban and rural samples, rural respondents more strongly with this statement than urban respondents (means 4.3 and 4.1).

ICM programs should have legislative backing. (New)

Response	Rating	N (388)	Percent
strongly agree	5	39	10.4
agree	4	152	40.4
neither agree nor disagree	3	142	37.8
disagree	2	24	6.4
strongly disagree	1	9	2.4
not applicable		10	2.7
TOTAL			100.0
Mean = 3.5			

While half of the respondents to this question agreed or strongly agreed that *ICM programs should have legislative backing*, nearly 40% neither agreed nor disagreed. Urban respondents were more likely to agree than rural respondents (means 3.7 and 3.4).

The government gives plenty of resources to voluntary groups. (New)

Response	Rating	N (388)	Percent
strongly agree	5	9	2.3
agree	4	28	7.3
neither agree nor disagree	3	154	40.0
disagree	2	144	37.4
strongly disagree	1	45	11.7
not applicable		5	1.3
TOTAL			100.0
Mean = 2.5			

The largest percentage of respondents (40%) neither agreed nor disagreed that *the government gives plenty of resources to voluntary groups.* The mean score was closer to disagreement than agreement and 37.4% disagreed with the statement. There were no differences between the upper and lower catchment or between the urban and rural respondents.

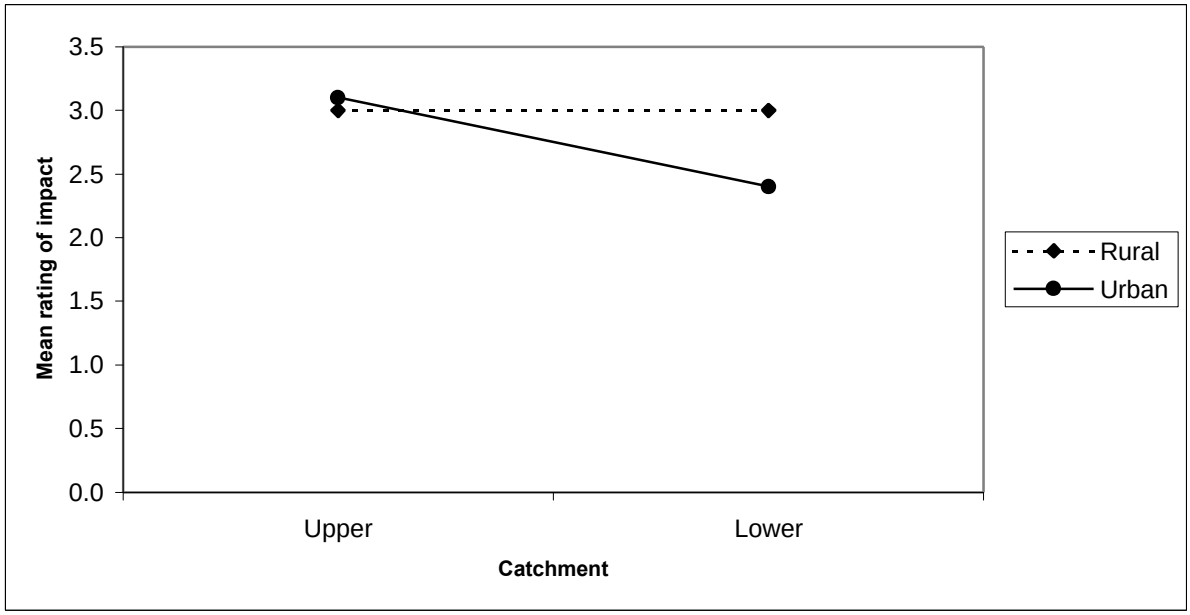
4.12.3 Awareness and Intentions

The local environment is no worse off than it was when I first lived here. (Repeat)

Response	Rating	N (388)	Percent
strongly agree	5	42	10.8
agree	4	92	23.6
neither agree nor disagree	3	70	17.9
disagree	2	113	29.0
strongly disagree	1	69	17.7
not applicable		4	1.0
TOTAL			100.0
Mean = 2.8			

There was a split opinion on this statement, as there was in Survey 1: while 34.4% agreed to some extent, 46.7% disagreed to some extent and only 17.9% neither agreed nor disagreed. Very few responded that this statement was not applicable. There were no significant differences between the two surveys.

Upper catchment respondents were significantly more likely to agree with this statement than lower catchment respondents (means 3.1 and 2.7). In addition, a two way interaction was found: within the lower catchment sample, urban respondents were less likely to agree than rural respondents and within the urban sample, lower catchment respondents were less like to agree than upper catchment respondents, as shown below. This is very similar to the Survey 1 results in which the lower urban sample were less likely to agree than the three other samples.

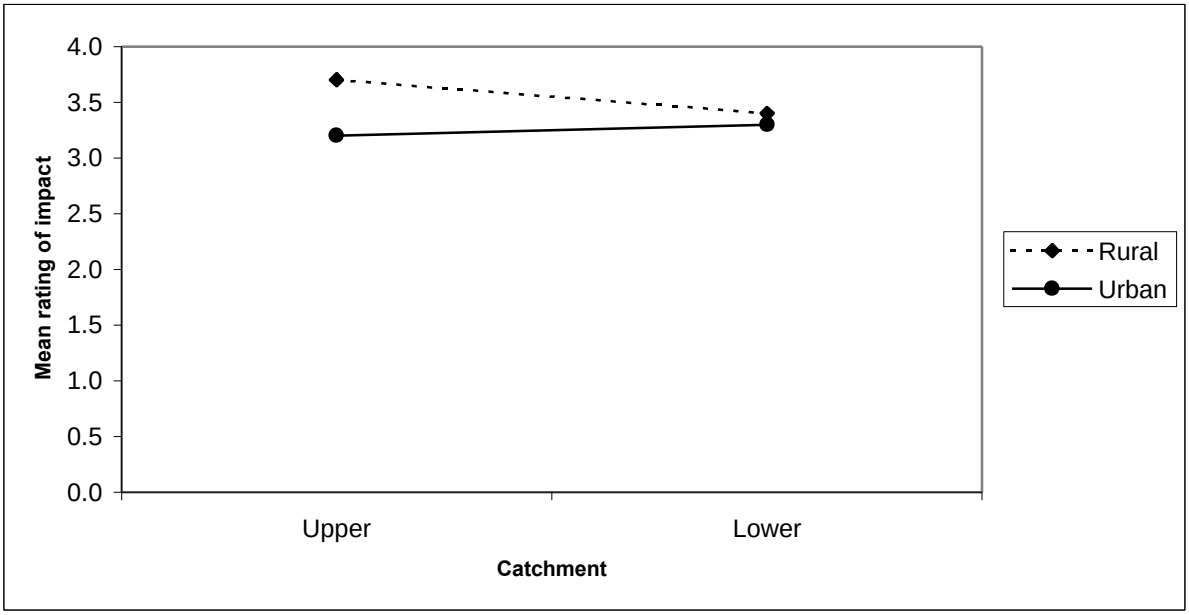


I would be prepared to assist in local projects such as riverbank stabilisation. (Repeat)

Response	Rating	N (388)	Percent
strongly agree	5	20	5.2
agree	4	142	36.9
neither agree nor disagree	3	100	26.0
disagree	2	45	11.7
strongly disagree	1	10	2.6
not applicable		68	17.7
TOTAL			100.0
Mean = 3.4			

While just over 40% agreed or strongly agreed that they would be prepared to assist in local projects, a relatively large percentage neither agreed nor disagreed (26%). Relative to other statements, a large percentage felt that this was not applicable to them. Interestingly, of those who felt that this statement was not applicable to them, 70.6% were from the urban sample (70% in Survey 1) while urban respondents made up 53.1% of the overall sample. There was consistency between the two surveys, both for repeat respondents and the overall sample.

Comparing catchment samples and location samples, rural respondents were more likely to agree than urban respondents (means 3.5 and 3.2) and a significant interaction was found, as shown below. Within the rural sample, upper catchment respondents were more likely to agree than lower catchment respondents and within the upper catchment sample, rural respondents were more likely to agree than urban respondents. In both surveys, upper rural respondents were most like to agree that they *would be prepared to assist in local projects such as riverbank stabilisation.* However, in Survey 1, they were only significantly more likely than the lower urban sample to agree.



It is likely that I will become involved (or stay involved) with a Landcare or catchment group over the next year or two. (Repeat)

Response	Rating	N (388)	Percent
strongly agree	5	16	4.2
agree	4	70	18.3
neither agree nor disagree	3	124	32.4
disagree	2	77	20.1
strongly disagree	1	21	5.5
not applicable		75	19.6
TOTAL			100.0
Mean = 2.9			

The most frequent response to this statement was neither agree nor disagree (32.4%), a little over one fifth of respondents agreed or strongly agreed and slightly more than one fifth of respondents disagreed or strongly disagreed with the statement. A relatively large percentage of respondents felt that this was not applicable to them. Of those who responded *not applicable*, 69.3% were from the urban sample (a similar percentage to Survey 1), higher than the 53.1% to be expected.

There was consistency between the two surveys, for both repeat respondents and the overall samples. Examining differences between the upper and lower catchment and urban and rural respondents revealed that rural respondents were more likely to agree with the statement than urban respondents (means 3.1 and 2.8). This was slightly different to the Survey 1 results in which lower rural respondents were more likely to agree than lower urban respondents.

I could personally benefit from being involved in group activities to help manage land and water. (Repeat)

Response	Rating	N (388)	Percent
strongly agree	5	19	4.9
agree	4	103	26.8
neither agree nor disagree	3	109	28.4
disagree	2	70	18.2
strongly disagree	1	19	4.9
not applicable		64	16.7
TOTAL			100.0
Mean = 3.1			

Nearly one third of respondents agreed or strongly agreed with this statement. A relatively large percentage neither agreed nor disagreed with the statement (28.4%) and a relatively large percentage felt that it was not applicable. Of those respondents who felt that the statement was not applicable, 73.4% came from the urban sample, higher than the percentage of urban respondents in the overall sample (53.1%), a similar result to Survey 1 (76%). Repeat respondents were less likely to agree in Survey 2 than in Survey 1 (means 3.2 and 3.3).

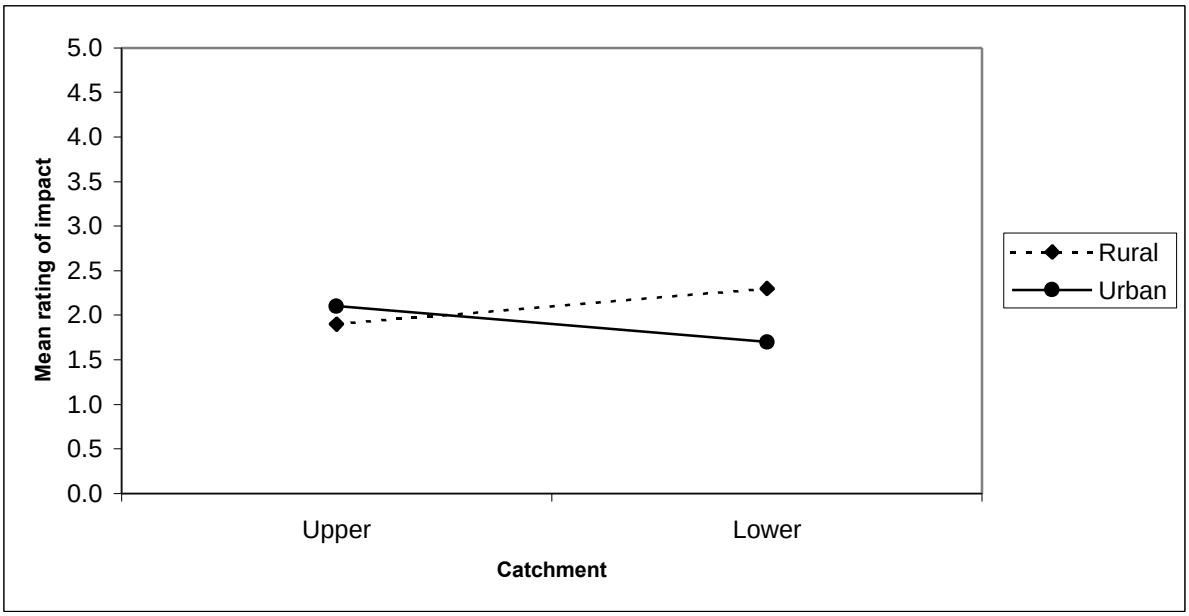
Rural respondents more strongly agreed than urban respondents (means 3.3 and 2.9), which was to be expected. This difference between rural and urban respondents existed in the lower catchment sample in Survey 1.

There aren't any environmental problems that need urgent action. (New)

Response	Rating	N (388)	Percent
strongly agree	5	13	3.4
agree	4	17	4.4
neither agree nor disagree	3	53	13.8
disagree	2	174	45.2
strongly disagree	1	125	32.5
not applicable		3	0.8
TOTAL			100.0
Mean = 2.0			

The mean rating for this statement was *disagree* and a large percentage (77.7%) disagreed or strongly disagreed with the statement *there aren't any environmental problems that need urgent action.* Less than 1% felt that this statement was not applicable.

A significant interaction was found, as shown in the figure below. Within the lower catchment sample, urban respondents more strongly disagreed than rural respondents. Within the rural sample, upper catchment respondents more strongly disagreed than lower catchment respondents and within the urban sample, lower catchment respondents more strongly disagreed than upper catchment respondents.



Discussion

The table below summarises the degree of agreement or disagreement with the statements.

Where greater than 80% of the sample agreed (strongly agreed or agreed) or disagreed (strongly disagreed or disagreed) with the statement, this is indicated by 'high agreement' or 'high disagreement'.

Where 60% to 80% of the sample agreed or disagreed with the statement, this is indicated by 'general agreement' or 'general disagreement'.

Where there was a spread of opinion from strongly agree to strongly disagree, this is indicated by 'split opinion'.

Responsibility and Control

Statement	Survey 2	Survey 1
There are things I can do personally to help improve the environment.	General agreement	General agreement

Catchment management should be paid for and run by the government.	Split opinion	n/a
ICM should remain a voluntary activity by community members.	Split opinionn/a	
Many environmental problems come from the way people manage their properties.	General agreement	General agreement
The government expects too much from local communities in catchment management.	Split opinionn/a	
Laws should be changed to make landholders more responsible for the consequences of their activities.	Split opinionSplit opinion	

In general, with respect to the perceived control residents had on land and water management, there was a great deal of agreement by all groups in both surveys, that there are things local community groups can do to help improve the environment. There was also general agreement by all respondents in both surveys, that there were things they could do personally to help improve the environment.

Most respondents in both surveys did not believe that it was too hard to think about land and water management issues for an area as big as the Herbert catchment, despite the general agreement earlier in the questionnaire that it did make land and water management more difficult. In Survey 2 rural respondents more strongly disagreed with this than urban respondents whereas in Survey 1 upper rural respondents more strongly disagreed than lower rural respondents.

Respondents believed that they and their community had control over land and water management issues in the Herbert catchment, despite the size. However, there was agreement by many respondents in both surveys that they did not have the finances available to plan more than a year ahead. This may make it difficult to plan for long term improvements.

Respondents generally agreed, in both surveys, that many environmental problems come from the way people manage their properties. There was a tendency in both surveys for urban respondents to agree more than rural respondents, although in Survey 1 only in the lower catchment.

When it came to changing laws to make landholders more responsible for the consequences of their activities, however, the sample of both surveys were divided. Although quite a large percentage agreed, quite a large percentage were undecided. Agreement was higher amongst urban respondents than rural respondents in Survey 2 and there was a tendency for this trend in Survey 1.

Three new statements were added in this section of Survey 2 relating to responsibility for dealing with land and water management issues. There was a split opinion on all three statements. Half of the respondents agreed that the government should pay for and run catchment management, however, one third neither agreed nor disagreed. Similarly nearly half of the sample agreed that the government expects too much from local communities in catchment management. There was less agreement that ICM should remain a voluntary activity with opinions being very divided. Rural respondents were more likely to agree than urban respondents.

In summary, respondents generally felt that they and the community could do things to help improve the environment despite the size of the Herbert catchment. Lack of finances may hinder the long term planning often required in environmental management.

While there was general agreement that many environmental problems come from the way people manage their properties, this did not follow through to widespread agreement that laws were needed to make landholders more responsible for the consequences of their activities.

In terms of the responsibility for catchment management, the answer was not very clear. While half of the respondents felt that the government should pay for and run catchment management and that the government expected too much from local communities in catchment management at the time, opinion was very divided on whether ICM should remain a voluntary activity by community members.

Views on Government

Statement	Survey 2	Survey 1
Programs like Integrated Catchment Management interfere with people's rights to make their own decisions.	Split opinion	Split opinion
The government needs to give more resources to voluntary groups.	General agreement	n/a
Different government agencies often give conflicting information on land and water management issues.	General agreement	n/a
There should be better government incentives for landholders to address environmental issues/problems.	High agreement	n/a
ICM programs should have legislative backing.	Split opinion.	n/a
The government gives plenty of resources to voluntary groups.	Split opinion	n/a

When it came to views on government, the table above shows that the highest agreement was with better incentives for landholders to address environmental issues/problems, rural more than urban respondents. While there was divided opinion on whether or not the government gives

plenty of resources to voluntary groups, the majority of respondents, across the samples, agreed that the government needs to give more resources to voluntary groups.

The majority of respondents, across the samples, agreed or strongly agreed that different government departments often give conflicting information on land and water management issues.

There was divided opinion about whether or not programs like Integrated Catchment Management interfere with people's rights to make their own decisions. This was consistent across the two surveys, location samples and catchment samples. While half of the respondents agreed that *ICM programs should have legislative backing,* nearly 40% neither agreed nor disagreed. Urban respondents agreed more than rural respondents.

In summary, respondents generally believed that better incentives were required for landholders to address environmental issues and while there was divided opinion about whether or not the government gave plenty of resources to voluntary groups, most agreed that more was needed. Government departments were perceived by most respondents to give conflicting information on land and water management issues.

The divided opinion about whether or not programs like ICM interfere with people's rights to make their own decisions and whether ICM programs should have legislative backing showed a range of opinions about the need for regulation.

Awareness and Intentions

I could personally benefit from being involved in group activities to help manage land and water.	Split opinion	Split opinion
There aren't any problems that need urgent action.	General disagreement	n/a

In terms of perceptions of environmental problems in the area, most respondents disagreed that there aren't any environmental problems that need urgent action (a new statement in Survey 2). There were some differences between the samples. Related to this, there was divided opinion in both surveys as to whether or not the local environment was no worse off than when people first lived there. Upper catchment respondents were more likely to feel that the local environment had stayed the same than in the lower catchment.

Opinions were fairly divided on the three statements about involvement, related to: preparedness to assist in local projects; becoming (or staying) involved in Landcare or a catchment group; or benefiting from being involved. There was a tendency in Survey 2 for rural respondents to agree more than urban respondents. For example, upper rural respondents were the most likely to agree that they would be prepared to assist in local projects; rural respondents agreed more than

urban that they would become involved (or stay involved) in Landcare or a catchment group and that they could personally benefit from being involved in group activities to help manage land and water.

A large percentage of the sample felt that the these were not applicable. As in Survey 1, around 70% of these were from the urban sample whereas overall urban respondents only made up around 53% of the sample.

4.13 Involvement

Over the last 12 months, have you been involved in any local community groups or associations?
While in Survey 1, 44% of the sample were currently involved in such groups, in Survey 121 (32%) of the 378 respondents to the question had been involved in local community groups or associations. The percentage was higher in the upper catchment (42%) than in the lower catchment (28%).

If yes, which groups or associations were they?
Those 121 participants who indicated that they had been involved in any local community groups or associations were asked in an open-ended question to list them. The following table provides a comparison with the categories used in Survey 1.

Community group/association	Survey 1 N (228)	Survey 1 Percent	Survey 2 N (121)	Survey 2 Percent
Progress Association	23	10.1	8	6.6
Rate Payers Association	13	5.7	4	3.3
Professional Association	18	7.9	2	1.6
Charity/Church/Welfare	66	28.9	15	12.4
Agriculture Related Organisation	65	28.5	15	12.4
Landcare, Conservation or similar	42	18.4	48	35.5
Sporting Group	103	45.2	11	9.1
Hobby/Craft Group	23	10.1	13	10.7
Community Action Group	23	10.1	0	0
Service Club	43	18.9	14	11.6
Parents and Friends	57	25.0	12	9.9
Other/s	44	19.3	61	50.4

If you were involved in any Landcare, conservation or similar types of groups, please write down the name of the group that you were most involved with.
Those 121 respondents who answered the previous question were asked to specify, if they had been involved in any Landcare, conservation or similar groups, which group they had been most involved with. Of the 37 responses made by participants, the main responses were Landcare groups (13), ICM (7); Waterwatch (3); Fishcare (2); and Trees for the Evelyn and Atherton Tableland (2). Other groups included the Australian Conservation Council, a tree planting program for future trees, town beautification, a progress association, rural women, Millstream redevelopment, Canegrowers, Herbert River Trust, and bushland rehabilitation.

Discussion
One third of those respondents had been involved in a local community group or association. The main categories were 'Landcare, Conservation or similar', 'Charity/Church/Welfare' and 'Agriculture Related Organisations'. As this was an open-ended question in Survey 2 a high percentage of responses fell into the 'Other' category, many only mentioned by very few respondents. Of the 37 respondents who indicated which Landcare, Conservation or similar group they were most involved with, the main responses were Landcare groups, ICM and Waterwatch.

4.14 The Local Community

Thinking of the local community where you live, please rate how much you agree or disagree with each of the following statements.
Results are presented below for each statement with a brief explanation of the degree of agreement or disagreement with each and significant differences between catchment samples or location samples. No significant two way interactions between catchment samples and locations samples were found. A comparison of the results from the two surveys is presented after the results for individual statements.

I'm not very interested in local issues.

Response	Rating	N (390)	Percent
strongly agree	5	6	1.5
agree	4	24	6.2
neither agree nor disagree	3	72	18.5
disagree	2	216	55.4
strongly disagree	1	72	18.5
TOTAL		390	100.0

Nearly three quarters of the sample (73.9%) disagreed or strongly disagreed that they weren't very interested in local issues and nearly one fifth neither agreed nor disagreed.

I feel quite comfortable in being a member of this local community.

Response	Rating	N (391)	Percent
strongly agree	5	65	16.6
agree	4	269	68.8
neither agree nor disagree	3	37	9.5
disagree	2	10	2.6
strongly disagree	1	10	2.6
TOTAL		391	100.0

The majority of respondents (85.4%) agreed with this statement, signifying that most respondents felt quite comfortable in being a member of their local community.

I have almost no influence over what happens in this community.

Response	Rating	N (389)	Percent
strongly agree	5	50	12.9
agree	4	169	43.4
neither agree nor disagree	3	85	21.9
disagree	2	71	18.3
strongly disagree	1	14	3.6
TOTAL		389	100.0

A little over half of the respondents (56.3%) agreed or strongly agreed that they have almost no influence over what happens in their community and a relatively large percentage neither agreed nor disagreed. Lower catchment respondents were more like to agree than upper catchment respondents (means 3.5 and 3.2) and urban respondents were more likely to agree than rural respondents (means 3.6 and 3.3).

It's very important to me to live in this particular community.

Response	Rating	N (389)	Percent
strongly agree	5	71	18.3
agree	4	170	43.7
neither agree nor disagree	3	119	30.6
disagree	2	21	5.4
strongly disagree	1	8	2.1
TOTAL		389	100.0

A large percentage of respondents (62%) agreed or strongly agreed that it was very important to them to live in their particular community and a relatively large percentage neither agreed nor disagreed. Lower catchment respondents were more likely to agree than upper catchment respondents (means 3.8 and 3.5).

People in this community generally don't get along with each other.

Response	Rating	N (390)	Percent
strongly agree	5	12	3.1
agree	4	42	10.8
neither agree nor disagree	3	87	22.3
disagree	2	194	49.7
strongly disagree	1	55	14.1
TOTAL		390	100.0

A large percentage (63.8%) disagreed with this statement, signifying that most respondents believed that people in their community generally do get along.

I often think about local community issues.

Response	Rating	N (389)	Percent
strongly agree	5	37	9.5
agree	4	222	57.1
neither agree nor disagree	3	100	25.7
disagree	2	28	7.2
strongly disagree	1	2	0.5
TOTAL		389	100.0

A large percentage (57.1%) agreed that they often did think about local community issues and one quarter of respondents neither agreed nor disagreed with the statement.

I and many others in this community share similar values.

Response	Rating	N (386)	Percent
strongly agree	5	41	10.6
agree	4	243	63.0
neither agree nor disagree	3	82	21.2
disagree	2	17	4.4
strongly disagree	1	3	0.8
TOTAL		386	100.0

The majority of respondents (73.6%) agreed or strongly agreed with this statement.

I think this community is a good place to live.

Response	Rating	N (392)	Percent
strongly agree	5	136	34.7
agree	4	229	58.4
neither agree nor disagree	3	20	5.1
disagree	2	7	1.8
strongly disagree	1	0	0.0
TOTAL		392	100.0

Most respondents (93.1%) felt that their community was a good place to live.

I can recognise many of the people who live in this community.

Response	Rating	N (392)	Percent
strongly agree	5	96	24.5
agree	4	267	68.1
neither agree nor disagree	3	22	5.6
disagree	2	6	1.5
strongly disagree	1	1	0.3
TOTAL		392	100.0

Most respondents (92.6%) could recognise many of the people living in their community.

I don't have the time to become involved in local community issues.

Response	Rating	N (388)	Percent
strongly agree	5	22	5.7
agree	4	116	29.9
neither agree nor disagree	3	147	37.9
disagree	2	87	22.4
strongly disagree	1	16	4.1
TOTAL		388	100.0

There were very divided opinions on this statement, while 35.6% agreed to some degree that they did not have the time to become involved in local community issues, 26.5% disagreed to some extent and 37.9% neither agreed nor disagreed.

Comparison of means in Survey 1 and Survey 2 (repeat respondents only)

Statement	Survey 2 Mean	Survey 1 Mean
I think this community is a good place to live. * 4.3	4.2	
I can recognise many of the people who live in this community.	4.1	4.1
I feel quite comfortable in being a member of this local community.	3.9	4.0
I and many others in this community share similar values.	3.8	3.8
It's very important to me to live in this particular community.	3.7	3.7
I often think about local community issues.	3.7	3.6
I have almost no influence over what happens in this community.	3.4	3.4
I don't have the time to become involved in local community issues.	3.1	3.2
People in this community generally don't get along with each other.	2.4	2.3
I'm not very interested in local community issues.2.2	2.4	

* denotes a significant difference ($p < .05$)

Discussion

There was greatest agreement by respondents about the feel of their community: that it was a good a place to live; they could recognise many of the people who lived there; they felt quite

comfortable living there; and people generally got along with each other. Most respondents felt they shared similar values with others in their community. Although it was very important to many respondents (more so in the lower catchment) to live in their particular community, a relatively large percentage neither agreed nor disagreed with this statement.

Opinions were more divided regarding involvement and influence in community issues. Over half the respondents agreed that they often thought about local community issues, related to the high degree of interest expressed in local community issues. In terms of involvement in local community issues, there was division over whether or not respondents had the time to be involved. A large percentage of respondents felt they had almost no influence over what happened in their community, more so in the lower catchment than the upper catchment and more so for urban respondents than for rural respondents.

4.15 Integrated Catchment Management and Local Government

Should Local Government have a role in Integrated Catchment Management?
Most (88.5%) of the 356 respondents who answered this question replied that Local Government should have a role in Integrated Catchment Management.

Please give reasons
The most prominent responses by participants are shown in the table below. In total, 394 answers were provided by 309 respondents of which 323 (82%) responses are shown. As the majority of respondents replied that Local Government should have a role in ICM, all of these reasons are related to why Local Government should have a role in ICM.

Reasons	N (309)	Percent
LG has knowledge of local environment	73	23.6
LG have more resources & information	38	12.3
A representation of local people, for views to be heard	30	9.7
In a better position to obtain funds for ICM	26	8.4
Within its region	25	8.1
Benefits all people and the environment	17	5.5
Uniformity of approach	15	4.9
More power to create changes and coordinate activities	15	4.9
Inform the community	13	4.2
Responsible for building and maintaining infrastructure	13	4.2
Affects/involves everyone in the community	11	3.6
Solve more problems	8	2.6
Pays rates to them	6	1.9
More supervision (eg. on the use of public monies)	6	1.9
Helps shire	6	1.9
Better management (eg. expertise)	6	1.9
Prevent conflict on land and water management issues	5	1.6
Affects Local Government planning	5	1.6
Share responsibility	5	1.6

The reasons respondents gave for the response that Local Government should not have a role in ICM were: too much inefficiency; ICM would be tied to politics; ICM is independent to Local Government; Government can not plan anything; different interests; Local Government activities conflict with measures needed for proper catchment management; and landowners are responsible for proper drainage.

Should Local Government Planning sometimes take into account Integrated Catchment Management?
Again, the majority of those who answered this question (93.8% of 336) believed that Local Government Planning should take into account ICM.

Please give reasons

The main reasons for participants' responses are shown in the table below. A total of 268 participants responded to the question, providing 307 responses. The table below lists 224 of those responses (73%).

Reasons	N (268)	Percent
Benefit or affect the community	34	12.7
Responsible for building and maintaining infrastructure *	20	7.5
Uniformity of approach *	18	6.7
Stop development in the wrong areas	18	6.7
LG have knowledge of local environment *	17	6.3
Provide better management for the future	16	6.0
Coordinate all activities	14	5.2
For local purposes/interests/issues	11	4.1
For management to be properly integrated	11	4.1
A representation of local people *	10	3.7
LG have more resources and funds for environmental issues	9	3.4
More planning is better/look at all issues of planning	8	3.0
Prevent conflict on land and water issues *	7	2.6
For greater control/to monitor local council work/watchdog	6	2.2
Affects ratepayers	5	1.9
A guide to verify plans to meet local conditions	5	1.9
Within its region *	5	1.9
Responsibility of LG	5	1.9
Should know what happens	5	1.9

* These categories were prominent reasons for Local Government to be involved in ICM.

Most of the respondents who believed that Local Government should not take ICM into account did not give reasons. The two reasons given were: Local Government is not capable of taking extra involvement; and too many inefficiencies would arise.

Discussion

The majority of respondents indicated that Local Government should have a role in ICM and that Local Government Planning should take into account ICM. The main reasons why Local Government should have a role in ICM were *Local Government has knowledge of local environment* and *Local Government have more resources and information.* There were no dominant reasons for why Local Government should not have a role in ICM.

The main reasons why respondents felt Local Government planning should take into account ICM were because it would *benefit or affect the community* and because they are *responsible for building and maintaining infrastructure.* Most respondents who did not think Local Government Planning should take ICM into account did not provide reasons. However, the two reasons given were *Local Government is not capable of taking extra involvement* and *too many inefficiencies would arise.*

4.16 Funding

For every $100 spent on catchment management and landcare,
A. how much of it do you think IS being contributed by:
B. how much of it do you think SHOULD be contributed by:

Parties	Perceptions of current contribution	Perceptions of what contributions should be
The Commonwealth Government	$29.08*	$34.39*
The Queensland Government	$29.84*	$27.03*
Local Government	$18.19	$15.82
Industry	$9.88*	$11.90*
Individual farmers	$12.41	$10.70

Means shown for 178 respondents who answered both sections. * Significant differences ($p<0.05$).

On average, the Commonwealth and Queensland Governments were thought to be contributing the largest amount of money to catchment management and landcare. Industry was seen to be contributing the least. Comparing the mean responses for those participants who completed both sections showed that respondents felt that the Commonwealth Government should be contributing significantly more than it was currently contributing, and still more than the other parties.

Comparing the upper and lower catchment and rural and urban respondents, the means were as follows. The underlining indicates significant differences between the perceptions of current contributions and perceptions of what the contributions should be in the future.

For a question of this nature, however, the differences were quite small. The overall system was therefore regarded as reasonably equitable by respondents.

Perceptions of current contributions

	Upper Catchment	Lower Catchment	Rural Respondents	Urban Respondents
Commonwealth government	$35.51*	$26.77*	$29.41	$29.09
Queensland government	$32.57	$28.29	$27.39	$31.98
Local government	$14.79	$19.35	$16.07	$20.35
Industry	$4.91*	$11.89*	$10.78	$8.87
Farmers	$11.85	$12.47*	$15.52*	$8.55*

* Significant differences between means ($p<0.05$).

Perceptions of what the contributions should be

	Upper Catchment	Lower Catchment	Rural Respondents	Urban Respondents
Commonwealth government	$39.03	$34.94	$38.75*	$33.34*
Queensland government	$29.82	$26.26	$29.35*	$25.10*
Local government	$12.11*	$16.94*	$14.69	$16.46
Industry	$10.23	$11.53	$9.65*	$12.74*
Farmers	$8.55	$10.23	$7.48*	$12.12*

* Significant difference between means ($p<0.05$).

Within the upper catchment, it was thought that industry should be contributing significantly more than they were at the time whereas in the lower catchment, respondents overall felt that the Commonwealth government should be contributing more.

Rural respondents on the whole felt that the Commonwealth government should be contributing more and farmers less. Urban respondents were quite different. They thought that the Queensland government should be contributing less and that industry and farmers should be contributing more than they were at the time.

A number of people chose not to answer the question, stating on their questionnaires that they did not know how much money was being contributed, that they found it difficult to answer or that they did not want to guess. Two respondents stated that they found the question to be pointless. In future, supplementary equity questions could be added to the questionnaire to….

Please comment on why you have chosen the amounts for part B.

Reasons	**N (228)**	**Percent**
Biggest share because they receive taxes	33	14.5
Unaware of how much is spent/guessing	23	10.1
Individuals have a responsibility	22	9.6
Least because already paid too much	22	9.6
Rewards gained/benefited/use water	21	9.2
Equal because share some responsibility	17	7.5
Government should contribute major share	15	6.6
To get all people to contribute/on behalf of all Australians	13	5.7
Biggest share because caused the environmental damage	11	4.8
Individual farmers should not have to pay/pay heavily	11	4.8
Equal contribution because equally interested	10	4.4
Looking after the environment/have environmental interests	9	3.9
Money should be put back	9	3.9
Levels of involvement	7	3.1
Authorities who make decisions should pay/pay for consequences of their actions	6	2.6
Local Government takes rates	6	2.6
Total community responsibility	6	2.6
Biggest share because have the most resources	6	2.6
Levels of interest	5	2.2
Biggest share because a national problem	5	2.2
Biggest share because owes it to the country	5	2.2

Overall, 228 participants responded to this question, providing 318 responses. The table shows the most prominent of these responses: 267 (84%) of the total number of responses.

The reasons have been broken down as listed below.

1. Reasons for assigning one party the biggest share were:
- they receive taxes;
- they have the most resources;
- they gain rewards or benefits;
- they caused the environmental damage;
- it is a national problem; or
- they owe it to the country.

2. Reason for assigning one party the lowest share:
- they have already paid too much.

3. Reasons for assigning an equal share to all parties:
- they share some responsibility;
- to get everyone to contribute/on behalf of all Australians;
- they are all equally interested; and
- it is a total community responsibility.

4. Reasons for various shares being assigned:
- levels of involvement;
- levels of interest.

5. Reasons for assigning, or not assigning, a share to particular groups:
- individuals have a responsibility;
- government should contribute a major share;
- individual farmers should not have to pay/pay heavily;
- authorities who make decisions should pay/pay for the consequences of their actions;
- local government takes rates;
- they are looking after the environment/have environmental interests; and
- money should be put back.

Discussion
while the Commonwealth Government was perceived to be contributing the most amount of money to catchment management and landcare, the results showed that respondents thought it should be contributing significantly more than it was at the time. Industry were perceived to be contributing the least amount of money and it was thought, on average, that this should increase slightly. Overall, it was thought that that the contributions of the Queensland Government, local government and individual farmers could all decrease slightly.

Reasons for the distributions of money related to access to factors such as: resources, degree of responsibility for problems, degree of interest in improvements, benefits from improvements, how much they have contributed in the past.

4.17 Resources

Have you visited the Herbert Resource Information Centre in Ingham?
The majority of respondents who answered this question (391) had not visited the Herbert Resource Information Centre in Ingham (79.8%) while 20.2% had visited the Centre.

Have you seen the Herbert River Catchment Atlas?
The majority of respondents who answered this question (390) had not seen the Herbert River Catchment Atlas (67.7%).

Have you seen the Herbert River Catchment Coordinating Committee's Catchment Management Strategy?
A very large percentage of those respondents who answered this question had not seen the Herbert River Catchment Coordinating Committee's Catchment Management Strategy (91.3%).

4.18 Demographics

Show which category best describes your age.

Age category	Frequency (N=397)	Percentage
Less than 24 years	1	0.3
24 to 39 years	71	17.9
40 to 55 years	157	39.5
56 to 65 years	95	23.9
66 to 75 years	58	14.6
More than 75 years	15	3.8
TOTAL	397	100.0

In Survey 1, the average age of respondents was 51.8 years. In Survey 2, the average age is, once again, in the 40 to 55 years category.

What is your gender?

The majority of the sample were male (61.6%) and 38.4% were female, very similar to Survey 1 in which 62.5% were male and 37.5% were female.

What is your main occupation?

Occupation	Survey 2 N = 392		Survey 1 N = 463	
	N	%	N	%
Cane farmer	111	28.2	143	30.9
Retired	61	15.5	59	12.7
Home duties	57	14.5	74	16.0
School teacher	22	5.6	11	2.4
Tradesman	18	4.6	20	4.3
Grazier	14	3.6	22	4.8
General farming (other than cane)	10	2.5	10	2.2
Mill worker	8	2.0	-	-
Nurse	6	1.5	8	1.7
Retired cane farmer	6	1.5	4	0.9
Office manager	5	1.3	-	-
Plant operator	4	1.0	-	-
Public servant	4	1.0	-	-
Small business	-	-	8	1.7
Community worker	-	-	1	0.3

The percentage of respondents in each occupation were extremely similar in both surveys.

How many years have you had this occupation?
There were 375 respondents to this question. The range was from one to seventy years and the average length of time was 23 years, almost identical to Survey 1 in which the range was from one to seventy-two years and the average length of time in their occupation was 22 years.

Looking at the dominant occupation, cane farming, the range was 1 to 55 years and the average was 29 years. In Survey 1 the range for cane farmers was from 2 to 69 years and the average was 29 years.

How long have you lived in this area?
Of the 394 respondents to this question, the length of residence ranged from 1 to 87 years with an average length of 34 years. This is again very similar to Survey 1 in which the range was from 1 to 89 years and the average length of residence in the area was 34 years.

Again looking at cane farmers, the range was from 8 to 76 years and the average length of residence was 47 years. In Survey 1, the range was from 4 to 75 years and the average length of residence was 46 years.

How often do you go fishing for recreation?

Response	Rating	N (398)	Percent
often	1	50	12.6
occasionally	2	167	42.0
seldom	3	88	22.1
never	4	93	23.4
TOTAL		398	100.0

As in Survey 1, fishing was an activity that tended to be carried out fairly infrequently.

Do you own or lease/rent a commercial rural, or rural property greater than 3 hectares (7.5 acres)?

		Survey 2		Survey 1	
Response	**Rating**	**N (391)**	**Percent**	**N (469)**	**Percent**
Yes - own	1	167	42.7	194	41.4
Yes – lease/rent	2	22	5.6	25	5.3
Yes - both	3	5	1.3	11	2.3
No	4	197	50.4	239	51.0
TOTAL		391	100.0	469	100.1

As shown in the table above, the results of Survey 1 and 2 were extremely similar. A little over 40% of respondents in both surveys owned a property greater than 3 hectares, approximately 5% leased or rented such a property and a very low percentage both owned and leased/rented a rural property of that size. Half of the respondents in both surveys did not own or lease/rent a rural property greater than 3 hectares.

Which one of the following best describes your current use of this property?

		Survey 2		Survey 1	
Use	**Rating**	**N (195)**	**Percent**	**N (228)**	**Percent**
Cane farming	1	131	67.2	163	71.5
Grazing	2	23	11.8	41	18.0
Mining	3	0	0	3	1.3
Industrial	4	0	0	0	0
Other farming	5	27	13.8	12	5.3
Other	6	14	7.2	9	3.9
TOTAL		195	100.0	228	100.1

As in Survey 1, the majority of properties were used for cane farming. Other farming had increased since Survey 1, but included similar types: maize, forestry, corn, avocadoes, navy beans, and vegetables. The 'other' categories included residential and hobby farming.

What is the size of your property?

For those 188 respondents who owned or leased/rented rural properties greater than 3 hectares, rounded to the nearest hectare, average property size in the lower catchment was 202 hectares (219 hectares in Survey 1) and in the upper catchment was 6258 hectares (6146 hectares in Survey 1).

Have you cleared any new land in the last twelve months?

Of the 158 respondents to this question who owned property greater than 3 hectares, only 8 had cleared any land in the last 12 months, or 4.8% (12% in Survey 1). These respondents were asked to specify the amount of land cleared. The range was from 1 hectare to 20 hectares, with an average of 7 hectares, compared to a range of 1 to 162 hectares and a mean of 18 hectares in Survey 1.

5.0 SUMMARY OF RESULTS

Response Rate

The response rate of 50% was less than the response rate in Survey 1 of 60%. This was not surprising as over-surveying was becoming an issue in the Herbert catchment (Bellamy, 1998). The response rates in the upper and lower catchment were very similar although higher in urban areas than rural areas (56% and 45%).

A higher percentage of repeat respondents (those who agreed in Survey 1 that they would participate again in the future) returned their questionnaires than new respondents (those people approached for the first time in Survey 2): 63% and 43% respectively.

Life Satisfaction
Generally, respondents reported moderate satisfaction with life in general, their standard of living, personal health, the area where they lived and the community in which they lived, very similar results to Survey 1. Satisfaction with existing community facilities and services was slightly lower, close to neither satisfied nor dissatisfied, as it was in Survey 1.

Ratings of satisfaction with life in general and the standard of living were still close to moderate in Survey 2 but significantly lower in Survey 2.

Lower catchment respondents were more satisfied with existing community facilities and services than upper catchment respondents.

Advantages of the Herbert River Catchment
Reported advantages experienced by respondents were very similar in both surveys despite being unprompted. Overall, the catchment offered a relaxed rural lifestyle, with a good climate, unspoiled, healthy and natural environment and good recreation opportunities. It was also described as a small, safe and friendly, close knit community which is also close to large centres.

Lower catchment respondents mentioned personal safety, closeness to large centres, ease of access to recreation, and the close knit community more than upper catchment respondents. Upper catchment respondents were more likely to mention the healthy environment, good climate, unspoiled environment and good quality drinking water.

Key Issues for the Herbert River Catchment
Unemployment was the key issue reported by respondents to an open-ended question, followed by lack of diversity in industry and a lack of opportunities for young people Unemployment was mentioned by a lower percentage of respondents in Survey 2 than in Survey 1, reflecting the actual decrease in unemployment during that time period (ABS, 1999). A lack of opportunities for young people was mentioned mainly by lower catchment respondents and was also mentioned more often in Survey 1 than in Survey 2.

Frequent responses related to land and water management included: clearing of marginal land; flooding; drainage; water quantity issues (ie. lack of water); fishing issues; the impact of weather and changing weather conditions on primary industry; and environmental issues.

Issue Importance
Ratings of personal importance, and importance for the Herbert in general, were gained for eight environmental issues. Land degradation, water quality problems, water quantity problems and nature conservation issues were repeated from Survey 2. Additional issues were flooding, wetlands, vegetation on riverbanks and loss of biodiversity. All of these issues were rated as at least moderately important by respondents on the whole. Water quality problems were most important and land degradation was ranked second overall.

Important to note is that flooding was ranked equal first in its importance to people in the Herbert and ranked equal last in its personal importance. This may be due to the fact that flooding does not affect a large proportion of people in the catchment, particularly in the upper catchment, but many people would be aware of its extreme impact on others.

Many of the issues were rated as more important personally than to people in the Herbert. As mentioned in Survey 1, this may be related to a finding in the literature that people often underestimate others' feelings about the importance of pro-social behaviours.

Overall, land degradation, water quality and nature conservation were rated as more important personally, and to others in the Herbert, in Survey 2. Repeat participants rated nature conservation higher in Survey 2 than in Survey 1 whereas water quantity problems were rated as less important in Survey 2.

Of the new issues, wetlands, vegetation on river banks and flooding were all found to be more important personally to respondents in the lower catchment. Flooding was also rated as more important for the Herbert by lower catchment respondents.

In terms of personal importance, wetlands and loss of biodiversity were rated higher by urban respondents and flooding was rated higher by rural respondents.

Impacts of issues
Ratings of the impact of various issues were gained, again both in terms of the personal impact on respondents and the perceived impact on the Herbert. The stability of community opinions over the two years between the surveys was quite strong.

The highest personal impact came from: higher taxes; poor drinking water quality; loss of environmental uses; and loss of confidence in government's ability to manage land and water resources. The impact of the latter issue signifies the importance of ICM and its community focus.

In Survey 1, however, the highest impact on respondents were from: loss of confidence in government's ability to manage land and water resources; higher taxes; loss of farm productivity; and lower fish numbers.

The highest impacts on people in the Herbert were perceived to be from: higher taxes; loss of farm productivity; higher production costs; and poor drinking water quality.

In Survey 1, the highest impact on the Herbert was from: higher taxes; higher production costs; poor drinking water quality; and loss of confidence in government ability to manage land and water resources.

Tractability
This section examined how manageable (or practical) catchment management might be, given perceptions of possible impediments to effectively managing land and water in the catchment. The greatest impediments to managing land and water in the Herbert were the same in both surveys:

- slow government strategies (only measured in Survey 2);
- slow reactions by government to new problems (only measured in Survey 2);
- the catchment's large area;
- the cost of solutions;
- a lack of easy solutions;
- low trust of government programs; and
- insufficient understanding of relevant problems.

Knowledge of government strategies
Landcare was the most familiar government strategy to respondents: the majority of respondents stated that they had heard about Landcare and the majority knew most about Landcare. Half the

respondents had heard of ICM and nearly one third had heard of PMP, very similar results to Survey 1. Also similar to Survey 1, those who had heard about the strategies were more likely to come from the lower rural sample (primarily canegrowers).

As in Survey 1, nearly 60% of respondents felt that the government strategy they knew most about had not been particularly useful to them personally. On average, respondents felt that it was neither effective nor ineffective in dealing with land and water issues, which may indicate either that respondents were unaware of the effectiveness of the strategy or were undecided.

When respondents were asked how they came to know of the strategy, newspapers were the most frequent source, followed by television/television advertisements and the media in general. The order of responses was very similar in both surveys considering the time span between surveys, slightly different samples, and open-ended nature of the question.

However, a higher percentage of respondents reported hearing of the strategy through personal experience in Survey 2, reflecting the finding of a study examining communication on ICM in the Herbert that many initial contacts were on a personal or mutual basis (McCreddin, Syme and Porter, 1999). In both surveys, the most frequent way for respondents to hear about ICM was through general meetings, or canegrowers' meetings specifically.

Respondents were asked if they were aware of any other government funded programs on wider environmental matters in the Herbert catchment. One fifth of respondents to this question were aware of other programs. Rather than ask to specify the programs, the study concentrated on respondents' opinions of these programs. While criticisms were evident, there was also some appreciation of programs, the main comments being that the program: lacked knowledge of the local situation; did not consult local people; did not use the best or most recent information; worked well; and was a good idea.

Activities of ICM

Survey 2 gained input from the community on their priorities for the activities of ICM. Overall, most of the eleven activities nominated in the questionnaire were rated as highly important. The only activity rated as moderately important was *separate ICM programs for the Upper and Lower catchments,* which, in addition, was not ranked in the top three activities by 90% of respondents to the question.

While most activities were seen to be important for ICM, the ranking of activities shows that the highest priorities were:

- encouraging joint projects between different parties;
- raising local awareness;
- developing solutions for and better understanding of environmental problems;
- encouraging research; and
- encouraging Local Government involvement.

Still highly important, but with the lowest ranking, starting with the lowest, were:

- undertaking specific on ground projects;
- separate ICM programs for the upper and lower catchments;
- providing a continuing source of advice to local government on catchment issues; and
- encouraging discussion between community interest groups.

The Herbert River Catchment Coordinating Committee

A little less than half the respondents had heard of the Herbert River Catchment Coordinating Committee, either definitely or vaguely. The percentage was higher in the rural sample than the

urban sample and higher in the lower catchment than the upper catchment. While a relatively large percentage were unsure of the purpose of the HRCCC or mentioned that it had never been fully publicised, the main perceived purposes were: care for the catchment area; conserve and manage water; preserve waterways; raise awareness; and improve drainage.

Similarly, a large percentage of respondents were unaware of specific activities of the HRCCC and combined with a low response rate to this question, there appears to be low awareness of the specific activities of the HRCCC. Those respondents who did respond mentioned activities such as:

- tree planting on riverbanks;
- surveys of water availability and quantity;
- work on the banks of the Herbert River;
- erecting owl boxes;
- weed control;
- formation of water drainage; and
- removal of flood gates.

Three quarters of those who had heard of the HRCCC felt that it had been effective to some extent in achieving its goals and purposes. Approximately half of those respondents who were aware of the HRCCC thought the group was progressing at an acceptable though moderate rate and generally heading in the right direction.

Resources

From the upper catchment, only 2% of respondents had visited the Herbert Resource Information Centre, compared to 28% from the lower catchment. Overall, approximately 30% of respondents had seen the Herbert River Catchment Atlas and approximately 10% had seen the HRCCC's Catchment Management Strategy.

Control

Feelings of control over land and water management issues were relatively high. Many respondents agreed that there were things they could do personally, or that local community groups could do, to help improve the environment and there was general disagreement that it was too hard to think about land and water management issues for an area as big as the Herbert catchment.

The agreement by many respondents that they don't usually have the finances available to plan more than a year ahead may place restrictions on these feelings of control.

Responsibility

Respondents generally agreed that many environmental problems come from the way people manage their properties and subsequently more respondents agreed than disagreed that laws should be changed to make landholders more responsible for the consequences of their activities.

There were split opinions regarding whether or not ICM should remain a voluntary activity, whether or not the government expects too much from local communities and whether or not the government should pay for and run ICM.

Views on Government

Although opinions were quite divided, similar to the views on government versus community responsibility, there was a tendency for respondents to disagree more than they agreed that ICM programs should have legislative backing. Most respondents believed that the government needed to give more resources to voluntary groups.

Related to the lack of personal resources and a need for more resources was the general agreement that there should be better government incentives for landholders to address environmental issues/problems.

It was thought that government agencies often give conflicting information on land and water management issues. Opinions were divided regarding whether or not programs like ICM interfered with people's rights to make their own decisions.

Awareness and Intentions

Overall, local awareness about land and water issues was considered to be moderate, as in Survey 1. While the perceived preparedness of local people to become involved in land and water issues had decreased from Survey 1 and was close to moderate, repeat respondents were more likely to become involved (slightly more than moderate). There was no difference between the two surveys when new respondents were compared with Survey 1. This suggests that participation in Survey 1 may have influenced the likelihood of becoming involved in land and water issues.

Respondents generally agreed that there were problems that needed urgent action (upper rural respondents agreed more than lower rural respondents). Respondents were divided on whether or not the local environment had worsened since they first lived there.

There were split opinions regarding respondents' preparedness to assist in local projects, likelihood of becoming or staying involved with a Landcare or catchment management group over the next year, and the degree of personal benefit to be gained from involvement in group activities to help manage land and water.

Involvement in Groups

In the upper catchment, 42% of respondents had been involved in local community groups or associations in the past year and 28% in the lower catchment. Overall, the percentage was less than in Survey 1 (32% and 44%). The primary categories overall were:

- Landcare, conservation and similar groups;
- charity, church or welfare groups;
- agriculture related groups; and
- service clubs.

There were relatively few responses when asked for the specific Landcare, conservation, or similar groups however most of these were Landcare groups.

Views of the Local Community

There was general agreement among respondents about the positive aspects relating to the feel of their local communities:

- it is a good place to live;
- they recognised many of the people;
- they felt quite comfortable there;
- they were interested in local issues;
- they shared similar values with others; and
- it was important to live there (more agreement in the lower catchment).

Opinions were divided, however, about issues relating to involvement, influence and conflict in their local community:

- the influence they felt over what happened (less agreement in the upper catchment);
- whether or not people in their community generally get along;
- whether or not they often thought about local community issues; and
- whether or not they had the time to become involved in local community issues.

ICM and Local Government

Approximately 90% of respondents felt that local government should have a role in ICM. The main reasons were:

- their knowledge of the local environment;
- they have more resources and information;
- they are responsible for building and maintaining infrastructure; and
- ICM is within their region.

Approximately 95% of respondents felt that local government planning should take ICM into account, mainly because:

- it would benefit the community;
- they are responsible for building and maintaining infrastructure;
- they have knowledge of the local environment; and
- it would provide better management for the future.

Funding

Respondents were asked how much they thought was being contributed, and how much should be contributed, for every $100 spent on ICM and landcare by five different parties.

Perceptions of current contributions (means)

	Upper Catchment	Lower Catchment	Rural Respondents	Urban Respondents
Commonwealth government	$35.51**	$26.77**	$29.41	$29.09
Queensland government	$32.57	$28.29	$27.39	$31.98
Local government	$14.79	$19.35	$16.07	$20.35
Industry	$4.91**	$11.89**	$10.78	$8.87
Farmers	$11.85	$12.47	$15.52**	$8.55**

** Significant differences between means.

Perceptions of what the contributions should be (means)

	Upper Catchment	Lower Catchment	Rural Respondents	Urban Respondents
Commonwealth government	$39.03	$34.94	$38.75**	$33.34**
Queensland government	$29.82	$26.26	$29.35**	$25.10**
Local government	$12.11**	$16.94**	$14.69	$16.46
Industry	$10.23	$11.53	$9.65**	$12.74**
Farmers	$8.55	$10.23	$7.48**	$12.12**

** Significant difference between means.

Within the upper catchment, it was thought that industry should be contributing significantly more than they were at the time. Lower catchment respondents overall felt that the Commonwealth government should be contributing more than they were at the time.

Within the rural respondents, it was thought that the Commonwealth government should be contributing more than they were at the time and farmers should be contributing less. Urban respondents felt that industry and farmers should be contributing more than they were at the time and the Queensland government should be contributing less.

Overall, while industry were perceived to be contributing the least at the time of Survey 2, respondents in general thought that farmers should contribute the least amount of the five parties.

However, as the differences were quite small for a question of this nature, by and large the system seemed reasonably equitable to respondents.

1. Using the scale below please rate your level of satisfaction with the various aspects of your life at the moment. *(please write your chosen number from the scale next to each item)*

Scale:

1	2	3	4	5
very dissatisfied	**moderately dissatisfied**	**neither satisfied nor dissatisfied**	**moderately satisfied**	**very satisfied**

Your life in general _____

Your standard of living _____

Your personal health _____

The area where you live _____

The community in which you live _____

Existing community facilities and services _____

2. What do you think are the major advantages of living in the Herbert?

_____

_____

_____

_____

3. Generally, what do you think are some of the key issues facing people in the Herbert?

_____

_____

_____

_____

4. How important are the following issues **(1) to you personally, and (2) to people in the Herbert generally**? *(using the following scale, please write your chosen number/s in the two boxes next to each issue)*

Scale:

1	2	3	4	5
very high importance	**high**	**moderate**	**low**	**very low importance**

	importance to you personally	**importance to people in the Herbert**
Land degradation		
Water quality problems		
Water quantity problems		
Nature conservation issues ..... (eg. loss of wildlife habitat, management of world heritage areas)		

5. Following are a list of issues which **some people** think have an impact on life in the Herbert. In **your opinion**, how much do each of the following impacts **(1) affect you personally**, and **(2)**

affect people in the Herbert generally? *(using the following scale, please write your chosen number/s in the two boxes next to each impact)*

Scale:

1	2	3	4	5		
very high degree	**high**	**moderate**	**low**	**very low degree**	**OR**	**8 not at all**

Possible Impacts	**affects you personally**	**affects people in the Herbert**
High cost of water		
Loss of farm productivity		
Higher production costs		
Poor drinking water quality		
Shortage of irrigation water		
Declining human health		
Loss of independence to make business decisions		
Emotional stress		
Conflicts with other local people		
Higher taxes		
Lower fish numbers		
Loss of access to recreation		
Loss of confidence in government's ability to manage land and water resources		
Loss of environmental uses or benefits (eg. wildlife habitat)		
Loss of scenery		

6. Generally speaking, what **awareness** do you think local people have about land and water issues in the Herbert? *(please circle one number only)*

1	2	3	4	5
very high awareness	**high**	**moderate**	**low**	**very low awareness**

7. How much do you think **local people** are prepared to become involved in land and water issues in the Herbert? *(circle one number only)*

1	2	3	4	5
to a very high degree	**high**	**moderate**	**low**	**very low degree**

8. How much are **you** prepared to become involved in land and water issues in the Herbert? *(circle <u>one</u> number only)*

1	2	3	4	5
to a very high degree	**high**	**moderate**	**low**	**very low degree**

9. Using the scale below please rate how much you agree or disagree with the following statements. *(please write your chosen number from the scale next to each statement)*

<u>Scale:</u>

1	2	3	4	5
strongly disagree	**disagree**	**neither agree nor disagree**	**agree**	**strongly agree**

Managing land and water in the Herbert is difficult because...

problems aren't well understood _____

solutions aren't easy _____

there aren't any problems that need urgent action _____

local people lack the money to spend on solutions _____

government strategies are a waste of time _____

solutions are expensive _____

there are few benefits and many costs _____

local people don't want to spend money on solutions _____

the Herbert River catchment covers a large area _____

it's hard to get around the catchment (eg from top to bottom) _____

people in the Herbert have a wide variety of opinions _____

local people don't trust government programs _____

local people aren't that interested in community-type activities _____

the government doesn't want to spend money on solutions _____

10. Before we contacted you about this study, which of the government strategies in the box below had you heard about and which one did you know most about?

STRATEGY	**HAD YOU HEARD OF THIS?** *(please tick as many boxes as apply)* ↓	**WHICH DID YOU KNOW MOST ABOUT?** *(circle <u>one</u> number only)* ↓
Property Management Planning or "PMP"	☐	1
Landcare	☐	2
Integrated Catchment Management or "ICM"	☐	3

☞ *If you haven't heard of any of these government strategies, please go to question* **12.**

11. When thinking of the government strategy you know most about:
A. how useful has this strategy been to you personally? *(please circle <u>one</u> number only)*

1	2	3	4	5
not at all useful	**not very**	**moderately**	**quite**	**very useful**

B. how effective has the strategy been in dealing with land and water issues in the Herbert? *(circle <u>one</u> number only)*

1	2	3	4	5
very effective	**fairly effective**	**neither effective nor ineffective**	**fairly ineffective**	**very ineffective**

C. how did you come to know of the strategy?

_____

_____

_____

12. Have you heard of a group called the Herbert River Catchment Coordinating Committee?

YES …. 1 VAGUELY …. 2 NO …. 3 ☞ *please go to question* **13**

If YES or VAGUELY, what do you think the main purpose of this group is?

_____

_____

13. Using the scale below, please rate how much you agree or disagree with the following statements. (*Write your chosen number from the scale next to each statement).*

<u>Scale:</u>

1	2	3	4	5	**<u>OR</u>**	8
strongly disagree	**disagree**	**neither agree nor disagree**	**agree**	**strongly agree**		**not applicable**

Governments should work out better ways to fix land and water problems	_____	_____
There are things I can do personally to help improve the environment	_____	_____
It's too hard to think about land and water management issues for an areas as big as the Herbert catchment	_____	_____
I don't usually have the finances available to plan more than a year ahead	_____	_____
I trust that public servants are working in my interest most of the time	_____	_____
I've seen incompetent government activities in this part of the courntry	_____	_____
The local community should take some responsibility for improving the environment	_____	_____
Programs like Integrated Catchment Management interfere with people's Rights to make their own decisions	_____	_____
There are things local community groups can do to help improve the environment	_____	_____
I am sure that our local views will be considered when planning for land and water management in this area	_____	_____
The local environment is no worse off than it was when I first lived here	_____	_____

I would be prepared to assist in local projects such as riverbank stabilisation	_____	_____
Many environmental problems come from the way people manage their properties	_____	_____
I can prevent any land and water problems from occurring on my property	_____	_____
It is likely that I will become involved (or stay involved) with a Landcare or catchment group over the next year or two	_____	_____
I've complete control over what happens to the land and water on this property	_____	_____
It is likely that I will look into ways to improve the environmental condition of my property over the next year or two	_____	_____
I can recall at least 1 government action which has damaged my livelihood	_____	_____
I could personally benefit from being involved in group activities to help manage land and water	_____	_____
Laws should be changed to make landholders more responsible for the consequences of their activities	_____	_____
Some people I know think that local groups are a good way to deal with many land and water management issues	_____	_____

14. Which of the following sources of information help you to **keep informed** about land and water management issues? (*tick as many boxes as apply*)

Neighbours	☐	The Australian newspaper	☐
A government agency (please specify)	☐	Cairns Post	☐
_____		Townsville Bulletin	☐
_____		Telegraph Times	☐
Industry groups (please specify)	☐	Herbert River Express	☐
_____	☐	The Tablelander	☐
_____	☐	Tablelands Advertiser	☐
Community groups	☐	Millstream Times	☐

Personal experience	☐	Government newsletters	☐
The local "grapevine"	☐	The Country Hour (ABC radio)	☐
Public meetings	☐	Landline (ABC television)	☐
Other (please specify)	☐		
_____		None/I don't keep informed	☐
_____		☞ please go to question **19**	

19. In the box above, which two sources of information would you say were the most **reliable** for helping you to make decisions?

1. _____

2. _____

16. Does what you read in newspapers ever change your opinions about land and water management

issues? (*please circle <u>one</u> number only*)

1	2	3	4
often	**occasionally**	**seldom**	**never**

17. Does what you hear on the radio or see on TV ever change your opinions about land and water management issues? (*please circle <u>one</u> number only*)

1	2	3	4
often	**occasionally**	**seldom**	**never**

18. How often do you discuss land and water management issues with your neighbours or others in this general area? (*please circle <u>one</u> number only*)

1	2	3	4
often	**occasionally**	**seldom**	**never**

19. When thinking about your **relationships with local people**, how comfortable are you about living here? (*please circle <u>one</u> number only*)

1	2	3	4	5
not at all comfortable	**not very**	**moderately**	**quite**	**very comfortable**

20. When thinking about how much **interest local people have for your ideas and opinions**, how comfortable are you about living here? (*please circle <u>one</u> number only*)

1	2	3	4	5
not at all comfortable	**not very**	**moderately**	**quite**	**very comfortable**

21. Are you a member of any regional, state or nationally-based groups or associations? (*please circle <u>one</u> number only*)

YES …. 1 **NO …. 2**

22. Are you a member of any local community groups or associations? (*circle <u>one</u> number only*)

YES …. 1 ☞ *please go to question* **25**

or

NO …. 2
↓

23. Generally, what are some of your reasons for not being involved in any community groups?

_____

_____

_____

_____

24. Would you ever consider joining a community group? (*circle <u>one</u> number only*)

YES …. 1 **DON'T KNOW …. 2** **NO …. 2**

↓ ↓

For what reasons would you join? _____

_____

_____

_____

☞ If you answered **NO to question 21** and **NO to question 22**, please go to question **28**

25. Which of the following categories describe *any* of the groups you have some involvement with? (*please tick as many boxes as apply*)

Progress Assoc.	☐	Sporting Group	☐
Rate Payers Assoc.	☐	Hobby/Craft Group	☐
Professional Assoc.	☐	Community Action Group	☐
Charity/Church/Welfare Group	☐	Service Club (eg. Lions, Rotary)	☐
Agriculture-related Organisation	☐	Parents & Friends Assoc.	☐
Landcare, Conservation or similar group	☐	Other/s (*please explain*)	☐
		_____	
		_____	

26. Of the groups you are involved with, please write down the name of the group that is **most important** to you.

- **Important group**_____

27. If you are involved in any groups in the "Landcare, Conservation or similar" category, please write down the name of the group that you are **most involved** with. This may not be the same as the group that is the most important to you.

- **Landcare, Conservation or similar group:**_____

_____

28. Thinking of the local community where you live, please rate how much you agree or disagree with each of the following statements. *(using the scale below, write your chosen number from the scale next to each*

statement)

Scale:

1	2	3	4	5
strongly disagree	**disagree**	**neither agree nor disagree**	**agree**	**strongly agree**

I'm not very interested in local community issues _____

I feel quite comfortable in being a member of this local community _____

The community is capable of getting things done without any outside help _____

I would like to remain living in this area for a long time _____

I have almost no influence over what happens in this community _____

It's very important to me to live in this particular community _____

People in this community generally don't get along with each other _____

I don't really care what others in the community think of my actions _____

Very few of my neighbours know me _____

I often think about local community issues _____

I and many others in this community share similar values _____

I think this community is a good place to live _____

I can recognise many of the people who live in this community _____

I don't have the time to become involved in local community issues _____

OTHER INFORMATION

29. How old are you? _____ **years**

30. What is your gender? *(please circle the number)*

MALE .... 1 **FEMALE 2**

31. Which country were you born in? _____

32. What is your marital status? (*circle the most appropriate number*)

Married/De facto	…. 1	Divorced/Separated	…. 2
Never Married/Single	…. 3	Widowed	…. 4

33. Do you have any family members living in the Herbert area other than those in your household? (*circle <u>one</u> number only*)

YES …. 1 **NO …. 2**

34. What is your main occupation? _____

35. How many years have you had this occupation? _____ **years**

36. How long have you lived in the Herbert area? _____ **years**

37. Is your property near to a river or creek which floods?

YES …. 1 **NO …. 2** **DON'T KNOW …. 3**

38. Thinking about where you live, what is the most important river or creek to you?

_____

39. How often do you use the river or creek near where you live? (eg. for commercial, domestic or recreational purposes) (*please circle <u>one</u> number only*)

1	2	3	4
often	**occasionally**	**seldom**	**never**

40. How often do you go fishing for recreation? (*circle <u>one</u> number only*)

1	2	3	4
often	**occasionally**	**seldom**	**never**

41. Do you own or lease/rent a commercial rural, or rural property greater than 3 hectares (7.5 acres)? *(please circle <u>one</u> number only)*

YES ↓ **OWN .... 1 or LEASE/RENT .... 2** **NO …. 3** ☞ *please go to question* **45**

42. Which one of the following best describes your current use of this property? *(circle <u>one</u> number only)*

Cane farming **.... 1** Grazing **.... 2** Mining **.... 3** Industrial **.... 4**

Other farming **.... 5** *(please specify)*_____

Other **.... 6** *(please specify)*_____

43. What is the size of your property? _____ **hectares** *<u>or</u>* _____ **acres**

44. Have you cleared any new land in the last twelve months?

YES .... 1 ↓ **NO .... 2** ☞ *please go to question* **45**

If YES, how much new land have you cleared? _____ **hectares** *<u>or</u>* _____ **acres**

45. Would you be prepared to answer another shorter questionnaire if needed in a few months time?

YES .... 1 **NO 2**

If YES, please write your name, postal address and phone number in the space provided.

Your Name:

Postal Address:

Phone number:

Thank you very much for your time.

Are there any comments you would like to add?

APPENDIX 2

1998 Questionnaire

CSIRO Australian Research Centre for Water in Society

LAND & WATER MANAGEMENT
ISSUES FOR THE HERBERT RIVER CATCHMENT
SURVEY QUESTIONNAIRE
November 1998

LOCATION:	Upper Catchment	…. 1	Lower Catchment	…. 2
LANDUSE:	Rural	…. 1		
	Urban			
	Herberton	…. 2	Allingham	…. 5
	Mt Garnet	…. 3	Ingham	…. 6
	Ravenshoe	…. 4	Halifax	…. 7
			Lucinda	…. 8
			Taylors Beach	…. 9

1. Using the scale below please rate your level of satisfaction with the various aspects of your life at the moment. *(please write your chosen number from the scale next to each item)*

Scale:

1	2	3	4	5
very dissatisfied	**moderately dissatisfied**	**neither satisfied nor dissatisfied**	**moderately satisfied**	**very satisfied**

Your life in general _____

Your standard of living _____

Your personal health _____

The area where you live _____

The community in which you live _____

Existing community facilities and services _____

2. What do you think are the major advantages of living in the Herbert?

_____

_____

_____

_____

3. Generally, what do you think are some of the key issues facing people in the Herbert?

_____

_____

_____

_____

4. How important are the following issues **(1) to you personally, and (2) to people in the Herbert generally**? *(using the following scale, please write your chosen number/s in the two boxes next to each issue)*

Scale:

1	2	3	4	5
very high importance	**high**	**moderate**	**low**	**very low importance**

	importance to you personally	**importance to people in the Herbert**
Land degradation		
Water quality problems		
Water quantity problems		
Nature conservation issues ..... (eg. loss of wildlife habitat, management of world heritage areas)		
Flooding		

Wetlands.....		
Vegetation on river banks		
Loss of biodiversity (numbers of different species).....		

5. Following are a list of issues which **some people** think have an impact on life in the Herbert. In **your opinion**, how much do each of the following impacts **(1) affect you personally**, and **(2) affect people in the Herbert generally**? *(using the following scale, please write your chosen number/s in the two boxes next to each impact)*

Scale:

1 = **very high degree** **2** = **high** **3** = **moderate** **4** = **low** **5** = **very low degree** **OR** **8** = **not at all**

Possible Impacts	**affects you personally**	**affects people in the Herbert**
Loss of farm productivity		
Higher production costs.....		
Poor drinking water quality		
Emotional stress		
Higher taxes		
Lower fish numbers		
Loss of access to recreation.....		
Loss of confidence in government's ability to manage land and water resources		
Loss of environmental uses or benefits (eg. wildlife habitat).....		

6. Generally speaking, what **awareness** do you think local people have about land and water issues in the Herbert? *(please circle <u>one</u> number only)*

1 **very high awareness** — **2** **high** — **3** **moderate** — **4** **low** — **5** **very low awareness**

7. How much do you think **local people** are prepared to become involved in land and water issues in the Herbert? *(circle <u>one</u> number only)*

1 **to a very high degree** — **2** **high** — **3** **moderate** — **4** **low** — **5** **very low degree**

8. How much are **you** prepared to become involved in land and water issues in the Herbert? *(circle <u>one</u> number only)*

1 **to a very high degree** — **2** **high** — **3** **moderate** — **4** **low** — **5** **very low degree**

9. Using the scale below please rate how much you agree or disagree with the following statements. *(please write your chosen number from the scale next to each statement)*

Scale:

1 — **2** — **3** — **4** — **5**

strongly disagree	disagree	neither agree nor disagree	agree	strongly agree

Managing land and water in the Herbert is difficult because...

problems aren't well understood _____

solutions aren't easy _____

local people lack the money to spend on solutions _____

government strategies are too slow _____

solutions are expensive _____

there are few benefits and many costs _____

local people don't want to spend money on solutions _____

the Herbert River catchment covers a large area _____

local people don't trust government programs _____

local people aren't that interested in community-type activities _____

the government doesn't want to spend money on solutions _____

government departments and other agencies are too slow to react to new issues or problems _____

10. Before we contacted you about this study, which of the government strategies in the box below had you heard about and which one did you know most about?

STRATEGY	**HAD YOU HEARD OF THIS?** *(please tick as many boxes as apply)* ↓	**WHICH DID YOU KNOW MOST ABOUT?** *(circle one number only)* ↓
Property Management Planning or "PMP"	☐	1
Landcare	☐	2
Integrated Catchment Management or "ICM"	☐	3
		N/A

☞ *If you haven't heard of any of these government strategies, please go to question* **12.**

11. When thinking of the government strategy you know most about:
A. how useful has this strategy been to you personally? *(please circle one number only)*

1 not at all useful	2 not very	3 moderately	4 quite	5 very useful

B. how effective has the strategy been in dealing with land and water issues in the Herbert? *(circle one number only)*

1 very effective	2 fairly effective	3 neither effective nor	4 fairly ineffective	5 very ineffective

ineffective

C. how did you come to know of the strategy?

_____

_____

_____

12. Are you aware of any other Government Funded programs on wider environmental matters in the Herbert catchment?

YES …. 1 ↓ **NO …. 2** ☞ *please go to question* **13**

If YES, please write down any comments you have on them.

_____

_____

_____

13. How important is it to you that the following activities are part of Integrated Catchment Management? *(Using the following scale, please write your chosen number next to each issue).* **Then…** please rank the three most important activities to you: 1 is most important.

Scale:

1	**2**	**3**	**4**	**5**
very high importance	**high**	**moderate**	**low**	**very low importance**

	Scale	Rank 1 to 3 ↓
Encourage community action at a catchment level.	_____	_____
Raise the level of local awareness and knowledge of environmental issues on the catchment.	_____	_____
Encourage Local Government to take an active role in environmental management issues.	_____	_____
Encourage coordination of state government programs.	_____	_____
Undertake specific on ground projects with other bodies.	_____	_____
Provide a continuing source of advice to local government on catchment issues.	_____	_____
Encourage research.	_____	_____
Develop solutions for and better understanding of environmental problems in the Herbert catchment.	_____	_____
Encourage discussion between community interest groups		

on environmental issues. _____ _____

Separate ICM programs for the Upper and Lower Herbert catchments. _____ _____

Encourage joint projects between community, industry and state and local government. _____ _____

14. Have you heard of a group called the Herbert River Catchment Coordinating Committee?

YES .... 1 **VAGUELY .... 2** **NO .... 3** ☞ *please go to question* **19**

If YES or VAGUELY, what do you think the main purpose of this group is?

_____

_____

15. Has the group been effective in achieving its goals and purpose?

YES …. 1 **TO SOME EXTENT …. 2** **NO …. 3**

16. Are there any specific things that you know they have done?

Please describe

_____

_____

_____

17. In your opinion, are they progressing quickly enough?

YES …. 1 **TO SOME EXTENT …. 2 NO …. 3**

18. In your opinion, are they heading in the right direction?

YES …. 1 **TO SOME EXTENT …. 2 NO …. 3**

19. Using the scale below please rate how much you agree or disagree with the following statements. *(write your chosen number from the scale next to each statement)*

Scale:

1	**2**	**3**	**4**	**5**	**OR**	**8**
strongly **disagree**	disagree	neither agree **nor disagree**	agree	strongly **agree**	not applicable	

There are things I can do personally to help improve the environment. _____

It's too hard to think about land and water management issues for an area as big as the Herbert catchment. _____

I don't usually have the finances available to plan more than a year ahead. _____

The government needs to give more resources to voluntary groups. _____

Programs like Integrated Catchment Management interfere with people's rights to make their own decisions. _____

There are things local community groups can do to help improve the environment. _____

Catchment management should be paid for and run by the government. _____

The local environment is no worse off than it was when I first lived here. _____

ICM should remain a voluntary activity by community members. _____

I would be prepared to assist in local projects such as riverbank stabilisation. _____

Scale:

1	**2**	**3**	**4**	**5**	**OR**	**8**
strongly **disagree**	disagree	neither agree **nor disagree**	agree	strongly **agree**	not applicable	

Many environmental problems come from the way people manage their properties. _____

It is likely that I will become involved (or stay involved) with a Landcare or catchment group over the next year or two. _____

I could personally benefit from being involved in group activities to help manage land and water. _____

The government expects too much from local communities in catchment management. _____

Laws should be changed to make landholders more responsible for the consequences of their activities. _____

Different government agencies often give conflicting information on land and water management issues. _____

There should be better government incentives for landholders to address environmental issues/problems. _____

There aren't any environmental problems that need urgent action. _____

ICM programs should have legislative backing. _____

The government gives plenty of resources to voluntary groups. _____

20. Over the last 12 months, have you been involved in any local community groups or associations?

YES …. 1 **NO …. 2** ? *please go to question* **22**

If YES, which groups or associations were they?

_____

_____

_____

21. If you were involved in any Landcare, conservation or similar types of group, please write down the name of the group that you were **most involved** with.

_____

_____

22. Thinking of the local community where you live, please rate how much you agree or disagree with each of the following statements. *(using the scale below, write your chosen number from the scale next to each statement)*

Scale:

1	2	3	4	5
strongly disagree	**disagree**	**neither agree nor disagree**	**agree**	**strongly agree**

I'm not very interested in local community issues. _____

I feel quite comfortable in being a member of this local community. _____

I have almost no influence over what happens in this community. _____

It's very important to me to live in this particular community. _____

People in this community generally don't get along with each other. _____

I often think about local community issues. _____

I and many others in this community share similar values. _____

I think this community is a good place to live. _____

I can recognise many of the people who live in this community. _____

I don't have the time to become involved in local community issues. _____

23. Should Local Government **have a role** in Integrated Catchment Management?

YES …. 1 **NO …. 2**

Please give reasons

_____

_____

_____

24. Should Local Government Planning sometimes **take into account** Integrated Catchment Management?

YES …. 1 **NO …. 2**

Please give reasons

_____

_____

_____

25. For every $100 spent on catchment management and landcare,

A. how much of it do you think **IS** being contributed by:
(please write the amount in the space provided)

The Commonwealth Government?		$_____
The Queensland Government?		$_____
Local Government on the Herbert Catchment?		$_____
Industry?		$_____
Individual farmers?		$_____
	TOTAL	**$ 100**

B. how much of it do you think **SHOULD** be contributed by:

The Commonwealth Government?		$_____
The Queensland Government?		$_____
Local Government on the Herbert Catchment?		$_____
Industry?		$_____
Individual farmers?		$_____
	TOTAL	**$ 100**

Please comment on why you have chosen the amounts for part B.

_____

_____

26. Have you visited the Herbert Resource Information Centre in Ingham?

YES …. 1 NO …. 2

27. Have you seen the Herbert River Catchment Atlas?

YES …. 1 NO …. 2

28. Have you seen the Herbert River Catchment Coordinating Committee's Catchment Management Strategy?

YES …. 1 NO …. 2

OTHER INFORMATION

29. Show which category best describes your age. *(please circle one number only)*

Less than 24 years	**…….**	**1**
24 to 39 years	**…….**	**2**
40 to 55 years	**…….**	**3**
56 to 65 years	**…….**	**4**
66 to 75 years	**…….**	**5**
More than 75 years	**…….**	**6**

30. What is your gender? *(please circle the number)*

MALE .... 1 FEMALE 2

31. What is your main occupation? _____

32. How many years have you had this occupation? _____ **years**

33. How long have you lived in the Herbert area? _____ **years**

34. How often do you go fishing for recreation? *(circle <u>one</u> number only)*

1	2	3	4
often	**occasionally**	**seldom**	**never**

35. Do you own or lease/rent a commercial rural, or rural property greater than 3 hectares (7.5 acres)? *(please circle <u>one</u> number only)*

YES: OWN .... 1 or LEASE/RENT 2

NO .... 3 ☞ *if you have any further comments, please use the back page.*

36. Which one of the following <u>best</u> describes your <u>current</u> use of this property? *(circle <u>one</u> number only)*

Cane farming **.... 1** Grazing **.... 2** Mining **.... 3** Industrial **.... 4**

Other farming **.... 5** *(please specify)*_____

Other **.... 6** *(please specify)*_____

37. What is the size of your property? _____ **hectares** *or* _____ **acres**

38. Have you cleared any new land in the last twelve months?

YES .... 1 **NO 2**

If YES, how much new land have you cleared? _____ **hectares** *or* _____ **acres**

Thank you very much for your time. Please use the back page for any additional comments.

APPENDIX 3

Newspaper Notice

Herbert River Catchment Management

CSIRO

CSIRO will be contacting people in the Herbert River Catchment early in November to ask if they will be involved in a survey about their views on land and water management.

This is a follow-up to a survey conducted in 1996. About 800 people were contacted and over 700 agreed to take part with a high percentage then responding. The results were very helpful in guiding understanding of community concerns. CSIRO would like a similar number involved once again.

Many respondents at that time agreed to participate in the future and we again invite their response. This survey will provide an invaluable opportunity to see how things have changed over the past two years and why.

With so many people putting time, effort and money into managing land and water it is very important that we find out what works and what doesn't work.

Community input will help CSIRO to develop more effective methods for catchment management.

For further information contact Jenny Bellamy on (07) 3214 2345.

APPENDIX 4
Information Pamphlet

A STUDY OF INTEGRATED CATCHMENT MANAGEMENT (ICM)

A five-year study in the Herbert River catchment is in its final year. The aim has been to develop methods that lead to more effective catchment management in Australia by trying to better understand just how ICM works.

- ❖ What difference does ICM make to the way people manage their land and water?
- ❖ What arrangements and procedures are necessary to help people with ICM?
- ❖ What sorts of things affect the progress of ICM?
  Are these economic, technical, institutional, or social?

Who is involved?

✓	Industry	eg. sugar, fishing, beef, horticulture, tourism
✓	Community groups	eg. Landcare, ICM, conservation
✓	Researchers	CSIRO, James Cook University, The University of Queensland
✓	Government	State and Local

Why is the study important?

Integrated management of land and water is a very challenging task and one that is of national importance. While many ICM programs are up and running, we don't really know *what works well*.

With so many people putting in so much time, effort and money, we really need to find these things out. This is the first time such a comprehensive and long-term investigation has been undertaken in Australia.

We need your help!

The study team cannot do this alone. For this project to be a success, we are dependent on local community support.

MANAGING LAND & WATER IN THE TROPICS

Appendix 5
Refusal Survey Form

REFUSALS INFORMATION

Questions:

1. What is your main occupation? (*ask for specifics eg. potato farmer*) _____

_____

2. Are you personally affected by any land or water management issues (eg quality or quantity)? (*circle <u>one</u> number*)

YES …. 1 NO …. 2 DON'T KNOW …. 3

What issues are you affected by? _____

_____

_____

3. Do you belong to any local groups or associations? (*circle <u>one</u> number*)

YES .... 1 NO .... 2 ☞ *go to question 4*

What groups do you belong to? _____

_____

_____

4. Have you heard of a group called the Herbert River Catchment Coordinating Committee? (*circle <u>one</u> number*)

YES …. 1 VAGUELY …. 2 NO …. 3

5. How often do you go fishing for recreation? (*read out the options and circle <u>one</u> number*)

1	2	3	4
often	**occasionally**	**seldom**	**never**

6. What is your age? _____ **years**

Thank you very much for your time

To be filled in by interviewer (after the phone call):

- Property List (eg. lower catchment urban) _____
- Phone number _____
- Surname and First Name (or initials) _____
- Address _____
- Gender (*circle or number*) **MALE …. 1 FEMALE …. 2**

APPENDIX 6
Individual Comments

Individual Comments

➔ I would like to introduce myself. Number 195 not a problem, and 'Link' to the people of the district. Thanks for personally signing the cover note, it makes me feel more genuinely involved even though it's a survey as such, and there are no 'correct' answers to the questions. The method of questioning was difficult because of its broadness.

I am not a farmer or grazier of this district, but would like to share some of my feelings about how land and water management doesn't appear to be working. Through my and other landowners (cane farming) friends eyes the big picture does not exist. This is part of the reason why I have not participated in Landcare. 'Tis only a token gesture when plantings are only ? between the creek bank up the slope to the cane headland. Marginal reforestation!

It is time these greedy, tunnel visioned farmers relinquished several headlands to create a living environment abutting a chocked watercourse. A new environment, not short lived weedicide or arrogant approaches are needed to be created immediately if there is any hope.

This addendum did not mean to sound long winded, but with so many issues and people involved I felt I had to voice my opinion. I have worked on and off through my life in the local sugar industry, especially the field sector and have observed the depravation of the environment first hand. It is not healthy, and most people take for granted the water continues to flow to the sea carrying all the pollution which is then not their problem.

People of this district have a very arrogant mindset: "every microbe of pollutant that goes into these waterways will be neutralized when it reaches the great water dump".

The people's ideas need neutralizing.

Anyway, my pen could continue to flow in anger but that doesn't solve the woes of the world, and besides I'm shitty because some company just woodchipped my soap box.

Would like to conclude with a passage that I'd like to share with you. No optimism here just the truth.

'Cree Indian Prophecy'

'Only after the last tree has been cut down,
Only after the last river has been poisoned,
Only after the last fish has been caught
Only then will you find that money cannot be eaten.'

➔ I have partly answered the questions because I feel they are worded to suit you. I am not happy about government putting money towards it because our taxes are too high. I feel you may be trying to stop us from farming in a profitable way as farming is getting harder each year. I feel you may be trying in the future to stop us from farming by taking land from us. We should be able to make a living and support our families.

➔ I have completed the questionnaire the best I can, and find that I need more knowledge than I currently have to do it justice!!

However, I quite enjoyed the challenge, for challenge it was, and it took much longer than the 20 minutes you promised me!

Love to do it again for you in the future – just phone me in advance as usual?

➔ I feel this is a very important issue and shall be trying to gain more knowledge. The map shall be very handy.

➔ Some of the answers to questions aren't always able to be so black and white according to scales.

➔ Dear Madam, I feel I am not what you are looking for to answer your questions so please don't send me any more questionnaires as I will not participate.

➔ There does not seem to be any controls for scrub pulling, in some places instead of leaving islands of timber, the lot is pulled, the greater percent of scrub being pulled is not for farming but for grazing of cattle.

I am against any type of Bradford Scheme or turning water inland, if inland waterways are managed better and land not overstocked then the land would do well.

Have you taken into account the impact of feral animals in catchment areas? Toads, etc. When the toads hit Kakadu in the Northern Territory I think they will do far more damage than any uranium mine.

I do not agree with mining uranium, but groups seem more worried about mines in areas than other causes. I don't think any mine anywhere in the north has ever done anywhere as much damage to the environment as graziers have.

➔ Getting too old to care much about things in general, health not good at present.

➔ Please bear in mind that I am 77 years of age and live alone these past eight years. I own my own home and still drive a car. When I can no longer drive, I will have to leave here for alternative accommodation (not a happy prospect). This is just to alert you to the fact that my answers will be somewhat biased.

➔ I spent much of my time away working. Our nearest neighbour in Silver Valley is 5km away and I do not know them. I pay HSC rates and do not even get a graded road. Where I live on the Dry(?) River there is only intermittent water flow and I keep no animals of any kind nor do I grow anything but endemic native vegetation.

➔ Please bear with me for not answering some questions – as I mentioned when asked if I would partake of this questionnaire that I had just buried my wife of some 48 years and that I was also suffering quite a severe illness myself – however I have done my best in most sections of this survey. Thank you.

➔ Some of the questions I find a little hard to decide about but generally speaking this is as close as I could get.

➔ My son helped me fill in this as I do not know very much about the area as I am a newcomer and an aged pensioner. Thank you.

➔ As I don't live in the Herbert River Catchment Area I found a lot of the questions I shouldn't have been answering but anyway I hope you got some use out of my survey.

➔ I would like to have access to any information that is compiled as in my position as a teacher I feel that it is important to give students a knowledge of their local area and how it is being managed. (Gave contact details for the Catchment Coordinator of HRCCC).

➔ While I deeply respect and hold concerns for the natural environment I feel the most important issue within Integrated Catchment Management is flood mitigation and that was not mentioned in any detail on this questionnaire.

➔ General: I don't really know how much is spent by individual governments. I do know, if we don't do something soon, we will be in big trouble as far as landcare and water management goes. Not for me, but for future generations. In 20-30 years, these things will be critical, especially the water management.

➔ The general community is generally concerned about the environment but not many wish to become involved, although the situation is changing.

➔ 9 metre high dam will be sanctioned by government department for Spring Creek which is a small permanent creek. 80 acres of rainforest also allowed to be cleared for cattle by landholder. Landholders use these methods to decrease tax on successful businesses. Many issues like tax dodges and negative gearing need to be addressed. The land is the foundation of everything we have including our health and wealth, most seem to forget this.

➔ The state and federal government has many initiatives going on in the Hinchinbrook area at the present time. Most of the funding is reliant on local government and industry. A small community only has so much money and time. Some initiatives the government has promised money to but it hasn't been forthcoming and projects have stagnated and people have been left in limbo.

The main problem facing the Hinchinbrook area is the accessible wilderness areas. Every government department wants a say in what happens – many have opposing views. As a result local initiatives cannot get off the ground or are stalled until the cost becomes prohibitive.

➔ It would be good to find out why Hinchinbrook Shire Council allows rubbish to be dumped in wetlands – mangroves, such as that on the main road into Lucinda!.. So much for the Local Landcare Group and Catchment Management.

➔ I am very concerned that the hot (thermal) springs are neglected and polluted and no department including the council take responsibility for its management. It should be recognised as an important natural phenomenon and included in the catchment considerations.
➔ Too many cane assignments have been given in wetlands and marginal country.

➔ I may not be able to help with time and money but I do care about what we are doing to our land and environment.

My main problem here in Herbert is poor water quality and water restrictions. Council's never seem to have enough money put away for next year's budget. My town lacks community pull together. Nobody will move to a town like this if our Council won't even support our local kindergarten. Please note even our small town is plagued with crime of all sorts – young people bored – crime and pregnancy. Ex jail mates – drugs. Murders etc. People come and go but the land hopefully will always be there.

➔ Just a few comments on some issues, my opinion is:

Wetlands, mangroves and river banks on private land should be exempt from rates and not used. The rest of the public should fit the bill. The public in general benefit from all of this. Landholders not wishing to agree should have the land resumed.

You can't blame the landholder for wanting a return from this land to pay for his rates but the cost to the environment from this practice is too great.

Waterways are all chocked up with grass because all the trees along the banks have been cleared, allowing the sun in. Water temperature rises, making it unfit for some species of fish.

I am no 'greenie' but what is going on in the sugar industry with development is a disgrace.

➔ As an individual NOT actively involved in any specific community activity relating to environmental management issues, I feel my opinions regarding the Herbert River area are reasonably objective. I feel, also, that there is a rapidly growing awareness of the issues which will affect the future viability of our community. Cane farmers, particularly the younger ones, are strongly in favour of working towards solutions. It's extremely important to me to monitor my own property for signs of degradation and I wish to see other individuals/local groups doing likewise.

➔ The Herbert assignment committee has allowed cane assignment to be given to individuals to grow cane in totally unsuitable areas such as swamp on wetlands which are being continually drained in some cases with flood lifter pumps and this has led to further problems with water quality and clearing of riparian vegetation on creek banks. A very common practice is to excavate the creek to build up the banks to enable cane to be planted right up to the drain, creek is no longer appropriate.

➔ My husband has a trawler, we rely on the quality of water coming from the river for our livelihood.

➔ All waterways should be deepened and cleaned so that fish etc can live without being entangled in all foreign grasses and weeds that have been introduced for cattle over past years.

Instead of present policy of don't touch sit back and watch the problem grow, blame general farming for problems.

➔ Newspaper article enclosed from the Herbert River Express November 7th 1998

"Fish kill epidemic continues"

The third major fish kill in the Herbert River district this year was discovered in Lagoon Creek, east of Ingham yesterday.

Several hundred dead barramundi and boney brim were found in a section of Lagoon Creek in the Mount Cordelia area by a local farmer.

Many of the dead fish, mostly juveniles, were banked together on the water's edge in a 10m stretch of the creek.

It is the latest in a series of significant kills in North Queensland and follows fish deaths in local waterways Cattle Creek and Palm Creek.

Officers from the Ingham and Townsville Department of Environment and Heritage inspected the site yesterday.

Cane farmers Allan Regazzoli discovered the dead fish during a routine tour of his Cook's Land property.

"I could smell the fish, but I didn't know what the smell was until I rode around to the creek", he said.

In the wake of the Cattle Creek kill in October, a forum will soon be held in Ingham or Townsville to investigate the reasons for a spate of kills in the region.

The latest one co-incided with heavy rainfalls in the Herbert River district.

North Queensland Conservation Council coordinator Jeremy Tager has spoken out over the fish kills, saying a report in to the state of fish habitat areas in Queensland was a "damming indictment of government incompetence and industry vandalism".

Mr Tager said the release of the Fisheries Habitat Review by the Federal Government painted a picture of declining habitat areas in the Herbert River district due to intensive farming.

"It's about time these practices were stopped," Mr Tager said.

"The release of this report by the Commonwealth Government and the recent comments from Queensland Environment Minister Rod Welford regarding cane practices gives cause for hope that finally something will be done".

Mr Welford this week called for the sugarcane industry to clean up land use practices to prevent further fish kills.

Canegrowers general manager Ian Ballantyne said growers were dedicated to more sustainable farm practices and had been cleared of blame for a recent fish kill in Mackay.

➔ The Herbert River is nothing short of a poisonous drain. My guess the arsenic content is very high, old mangrove area drained and swamps in to river has killed all shell fish and small crabs in river except the last quarter mile to mouth of river.

There are no small crabs (Red claw, Black and purple types) no oysters, no barnacles, no shell fish in sand bars or yabbies in river till you get to channel almost on island side of channel all the above are plentiful.

There are Barra, jacks and cod in the river which are predators, all other types are few and far apart. The river has few bottom feeders it is rare to catch catfish, mullet etc.

➔ In the last year I have noticed some changes. Farmers have been prosecuted for disturbing mangroves. There has been some education about disturbing waterways and creeks and fish kills have been brought to public notice. Each is trying to absolve oneself, some are saying that this is caused by stockpiles of mill mud and some are saying that this is a natural occurrence that has happened for centuries.

Sampling by people from government agencies will probably find that the cause comes from the thousands of tonnes of fertilisers and poisons that are used to grow the cane crop and are spread

on the land each year. At times, I have seen dozens of chemical containers, at the Taylors Beach dump, used for cane production laying openly and these are labelled and marked 'poison'.

When the first rains come these chemicals, applied to farmland, probably wash into creeks and river poisoning the food cycle/chain. Fish kills.

We need government involvement and control in what is sold to these people and they should be educated in the use of poisons. The older generation mostly are illiterate.

Farmers drive past my home on their way to work with 8 or 10 x 20 litre containers of different chemicals and we the townsfolk suffer from wind drift.

On the positive side I have noticed changes in my workplace towards environmental issues and directions have come from higher authority about discharges to waterways and pollution and also changes in local council policy towards waste management and wetlands and wildlife.

➔ Cane farming, contrary to what the cane farmers say, has a big impact on the land. Ploughing fields up to river banks, filling in drain off areas. All contribute to flooding and erosion.

After a big fall of rain the water in the local small waterways is badly contaminated. For instance, Gentle Annie Creek, there the water is almost red, stinks and deposits a coating of slime on the banks. All this kills fish, and packs into carry out to sea and the Barrier Reef. It also kills grass and growth on the banks that help hold the creeks bank together.

➔ In my opinion until get a body to more strictly control the clearing of riverine vegetation and remaining areas of timber in one area we will be like so many third world countries – stuffed! Greed which permeates from the farming community right through to the top government departments is slowly but surely turning this great land of ours into an environmental desert.

➔ I apologise for my late reply to this questionnaire. The past season has been somewhat of a maverick year due to excess rain. There are many problems facing the Herbert River. Stream degradation is occurring throughout the district and addressing these problems should be put in motion as early as possible.

I feel that all sectors of the community and government departments should coordinate a strategy to try to solve the enormous drainage problems that exist in the Herbert District.

➔ It disappoints me to see how in this local area, in the past five years, that large tracts of land which was covered in scrub and bushland are now cleared and planted to sugar cane. Much of this area acted as a soil binding agent, which now that it is cleared is causing massive amounts of soil erosion, which eventually finds its way to the waterways and ultimately our ocean and coral reefs. Along with the loss of scrub I have noticed a dramatic decline in the numbers of wallabies and kangaroos along certain sections of the railway line, between Ingham and Bambaroo. There is also a large amount of laser levelling of cane land which fills in natural drains and waterways again causing soil erosion when the wet season comes and the run off water makes a new path across the land.

➔ I have lived in Ingham since 1965 and was in the 65 flood. I purchased a house in a flood area as I was advised this size of flood occurred only every 20 years – I have hardly missed a year since. These floods appear to be getting more regular and in some areas bigger. I live on the up side of the QGR rail line. Every flood the railway lifts the amount of ballast under the line but never increased the size of culverts on any additional drainage under it. It has now reached the proportion of a dam.

In the early years after the 1967 flood I was forced to lift my house out of flood height and proceeded to petition QGR, the local council and Federal members to do something about the rail line. I was amazed that most locals would not sign a petition – because of personal interests and was advised to give it up by one politician because the cane farmers on the down side of the line didn't want the flood water to come any faster and it would put more flood water over their cane.

In some of your questions you refer to local community. There are local non-cane farmers and local cane farmers – with two totally different aspects on life and attitudes and I don't think you will ever get both factions to agree.

I would be quite happy to live in Ingham if I didn't have the threat of a flood (some times two) every year. If it keeps on like this I will eventually move out. This situation has been caused, I feel, by the filling of all the swamps and drains in the area to grow cane where cane should never be grown.

➔ At this moment we have mill mud which is full of chemicals being dumped anywhere and everywhere because the mill can not cope with so much, but this will eventually wash into our waterways and seep into our local drinking water. Truck loads of mud have been going all day and night all throughout our area. This can not be good so what do we do?

The farmers are laser levelling their land therefore stopping the natural flow of waterway.

➔ I was born in Ingham 1925 and I have farmed in the Herbert all my life. My older brother and I have been keen fishermen all our lives, we used to fish all the way up to Abergowrie, one could fill a bag of fish in a couple of hours.

The tin dredges up top ruined the Herbert River, completely, and also waters from Lucinda and nearby, as the run off goes more out to sea than up the channels. On a trip to the reef, we actually travelled three quarters of the way to North Palm on yellow water before finding blue sea water and it was a sudden drop off from yellow water to blue.

Where were the Greenies, etc, then? We top dressed our bowling green with sand from the river and the clay content ruined our Green.

➔ I consider cane farmers due to lack of control have planted cane much too close to waterways in some cases and have seen cane growing in mangrove swamps. Though it would be costly I feel that all streams should be bonded with flow directed to settling ponds. There should be a minimum distance that separate cultivated area from streams.

The Taylors Beach Progress Association which did start out with good intention has fallen under the influence of a few disruptive people who have been successful in splitting this community apart. I have dissociated from this group. I consider my personal integrity affronted by some of their activities.

➔ 1. I feel there should be greater monitoring of pollution (air and water) at both sugar mills. 2. Filling in of swamp land which affects breeding habitat of fresh water fish. 3. The disposal of toxic waste from industrial sites. 4. Foreshore clearance. 5. Loss of habitat for native animals.

There should be greater education of the public about the land and water (programs, care and destruction) – not by sending out brochures but by television. Television has greater impact.

Yes my husband is a fisherman and yes I am a greenie (whatever that is supposed to mean – a lover of nature) but we both believe in management where industry, tourism and nature can be together. The natural beauty of this area is the main attraction to tourists and the local economy is heavily dependent on the sugar industry.

Management of land and water by the individual/industry and farmers may take a bit more of their time but is worth it in the long term.

➔ A barrage of education of sustainable agriculture and is your neighbour doing the right thing, penalties for those who don't. A farm plan should be part of having a cane assignment, if alterations are made without approval to drainage etc cancellation should be proceeded with.

All this is too much to put on paper by myself but it is all important.

➔ General: This district needs a strong, efficient, fair water management body that is game to tackle all issues. So this district can prosper with unusual vagrancies in the weather.

Drainage Boards run by farmers with government representation are a farce.

➔ The Herbert is a great area. We have enjoyed camping and fishing trips to may different locations along the river. After our wet season the river changes, there's a lot of change. The bed becoming silted, there are many noxious weeds along the banks, but it's still a beautiful river through the dry seasons of which we have had a few, the river has stopped running and is a string of large holes. Although I would not like to see rain forest or rare species of animals flooded, I see a strong argument for some sort of dam. At the moment, the river has a strong flow, all out to sea. There's a lot of potential for farming and industry but without water the country has to rely on seasonal rain which is too big a risk.

➔ Unless farmers are stopped from clearing scrub, filling in waterways, and unsafe chemicals being used with little or no training is the fastest way to kill this beautiful picture that we call home.

The proof that farmers have already destroyed the Herbert is overwhelming, where in the years when my grandfather was young, large boats were used to carry the sugar from as far up the river as Ingham and Hawkins Creek, now you can't drive a punt up the same river without running aground on silt banks caused by erosion of soils from farming areas.

Creeks that were the nurseries of the Barra have been either filled in or redirected they have silted up and turned sour… fish kills are becoming more and more common.

One can only hope it's not all too late.

It is sad that a local sporting shooters club can not get the land the build a rifle range in this district because of so called lead pollution and scrub destruction, when farmers go out of their way to clear land with the government blessing to plant sugar bush.

Money talks loudest.

➔ For 50 odd years I followed the pastoral and farming business. I cut down more than my share of trees and degraded many acres.

In my extended reading on the subject of greenhouse problems I have realised that this behaviour must stop. Sustainable progress with care – yes. Individuals will not voluntarily comply especially if pecuniary interests are at stake.

It is imperative that the three levels of government be shocked into line and be held fully responsible for leading. We are all in this boat together therefore we should all contribute.

The greatest problem in these environmental matters is apathy and ignorance. It is almost like a wall.

The education of our school students should have been started 25 years ago. If it is not too late that is where we should be also concentrating our effort now.

We rely on your youth, vigour and good sense to see the program proceeds.

➔ Over the years all levels of government have made funds available for mitigation and drainage of the district. However the community have been very suspicious of any worked carried out in the river and low lying areas – for fear of being personally affected. Unfortunately very little money has been spent – much to the disappointment of "ICM" and "Rivertrust".

To define benefited areas is almost an impossible task in this community – Hence it hinders major programs to be constructed.

➔ We had a very peaceful existence in this community for thirty years. My husband is an engineer and we lived in Macknade by the flooded Herbert for many years. The Herbert has levee banks along the Macknade side to protect the mill and environs. We still had flood waters to contend with. We now live at Taylors Beach and have a modest retired cottage. The new people at Taylors Beach (mostly from Southern states) we call "Mexicans" are all intent on changing everything, without any thought to the fact that it is only a paradise because we have kept it so. They blame the Government for everything. Enough said. Ta

➔ I'm of the opinion that there are too many government departments with their finger in the pie. Less Government nominees should result in better, faster results. Basic requirements for positions should be (put your money where your mouth is) and that <u>should</u> lead to a better result all round.

My experience has shown that the university trained expert has just about lost all common sense and practical solutions.

➔ Up until the instalment of flood gates on the Herbert River the Halifax area was slightly affected by flood water by major floods only as often as approximately ten yearly. Our elderly neighbours were here for the 1927, 1967 floods and have told us of the heights of the flood water. Since the flood gates we get more water and it rises very fast. Yes it keeps the water out of the township of Ingham nicely but pushes a large volume down to the Lower Herbert end. The promise of levee banks is still a non-event. We have managed to create a levee bank on the river behind our group of homes in Halifax and have seen how well they work. If the Lower Herbert was cleaned out by using dredging to deepen the water river (it is filled up by sand) and using the levee bank system we feel this could ease the volume of flood water in our district.

We would like to hear a much better flood warning system in this area. Trying to get river heights is useless. Most times our phones go down and we <u>can't</u> ring the council number. Radio stations only care what's going on in Townsville and should be forecasting at least as many times as local news is announced.

When it floods our upstairs sink and bathtub have floodwater pushed up into them (we have a high home) we also can't use our toilet. Luckily we undo the bung (plug) in our bathroom pipe to let bath water out, but have had to cut the drainpipe to be able to use the sink. This is why we are a bit more concerned than the everyday person as they don't realise these things.

➔ There is not much 'cultivational' land on the Wild River from its head at Herberton to the junction with the Millstream on Woodleith Station making the start of the Herbert River. From then on there are extensive flats that could be irrigated farms above the junction of Cameron Creek. This would have been a twenty mile long dam right up to the junction of Rudds Creek. Purpose to serve the Herbert River power station which was aborted by the J Peterson Queensland government. Instead the money was spent on coal power station at Collinsville to burn MIM coal. The water from this dam would be better used if sent over the range (Bradfields scheme), to grow such crops as rice, etc. The power eventually will have to be generated from the sun's rays, and coal left for the production of chemicals for future generations. Time Magazine's (22-7-94), account of the plight of the solar powered aeroplane to a height of 400m, stunted for 15 minutes and then landed safely, powered by a 21 square metres of solar panels generation 12KW of power demonstrates the future power source where giant power stations will be built in deserts generating sufficient power by day for day power plus enough Hydrogen from water to be burnt back to the same water for night power.

All vegetation can be grown and mature vegetation can be harvested for man's use, and make way for regrowth instead of being left to die and rot. Big squeals about the felling of trees but nothing said about the mining by a Yank company of our Phosphate deposits in central Queensland for export of phosphate fertiliser. This mineral is very scarce and should be reserved for Australian use. Politicians only think of the dollar in their pocket and the next election and the greenies are too dumb.

➔ Dear Sirs, Mesdames,

I've answered so many of these reports over the years, and still the water goes to waste in this Upper Herbert area. It's a sad state of affairs in a continent the driest in the world and least conservation of water.

Rats and possums etc all gravitate to the dams that farmers etc some how manage to put in to conserve water. In the times of drought (and this Upper Herbert gets those most each year), flood, and disastrous fires. (I've known people to light these deliberately). Little animals get to the nearest water and one time I saw the leaves from drought stricken trees floating on a rather polluted pond on an almost dry river burn on top of the water. I got in and put it out, or it would have gone for miles in a WILDFIRE. UGH! That water stank, but that was about all there was in the Blunder or the Wild River at the time. Of the Herbert had not much more that year. WE NEED THAT WAROORA DAM, for the future, to conserve water and the animals, that can't take drought better than man can.

Yes, I'm old, but have done a lot of living and been very much part of the community in lots of ways. Politics, business, civic, etc. Slowing down now though, but hate to see resources being wasted as they are at the present time.

Inspection tool place first forty eight years ago, with pegs way out in the paddocks, and still it's more and more investigations, and wasted public money as our taxes rise and rise to keep people on the investigation jobs, that any man on the land could talk about easily IF THEY WERE LET. INVESTIGATORS ignore any knowledge the man on the land may have and go their own way without listening to a lifetime of experience. So wrong ideas and impressions get

bruited around and ignorance gets accepted as fact when often the facts are quite another matter. WE NEED AND WANT THAT WAROORA DAM ON THE HERBERT RIVER CATCHMENT AREA, ACROSS THE BLUNDER. This country could be a food growing belt for so many people in the cities and overseas.

➔ The day of the small business is fading fast, they are too vulnerable to every sort of corporate predator. "Divided we fall". It is a natural process which should be taken into account to provide a "soft landing" instead of making the victims of change disposable environmental pollutants. Some of these old pioneering coots still remember Gallipoli in connection with "developing" this country.

Let us accept the one world reality and the efficiency of Big business and exchange ideas and knowledge and level <u>that</u> playing field before we carve up the neighbours resources in the present way.

It would be best for government to research actual environment pressure sources and accept responsibility because <u>that is their job.</u> Giving some top administrators jobs on properties for a full year would be a rich source of information at the most effective level. Policies of all persuasions are most effective with a real basis. The "coal face" workers are expected to be environmentally responsible and on the Internet in futures trading picking the international weather. Our politicians are swearing allegiance to a feudalistic Imperium which observes the letter of the Law of Moses and denies responsibility for the spirit of the Law. Try a day in court, before resorting to adding to legislation. It qualifies more realistically as the "Dead Heart" of Australia than Ayres Rock. The actual freedom of this country's people allows me to say these things, which I appreciate No. 5. By contrast the Indonesian Military are provoking violence and sedition as an excuse for suppression and murder. Australia has a touch of the same disease. Competition policies etc are being used to isolate and separate, forcing large scale business to use Kerry Packer's techniques in defending themselves, at the expense of Australia. That is what seems to be the driver of land degradation to me, world wide. What is needed is true democracy which includes. Although we are legally expected to vote, party selection committees are not democracy and neither is allegiance to the Queen <u>before</u> God or Country. A secure job biases your thinking and distracts your attention, bring back the swaggies as an environmental research tool. I'm nearly serious.

➔ Being a sugar-cane growing district, crop returns are vital. CSR and other big companies such as Coles and Woolworths do NOT leave much finance to benefit Shire. There are too many bureaucrats pushing their own barrow. Shire Council, Canegrower organisations, CSR, millers and community groups contain too many people who only think for themselves. Government ministers (ARE NOT AWARE) of the nitty gritty position that many people who have over 80 years of family work etc to show, are being exploited by bureaucracy is serious exploit. All ministers should be seeking advice of rank and file people who are the backbone of the Herbert. Ministers should bypass elected people and speak to the rank and file person who is the main contributor.

➔ Statement three: "local people lack the money to spend on solutions", rates as 3, neither agree nor disagree:

Local people are a mixture of pensioners, workers and cane farmers and graziers.

The first two groups do not have money to spend on solutions.

Farmers, on the other hand, are mostly extremely affluent – some millionaires – do have money to spend on solutions to problems which they have caused – user pays!!

➔ Creeks rising from heavy rainfall ad requiring the re-location of private water pumps, to avoid inundation – mainly due to siltation of creek beds which do not have an ongoing maintenance by any water authority – I personally need to engage the services of a back-hoe operator at my expense, to clean my creek of silt and water-grass every three years.

➔ Sadly community know very little about Strategies because you have people (so called elected people) who keep most information behind closed doors.

➔ Considerable environmental impact studies were done for the Tully-Millstream Hydro-electric scheme which I believe showed that this quite large scheme would not have as much environmental impact as what most people thought.

➔ The Government is very wise in having nothing to do with the Millstream-Tully power scheme. This proposed white elephant starts with a dam on the Millstream a few miles below Ravenshoe – water channelled for miles to another dam on Blunder Creek through a tunnel 10 miles or so to another dam on Mitcheter Creek. This dam has to be high enough to gravitate water upstream to the Koomboomba Dam then an inclined tunnel down to a new power station in the Tully Gorge. The water from the Blunder dam has to be pumped to the Mitcheter dam.

➔ Hinchinbrook Channel – Money is the root of all evil.

Related to the question on awareness of the HRCCC:
➔ We don't know, because if you take a local problem, they do not want to know of it. They say they are looking at the broader picture.

Related to the question about specific HRCCC activities:
➔ Were effective in planting Palm Creek but only until funds ran out – rather prematurely. Lots of effort and good work but hardly started when they had to stop!

➔ Have read that they are active but have not seen any information on their actions or recommendations.

Related to the question about Local Government planning taking ICM into account:
➔ In answering question 24, I would say there was no input by the Mareeba or Atherton Council in the Mareeba, Dimbulah irrigation scheme, likewise with the Tully Falls, Koombooloomba Hydro-Electric Scheme. I would say there was no consultation with the Herberton Shire Council.

Related to the question about funding of ICM:
➔ The government want$ and need$ primary industry but take little responsibility in the utilisation and care of the same industry – by the same token, they are not totally responsible for the geographical placing of the industry – so costs should be shared fairly evenly.

➔ I have no idea. This is a complex matter: Industry/farmers should pay a levy on productivity/profit. The others to pay a pro rata % stipulated by a variety of factors.

Related to the question about seeing the Catchment Management Strategy:
➔ Have tried to get hold of it but so far it has been unavailable to me and the club I belong to although we have had speakers on the topic. (A copy of the Catchment Management Strategy was sent to this respondent).

Summary of Individual Comments

Participants were invited to include any additional comments at the end of the survey. Of the 401 surveys returned, 53 included extra comments and many covered a number of issues. The main areas were: feedback on the survey (11 comments); apologies (9 comments); the environment (48 comments); government (21 comments); and local issues (27 comments).

Feedback
Feedback on the survey included: this is an important issue; questions were difficult; thanks for personally signing the cover letter; I enjoyed participating; not happy that the government funded this questionnaire; would like to use the results for educational purposes; shall try to gain more knowledge from now on; and I don't want to take part again.

Apologies
A number of people apologised for not filling out questions or for the quality of their answers. The reasons given were due to age (4 respondents); not home a lot; illness; family problems; new to the area; some questions don't apply to me; and it was hard to make decisions on some questions.

Environmental Issues
Environmental issues were commented upon most frequently, these were related to land and water issues (41 comments); land use problems (4 comments); and damage caused by animals and the loss of habitat for local species.

Of the land and water issues mentioned, water quality and clearing of land were the most frequent (10 and 7 respondents respectively). Wetland issues were raised by 5 respondents; flood issues by 4 respondents and stream degradation and erosion by 3 respondents.

Other issues raised were water restrictions and monitoring; a new water scheme; the lack of ongoing maintenance of creek beds; filling in swampland; hot springs; need for a new dam; problems with Spring Creek dam; potential and current problems with land and water management; the Millstream-Tully power scheme; and the comment was made that "land is the foundation of our lives".

Land use issues were also commented upon in some individual comments, such as damage to the area by the use of chemicals; disposal of toxic waste in the area; damage to the area by graziers which was perceived to be greater than damage by mining; and mud problems caused by the mill.

Government
There were 21 comments regarding government issues, such as financial issues (8 comments), government interference (5 comments), community needs (3 comments) and other issues.

Financial issues dominated this area: financial dependence of the community upon the government; lack of money in councils; concentration by government and politicians on

money and elections; greed of the community and government; wastage of tax money by conducting investigations; sharing of costs by all involved in the area; and the fact that little of the funds made available for floods were actually spent in the area.

Government interference and stalling of progress were other issues raised by a number of people: "the government is trying to stop farming and take away land"; "there is too much government

interference"; "the community know little about strategies as you have people who keep most information behind doors"; "there are too many stalled projects"; and "government department conflict sometimes results in projects not going through".

There were also comments on what the community needs from the government – the need for government involvement and control of the use of chemicals in the area and a strong management body.

Other comments concerned activities in the Hinchinbrook area; drainage boards; lack of government consultation of the community; and the lack of commonsense.

Local issues
Comments concerning local issues can be further categorised under community and financial issues (8 comments each), suggestions for the area (8 comments) and other issues.

Community issues raised were the lack of community pull-together; that the community cares but takes no action; the rapidly growing awareness and change in community attitudes; variety of different opinions lack of agreement; everyone blaming everyone else; lack of a big picture vision; and negative attitudes.

Financial issues included: the perception that "money talks loudest"; the cost to the environment due to desired profit; community paying for the wetlands; lack of funding doesn't mean that people don't care; too many tax dodgers; rates not being spent on a graded road; some locals have more money than others to spend on solutions; and big businesses taking over individual businesses.

Suggestions for the area were that individuals should monitor their own environment; we should blame farming; the whole community should coordinate a strategy; greater education of environmental issues is needed; use television; have penalties for those who do the wrong thing; and the necessity of farm plans.

Other comments made were about the Taylors Beach Progress Association; that it is hard to obtain the Catchment Management Strategy; new people coming which changes everything; the HRCCC; the question of future power sources; that it is not too late to fix problems; and that it is a really nice area.

Those who included extra comments covered a wide range of issues of concern to them. While some issues were raised more frequently than others, these were all very important to respondents and therefore no priorities can be assigned to the issues.

ACKNOWLEDGEMENTS

The authors wish to acknowledge the financial support of the Land and Water Resources Research and Development Corporation, which made this research possible.

The authors wish to express their extreme gratitude to all those people with have an interest or who are actively involved in the implementation of Integrated Catchment Management in Queensland and who gave time from their busy schedules to complete interviews or questionnaire survey forms that were fundamental to the success of many project activities. Of special note are the following people and agencies who willingly co-operated and provided valuable assistance to this five-year research project:

- The members of the Herbert River Catchment Coordinating Committee who actively participated and contributed their valuable time, views and knowledge.
- Dave Horsley, CSR Herbert River Mills, who was an invaluable source of information on natural resource management and related activities in the Herbert River catchment, provided substantial advice to the researchers and contributed actively to many of the research activities of this project.
- The Herbert River Catchment Coordinators, Rob Hunt and subsequently Andrew Petroeschevsky, who provided valuable comment and information as well as facilitating interactions with HRCCC members.
- Ray Quabba, Chair of the HRCCC, who gave his time, knowledge, invaluable assistance and encouragement to the researchers over the life of the project.
- Philip Rowland, Mike Merrin and Don Begbie, Department of Natural Resources, Queensland who have actively supported the project since its commencement and provided valuable assistance and access to information to the researchers involved.
- Luis Laredo, CSIRO Tropical Agriculture, Brisbane, who has provided valuable general computing assistance to the researchers involved and contributed actively to database development and management for some key research activities.
- Kathy Mitchell and Leesa Austin, CSIRO Tropical Agriculture Brisbane for invaluable assistance in the preparation of this publication.

1.0 INTRODUCTION

1.1 Evaluation of Integrated Catchment Management in a Wet Tropical Environment

In 1994, the Land and Water Resources Research Development Corporation (LWRRDC) funded research staff at CSIRO Tropical Agriculture (in Brisbane and Townsville), CSIRO Land and Water (in Perth) and the University of Queensland, Department of Geographical Sciences and Planning, to undertake research on Integrated Catchment Management (ICM) processes. The research is a longitudinal study, conducted over five years, focussing on the implementation of ICM in the Herbert River catchment in North Queensland as a case study. The objectives of the research are:

1. To monitor and document the process of implementation of ICM in the Herbert River catchment and identify the social, economic and institutional factors which facilitate or hinder this process.
2. Evaluate key impacts of the implementation of the ICM process in terms of attitude and behaviour changes in the community and changes in the severity or tractability of the resource use conflicts for the catchment.
3. Assess the specific technical and related information needs that are relevant to an effective ICM implementation process in a wet tropical environment.
4. Develop a framework and related methods for evaluating the process of ICM implementation that will facilitate the development of more effective catchment management programs in Australia.

The temporal complexities of catchment management require a longitudinal study. A longitudinal study facilitates an evaluation of processes and the impact of the implementation of these processes over a period of time. A study of this nature is essential if the issues of catchment management are to be understood and appropriate lessons learned. The project acknowledges that, by its nature, a study of ICM requires a multidisciplinary approach. For example, ICM needs to take into account social, economic, institutional and environmental considerations, all of which operate under conditions of uncertainty. Moreover, indicators of progress are not easily defined and difficult to measure. Research in this area has raised more issues than it has resolved.

In responding to the complexities and multidisciplinary nature of ICM, this research has adopted a multidisciplinary approach to an evaluation and draws on areas of expertise including natural resource sciences, social science, land-use planning, economics and media analysis.

An economic evaluation of the ICM organisation in the Herbert River Catchment requires an approach which is expected to provide information to decision-makers about the efficiency of investment. An appropriate approach is expected to provide consistent and reliable evaluations of this organisation and other organisations of this nature.

This study will establish the information that an economic evaluation would be able to provide to decision-makers. It will also identify a number of assumptions that will need to be made to undertake an economic evaluation of ICM and the limitations associated with a study of this nature.

In relation to the overall evaluation of ICM, it is expected that the economic evaluation will provide information that will:

- assist in the identification of factors that foster or constrain an ICM organisation from achieving stated objectives;
- identify potential impacts of ICM;
- assist in assessing the technical needs for effective ICM.

- assist in identifying appropriate indicators to support future evaluations measuring performance and efficiency of ICM organisations.

This is the first report on the economic evaluation of ICM.

1.2 Grounds for this Study

Natural resources in river catchments in Australia are coming under increasing pressure from industrial, urban and agricultural development. Development and redevelopment of land and water resources is directed towards earning the highest financial return from investment. Short-term gain is sometimes placed ahead of long-term ecological sustainability. The condition of Australia's agricultural resource base is cause for particular concern. The Prime Minister's Science and Engineering Council (1995) registered its concern that "the maintenance of productivity and competitiveness has been bought at the price of the condition of the land itself" (p.1). Economics is the study of making choices when resources are scarce, that is, when there are competing and sometimes conflicting uses for resources. The economic problem to be addressed by authorities (which includes community organisations) managing river catchments is how the land and water resources within a catchment are to be managed to best satisfy the criteria for ecological sustainable development (ESD).

Prior to the 1970s resource management would have been interpreted as satisfying the material needs of society, namely food and shelter. In the 1990s resource management encompasses the concept of ESD. ESD recommends the development and management of natural resources to "ensure that it meets the needs of the present without compromising the ability of future generations to meet their own needs (WCED, 1987, p.8). In addition, "the ecological dimensions of policy [need to] be considered at the same time as the economic, trade, energy, agricultural, and other dimensions" (WCED, 1987, p.10).

A number of state governments in Australia have adopted integrated approaches to natural resource management, particularly with regard to the development and management of land and water resources. To assist in the identification and implementation of resource management a number of state governments have established integrated catchment management (ICM) organisations. These organisations are, at least partly, funded by public sector investment. Decision-making in Australia, with regard to public sector investment in a project or program requires an economic evaluation to provide information about the efficiency of resource allocation and investment, such an evaluation includes consideration to the quality of the environment.[1]

Accountability of public expenditure is an increasingly important requirement of agencies that have been allocated public funding and/or have applied for public funding for the provision of a program or a public good. In this regard, the Australian National Audit Office (ANAO) (1997) is particularly critical of the lack of progress of organisations, such as DPIE and Environment Australia which manage funding for programs which aim to encourage ESD principles, towards measuring program outcomes, particularly in relation to performance and financial accountability. This requirement of ICM organisations in Queensland is acknowledged by Rowland and Begbie (1997), from the Department of Natural Resources (DNR), who identify the need for accountability and performance as an area requiring attention. Since 1995, the Liberal party government in Australia has substantially increased funding to natural resource management through the National Heritage Trust (NHT). Curtis and Lockwood (1998) have expressed concern that government has also invested increased sums of public money in natural resource management through NHT on the basis that regional catchment plans are of sufficient quality to ensure investment returns which would satisfy the Department of Treasury (Curtis and

1 Where a program is defined as an aggregation of individual projects (AACM, 1997).

Lockwood, 1998, p.15).

They continue to claim that formal assessments indicating how limited resources should be allocated or of the benefits associated with investment already made, have not been undertaken. (p.15).

The NHT uses cost-sharing principles that enable community and private benefits from specific works to be identified. Applications for funding require that the relative proportion of public and private benefits flowing from projects is demonstrated. In Victoria catchment management committees operate under business plans, employing staff and purchasing services to implement catchment strategies. In short, ICM organisations are developing into well-defined and well organised community structures with greater financial resources for which they are required to be accountable.

For many programs or projects, an element of private investment is required for successful implementation. The level of private investment is necessary information for decision-makers. Firstly, it is an important consideration for establishing the cost sharing arrangements for funding of projects. Secondly, if programs or projects which necessitate private investment are to be undertaken by individuals then information needs to be provided to individuals which indicates the possible return from their investment. In relation to the increasing need for performance and financial accountability, an economic evaluation is required of ICM organisations in Queensland, more specifically, of ICM organisations representing and implementing their interpretation of the Queensland strategy in their own catchments.[2]

1.3 Objectives of this Report

The objective of this report is to identify and describe an appropriate methodology for conducting an economic evaluation of ICM organisations, using the Herbert River Catchment Coordinating Committee (HRCCC) as a case study. The remainder of this paper is organised to complete a number of tasks. Firstly, a review of previous studies which provide economic evaluations of natural resource management programs is undertaken to identify the approach of previous evaluations and to highlight issues which would need to be addressed in this study. The second task reviews a number of economic techniques or tools which might be applied to evaluate programs to establish an appropriate evaluation technique for this study. The choice of technique will largely be determined by the information it can provide to the decision-maker; the data requirements, and; by the ability of the technique to provide consistent and valid outcomes. A number of the problems associated with the application of an appropriate technique to evaluate projects or programs concerning environmental issues are discussed and a methodology described which could go some way towards addressing these problems.

2.0 PREVIOUS APPROACHES TO ECONOMIC EVALUATIONS OF NATURAL RESOURCE MANAGEMENT PROGRAMS

A review of the literature describing economic assessments of programs in Australia that have the objective of managing natural resources suggests that an economic evaluation, where the social costs of undertaking investment in a natural resource management program are compared to the social benefits, has not been undertaken routinely. Curtis, Robertson and Race (1998) suggest that the lack of published studies could be a reflection of evaluator concerns for confidentiality

2 The distinction between ICM and Landcare is made at this point to prevent subsequent confusion. Stallman (1994) distinguishes between them, defining ICM as involving "the community and government working together through various forums to develop and implement strategies for the better management of catchments" (p.28). Landcare, on the other hand, is defined as relating to " groups of local people forming landcare groups or associations. Landcare is the body working to solve those local issues at a local level" (p.28).

and of the potential for the findings to be controversial. Regardless of the reason however, lack of published evaluations has reduced the possibility of transfer of information between project managers about how studies of this nature could be approached and how problems encountered through the studies might be addressed.

Assessments have been undertaken of projects or programs involving consideration to ecological or environmental issues which concentrate on assessing the impact of the project on the financial viability of individual farm units (Greiner, 1994; 1997). Although studies of this nature make an important contribution towards increasing the understanding about the ability of individual farm units to invest in resource management on their own properties, they do not provide information about the net social benefits of public investment in resource management programs.

Identification of appropriate methods to value the environment, for example, Common, Blamey and Norton (1993); Sinden, (1994); Morrison *et al*., (1996) dominate the literature about economic evaluation of the environment. Although these studies are important because they assist in establishing consistent and reliable methods to quantify non-marketed environmental goods and services, how information about the *value* of an environmental good is to be used in an *evaluation* is not necessarily made clear. Cameron (1997) describes a contingent valuation (CV) approach to valuing the water quality in the Hawkesbury-Nepean catchment. Although Cameron does not conduct an economic evaluation of the ICM organisation in the catchment using the information acquired through the CV, he does suggest that such information would be valuable in a CBA or to establish catchment community priorities for resource management. Interestingly, Cameron argues that the information about the value of an environmental good, such as water quality, is not necessarily useful to ICM organisations. He contends that "if it were to be introduced into ICM in a widespread way, there would be pressure from participants to modify the use of CV into a more qualitative and educative role" (p.164). These sentiments are not shared by Curtis and Lockwood (1998) who claim that extended CBAs incorporating "comprehensive valuation studies can … enable explicit representation of all stakeholders" (p.20) and facilitate improved evaluation of investment of public funds. It is very possibly the process of actively involving the catchment community in the decision-making process, by soliciting their opinion, that Curtis and Lockwood find appealing about CV rather than the estimates of willingness to pay.

General appraisals or assessments of ICM programs frequently concentrate on assessing the process rather than the outcomes from the implementation of the process. For example, a study appraising the Lockyer Valley ICM organisation in Queensland (Stone and Assoc., 1995), reviewed and assessed the process rather than the extent to which the organisation had achieved its stated objectives. No attempt was made to evaluate the performance of the organisation in economic terms. Indeed, lack of information about an appropriate set of performance indicators was cited as the reason why this had not, and could not, be undertaken.

Lack of economic analysis of catchment management programs has been identified by AACM (1995) in their report assessing the strengths and weaknesses of current catchment management policies and programs.

> In the activities reviewed there was no use of resource economic analysis to identify priorities and allocate costs and benefits between public and private sectors. Social costs and benefits were rarely identified and almost never used to justify public investment. Very few of the investments in activities reviewed were based on financial analysis of the costs and benefits associated with natural resource management. None of the investments were based on analysis of the economic costs and benefits of resource management. (AACM, 1995, p.6)

As a result therefore, the report concludes that no government agency or community group could justify the investment in their projects in terms of national (economic) benefits.

An evaluation of the National Dryland Salinity Program (VCG Australia, 1997) includes a CBA of the predicted costs and benefits of the program over a period of 60 years. However, the assumptions underlying the identification, measurement and valuation of costs and benefits are not made explicit. In addition, apart from valuing the avoided costs of lost production, no other benefits were identified or discussed. In brief, the CBA is in the form of a financial evaluation where only the financial transactions associated with the implementation of the program are evaluated. For example, downstream impacts on the biological diversity of the river environs are not considered, neither are the financial outlays and economic costs to individuals in the catchment community.

More recently, the Land and Water Resource Research Development Corporation (LWRRDC) commissioned a series of studies which firstly, established guidelines for the selection of appropriate techniques for evaluation of LWRRCD funded research and development projects (AACM, 1997) and second, evaluated a number of projects (ACIL, 1997; Sloane Cook, 1997; Harrison and Tisdell, 1997). Evaluations had the objective of "identifying actual and potential outputs and benefits of projects and where possible to quantify the benefits accruing to users of natural resources and to the Australian Community in general" (ACIL, 1997, p.x). These studies go a considerable way towards addressing the need for economic analysis of research projects. One of the acknowledged limitations of a large proportion of these evaluations is the quantification of non-market benefits.

An evaluation of a project entitled "Developing methods for assessing the effectiveness of whole catchment management" (ACIL, 1997) is of particular interest to the current study. Essentially, the evaluation is of an evaluation project. The purpose of the project is described as facilitating evaluation of whole catchment management (WCM) which will provide recommendations for ongoing evaluations of WCM nationally. Assessment of the project stresses the option value of the information gathered which is estimated to result in a 1 per cent improvement in the control of one specific natural resource problem (dryland salinity). The evaluation of the project is reliant on the assumptions about the potential of WCM to change the salinity situation which relies also on assumptions about the ability of WCM to change the behaviour of land managers. This evaluation acknowledges that identification of *potential* benefits is not a problem, the real problem lies in *realisation* of the benefits. A number of the issues raised in this evaluation, in particular attributing any improved condition in natural resources to a specific project or program and determining the extent to which potential project or program benefits will be realised, will need to be addressed for the current study.

Enters (1998) reviews a number of projects dealing with soil erosion, drawing attention to the issues surrounding economic assessment, including methods of valuation, the time horizon of studies and the choice of discount rate, and drawing some conclusions about how these issues could be addressed. He takes the approach that "strong arguments for soil conservation need to be based on thorough economic assessments of the on- and off-site impacts of soil erosion…to provide the necessary input to environmental decision making" (p.v). In so saying, he contends that CBA is an appropriate technique for evaluations of this nature because it has the capacity to incorporate all of the information about a project and because it provides valuable information to decision-makers. Enters stresses the importance of stating the assumptions underlying a CBA and in particular for identifying, measuring and valuing costs and benefits.

In summary, economic evaluations of projects or programs which have the objective of improving the quality or condition of natural resources have not been undertaken on a routine basis. A review of published economic evaluations indicates that many are in the nature of a financial analysis where the financial returns to the implementing or funding agency are estimated rather than the returns to society as a whole. Problems encountered by analysts undertaking

economic evaluations include measuring environmental improvements and valuing environmental benefits. The next section reviews a number of economic evaluation techniques which are capable of providing valuable information to decision-makers about the economic impact of projects or programs or about the net social benefits of projects or programs.

3.0 ECONOMIC EVALUATION TECHNIQUES

Although there are a number of economic evaluation techniques or models available to project analysts which provide information to assist in decision-making, the choice of technique will ultimately come down to the nature of the information required from the analysis, the data requirements and the robustness of the assumptions underlying the technique.

3.1 Economic Evaluation Approaches

Input-output techniques which measure the economic impact or a project or program on industry sectors in a regional or state economy are appropriate in situations which do not require information about the efficiency of the investment. Input-output techniques estimate the direct and indirect effects on industry sectors of an initial investment in the economy through market transactions (assuming a linear relationship between economic variables). The results from an analysis are conventionally provided in terms of a number of economic indicators, including: employment, gross output, gross income or value-added. Only market transactions are included using this type of impact assessment. The impact of investment on the quality of the environment is not directly measured. Conventionally, qualifying assumptions are made to suggest that environmental impacts require additional work needs to be undertaken. For example, Robinson *et al.* (1994) provides a regional impact assessment of options to expand irrigation infrastructure in the Burdekin River Irrigation Area (BRIA). An important assumption stated up-front in the report was that environmental impacts were not included in the evaluation.

Although there is scope for input-output models to be developed that could provide this information, the data requirements would be substantial and difficult to collect. In addition, the assumption of linearity between economic variables may not reflect the "real world" situation, particularly for environmental impacts.

An advance on input-output analysis is the more complex computer generalised equilibrium model (CGE), for example the ORANI model (Dixon, 1982; IAC, 1987). These models, like the previously discussed input-output models, rely on powerful assumptions about the relationship between variables in the model and suffer from the same uncertainties underlying all models which attempt to reflect the real world. Data requirements for these models are substantial. A CGE model has been developed to measure the impact on industry of taxes to reduce greenhouse gas emissions (McDougall, 1993; Hinchy and Hanslow, 1996). Conventionally, these models are used to measure the impact of a policy change on industry rather than the impact on the environment of a change in resource use or management.

Another evaluation technique which is increasing its scope of applications is a Multiple Objective (or criteria) Decision Support System (MODSS). Although economic considerations are not necessarily central to the MODSS approach to decision-making it does have the capacity to incorporate economic criteria within the evaluation and decision-making process. It is regarded as worthy of consideration to evaluate a project or program which has multiple outcomes, some of which might be of an economic nature. It is particularly appropriate in situations where some outcomes are difficult to value in monetary terms and could be in conflict with other criteria. Examples of MODSS approaches to decision-making are described by Shaw *et al.* (1998); Robinson *et al.*, (1998) and Bellamy *et al.*, (1997). Closely related to MODSS approaches are Lexicographic Goal Programming and Weighted Goal Programming techniques which are

mathematical approaches, using linear programming techniques, to identify a solution when there are multiple criteria to be met (for example McGregor and Dent, 1993).

Although MODSS techniques facilitate the incorporation of qualitative information about project outcomes (including environmental impacts) which is valuable information, they also require subjective assessment of the criteria for project evaluation, the assigning of weights to the criteria and frequently a subjective score for the performance of project options. Reduction in the degree of subjectivity requires detailed information and research which take resources and time to gather. A MODSS provides valuable information to assist decision-making when a choice between projects or programs is required. It does not specifically address environmental impacts or provide estimates of economic returns from the implementation of a project, in addition the scores assigned to the expected performance of project options could be uncertain.

Investment Decision Analysis (IDA) which incorporates probability estimation of outcome into decision-making is an extension of CBA. The real value of this technique is in the results from the simulation of outcomes or actions. The choice of action or alternative is made on the basis of information which reduces the risk associated with a decision. Increasingly, IDA is carried out as a useful adjunct to a CBA and is described as a risk analysis (see for example Brown *et al.,* 1994). For the simulations to be meaningful and reliable considerable data are required. Although this approach addresses the uncertainty surrounding decision-making, on its own, it has limited usefulness.

3.2 Economic Cost-Benefit Analysis

An economic CBA is employed mainly by governments to determine whether or not particular projects or policies will improve a community's welfare and should therefore be supported. A CBA is regarded as a way of systematically organising information to present arguments about whether or not a project or policy should proceed. An economic CBA provides more than an accounting statement or balance sheet of financial transactions associated with a project or program. It provides a consistent and valid procedure for comparing alternative courses of action by reference to the net social benefits they produce (Dept. Finance, 1992).

The term 'net social benefits" refers to the difference between social benefits and social costs. Benefits and costs are "social" as distinct from private or individual in the sense that they are measured irrespective of the people to whom they accrue. In the case of many public sector projects, and particularly those for which there is an environmental component, market prices are not available. In these cases estimates of costs and benefits are made using non-market valuation techniques.

CBA can also play a role in measuring the effectiveness of a project or program. These evaluations look at whether a project or program, which still has some time to mature, is achieving its stated objectives and whether the objectives themselves are still relevant. The project or program outcome that is measured using a CBA is the value that consumers in a competitive market place on goods and services, or would place on goods and services if a competitive market existed. A CBA should address the question "do the expected program outcomes justify the commitment of the proposed level of resources?"

Cost effectiveness analysis (CEA) which is closely related to CBA provides another approach to an economic evaluation of a project or program. This technique is particularly applicable when it is easier to identify benefits than to value them. An evaluation using a CEA offers a priority ranking of projects on the basis of comparative "cost per unit of effectiveness". The analytical requirements of a CEA mean that the chosen measure of effectiveness adequately captures the predominant impact of the project alternatives under consideration. CEA is therefore not

regarded as appropriate when the outcomes of a project and the alternatives to the project have multiple outcomes. The difficulties inherent in identifying and valuing the outcomes from an ICM organisation, such as the HRCCC, might suggest that a CEA would be appropriate. However, data about the possible costs of alternatives to an ICM organisation, including regulations and economic policy instruments are not readily available. In addition, not only are the outcomes from an organisation, such as ICM, which provides a service to the community, not easily measured, but there is not a common indicator of effectiveness of these organisations. Specifically, ICM organisations commonly undertake multiple activities with multiple and sometimes poorly defined outcomes. This discussion is continued in relation to the identification of appropriate sustainability indicators.

CBA provides valuable information to decision-makers. This includes:

- A definition of the scope and objectives of a project or program and alternative options, including policy options, which might be available to government to meet the same objectives.
- Identification and valuation of costs and benefits associated with the implementation of a project, particularly when these costs and benefits are in the nature of externalities and are not marketed. Estimating an economic value for non-market costs and benefits raises policy issues about the appropriateness of non-market valuation techniques to estimate a willingness to pay (WTP) or a willingness to accept compensation (WTA).
- Information about the uncertainty associated with a project or program. By providing decision-makers with information about the nature of the uncertainty and estimating the impact of uncertainty on project worth, a number of policy issues can be highlighted. For example, the speed of implementation of a project or program is likely to impact on project returns. CBA can demonstrate to decision-makers the additional benefits of funding a project early, or, conversely delaying an investment decision until further information can be made available.
- CBA can identify appropriate policies to improve the performance of a project or program. For example, it can identify pricing structures or areas where a subsidy or tax might improve the ability of a project or program to meet its overall objectives.
- CBA can provide information about the distribution of the costs and benefits associated with a project or program. This is important information which is particularly appropriate where cost-sharing decisions are required. Information about the distribution of costs and benefits provided through a CBA may provide information which enables statements to be made about cost-sharing policies but not about equity. Equity implies value judgements about "fairness" which introduces moral judgements about what is fair and these value judgements are beyond the scope of a CBA. The Department of Finance (1991) suggests that CBA should provide decision-makers with information about the distribution of costs and benefits and leave any value judgements about fairness to policy-makers.

An economic evaluation is not merely an accounting statement of a project or program. It provides a source of valuable information to decision-makers about the project or program under review. The limitations associated with CBA are discussed in more detail below. The choice of approach to a natural resource management evaluation and the methodology underlying the application of the evaluation technique will be determined by the information the decision-maker requires and by the data availability surrounding the project or program under review. It is important to stress however, that a consistent approach to evaluation is required if decision-making is to be regarded as reliable and valid.

3.3 Appropriateness of CBA as a Tool to Evaluate ICM

Resource economists traditionally have used CBA to establish the efficiency of investment in a project or program. Laut and Taplin (1989) are sceptical of the appropriateness of CBA to

examine the economic success of catchment management techniques. They claim that it is more appropriate for pre-development proposals than for post-development evaluation. The lack of suitable performance criteria, particularly sustainability indicators, the likely cost of monitoring market surrogates and the lengthy time-scales are cited as mitigating against the successful adoption of CBA as an evaluation technique.

Criticisms of CBA, particularly in its application where environmental issues are involved, include:

(i) Ecosystems are complex and the information about the impact of development is uncertain and could lead to irreversible damage to the ecosystem. How is a change to the ecosystem to be measured? What are the indicators of change? How are the changes to be valued? Does the possibility of damage to the ecosystem mean that an investment decision is delayed until the necessary information is available? This course of action could result in present generations being made worse off to accommodate future generations.

(ii) The valuation of non-market goods and services such as native flora and fauna as well as the landscape poses a problem. Problems which need to be addressed include the method used to estimate values and the reliance that can be placed on estimates. Questions have been raised about the morality of placing money values on the environment.

(iii) The discounting of future costs and benefits raises a number of questions about the appropriate rate. Does discounting violate the rights of future generations? If we do not discount would we be encouraging exploitation of natural resources? How do we set a discount rate that will safeguard the ability of future generations to meet their needs?

All of these problems need to be addressed before an economic evaluation of an ICM organisation can be undertaken. Specifically, what are the appropriate indicators of improved environmental quality? How is an improvement in the ecological sustainability of resource use in the catchment going to be measured? How is an estimate to be made of the value of the improved quality of the environment? What is an appropriate discount rate for future costs and benefits? What is the time frame for the evaluation?

Sustainability Indicators

The Standing Committee on Agriculture (1991) endorsed a definition of sustainable agriculture from which sustainability indicators could be inferred. Sustainable agriculture is defined as the use of farming practices and systems which maintain or enhance:

- The economic viability of agricultural production
- The natural resource base
- Other ecosystems which are influenced by agricultural activities.

The identification of measurable attributes of the ecological sustainability of the economy of a nation, region, catchment or farm unit is explored by Walker and Reuter (1996). They define indicators as "key attributes that give an impression of major trends and condition, and are based on the key components of the whole agro-ecosystem" (p.7). It is proposed that ecological sustainability indicators are "precise and accurate in describing a particular function of the environment and will serve to signal desirable or undesirable changes" (p.7).

More recently, the State of the Environment Advisory Council (SEAC) (1997) and the Australian Local Government Association (ALGA) (1997) have adopted the pressure-state-response model developed by the Organisation for Economic Cooperation and Development (OECD) to propose a set of indicators that reflect priority issues in regional policies, plans and strategies. The pressure-state-response model is based on indicators which represent key elements of more complex systems. It is a model developed to assess or evaluate natural resource management. Pressure indicators are selected as representing human activities that affect the environment;

response indicators represent the human response to a perceived environmental problem; and state indicators register changes in the environment which reflect the impact or pressures and/or the effectiveness of the response. The report by the ALGA has identified data sources of selected indicators and identified gaps in the currently available data. One of the findings from the report states that "there is currently a dearth of reliable baseline data" and that establishment of quantifiable benchmarks or indicators for evaluation of resource management is an important requirement (p.10).

Preparation of the State of the Environment (SoE) reporting (SEAC, 1997) has involved the development of a set of indicators that can be used to assess the condition of natural resources. It is anticipated that these indicators will provide "a good foundation for future development" (p.ES-6).

Since 1991 the Australian Bureau of Statistics (ABS) has made progress towards establishing a set of indicators of the ecological sustainability for agriculture in Australia. Using the report from the Standing Committee on Agriculture and Resource Management (SCARM) (1993), the ABS has produced a report providing data about a set of key indicators which "embody a particular aspect of agriculture, with the attributes being numerical descriptions of individual parameters" (ABS, 1996, p.5). The SCARM (1993) indicators include:

- long-term real net farm income
- land-water quality to sustain production
- managerial skills
- off-site environmental impacts.

More recently (SCARM, 1998), the indicators have been revised to include socio-economic impacts.

These proposed indicators of sustainability embody a number of individual parameters of attributes. For example, long-term real net income could embody parameters such as net farm income, productivity, terms of trade and number and size of agricultural establishments. Compiled over time, it is suggested by SCARM that these parameters could reveal information about the economic and ecological viability of the agricultural sector. Unfortunately, no suggestions are offered about how changes in these indicators, if detected, are to be valued. The SCARM (1998) indicators and descriptive attributes are shown in Table 1.

Table 1. SCARM Indicators of Sustainable Agriculture

Key Indicators	Descriptive Attributes				
Long-term Real net Farm income	Real net farm Income	Total Factor productivity	Farmers' terms of trade	Average real net farm income	Debt servicing ratio
Natural Resource Condition	Nutrient balance: P and K	Soil condition: acidity and sodicity	Rangeland vegetation condition	Agricultural plant species diversity	Water utilisation by vegetation
Managerial Skills	Farmer education level	Extent of participation in Landcare and training	Implementation of sustainable practices		
Off-site Environmental Impacts	Chemical residues in products	Salinity in streams	Dust storm index	Impact of agriculture on native vegetation	
Socio-economic Impacts	Age structure of agricultural workforce	Access to key services			

Source: SCARM ,1998, p.7.

The choice of indicators of sustainability is highly dependent upon subjective assessment of what constitutes ecologically sustainable agriculture and what is unsustainable. SCARM (1998) claims that "these indicators are not comprehensive, but have been chosen for their ability to record the sustainability of agriculture. The attributes used to measure each indicator are those for which reliable and consistent data are available" (p.3).

To measure an improvement in the ecological sustainability of agriculture as a result of the activities of ICM would require a number of indicators of ecological sustainability in a catchment to be established at the outset of implementation of the ICM organisation. Identification of appropriate indicators would need to accommodate spatial and temporal considerations. Measuring the achievements of an ICM organisation is not simply a case of identifying particular attributes for sustainability indicators and measuring a change over time. Evaluation of an ICM organisation using measurable change in sustainability indicators would require the identification of particular issues and for indicators to be identified which would best measure the effectiveness of ICM activities towards addressing the issues. For example, an issue such as river bank erosion would require an ICM organisation to undertake a number of activities, such as encouraging wider riparian zones and stabilisation of the river bank. The outcome of these activities could be improved and/or increased stability in agricultural production along river banks as well as improved water quality. An appropriate indicator in this situation would be the area under riparian vegetation, water quality indicators such as turbidity, as well as improved on-farm production. Attributing or apportioning any change in these indicators to the endeavours of an ICM organisation would be problematic because ICM does not work in isolation from other resource management agencies or organisations.

Although, in the case of the Herbert River catchment, there is considerable information currently available about the condition of the natural resources in the catchment, see for example, Department of Natural Resources (1996) and Johnson and Murray (1997), this information has not been collected as a time series which would demonstrate a change in the condition of the natural resources. As a result, therefore, any change in the condition of natural resources in the catchment would be estimated on an *ad hoc* basis.

Choice of indicator however does not need to be based on specific scientific, economic or social data but rather on what is important for a particular catchment. In relation to the choice of appropriate indicators, Brown (1998) recommends that

> a good indicator is visually arresting, politically significant, and scientifically valid for the use to which it is to be put. It must carry meaning at the individual as well as the social level. Most of all it must fit within a framework familiar to scientist, politician, administrator and conservationist alike. For indicators to speak to decision-makers at local, national or global scales, they must be sensitive to matters of time and social priorities, of place and scales, and in a framework that links social, economic and environmental data.
> (Brown, 1998, p.272)

Performance Indicators

Establishing a common set of performance indicators or criteria to measure the performance of ICM organisations is difficult because the levels of performance of each catchment vary in accordance with the inherent natural resources of catchments, the problems a resource management strategy is required to address as well as the resources available to the catchment organisation (including social, institutional and financial resources).

The ANAO and the Department of Finance (1996) guide for the Australian Public Service suggests monitoring and evaluation of performance of programs or work units. Accountability of agencies relies on performance information which is considered to be a critical tool to assist in

management of programs. Performance is defined as "the carrying out or achievement of a particular purpose, task or function" (ANAO and Dept. of Finance, 1996, p.3). It is suggested that the identification of appropriate performance indicators be developed within a framework which includes the objectives and strategies of the project or program. In addition, early identification of performance indicators is recommended to facilitate on-going monitoring and evaluation of programs.

The Industry Commission (IC) (1997) describes two performance indicators to measure the efficiency and effectiveness of an organisation providing a service to the community.

1. Efficiency describes how well organisations use their resources in producing services – that is, the relationship between the actual and optimal combination of inputs used to produce a given bundle of outputs. This would normally be measured by means of CBA where the opportunity cost of producing the services was estimated.
2. Effectiveness is the degree to which a system achieves its program and policy objectives. It normally encompasses a number of different, desired aspects of a service linked to program outcome objectives. These outcomes can be classified in terms of:
    - Appropriateness;
    - Accessibility; and
    - Quality

Performance refers to the carrying out or achievement of a particular purpose, task or function. For a program organisation, the key components of the program "include the resources used (inputs) what is done (processes) what is produced (outputs) and what impacts are achieved (outcomes)" (ANAO and Dept of Finance, 1996, p.3). Performance information addresses the relationships between these components.

Performance indicators, however, need to be used with care. Evaluation of programs has a tendency to concentrate on performance indicators that are quantifiable which could result in important outcomes of a qualifying nature being overlooked. This situation could arise in relation to an evaluation of ICM. In particular, ICM is defined as a process specifically designed to enhance the participation and cooperation of the community in natural resource management decision-making and implementation. However, the degree to which an ICM organisation successfully meets this objective might be measured only in terms which suggest that the performance of the organisation is indicated by the extent to which it has put projects in place rather than by the extent to which the community are involved in the decision-making. It is for this reason that it is stressed that an economic evaluation, and in particular a CBA, measures the efficiency of the investment in the organisation, it does not measure directly the performance of the organisation in terms of quality of service delivery or the level of involvement of the catchment community in decision-making. An economic evaluation can evaluate only measurable outcomes from the process, it does not evaluate the process itself. Evaluation of the process of ICM, in terms of social, institutional and technical outcomes, is dealt with in other reports resulting from this research project (see Bellamy *et al.,* In Press)

Performance indicators, in particular measurable indicators, have not been identified specifically for ICM organisations. In 1995, a report on the Lockyer Valley ICM (Stone and Assoc., 1995, p.64) recommended that "Performance Indicators be established for all Catchment Coordinating Committees".

Valuing the Costs and Benefits of Environmental Improvement

CBA requires an economic value to be estimated for all costs and benefits associated with a project or program under review. The concept of economic value is broadly defined as associated with anything from which an individual gains satisfaction, and, for which the individual is willing to give up scarce resources. Economic value is comprised of both use as well as non-use benefits.

Use benefits are those explicitly accruing from the physical use of something. For example, production from farming an area of land or recreational fishing from a river or stream. Non-use values refer to the benefits individuals may obtain from a resource without directly consuming or acquiring a service from them. For example, the knowledge that a national park exists, such as Kakadu, attributes an existence value to the park, whilst retaining the option or opportunity to use a resource in the future is an option value. Non-use values encompass existence values, option values and bequest values.

Biodiversity, one of the objectives of ESD policies, is valued because "it satisfies human wants or is biologically important in supporting other species that do" (Harris, 1996, p.159). Valuation poses problems because the basis for valuing natural environmental resources is weak. Specifically, people may be unaware that they may depend upon certain biological resources even where information exists.

Because there are both technical and ethical limitations associated with estimating a monetary value for environmental resources, the Commonwealth of Australia (1995) suggests that monetary valuations should be regarded as bounding values – as orders of magnitude rather than as a precise value.

The net value or net benefit of environmental quality is calculated as:

Net value = benefit – cost

This is equivalent to the willingness to pay or accept compensation less the opportunity cost.

Methods to estimate the willingness to pay/accept and the opportunity cost will vary with the market situation. In competitive markets, the market price is regarded as a direct value for willingness to pay/accept and for estimates of opportunity cost. However, where markets don't exist, or are imperfect, then other data, such as the willingness to pay in surrogate markets, are used. Competitive markets rarely exist for environmental goods and services.

Valuation techniques can be categorised as using observable market data or non-observable market data. Techniques using observable market data derive values from comparisons of costs and revenues in existing markets or from surrogate or related markets. These techniques include Travel Cost and Hedonic pricing. Techniques using non-observable data derive values by survey techniques where markets are simulated and respondents are asked to state their preferences. Examples of these techniques include Contingent Valuation (CV), Conjoint Analysis and Choice Modelling.[3]

Market value approaches include deriving values for environmental goods and services by estimating the effect the change in the quality of the environment could have on productivity or on income. Other approaches include estimating a value for replacing or preserving an environmental asset. All of these approaches use observable revenues and costs and interpret the behaviour of the individual in the market. Attributing the effect of a change in the environment on productivity or income however is difficult because we need to know how much of the change in productivity or income is directly due to a change in the environment. Values for replacement or preservation of an environmental asset could be underestimated because the costs of replacement/preservation would likely be minimal values of benefits expected to be earned.

3 Examples of these studies include the RAC (1990) CV of the Kakadu Conservation Zone in the Northern Territory; Beggs *et al.,* (1981) Conjoint Analysis of electric cars and Morrison et al., (1998) Choice Modelling of an ephemeral wetland in North – West New South Wales.

The use of surrogate or related markets to derive a market value uses actual prices and actual costs from actual market transactions. The surrogate or related market is directly or causally related to the environmental good or service of interest. Typical of these techniques is the travel cost technique used to value recreational benefits of the environment (for example, Willis and Garrod, 1991).

Simulated market approaches are contingent on the successful simulation of a hypothetical market for an environmental good or service. These techniques use survey techniques to directly solicit the stated preferences or willingness to pay or accept bids for the environmental good or service in question. Survey questionnaires are of a specific format. They seek to inform before soliciting a response and collect information from respondents about their socio-economic circumstances to provide a check for consistency of response. Morrison *et al.,* (1996) provide a comprehensive review of these techniques.

It is worthwhile noting a paper by Diamond and Hausman (1994) in which CV estimates of willingness to pay were discussed in relation to their usefulness in CBAs and for estimates of environmental damage where non-use values for environmental goods is required. Their conclusions are somewhat forceful, stating that "current contingent valuation methods should not be used for damage assessment or for benefit cost analysis" (p.63). A problem with adopting CV estimates of willingness to pay to value environmental goods or services is that although project analysts state the assumptions and limitations underlying their estimates, these assumptions are frequently ignored by decision-makers. Decision-makers are notorious for reading only the executive summary of a report and looking for the "bottom-line", the NPV or benefit cost ratio. How the numbers have been arrived at is frequently overlooked.

Queensland Treasury (1992) acknowledges that, in circumstances where prices to directly value benefits are not available, an appropriate technique is the damage cost method. This method is described as attempting to assess the cost of preventing environmental damage or of restoring or replacing natural resources.

The Department of Finance (1991) suggests that one method to overcome a valuation problem when there are no market prices, is to use the opportunity cost concept. It is suggested that this can be used to establish the cost of an activity, thereby identifying a threshold value that beneficiaries must place on the outcome if the program is to be worthwhile. Analysts may then leave it to the political process to resolve whether or not the expected benefits equal or exceed the threshold value.

Another approach suggested by the Department of Finance for valuing publicly supplied services is to value the savings in costs made possible by the program – these could be cost savings as well as avoided cost savings.

The choice of valuation technique or techniques should include consideration towards:

- The suitability of the technique to value a specific environmental impact. This requires that there is knowledge about the nature of the environmental effect. For example, do we require a use value only to be estimated or are there also non-use values involved? This criterion might require a number of techniques to be utilised to capture the full environmental effect.
- The theoretical validity of the technique. This requires consideration towards the reliability of the technique. Are the assumptions about what the technique is valuing and how the technique is implemented valid? For example, if we use surrogate market information, is this market valid?
- The data requirements. This means simply that data is available to employ a specific technique.

To estimate a value for an improvement in the ecological sustainability of natural resources resulting from the activities of an ICM organisation requires values to be estimated for both use and non-use impacts. Specifically, activities such as increasing the areas of remnant rainforest or riparian vegetation along rivers and creeks have a use value in terms of recreational value, an avoided cost associated with avoiding the loss of productive farm land and/or damage or loss of crops, and a non-use value in terms of the biological diversity which might be preserved as a result of maintaining or increasing these areas. There is not an existing market for all of these benefits on which to base an estimated value. Pest and weed control using natural conservation measures provide another example of an activity which can be only partially valued. These activities have a marketable benefit in terms of increased production but a non-use value in terms of preservation of biodiversity.

Other activities undertaken by ICM organisations which have the objective of increasing the awareness of farmers to improve their land management practices, are not readily valued. An estimate of the opportunity cost of providing the service to the community may be the most appropriate approach in these circumstances.

Appropriate Discount Rate

Discounting, or at least choice of an appropriate discount rate, is an important issue for environmental management. A large volume of literature is available that debates the pros and cons of discounting mostly in relation to evaluation of projects for which there could be a significant environmental cost in the future. In these circumstances, a positive discount rate has the effect of reducing the impact of an environmental cost on project outcome. Where long-term environmental damage is acknowledged and estimates of cost included in an analysis, a positive discount rate has the effect of weighting these costs to be less important than the present benefits. The common argument against adopting a lower discount rate in these circumstances is that current generations need not be concerned about the loss or injury caused to future generations, from loss or damage to natural capital, because they will benefit from advances and developments in human-made capital which will enable them to maintain their standard of living.

For the evaluation of organisations, such as ICM, which provide a service to the community, the costs of establishing these organisations are generally incurred early in the life of the program and the benefits are earned later. In these circumstances, a positive discount rate has the effect of reducing the value of benefits. The argument supporting a positive discount rate in these circumstances is similar to that used in the previous case. Specifically, that monies spent on improving the well being of future generations when they will, regardless of such projects, inherit a larger capital stock than current generations, can not be regarded as an efficient use of public monies. The question which needs to be addressed is: what is an appropriate discount rate? Hanley and Spash (1993) contend that choice of discount rate depends on our view of intergenerational equity. Ultimately, the choice of discount rate is a political choice. Government, acting in the interests of society as a whole, and with consideration to intergeneration equity issues, takes responsibility for setting an appropriate discount rate. Queensland Treasury (1997) suggests the appropriate rate for projects of a non-commercial nature to be 6 per cent real with sensitivity testing at 4 per cent and 8 per cent. LWRRDC (1994) concur with this recommendation, suggesting that, because the issue of appropriate discount rates for natural resource projects has not been satisfactorily resolved, the approach recommended is to present the results from an analysis under a number of rates, ranging from 4 per cent to 10 per cent.

Appropriate Time Frame

Closely associated with the choice of an appropriate discount rate is the choice of a time frame over which the estimated costs and benefits associated with a project or program are to be evaluated. Where natural resource impacts are involved, as is the situation for an assessment of ICM organisations, the full effects of the specific project undertaken or of the improved

cooperation and communication process to influence the attitude of the catchment community towards natural resource management, may very likely show no measurable change for 10, 15 or more years into the future. Once a change has become apparent however, it is likely to continue to have a positive impact for some considerable time into the future. If a positive discount rate is applied to the predicted net benefit stream, benefits earned late in the life of a project (and in particular, beyond 20 years) will not impact significantly on the estimated project returns.

Variations in both the time frame and the discount rate can be accommodated in an economic evaluation of an ICM organisation by including them as a part of the sensitivity analysis. Specifically, the results from the analysis can be reported with the life of the organisation estimated at 15, 20, 25 and 30 years with the discount rate set at 4, 6, 8 and 10 per cent.

Despite the apparent problems associated with conducting a CBA of ICM organisations, these problems are not insurmountable. CBA has the capacity to provide valuable information about the extent to which ICM organisations, in this case the Herbert River Catchment Coordinating Committee (HRCCC), has to date been successful in achieving its objectives and the extent to which it is predicted it will meet its objectives in the future. In addition, information can be provided through the CBA about and the possible distribution of costs and benefits amongst the major stakeholder groups.

3.4 CBA Approach to an Evaluation of the HRCCC

After consideration to the previous discussion about economic evaluations of projects and programs that have the objective of improving community awareness about environmental problems by providing research information or undertake activities to improve the quality of natural resources, a CBA approach is considered to be appropriate to evaluate the HRCCC. The limitations of CBA for an evaluation of this nature are acknowledged; in particular establishing suitable indicators of environmental quality and valuing improvements in the condition of natural resources. However, it is expected that by stating the assumptions underlying the analysis the outcomes can provide meaningful information to decision-makers. It is expected that a CBA will provide valuable information about the extent to which the investment in establishing the organisation and implementing the stated strategy has been efficient as well as information about the distribution of the costs and benefits amongst major stakeholder groups.

The ICM organisation in the Herbert River catchment (the HRCCC) was established in the catchment in 1992 with the appointment of a steering committee. The organisation is in its infancy. Since its inception a draft catchment strategy has been produced and a number of activities undertaken with the assistance of funding from DNR, NLP, NHT state government agencies, local industry organisations as well as payment in kind from the people within the catchment community. Funding has not been confined to specific activities but has supported the appointment of a coordinator in the catchment. Funding is on-going and is expected to continue over the life of the organisation.

Many of the benefits which could be expected to result from the activities of the organisation including specific activities undertaken, as well as data collection projects, have been designed to increase community awareness and to establish the state of the natural resource base in the catchment. Realisation of the benefits from these activities involves a change in attitude on the part of the catchment community towards stewardship of the natural resources in the catchment. Any future benefits cannot realistically be expected to become apparent in the catchment until some time into the future.

To evaluate the HRCCC on its economic cost to date and its estimated benefits to date would be misleading because the activities of the organisation are on-going. For the purpose of this

economic evaluation, the estimated economic life of the HRCCC is assumed to be 20 years. The estimated future costs and those benefits which can be identified and valued are estimated over a period of 20 years from 1992 when the HRCCC was officially established as an ICM organisation. It is expected that an economic evaluation conducted over this period will provide a predictive estimate of the net economic worth of the organisation.

Bellamy and Johnson (1997) describe the HRCCC approach to implementation of ICM as being pragmatic and opportunistic motivated by a perceived need to raise the awareness of the organisation in the catchment and to "get runs on the board". This is view is consistent with that of Laut and Taplin (1989) who claim that ICM was in the past and would, in the future, become increasingly *issues-based*. However, it is the "runs on the board" which provide an opportunity to value the costs and benefits of the achievements of the organisation to date. Activities which have been undertaken by the HRCCC to date include:

- Fostering the construction of roosting boxes for owls. This activity had the objective of increasing community awareness that pest management, which would increase sugarcane production, could be achieved without adversely affecting nature conservation.
- Supporting on-farm tree planting of commercial hardwoods and rainforest species on cane fields where the field-design was inferior or access to the field was limited. Again, some financial gain for landholders was suggested.
- Undertaking, with the support of the cane farmer, the removal of exotic grasses from farms to clear drainage channels and improve farm productivity.
- Developing artificial wetlands on-farm to mitigate local drainage problems and improve the productivity of farms.
- Management of riparian vegetation which has, in the past, been cleared for agricultural purposes has been promoted to ensure that further degradation of water courses does not occur and that those areas that have been degraded are rehabilitated.
- Management of acid sulphate soils by increasing farmer awareness of the problems associated with disturbing these areas.
- Establishing revised guidelines for tree clearing and future subdivisions following the redevelopment of the Pomona wetlands.
- Establishing data-base on the condition of mining dams in the Upper Herbert which could adversely affect downstream water-users, natural drainage in the Lower Herbert and the biodiversity of aquatic habitats.
- Working in cooperation with the Herbert River Management Trust to manage the river at Long Pocket to prevent erosion which would put public infrastructure at risk
- Assistance in designing and construction of suitable drainage for a new 1,000 ha caneland development at Wharps Holding.

The costs associated with the establishment and administration of the organisation are mostly identifiable and can be valued in monetary terms (including an estimate of the opportunity cost of voluntary time incurred by committee members and the catchment community). In addition, the costs (to the HRCCC, landowners and the catchment community generally) of undertaking specific activities in the catchment are mostly identifiable, measurable and can be valued. The impact or benefits of the HRCCC, in terms of its effectiveness in facilitating a cooperative approach to sustainable development in the catchment, although measurable in terms of attendance at meetings and hearsay evidence of a change in attitude towards stewardship of the land resulting in changed management practices, is less obvious and does not lend itself readily to measurement and valuation. However, some benefits can be valued, in particular avoided costs and improved on-farm productivity.

The Outcome-Scenario Approach

Due to problems associated with both identifying outcomes *per se* (including an improvement in the condition of natural resources in the catchment) and outcomes which can be regarded as *solely*

attributable to the endeavours of the HRCCC as well as valuing these outcomes in monetary terms, an outcome-scenario approach is required. The evaluation is approached by estimating the present value of the costs associated with the organisation and its activities over a specified period and then presenting the returns from the investment under a number of outcome-scenarios.

The outcome-scenarios target two specific areas of uncertainty, namely:
- the apportionment of apparent benefits to the HRCCC; and,
- temporal issues, in particular how long it takes for the effect of a project to be realised.

The apportionment of apparent benefits to the HRCCC is largely determined by the assumptions underlying the identification of the "do nothing" scenario. Specifically, the "do nothing" scenario is the situation in the catchment with regards to natural resource management and the resultant condition of natural resources in the catchment which would have occurred in the absence of the HRCCC. Because this situation is not clear-cut, and because it is difficult also to identify and measure a change in the condition of natural resources directly resulting from the activities of the HRCCC, a number of scenarios apportioning apparent benefits to the HRCCC has been developed. The scenarios estimate the net return from investment so that 100 per cent, 75 per cent, 50 per cent and 25 per cent of quantifiable benefits are attributed to the HRCCC.

Temporal issues identified as important for the evaluation are primarily concerned with the time lag between when an activity is undertaken and when the benefits are realised. These issues can be accommodated in the CBA by developing a number of scenarios where estimated the benefits are delayed for 5, 10 or 15years. Another temporal issue that would be worthy of investigation through the CBA is that the benefits attributable to the endeavours of the HRCCC might have been forthcoming regardless of the HRCCC. The impact of the HRCCC might well be to bring improvements in the condition of natural resources forward by 5 or 10 years. Again, this situation can be analysed through a scenario analysis.

Sensitivity and Risk Analysis
It is acknowledged that an analysis which predicts future costs and benefits will result in uncertain outcomes. Conventionally, sensitivity and risk analysis are utilised to test the robustness of the results from the CBA. Sensitivity analysis is useful in measuring the effect on estimated outcome of a change in the value of specific uncertain variables in the model and presents the outcomes in terms of NPV or IRR. Sensitivity analysis is commonly employed to estimate the return to investment under a number of discount rates and when the life of a project or program is varied. Risk analysis is somewhat more versatile, allowing the analyst to vary a number of uncertain variables simultaneously and presenting the results in the form of a probability distribution of outcomes for specified confidence levels. Both forms of analysis will be utilised to test the robustness of the outcomes from the CBA of the HRCCC.

4.0 SUMMARY COMMENTS

This report has reviewed previous studies in the literature which have undertaken economic evaluations of projects or programs dealing with natural resource management. In addition, it has reviewed a number of evaluation techniques which might have been appropriate for this study. The objective of these reviews has been to determine what has been done in the past and to identify the problems which have been encountered previously. The findings from these reviews have contributed towards the identification of an appropriate approach towards conducting an economic evaluation of ICM.

The review of previous evaluations of natural resource management projects or programs shows that economic evaluations are not routinely undertaken. In addition, they have not necessarily

addressed the social costs and social benefits arising from the implementation of the project or program. In addition, measuring and valuing a change in the condition of natural resources has been flagged as requiring further work. No consistent methodology has been identified that is purported to address this problem.

The review of evaluation techniques that might be appropriate to undertake an economic evaluation of ICM organisations has determined that CBA offers a consistent framework for evaluation. CBA is capable of providing valuable information to decision-makers about the efficiency of investment in ICM organisations, the distribution of the costs and benefits arising from the activities undertaken by ICM organisations and the uncertainty underlying the evaluation.

A CBA approach has been outlined which addresses the problems associated with measuring and valuing improvements in the condition of natural resources, the choice of discount rate, the project life and the realisation of potential benefits. An outcome-scenario approach is aimed at providing information to the decision-maker under a number of alternative scenarios.

EXECUTIVE SUMMARY

This report provides an economic evaluation of the Integrated Catchment Management (ICM) organisation in the Herbert River catchment, the Herbert River Catchment Coordinating Committee (HRCCC). Although it provides information specifically about the HRCCC, it is indicative of the type of information likely to result from an economic evaluation of organisations of this nature. In addition, it provides an indication of possible problems, including data availability and the limitations of valuation techniques that may be encountered when undertaking an economic evaluation.

The economic structure of the regional economy within which the HRCCC pursues its objectives could influence the type of activities undertaken by the organisation. As well, the financial viability of land and water users in the catchment, specifically farmers, could have at least some impact on the apparent effectiveness of the organisation in meeting its stated objectives.

The economy of the lower catchment is heavily dependent on the sugar industry and the economy of the upper catchment is dependent on the cattle industry. The economic impact of these industries on the regional economy of North Queensland shows that, together, these industries make a significant contribution (both direct and flow-on effects) to gross output and employment in the region. Specifically, in 1995 the contribution to regional output and employment of sugar production in the Herbert River District and the Cattle industry in the upper catchment have been estimated as:

- *Output*: the sugar industry of the lower Herbert River catchment contributed to over $354m of output in the regional economy, including $206m of output from sugar production and a further $148m in flow-on impacts from other industries in the region. The cattle industry in the upper Herbert River catchment contributed $16m in output to the regional economy, including $13m in output from Cattle production and a further $3m in flow-on impacts.
- *Regional employment*: the sugar industry of the lower Herbert River catchment provided employment for over 3,300 people in the Northern statistical division in 1995. Over 1,300 of these people are estimated to be employed directly in the production of sugar with a further 1,936 people employed in industries supporting the sugar industry. The cattle industry in the upper Herbert River catchment is estimated to provide employment for 170 people, which includes 120 people employed directly in cattle production and a further 49 in support industries.

This information suggests that the economic sustainability of these industries, particularly the sugar industry, is important to the regional economy. However, the financial viability of cane farmers in the future is not optimistic. Although the real prices of agriculture have increased steadily over the past 25 years, the rate of increase has not been as rapid as the increase in costs of inputs to production. The possibility of reduced financial viability could result in a reluctance, on the part of farmers, to engage in farm management practices which, though regarded as improving the state of the environment, would not directly improve the financial status of individual framers.

Cost-benefit analysis was adopted to evaluate the HRCCC because this approach has the capacity to provide information about the economic efficiency of investment in the HRCCC as well as the possible distribution of costs and possible benefits associated with the activities undertaken.

The objectives of the HRCCC are caste in general terms that encompass both its role as a coordinator between the catchment community and government agencies as well as its role as a monitor of catchment health. The HRCCC is constrained in undertaking these roles both

financially, in terms of funding to carry out specific activities, as well as institutionally, in terms of its legislative or statutory power to regulate resource management. The achievements of the HRCCC need to be considered in the light of the "without the HRCCC" scenario. This is identified as *ad hoc* programs and projects which are likely to take some time to implement. In short, *all* improvements to the condition of the natural resources in the catchment, cannot realistically be attributed solely to the endeavours of the HRCCC.

It would be expected that, regardless of whether the HRCCC were established in the catchment as a coordinating body, most of the activities undertaken by the HRCCC would have been taken-up by other community or industry support organisations or by government agencies at some time in the future. In addition, attributing outcomes solely to the endeavours of the HRCCC would be an exaggeration of the work of the HRCCC. Specifically, the HRCCC does not work in isolation from community organisations, such as the Native Wildlife organisation or from industry support organisations such as the Bureau of Sugar Experiment Stations (BSES). In brief, the HRCCC has accepted a coordinating role, taking on activities in response to research initiatives undertaken by other organisations.

The present value of the costs associated with the establishment and on-going administration of the HRCCC over a period of 20 years is estimated to be approximately $974,000. The HRCCC has undertaken a number of specific activities in the catchment to meet its stated objectives that offset these costs. These activities have been funded from both the public purse as well as from the catchment community. The findings are summarised in the table below.

It was found that these activities have the potential to significantly improve or preserve the condition of natural resources in the catchment. It was found also that, for the successful implementation of a number of these activities, notably management of riparian vegetation, management of acid sulfate soils and management of wetlands, private property owners would incur considerable financial expense. In addition, all of the potential benefits resulting from investment in these activities were not equitably distributed among farmers incurring the cost and that those who do not contribute to the cost could not realistically be excluded from enjoying the benefits. In an economic climate where the financial viability of farmers is generally deteriorating, the ability, and therefore the willingness, of farmers to invest in improved resource management is considerably reduced. Community-based organisations, which rely on the voluntary cooperation of individual resource managers, may need to take this into consideration to improve the effectiveness of their strategies.

In undertaking the evaluations, a number of simplifying assumptions were required. Assumptions included those concerning the causal relationship between the activities of the HRCCC and potential improvement in the condition of natural resources. Indicators measuring the condition of natural resources need to be identified and monitored in the future to enable substantiation of claims of natural resource improvement.

In conclusion, a number of problems associated with data availability were encountered during the course of this study. These problems include limited data availability to identify the "without project" scenario; on-going data collection to determine any improvements in the condition of the natural resources in the catchment and limited data to enable credible valuation of any deterioration in the condition of the environment as well as valuation of the benefits resulting from improvements in the condition of the environment. In brief, insufficient data was available to establish, measure and value causal relationships between the condition of the natural resources in the catchment and the activities of the ICM organisation.

Table 1. Summary of potential costs and benefits of HRCCC activities.

Issue	HRCCC Activity	Potential Costs of Activity	Potential Benefits
Management of vegetation in riparian areas	· Mapping of riparian vegetation · Raising community awareness of restoration and retention of riparian vegetation · Organising a Community Riparian Forum with guest speakers	*Individual landowners:* · Cost of revegetation/restoration of riparian areas varies with width required along watercourse and extent of revegetation (eg. 40m buffer corridor costs $120K/km) · Opportunity cost of land which varies with cane assignment/farm size (eg. a 4ha riparian area, with 40% normally under cane would incur a net income loss of $4,000 per annum. This would represent 4% per annum of the net income for a farm with 100ha assignment but 10% per annum net income loss for a farm with 40ha assignment)	*Individual landowners:* · Reduced rat damage to cane crop (eg. value of protection of 8ha area of riparian vegetation is $23K per annum) · Avoided cost of baiting control (where applicable) · Reduced damage to cane resulting from aquatic weed inundation · Improved drainage · Stabilisation of river bank leading to reduced risk of cane loss due to stream bank collapse and scouring *Catchment Community:* · Improved water quality downstream · Improved habitat for fish and crustacea leading to reduced fish kills · Improved natural habitat and source of nutrients for riverine plants and wildlife · Aesthetic benefits (eg. Native wildlife habitat)
Preservation of natural habitats	· Owl box program in support of an integrated approach to pest management	*Individual landowners* · Cost of building owl nesting box and hunting perches ($80/box) *Catchment Community:* · Cost of hire of cherry picker of $1500	*Individual landowners* · Reduced rat damage to cane (see above) *Catchment Community:* · Adoption of ecologically sensitive pest control · Aesthetic benefits
Management of drainage	· Lobbying for technical drainage expert extension officer · Fostering of Landcare group to resolve Wharps Sub-division drainage problems	*Catchment Community:* · Cost of drainage reparation works	*Individual landowners* · Reduction in loss of cane production due to poor drainage *Catchment Community:* · Reduction in adverse impacts of inappropriate drainage infrastructure on other land-owners and habitats · Reduced social conflicts and reduction in litigation and transaction costs associated with negotiation over drainage management

Issue	HRCCC Activity	Potential Costs of Activity	Potential Benefits
Management of wetlands	· Raising awareness of ecological importance of retaining natural wetlands on farm · Fostering the development of artificial wetlands on cane farms	*Individual landowners:* · Opportunity cost of land · Construction costs of wetland vary according to size and site of area to be constructed and availability of suitable areas for disposal of soil (eg. Cost of 0.3ha lagoon up to 3m deep range from $15K to $20K) *Catchment Community:* · Contribution to salary and on-costs for DNR extension officer	*Individual landowners:* · Improvement to on-farm drainage · Source of water in dry periods · Aesthetic attraction of habitat etc. *Catchment Community:* · Retention of significant natural habitats on the Herbert floodplain for fish and wildlife · Providing a retention basin for nutrients and sediments in wetland leading to improved water quality downstream · Improve recharge of groundwater · Aesthetic benefits
Management of acid sulfate soils	· Raising farmer awareness of potential problems of acid sulfate soils	*Individual landowners:* · Estimated opportunity cost of land (eg. decision not to convert grazing land to caneland) for area 'at risk' in catchment (approx. 787ha) is approx. $1,772K per annum. *Catchment Community:* · Costs of media releases and distribution of literature to "at risk" farmers	*Individual landowners:* · Avoided costs of loss of cane production (eg. 1% reduction in yield on current caneland in ASS prone areas is approx. $20K per annum) varies with size of area of potential impact *Catchment Community:* · Avoided costs (eg. Avoidance of fish kills and degradation of estuarine habitat)) varies with size of area of potential impact
Strategic river bank protection	· Joint project with Herbert River Improvement Trust at Long Pocket	*Catchment Community:* · Cost of works (eg. bank stablisation using vegetation and rock protection as well as land use changes)	*Individual landowners:* · Avoided costs of loss of cane production *Catchment Community:* · Protection of existing infrastructure (eg. cane railway link to mill and road bridge across river) · Prevention of river bank erosion upstream causing loss of riparian vegetation and adjacent productive cane land · Reduction in siltation downstream
Stabilising relict mining dams in the upper catchment	· Inventory of derelict tin dams in upper catchment to assess risk and prioritise work needed · Fostering of coordinated action between government agencies and landowners	*Individual landowners:* · In-kind contribution of time and earth moving equipment *Catchment Community:* · NLP Project grant of $21K p.a. for dam wall stabilisation	*Individual landowners:* · Improved water supply to property owners *Catchment Community:* · Improved water quality downstream · Avoidance of risk of dam failure

1.0 INTRODUCTION

In 1994, the Land and Water Resources Research Development Corporation (LWRRDC) funded research staff at CSIRO Tropical Agriculture (in Brisbane and Townsville), CSIRO Land and Water (in Perth) and the University of Queensland, Department of Geographical Sciences and Planning, to undertake research on Integrated Catchment Management (ICM) processes[1]. The research is a longitudinal study, conducted over five years, focussing on the implementation of ICM in the Herbert River catchment in North Queensland as a case study (Bellamy *et al* 1999; Bellamy and Johnson 1999). The objectives of the research are:

1. To monitor and document the process of implementation of ICM in the Herbert River catchment and identify the social, economic and institutional factors which facilitate or hinder this process.
2. Evaluate key impacts of the implementation of the ICM process in terms of attitude and behaviour changes in the community and changes in the severity or tractability of the resource use conflicts for the catchment.
3. Assess the specific technical and related information needs that are relevant to an effective ICM implementation process in a wet tropical environment.
4. Develop a framework and related methods for evaluating the process of ICM implementation that will facilitate the development of more effective catchment management programs in Australia.

As part of this research, the economic evaluation of the ICM organisation in the Herbert River Catchment has required an approach which provides information to decision-makers about the efficiency of public sector investment in these organisations and about the possible distribution of identified costs and benefits. Detailed discussion has been provided in a previous report, Robinson, Bellamy and McDonald (1998), establishing the appropriateness of cost-benefit analysis which is argued to provide a consistent and reliable evaluation of this organisation and other organisations of this nature.

This report provides an economic evaluation of the ICM organisation in the Herbert River catchment, the Herbert River Catchment Coordinating Committee (HRCCC). Although it provides information specifically about the HRCCC, it is indicative of the type of information likely to result from an economic evaluation of organisations of this nature. In addition, it provides an indication of possible problems that may be encountered when undertaking an economic evaluation. The information resulting from this economic evaluation contributes to the broader research on ICM in the Herbert River catchment in a number of ways:

- assists in the identification of factors that foster or constrain an ICM organisation from achieving stated objectives;
- identifies potential impacts of ICM; and
- assists in identifying appropriate indicators to support future evaluations measuring performance and efficiency of ICM organisations.

2.0 OUTLINE OF REPORT

Section 3 of this report describes the economic context for the ICM organisation in the Herbert River catchment. It is intended that this information will define the extent of agricultural land use in the catchment and the dependency of the economy of the region on agricultural related activities. This information could provide some basis for considering the extent to which farmers in the catchment have the financial ability to implement improved farm management practices.

Section 4 deals with the initial steps in the CBA process. Specifically, it describes the objectives of ICM and the constraints the HRCCC has encountered in meeting its objectives. In addition, the

[1] LWRRDC R&D Project CTC7: Evaluating integrated catchment management in a wet tropical environment.

"without" ICM scenario for the catchment is considered and alternatives to the HRCCC are discussed. Finally, this section identifies and estimates the components of cost associated with the establishment and on-going administration of the HRCCC.

Section 5 provides a detailed evaluation of a number of the activities undertaken by the HRCCC to implement its stated strategy. The final section makes a number of concluding comments about the evaluation of the HRCCC which are relevant for other organisations of a similar ilk. A number of issues are raised which will need to be addressed by the HRCCC to assist future economic evaluations.

3.0 THE ECONOMIC CONTEXT FOR THE HERBERT RIVER ICM ORGANISATION

For the most part, the Herbert River Catchment is encompassed by two statistical local areas (SLA), namely: the Hinchinbrook Shire (in the Northern statistical division) and the Herberton Shire (in the Far North statistical division). These SLAs are generally referred to as the "lower catchment" and the "upper catchment" respectively. See Figure 1.

The economic structure of the regional economy within which the HRCCC pursues its objectives could influence the type of activities undertaken by the organisation. As well, the economic structure of the regional economy could have at least some impact on the apparent effectiveness of the organisation in meeting its stated objectives. Information is therefore required about the economic structure of the economy of the region and of the sub-region, the Herbert River catchment.

This section firstly provides a broad overview of the economy of the two areas within the catchment, particularly with respect to land-use. Some historical data on employment is provided as a means of highlighting the different economic structure of these areas. Secondly, an economic modelling technique (input-output analysis) is employed to describe the relative contribution of major land-use industries in the catchment to the economy of the region and also to estimate the impact of these industries on the regional economy.

3.1 Overview of the Economy of the Hinchinbrook and Herberton Shires

The Hinchinbrook Shire encompasses a total area of 271,000,000ha. In 1991 it was estimated that there were 608 agricultural establishments occupying a total of 231,000,000ha (ABS, 1992). The Herberton Shire on the other hand encompasses a total area of 953,000,000ha, which is over three times the area of the lower catchment. There are significantly fewer agricultural establishments in the upper catchment (95) occupying a total area of 695,000,000ha (ABS, 1992).

Arable agricultural production in the catchment is dominated by the production of sugar cane in the lower catchment. Johnson and Murray (1997) list forestry, beef cattle and small crops including pineapples, melons and pumpkins as important industries. The major land-use in the lower catchment is sugar cane production, whereas in the upper catchment the major land use is indicated to be cattle production (ABS, 1992).

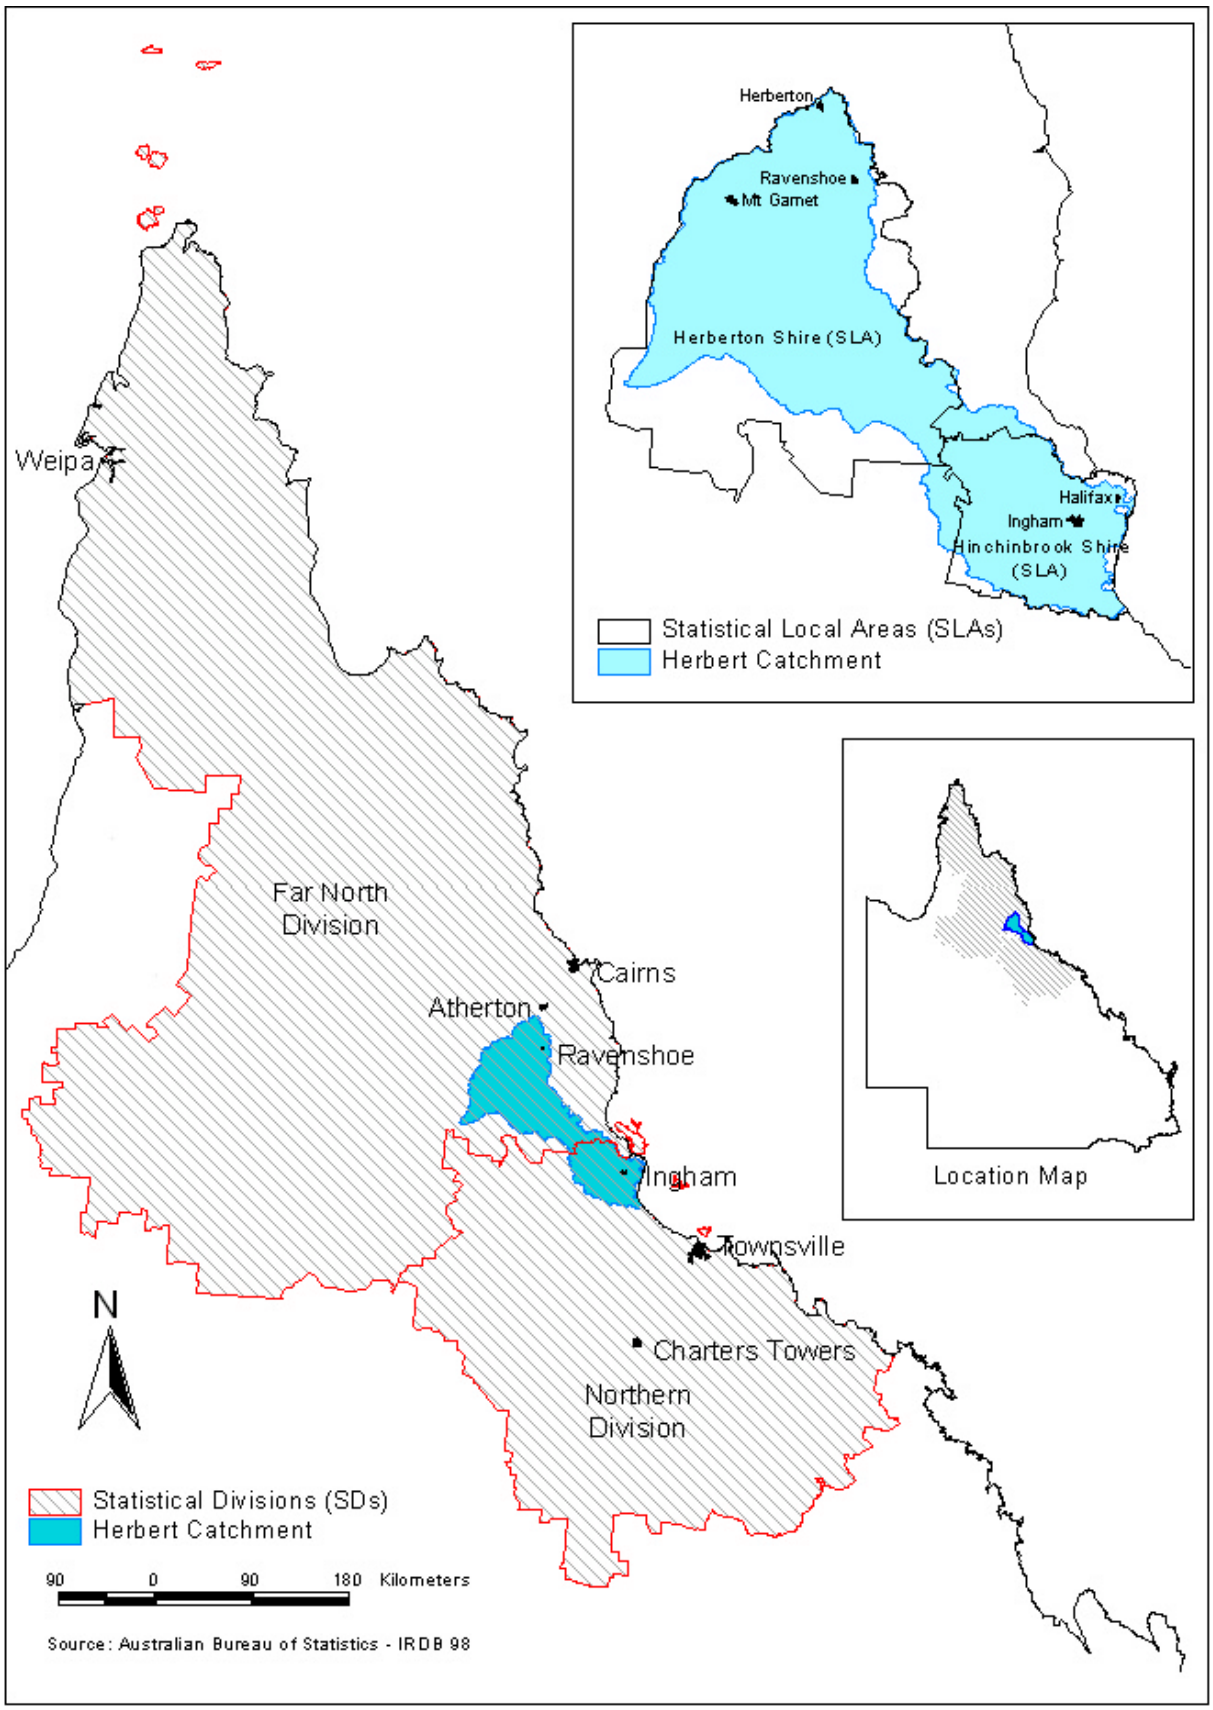

Figure 1. Location map showing the Herbert River catchment boundary and statistical division and statistical local area boundaries.

Table 3.1 provides some summary statistics about land use in the two SLAs.

Table 3.1 Land Use in the Hinchinbrook and Herberton Shires 1991/92

	Hinchinbrook Shire	Herberton Shire
Shire Area ('000 ha)	271,000	953,000
Area under agriculture ('000ha)	231,000	695,000
Number of establishments	608	95
Number of cattle	30,822	66,416
Area under crop (inc. cane) ('000ha)	110,000	17,000

Source: ABS Cat. No. 3235.3 (1992)

The 1996 Population Census (ABS, 1996) estimates the resident population of the Hinchinbrook Shire to be 15,495 people and the Herberton Shire to be 5,253 people. Agricultural establishments are not the sole source of employment in these sub-regional economies. Table 3.2 provides summary statistics about estimated employment at the 1991 population census and for the more recent 1996 population census for the two areas.

Table 3.2 Industry Employment in the Hinchinbrook and Herberton Shires 1991 and 1996 (No. persons)

	Hinchinbrook Shire		Herberton Shire	
Industry Sector*	1990/91	1995/96	1990/91	1995/96
Agriculture, Forestry, Fishing, Hunting	1291	1357	242	257

Community Services	685	1049	236	268
Recreation and Personal Services	245	392	64	120
Other				
TOTAL	5198	6185	1221	1410

Source: ABS, Cat. No. 2015.3 (1991); ABS, Cat. No.2015.3 (1996).
* ABS changed the industry classification from AISIC to ANZSIC between the 1991 Census and the more recent 1996 Census.

Table 3.2 shows that growth in employment is greater in the Hinchinbrook Shire (19 per cent) than in the Herberton Shire (15 per cent). A significant source of the employment growth in the Hinchinbrook Shire is from Community Services which grew by 364 persons (approximately 50 per cent). A significant contribution to the growth in employment in the Herberton Shire over the period was from the Manufacturing sector in which 67 additional people were employed (an increase of approximately 85 per cent).

3.2 Input-Output Approach

Input-Output (I-O) economic analysis offers an approach, which has the capacity to provide valuable information, about a regional or sub-regional economy. In particular, an I-O model of a regional economy provides information about the economic structure of the region in terms of a number of economic indicators such as employment, gross output and exports. In addition, and more importantly, the I-O model provides a detailed analysis of the nature and extent of the economic linkages between industries within the regional economy.

Previous studies which adopted an I-O approach to determine the economic impact or economic

significance of the sugar industry on a regional economy include McGoven *et al.,* (1988) and Robinson *et al.,* (1994). Limitations of the earlier work of McGoven *et al.*, which specifically estimated the impact of the sugar industry in the Herbert district to the economy of the Northern statistical division, include the lack of differentiation between the structure of the sugar industry in the Herbert district with that of the Burdekin district, and that the I-O transaction table used to model the industry was somewhat dated (1978/79). Although technological change in an economy is generally considered to be slow, the sugar industry in Queensland underwent considerable structural change in the early 1980s to improve its technological competitiveness in an increasingly competitive world market. The I-O transaction table adopted by McGoven *et al.* to estimate the impact of the sugar industry on the regional economy pre-dates these changes in the industry. The report by Robinson *et al.* is more recent, utilising an I-O transaction table of the regional economy for 1992. It provides a detailed account of the regional impact of a number of components or economic activities which contribute towards the sugar industry in the Burdekin district. However, the cost structure of the sugar industry in the Burdekin district is considerably different to that of the Herbert where sugar cane is largely grown without irrigation and where the average cane farm is smaller than in the Burdekin. In addition, the information required for this study about the impact of the sugar industry in the Herbert district on the regional economy, does not require the level of disaggregation provided in the Robinson *et al.* study.

This section describes the I-O methodology and provides information about the economic structure of the Northern statistical division and about the economic significance of major land-use industries in the Herbert River catchment on the economy of that region.

3.2.1 The Input-Output Model

The I-O model, in the form of a transactions table or matrix showing industry sector sales (rows) and purchases (columns), provides a detailed picture of the structure of an economy at a particular point of time. It thus provides the foundation for analysis of the contribution of individual sectors to economic indicators such as employment and gross output and of the intersectoral relationships within an economy. The input-output approach uses the intersectoral relationships of industries in the regional economy to assess the impact of an industry on the economy of a region in relation to both direct and flow-on effects. Impact analysis is concerned with measuring the impact or effect of a given stimulus on the economy, which could include specific industries, in this case, major land-users within the Herbert River catchment. The impact of these industries is measured in economic terms including gross output and employment generated in the region.

Industries of Interest.

In the case of the Herbert River catchment, two industries have been identified as the major land-use industries in the Herbert River catchment: the sugar industry in the lower catchment, and the beef cattle industry in the upper catchment.

The sugar industry in the lower catchment is defined, for this study, as including those economic activities which constitute the growing of sugar cane and the milling of the cane to produce raw sugar (94 net titre or 94nt). The growing of sugar cane is conventionally modelled in an I-O transaction table as a part of the sector "Other Agriculture" and the milling of the cane is included in "Food Manufacturing". For the purpose of this study, these two activities have been disaggregated from these sectors and are depicted as a single industry labelled, "HR Sugar". Data available from the Australian Sugar Year Book (1996) and from ABS (1996-97) publications has been used to confirm the structure of the Herbert District sugar industry in the region for inclusion in the existing transaction table.

The beef cattle industry in the upper catchment has been modelled as a separate industry, labelled "HR Cattle". This industry essentially involves extensive grazing with limited pasture

improvement.

Region of Impact
Rather than develop I-O transaction tables for both the Far North statistical division, in which the Herberton Shire or SLA is a sub-region (see Fig. 1), and the Northern statistical division, in which the Hinchinbrook Shire or SLA is a sub-division, only one I-O table has been constructed, that for the Northern statistical division (see Fig. 1). This course of action has been taken because the beef industry in the upper catchment (Herberton Shire) is comparable with the beef industry in parts of the Northern statistical division and the impacts and industry linkages are likely to be similar.

An input-output transaction table for the Northern statistical division, identified as the appropriate statistical division which incorporates the lower catchment, has been constructed by the Urban and Regional Economics Research Unit at the University of Queensland (Robinson *et al.*, 1994). This existing transaction table has been updated to reflect the structure of the regional economy in 1995 using currently available ABS data as well as survey data about specific industry sectors.

Indicators of Economic Impact
It is conventional in impact studies to use a 'standard' list of indicators of economic impact. These include:

- *gross output* levels, referring to the effects of the impacting agent on the output levels of firms and industries in the region,
- *employment* levels, or the effects of employment in the region in terms of full-time employment equivalents.

Table 3.3 shows the estimated contribution by HR Sugar and HR Cattle industries to gross output and employment in the regional economy of North Queensland in 1995.

Table 3.3 shows that the contribution by HR Cattle to output and employment in the regional economy of North Queensland in 1995 is estimated to be relatively small (0.2 per cent in both cases). In contrast to HR Cattle, HR Sugar is estimated to make a contribution to output and employment which is comparable to a number of manufacturing sectors in the regional economy, including Wood and Paper manufacturing, Machinery and Appliances and Non-metal manufacturing.

Table 3.3 Estimated Sectoral Contributions to Regional Output and Employment, Northern Statistical Division, 1995.

Sector	Output		Employment	
	Amount ($000's)	**%**	**Persons (no.)**	**%**

Sectoral Distribution of Impacts

One of the strengths of the input-output approach is the ability to disaggregate the estimated impacts (both direct and flow-on effects) on the region of specific sectors in the region. For example, the total employment in the region generated by the sugar industry in the Herbert District can be disaggregated into the number of jobs generated directly by the industry, and those resulting from flow-on effects. Direct employment includes those persons employed in the growing and milling of sugar cane. The flow-on employment results from the industry support effects generated by the purchase, by the sugar industry, of goods and services from each of the sectors defined in the input-output table. Tables 3.4 and 3.5 show the industrial significance of HR Sugar in terms of output and employment effects respectively. Tables 3.6 and 3.7 show the industrial significance of the HR Cattle industry on output and employment in the regional economy.

Table 3.4 shows the industrial significance, in terms of output effects, of the Herbert District sugar industry in the regional economy of North Queensland in 1995. It shows that the initial or direct impact of the sugar industry on the regional economy is $206m with an additional $148m in flow-on effects. The total output effect on the regional economy is estimated to be $364m. The more significant flow-on effects are estimated to be on the Finance sector ($28m), Trade (which includes both retail and wholesale trade) ($24m) and Other Agriculture ($21m). Flow-on output from the Herbert River sugar industry is estimated to produce an additional 0.719 dollars from other industries (a total multiplier effect of 1.719).

Table 3.5 shows the industrial significance, in terms of employment, of the Herbert River sugar industry on the regional economy of North Queensland in 1995. Specifically, it is estimated that

1,367 people are employed directly in the industry and approximately 1,936 additional people are employed in the regional economy in industries supporting the sugar industry in the Herbert district. It is estimated that total employment generated in the region by the sugar industry is approximately 3,304 people. The employment multiplier (2.417) shows that, for every additional person employed in the industry, a further 1.417 people are employed in other industries in the regional economy.

Table 3.6 shows the industrial significance, in terms of output effects, of the Herbert River Cattle industry in the regional economy of North Queensland in 1995. It shows that the initial impact on the regional economy is estimated to be $13m with an additional $3m in flow-on effects. The contrasts significantly with the estimated impact of HR Sugar (Table 3.4) where both the initial and flow-on effects were substantial.

Table 3.7 shows the industrial significance, in terms of employment, of the Herbert River Cattle industry on the regional economy of North Queensland in 1995. Specifically, it is estimated that 121 people are employed directly in the industry and approximately 49 additional people are employed in the regional economy in industries supporting the cattle industry in the Herbert district. A large percentage of the flow-on employment is expected to be sourced from the trade sector (38.7 per cent).

3.3 Profitability of Farm Business

The previous section estimated the economic impact of the sugar and cattle industries, located in the Herbert River catchment, on the regional economy of North Queensland. Although this information demonstrates that, together, HR Sugar and HR Cattle contribute to the employment of nearly 3,500 people in the Northern statistical division and to over $370m of output, it does not indicate the financial viability of individual farm units in the region. The profitability of a farm business is a key determinant of the ability of that business to undertake farm management practices which are ecologically sustainable. This section considers the overall profitability of farm businesses in Australia and the profitability of the sugar industry in particular. The profitability of a farm business is dependent on a number of factors including: the quantity of output and the value of output. The quantity of output is dependent on the size and the productivity of the business whilst the value of output is dependent on the quality and the marketing of the product.

Wegener (1997) reports that Australian farmers' terms of trade, expressed as a ratio of an index of prices received by farmers to an index of prices paid by farmers for inputs, have declined steadily over the past 25 years. It is suggested that although the real prices for agriculture have increased steadily over the past 25 years, the rate of increase has not been as rapid as the increase in costs of inputs to production. Wegener continues to report that sugar farmers, in particular, have not experienced a significant change in real sugar prices.

In order to improve productivity, many farmers have increased variable inputs such as fertiliser but have experienced diminishing marginal returns. Wegener suggests that a more appropriate response by farmers to falling real product prices is to adopt farm management practices which would put them on a different production frontier. Farm management practices that are identified as appropriate include introducing irrigation and adopting new breeds of cane.

As far as product prices go, however, the action of cane farmers has little or no effect. Growers are restricted to selling their cane to the nearest mill (due to the high correlation between time since harvesting and falling sugar content) and sugar produced in Queensland is marketed through the Queensland Sugar Corporation.

In brief, the financial situation for farmers in Australia, and for cane farmers in particular, is not especially optimistic. This could result in a reduced ability of farmers to undertake on-farm environmental work which might further reduce their capacity to improve their income.

3.4 Summary Comments

This section has provided descriptive comment about the structure of the economy of the Herbert River catchment. It has shown that the economy of the lower catchment is heavily dependent on the sugar industry and the economy of the upper catchment is dependent on the cattle industry. The economic impact of these industries on the regional economy of North Queensland has been estimated showing that, together, these industries make a significant contribution (both direct and flow-on effects) to gross output and employment in the region. This information is valuable to decision-makers. It suggests that the economic sustainability of these industries is important to the regional economy.

Consideration was given also to the financial viability of sugar cane farmers generally. It was suggested that the financial viability of cane farmers in the future is not optimistic. The possibility of reduced financial viability could result in a reluctance, on the part of farmers, to engage in farm management practices which, though regarded as improving the state of the environment, may not directly improve the financial status of individual framers.

4.0 ECONOMIC EVALUATION OF THE ACTIVITIES OF THE HRCCC

An economic CBA is a process. It is a process which organises information to aid decision-making about the efficient allocation of resources. The Department of Finance (1991) suggests a number of steps in the process of conducting a CBA. These are listed below.

- What is the objective of the project or program?
- What are the constraints?
- What are the alternatives?
- Identify the costs and the benefits.
- How can the costs and benefits be valued?
- Are there additional costs and benefits which cannot be quantified?
- Calculate the net benefits.
- Conduct an analysis to deal with risk and uncertainty.
- How are the costs and benefits distributed?
- Present a report on the project.

The remainder of this report is structured to address each step in the process of conducting an economic evaluation of the HRCCC.

4.1 Objectives of the HRCCC

ICM in the Herbert River catchment was initiated in 1992 by key stakeholders in the catchment. In 1996 the HRCCC released a Draft Catchment Management Strategy. The strategy suggests a "community-based approach to solving problems – an approach that integrates the needs of individuals, community groups and industry" (HRCCC, 1996, p.1). The Coordinating Committee has identified its objectives to be:

- Coordinate government agencies and the community to pursue common goals
- Seek community involvement in catchment management
- Reflect the requirements of the wider community within the Catchment
- Identify and rectify natural resource degradation
- Promote ways to prevent and reduce natural resource degradation
- Promote the wise use of all natural resources within the Catchment
- Identify key indicators of biodiversity and monitor as a measure of catchment health
- Encourage the retention of significant natural habitats within the Catchment.

(HRCCC, 1996, p.i)

Although the objectives are couched in terms which suggest an overall policy framework for the catchment, the strategy itself is issues based. Specifically, key management and planning issues are discussed, identifying what needs to be done, who should take responsibility for undertaking the work and how the issue is to be addressed. This suggests that a feasible approach to conducting an economic evaluation of the organisation is to determine and value the extent to which the organisation has addressed its specified objectives.

4.2 Constraints to the HRCCC Activities

The major constraints to ICM which effect its ability to implement resource management initiatives are of a financial and institutional nature (eg. see Bellamy and McDonald 1999).

4.2.1 Financial Constraints

Apart from the catchment coordinator, who has been funded through the federal government's National Landcare Program (NLP) and based in the Department of Natural Resources (DNR), the organisation is staffed and supported, in terms of administrative and office accommodation, by local stakeholder bodies such as the local council and sugar industry bodies. No formal cost-sharing of resource management activities is in place. For the most part, HRCCC activities, including data collection research activities as well as specific projects and programs, are funded by grants from state and federal governments as well as industry support organisations which are awarded through a competitive bidding process. In brief, the HRCCC is financially constrained. The extent and speed with which the organisation can implement its strategy is largely determined by the level of funding it can attract. To a large extent, rather than applying for funding to support itself, the HRCCC has taken the role as coordinator or broker; encouraging and supporting funding applications from organisations including the local council or the HRIT (Bellamy and Johnson In press).

4.2.2 Institutional Constraints

The ICM organisation in Queensland does not have legislative jurisdiction. This means that it does not have the authority to legislate or pass laws to regulate resource use. The organisation is only able to influence the regulation of resource use through an organisation, such as local government, which does have this authority. Alternatively, where regulations are not enforceable, for example on freehold land, the voluntary support of the community may be the only alternative. As a result, implementation of strategies for resource management by individual ICM organisations requires the voluntary cooperation of the community, local government and government agencies.

The problems faced by organisations wishing to influence human behaviour can be described in terms of property rights and norms of good behaviour. Wills (1997) argues that "humans devise rules (more formally, institutions) as constraints on behaviour that reduce conflict and uncertainty in people's dealings with others" (Wills, 1997, p.20). He suggests that these rules include property rights and norms of good behaviour.

Property rights are legally defined and enforced rules that describe what people or firms may do with their property. When property is bought or sold, it is the rights to the property which are bought or sold, not the object itself. In brief, property rights are "enforceable claims to use and to benefit from resources" (Anderson and Hide, 1989, p.7). Norms of good behaviour, on the other hand, are "rules that govern asset use that are informal and not usually actively enforced, but are nevertheless widely observed within a community" (Wills, 1997, p.21). The constraints on the HRCCC can be described as dealing with a failure of the legislature to redefine and enforce property rights which would ensure appropriate management of land and water resources. Because the HRCCC cannot rely on the legislature to introduce and enforce property rights which would be environmentally appropriate, informal and frequently less reliable methods to encourage the adoption of norms of good behaviour have been adopted.

A more recent legislative approach towards promoting ecologically sustainable development in Queensland, the *Integrated Planning Act* (1997), does not specifically identify a role for ICM organisations in the planning and management of natural resources.

4.3 Alternatives to the HRCCC in the Herbert River Catchment

Decision-makers are interested in the apparent achievements of ICM as well as the alternatives and whether an alternative approach might have been more appropriate. This section first defines and describes the "do nothing" alternative and then it considers what other approaches might have been appropriate.

CBA is conducted on the incremental costs and benefits associated with a project or program. This means that only the costs and benefits that are additional to any costs and benefits which might have occurred if the HRCCC had not been established in the catchment are relevant. For this study, the "do nothing" alternative is defined as the situation which would have eventuated in the catchment in relation to natural resource use and management if an ICM organisation had not been established.

It is difficult to describe the "do nothing" scenario in the Herbert River catchment because ICM, and in particular the HRCCC, is not a specific project or program with readily identifiable and measurable outputs. The "do nothing" scenario does not necessarily mean that no research and no resource management projects or programs would have been implemented in the catchment. It is likely that at least some of the work which has been undertaken by the HRCCC would have been carried out by local, state or federal government agencies or by industry support organisations. For example, the Northern District Sugar Industry Production Group (NDSIPG) was formed in 1975 "to plan ways and means of optimising land usage of all Northern District Mill Areas with the objective of exploiting productivity and production" (NDSIPG, 1975). It is an industry based organisation that has provided an opportunity for a coordinated approach to resource management but is primarily focused on local issues (particularly drainage) affecting sugar production. Achievements of the NDSIPG include encouraging the Queensland Government, through the Irrigation and Water Supply Commission, to commission a number of studies which provide an overview of drainage and flood mitigation with respect to the north Queensland sugar industry. That few of the recommendations contained in the reports have been implemented in the Herbert is evidence of the need for a more integrated approach to resource management. To a large extent, this organisation has been superseded by the establishment of the

HRCCC.

ICM organisations, including the HRCCC, do not work in isolation from government agencies, industry support agencies or other ICM organisations researching and working in the area of natural resource management. Much of the research in the catchment for which the HRCCC might claim responsibility may have been undertaken at some time in the future, regardless of the HRCCC. However, it can be argued that resource management in the Herbert River catchment without the HRCCC would have been largely *ad hoc*. Decision-making would very likely have been in the form of top-down direct regulation and policy measures for resource development and management with minimal prior consultation with affected stakeholders. It is likely that this approach would have resulted in significant expenditure on enforcement of regulations and protracted negotiation about appropriate policy. It is likely that funding for research in the catchment would have been initiated by government agencies, including CSIRO, DPI, DNR and the DOE, on a need-to-know basis.

With these comments in mind, how much of a perceived improvement in the condition of natural resources can be attributable to the activities of an ICM organisation such as the HRCCC? ICM organisations are not the sole source of resource management information to farmers, agencies and the community generally. In this regard, the results from a survey of rural and urban residents in the Herbert River Catchment (Butterworth *et al.,* 1997) report that Landline was considered to be the most reliable source of information about the catchment. In addition, it was found that participants in the survey who used Landline as an information source were more likely to agree that their actions could assist in improving the environment and were more likely to agree to become involved or stay involved in a community organisation such as ICM or Landcare.

Community-based organisations such as ICM provide an alternative to top-down direct regulation and to the introduction of economic instruments to control activities which are responsible for negative externalities. Economic instruments include policies or measures that attempt to address environmental problems under the perception that market failure has resulted in an inefficient and inequitable allocation of resources. Economic measures or policies include taxes/subsidies in the form of user charges on activities or inputs which could be harmful to the environment; or, for property rights over externalities to be defined and enforced. Measures which establish property rights over externalities, which can then be traded in a competitive market, include tradeable rights such as pollution or emission permits and tradeable water rights.

There are a number of criticisms of the alternatives to community-based approaches to resource management. One of the major criticisms of property right approaches to controlling externalities is the initial delineation of the polluter and the recipient of the pollution. Temporal and spatial issues, specifically, that it is not always possible to point-source the externality and that it may be some time before the effects of the externality problem are apparent, frequently reduce the possibility of effectively implementing economic instruments.

Regulations are not necessarily regarded as being any more effective, particularly to address degradation of natural resources resulting from agriculture. They have been described as "often poorly conceived, time consuming, arbitrary and manipulated for political purposes" (Harris, 1996, p.161). The OECD (1991) is of the opinion that the acceptability of regulations is particularly important where it is not possible to point-source the externality and where enforcement costs are high. This situation is applicable for externalities associated with the use of natural resources for agriculture. The OECD recommends that one way to improve compliance would be to keep farmer organisations and/or conservation bodies involved and to take joint responsibility for managing natural resources (p.76). ICM is regarded as having the ability to promote management of natural resources through cooperation and communication with

catchment communities.

Although economists can explain the emerging resource problems in a catchment in terms of externalities and property rights, management of the problems frequently requires a scientific and technical understanding of the interaction between resource use and management and the resulting impact on the environment. In addition, once scientists and engineers, in cooperation with representatives of the catchment community, have identified what they believe to be appropriate management strategies, there is then a need for a community-based organisation, such as ICM, to validate the strategy and to implement the strategy. If the strategy is not regarded by the catchment community (and in particular farmers who are frequently the current custodians of the land) to be valid then they will not comply (the costs of enforcement of regulation can be prohibitively high).

If ICM organisations such as the HRCCC had not been established then the alternative would possibly have been direct regulation by government of land and water resource use or economic measures initiated by government which could restrict resource use. For the purpose of this study, the activities of the HRCCC are considered as contributing to, but not wholly responsible for, the alternative to *ad hoc* decision-making and project implementation. As outlined previously, a number of outcome-scenarios have been developed to evaluate the HRCCC. This approach is expected to reduce the difficulties associated with attributing specific outcomes to the endeavours of the HRCCC.

4.4 Identification and Valuation of the Costs and Benefits of the HRCCC

4.4.1 The Costs of the HRCCC

Identification and Valuation of Costs of the HRCCC

The costs associated with the Herbert River ICM organisation can be divided into establishment costs, operating costs and research and project costs.

Establishment costs include those costs which were incurred to establish the organisation in the catchment. These costs include those associated with conceptualising the principles of ICM in Queensland. Since 1992, approximately $3.1m in base funding has been allocated annually to activities associated with ICM organisations (Begbie, per.com., 1999). Although the budgeting accounts do not show the direct allocation to specific ICM organisations, at least a proportion of this grant should be apportioned to the establishment of the HRCCC. Included in this base funding is specific monies paid directly to the HRCCC to meet initial establishment costs ($2,000). In the absence of further information an amount of $20,000 has been apportioned to the HRCCC to cover government agency expenses to conceptualise and operationalise ICM in Queensland.

On-going operating and administration costs include the wages and salaries of the paid coordinator as well as the on-costs associated with equipping and servicing office accommodation, a vehicle and to cover meeting expenses. Apart from the Catchment Coordinator, the organisation is staffed and administered by voluntary support. Funding has been provided by local and state governments, by community groups as well as industry support organisations. On-going administration costs covering the salary for the catchment Coordinator and on-costs including the operation and maintenance of a vehicle, communication expenses and out-of pocket meeting expenses are estimated to be approximately $75,000 per annum.

Voluntary support for the organisation has been largely in the form of time spent on ICM matters by committee members. Voluntary support is valued in terms of the opportunity cost of members' time. Apart from the Coordinator, there are 17 members on the Committee of whom 11 are employed in some capacity in the sugar industry. Committee meetings are not held on a strictly regular basis and attendance at the meetings is not regular. However, over the period since

its establishment, the HRCCC minutes show that the Committee has met approximately 10 times per annum since 1992, with attendance, on average, being approximately 11 persons (excluding the Coordinator).

A survey of members of the committee in 1995 and again in 1997 (Bellamy and McDonald, 1998) identified a divergence of opinion between committee members over whether the time they spent on ICM interfered with their business/job requirements as well as family commitments. However, there was agreement amongst committee members that involvement in the HRCCC activities had not incurred significant personal out-of-pocket expenses. In addition, the survey established that members of the committee found involvement with the HRCCC personally rewarding. Time spent by committee members on ICM related business is estimated to be approximately 4 hours per month (Bellamy and McDonald, 1998). To calculate an opportunity cost of the time spent on ICM matters an average hourly wage rate of $14.50 (ABS, 1996) has been estimated, resulting in an annual cost of committee members' time of approximately $6,380. As 11 of the 17 non-paid committee members work in the sugar industry where the weekly wage is estimated to be as high as $50 per hour, it is acknowledged that this estimate underestimates the opportunity cost of members' time. Summary estimates of the present value of the on-going costs of administration and on-costs of the HRCCC over a period of 20 years are presented in the form of a sensitivity analysis, see Table 4.1. The average hourly wage rate and the discount rate have been varied to show the estimated present value of the establishment and on-going costs of the HRCCC using a discount rate of 4, 6 and 8 per cent and an average hourly wage rate of $14.50, $30.00 and $50.00.

Table 4.1 Present Value of Establishment and On-going Costs of the HRCCC, over a period of 20 years ($'s)

	Discount Rate		
Average Hourly Wage	**0.04**	**0.06**	**0.08**
$14.50/hour	1,049,444	900,018	781,203
$30.00 /hour	1,135,781	973,863	845,119
$50.00/hour	1,247,183	1,069,145	927,592

Using a discount rate of 0.06 per cent and an hourly wage rate of $30.00 per hour, the estimated present value of the costs of establishing and operating the HRCCC over a period of 20 years is $973,863. This estimated cost would need to be offset by net benefits earned over the same period.

Project and research costs include the funding received by the HRCCC or administered by the HRCCC to establish consultancies for research to be carried out on the catchment. These costs are estimated on a project by project basis. Typical of these costs are the data collated on the old mining dams in the upper catchment which was followed by specific projects funded by government agencies to address the perceived problems. These costs are included in the discussion and valuation of the net benefits of the activities undertaken by the HRCCC.

4.4.2 Identification and Valuation of the Benefits of the HRCCC

All of the potential benefits from implementation of specific natural resource management projects in the Herbert River catchment cannot realistically be attributable to the endeavours of the HRCCC. In addition, it could be expected that other ICM organisations, government agencies, or industry support organisations could benefit from the work undertaken by the HRCCC.

It can be argued that the benefits from an ICM approach to resource management are primarily associated with the increased collaboration between stakeholder groups. In relation to this, Marshall *et al.* (1997) regard the reduction in transaction costs associated with negotiation over

the use or management of resources over which there are no clear property rights as a major economic benefit from the process. Transaction cost savings are identified as being associated not only with bargaining for property rights over resources but with the flow of information and with the enforcement of solutions to resource degradation problems.

The problem of enforcement of property rights suggests that a cooperative approach between conflicting parties might be appropriate. ICM, because it offers a formal process for consultation and cooperation, could improve the validity and acceptance of resource management solutions and reduce enforcement costs. In this regard, Marshall *et al.* (1997) claim that the "strength of peer pressure can be expected to increase with greater involvement of parties in deliberations" (p.174).

Marshall *et al.* (1997) define ICM as an institutional instrument designed to reduce or address economic inefficiencies resulting from the incomplete specification of property rights. ICM as an organisational structure is designed to provide an opportunity for the community to identify resource problems, to formulate ways of addressing identified problems and to negotiate and to make relatively costless transactions about the ownership and transfer of ownership of property rights. In brief it can be regarded as a vehicle to reduce transaction costs which will in turn improve the allocation of resources.

Although it is assumed that the process leads to improved natural resource management, the causal relationship is difficult, if not impossible, to establish particularly over a relatively short period of time. The complexity of natural resource management is compounded by spatial and temporal considerations. The impact of the HRCCC, in terms of its effectiveness in facilitating a cooperative approach to sustainable development in the catchment, although measurable in terms of attendance at meetings and hearsay evidence of change in attitude towards stewardship of the land resulting in changed management practices, is less obvious and does not lend itself readily to measurement and valuation.

How long does it take for a change in attitude of the community to be manifested in a change in behaviour and a subsequent change in the management of resources? Again, how long does it take for change in management to manifest itself in a measurable improvement in natural resources. For example, a natural resource problem such as rising groundwater requires the cooperation of all farmers if the condition of the groundwater is to be stabilised or reversed. It might take three years before an organisation such as an ICM organisation is established in an area with a committee and a strategy in place. A further two years might elapse before a specific management strategy is identified and adopted by farmers. On top of this, it could take an even longer period of time before the pressure on the groundwater is relieved and the effects become measurable. In this regard, Blackmore and Connell (1997) report, in relation to land management in the Murray-Darling Basin where salinity is now regarded as a major threat to the ecological sustainability of the area, that even if improved irrigation management could successfully halve recharge of the groundwater "there would be no reduction in impact" on the situation in the Basin (p.1041). Further to this, the study notes that even if it is assumed that recharge of the groundwater is successfully reduced across the whole area, "it takes 50-60 years for groundwater pressure to reduce" (p.1041). The ICM organisation in the Herbert River catchment is in its infancy. Many of the benefits which could be expected to result from projects, including data collection projects, have been designed to increase community awareness and to establish the state of the natural resource base in the catchment. Realisation of the benefits from these projects involves a change in attitude towards stewardship of the natural resources in the catchment. Any future benefits can not realistically be expected to become apparent in the catchment until some time into the future.

These and other problems associated with the identification and valuation of benefits from ICM

activities in relation to the management of natural resource use have been discussed previously. To some extent these problems are addressed in this evaluation through the development of a number of outcome scenarios.

The next section provides a detailed evaluation of a number of the activities undertaken by the HRCCC.

5.0 THE HRCCC ACTIVITIES

The HRCCC has undertaken a number of specific activities to meet its stated objectives. This section provides detailed discussion and an economic evaluation of a number of these activities. The objective of the evaluation undertaken here is not to provide an accounting audit of the HRCCC but rather to provide information that indicates the extent to which the HRCCC is meeting its stated objectives. The activities discussed here are:

- Management of vegetation in riparian zones
- Preservation of natural habitats
- Management of drainage
- Management of wetlands
- Management of acid sulfate soils
- Strategic river bank protection
- Mining dams in the Herberton Shire

5.1 Management of Vegetation in Riparian Zones

5.1.1 The Issue

Erosion of river and creek banks is a natural process. To some extent, regardless of the measures taken to prevent its happening, erosion will occur. However, the State of the Environment Advisory Council (SEAC) (1996) claims that before European settlement, when vegetation in riparian zones was extensive and natural vegetation undisturbed, erosion was relatively slow and trees, which were undermined through natural water flows, fell into the water and provided a habitat for fish species and slowed sediment flows down stream (SEAC, pp.7:28-29). Two terms require definition at this point; "riparian vegetation" and a "watercourse". The Department of Natural Resources (DNR) defines "riparian vegetation" as "vegetation which is found on the banks and adjacent to a watercourse" (DNR, 1998, p.33). The Department defines a "watercourse" as:

> a river, creek or stream in which water flows permanently or intermittently:
> - in a natural channel
> - in a natural channel artificially improved or
> - in an artificial channel that has changed the course of the watercourse.
>
> (DNR, 1998, p.33)

A report on the state of the rivers and streams in the Herbert catchment describes the general state of vegetation in riparian zones across the catchment as being poor to very poor (DNR, 1996). The poor quality of the vegetation is attributed to the narrowness of the vegetation that has not been cleared for agricultural purposes and to the level of exotic plants present within the area (p.ii). Two issues arise for management of riparian vegetation: increasing the area under vegetation and improving the quality of the vegetation.

Protecting riparian vegetation has been a contentious issue for the HRCCC. McDonald and Bellamy (1997) cite a number of planning issues which need to be addressed by the HRCCC in relation to the management of vegetation in riparian zones. These include: should there be a buffer zone along watercourses or preferred flow-paths? What constitutes a watercourse? How wide should the buffer zone be? And what management requirements apply to the buffer? There

is currently no legislation to protect riparian vegetation beyond the top of the stream bank, except on leasehold land.[2] At present, there is not a definitive width for riparian vegetation on freehold land. Although there is no legislation to protect riparian vegetation on freehold land, it is recommended (DNR, 1998, p.13) that, for the wet tropical coast, the vegetated riparian zone should be at least 20m each side of the banks of all minor watercourses, wetlands and drainage lines, and at least 40m each side of major watercourses. DNR concede that "conditions vary markedly between catchments in Queensland" (DNR, 1998, p.13). As the majority of agricultural land in the lower catchment is freehold land, the only course of action available to authorities managing these areas is to improve landowner and community awareness of the importance of maintaining vegetation in riparian zones.[3] This has been primarily the role taken on by the HRCCC.

A recent mapping project of riparian vegetation areas in the lower Herbert River catchment, initiated and partly funded through the HRCCC, recommends that the riparian zone requirement be re-addressed to be sensitive to the local circumstances and needs. Specifically, it is suggested that the width of the buffer zone should be a product of consideration towards the risk of flood and bank erosion (Petroeschevsky, 1997). This recommendation is supported by the DNR (1998) which suggests that riparian vegetation zone boundaries should be determined by consideration to ecological factors including a combination of topography, vegetation type as well as its effectiveness in flood conditions.

Drummond and Associates (1993) identify a number of factors requiring consideration for the design of vegetation in riparian zones. These factors include consideration to the species composition and density of planting, preparation of the site and on-going maintenance.

Activities undertaken by the HRCCC to address the management of vegetation in riparian zones meet their stated objectives of encouraging the retention of significant natural habitats within the catchment and also of promoting ways to prevent and reduce natural resource degradation.

There is considerable support for riparian zone vegetation management from natural resource research organsations including SEAC (1996), LWRRDC (1996), DNR (1996; 1998) and sugar industry support organisations including the Canegrowers (1997; 1998), Sugar Research Development Corporation (SRDC) and the Bureau of Sugar Experiment Stations (BSES). Management of riparian zones to encourage the retention, revegetation or rehabilitation of these areas with appropriate vegetation is believed to contribute towards:

- Stabilising the banks of rivers and creeks and helping to reduce sumping and undercutting.[4] Raine and Gardner (1995) claim that tree roots physically bind the soils and reduce the water content of the soils on the river or creek bank by transpiration which reduces the incidence of sumping. In addition, some of the energy of water flow during flooding is absorbed by riparian vegetation which can reduce erosion and scouring of adjacent land.
- Providing a natural habitat and source of nutrients for river plants and wildlife. Riparian zones provide corridors for the movement of terrestrial and aquatic animals and contribute towards provision of a natural habitat and food source for fish, crustaceans and terrestrial animals.
- The provision of shade which inhibits the growth and spread of grass and exotic plants.

[2] Riparian vegetation on leasehold land is protected within 40 metres of a water course under the Qld. *Water Act 1989.*

[3] Under current legislation (the *Integrated Planning Act, 1997*) if a landowner wishes to redevelop his/her property then the proposed development must be consistent with ESD principles and submit a property management plan (PMP). This legislation provides an opportunity for local authorities to manage vegetation in riparian zones.

[4] Bank sumping occurs when river or creek bank material containing high proportions of fine sediments, which is poorly drained, collapses. Undercutting occurs on the outside bend of rivers and creeks where higher flow velocities erode the toe of the bank so that the bank collapses (Raine and Gardiner, 1995).

Inhibiting the growth of exotic plants, such as *Brachiaria mutica* (paragrass) and to some extent *Eichornia crassipes* (water hyacinth), results in the improved drainage of natural watercourses which might otherwise be choked by exotic weeds and grasses and, by reducing the light and heat reaching the stream, improves the habitat for fish and crustaceans. In addition, the reduction in the growth of grass reduces the population of rats in these areas protecting the cane from destruction by rats.

- Water quality improvements. Riparian zones provide a buffer between terrestrial and aquatic ecosystems preventing nutrient and insecticide run-off into watercourses.
- In addition to these potential benefits it is claimed that rivers and creeks which have retained vegetation are aesthetically appealing and provide a valuable asset for local enjoyment as well as for eco-tourism. Water quality improvements may reduce the number and/or size of fish-kills.

Vegetation of riparian zones is also cited as a safety consideration, where the buffer zone between the river and the area under cane increases the safety of the operation of farm machinery in these locations.

There are, however, significant costs associated with the management of vegetation in riparian zones which need to be considered. These include the cost of establishing or rehabilitating vegetation in a riparian zone as well as loss of production from land, currently under crop, which would need to be restored to native or appropriate vegetation. In the lower catchment, loss of agricultural production would be primarily sugar cane. This agricultural land, because of its proximity to a river or creek, is generally regarded as highly productive. In the upper catchment, grazing properties would potentially lose stock access to a water source.

To off-set reduced production resulting from loss of farm land in the lower catchment, there is the possibility of reduced rat damage to cane and a reduction in the infestation of cane land by exotic weeds. The establishment of native vegetation, specifically shade trees, provides natural management of exotic weeds and plants. Shade trees inhibit the growth of grass (a major source of protein for rats) and exotic weeds such as paragrass and water hyacinth which reduce the quality of the water. In addition, these weeds block drainage channels and inundate cane fields. In some areas of the lower catchment water hyacinth has been known to inundate adjacent cane fields following medium to heavy flooding. The hyacinth smothers the young cane and contributes to prolonged waterlogging which considerably reduces cane production. In such situations riparian vegetation would act as a barrier to the weed, and the canopy of the vegetation could inhibit their growth.

In addition, trees provide a habitat for owls which, by preying on the rats, provide a natural form of pest management. Crop destruction by rats in the past is claimed to be considerable (Herbert Cane Protection and Productivity Broad (HCPPB), 1998).

In some areas, the riparian vegetation provides a buffer, acting as a barrier between aquatic and terrestrial ecosystems. Water quality improvements are cited as a benefit of riparian vegetation which can act as a sink for agricultural run-off and inhibit the growth of exotic aquatic weeds which can deplete oxygen levels in streams. These water quality improvements could reduce the frequency and magnitude of fish kills.

Riparian vegetation can absorb some of the force from flood waters, reducing cane loss attributable to scouring and deposition of sediments.

Risks associated with establishing vegetation in riparian zones

There are risks associated with the establishment of vegetation in riparian zones. If river or creek banks are not appropriately stabilised before tree planting, erosion of river and banks is likely to

continue and result in loss of investment in work undertaken. Planting of trees is not likely to provide protection from erosion of the toe of the river bank (the under-water section of the bank). In addition, if inappropriate trees are planted then realisation of the potential benefits could be delayed and some crop loss might result from pests such as sulphur-crested cockatoos, although this is likely to be minimal.

Qualitatively, there are potentially significant benefits if vegetation of riparian zones is established where there is none, rehabilitated where it is not sufficiently wide or requires more appropriate vegetation or rehabilitated if it is infested with exotic plants. To quantify and estimate a monetary value for all of the potential benefits is difficult because detailed information about the willingness of people to pay for these benefits, which are not marketed, is currently unavailable. However, estimates can be made of the potential productivity benefits and of the costs associated with the initial establishment of vegetation in riparian zones across the catchment as well as for estimates of reduced production resulting from land being taken out of production. These estimates are made under a number of simplifying assumptions which may or may not be valid for an individual farmer or for a specific area in the lower catchment.

The potential benefits associated with the establishment of vegetation in riparian zones do not accrue to specific persons or groups of people. Specifically, a farmer undertaking investment to increase or establish the vegetation of a riparian zone on his/her property is not able to exclude others from enjoying the benefits associated with the establishment of this area, including improved water quality flowing down stream and/or from catching fish which have been provided with a natural habitat on his/her farm. In addition, the removal of exotic plants from the area is likely to not only improve the drainage of water through an individual farmer's property but could also improve flows upstream. In brief, the farmer does not have a property right over the benefits (externalities) created as a result of establishing or rehabilitating vegetation of a riparian zone on his/her property. Neither is the farmer able to exclude others from enjoying all of the benefits he/she has created. This raises the issue of "user pays" where those who enjoy the benefits from vegetation of riparian zones are not necessarily the same people as those incurring the costs.

5.1.2 The Estimated Cost of Establishing Vegetation in Riparian Zones

There are two primary sources of cost associated with the establishment of appropriate vegetation in riparian zones. The first is the cost of planting trees in these areas (assuming trees are appropriate). The second is the opportunity cost of the land. This cost is primarily on-farm loss of production as land is taken out of agricultural production (in the lower catchment this is assumed to be sugar cane production). Estimates of the cost of establishing vegetation in riparian zones require assumptions to be made about the extent to which an area requires re-establishment or rehabilitation. Three scenarios are considered:

a) total re-establishment of vegetation
b) some rehabilitation by removal of inappropriate vegetation and some additional planting
c) minor rehabilitation.

Estimates of cost assume an "average" cane farmer and an "average reach of a water course". There is no such person as an "average cane farmer" or an "average reach of a water course". Soils, the shape of the farm block and farm management practices are examples of factors which differentiate one farmer from another. The width of the water course, the velocity of the water, the height of the bank and the extent and quality of a reach of a water course are examples of factors which would differentiate one reach of a water course from another. Some river or creek banks might require substantial structural stabilisation before revegetation was undertaken, others might require the addition of only a small area of trees whilst other areas might require rehabilitation by replanting of appropriate vegetation. For the purpose of this evaluation, no consideration is given to the possibility of the need to stabilise a bank before planting. In short, it

is assumed that re-vegetation by planting trees will provide at least some of the potential benefits. Although estimates of cost can be made, these estimates are subject to substantial variation if the assumptions underlying their estimation are altered. It is therefore stressed that estimates of costs are made, given a number of assumptions which are set out below.

5.1.3 Assumptions Underlying Estimates of Cost

A number of assumptions have been made to estimate the cost of establishing vegetation in a riparian zone. These are summarised in Table 5.1. The average cost of planting appropriate trees along water courses has been estimated at $3.00 per tree. This is assumed to include the cost of raising, planting and maintaining the tree until it is "out of hand" (assuming that the trees will not require fencing-off) (North Queensland Joint Board (1997) Afforestation Programme). This cost can range between $2.00 and $4.00. The Wet Tropics Tree Planting Service plants between 5,000 and 10,000 trees per hectare. It is assumed, for the purpose of this study, that 5,000 trees are planted per ha in areas requiring complete revegetation; that 2,000 trees per ha are planted in areas requiring some revegetation and rehabilitation and that 500 trees per ha are planted in areas requiring minor rehabilitation. Initial maintenance of the area, including the cost of slashing and herbicide spaying is assumed to be incremental to maintaining the area required if vegetation was not established and is included in the cost of the tree.

Although the *Land Act* (1967) requires a buffer zone of 40 metres along major water courses for leasehold land, this requirement is open to interpretation for freehold land and has been discussed previously. Assuming that the 40 metre zone does not include the water course itself, and that the total zone is suitable for complete re-vegetation, then the cost per ha of planting 5,000 trees at $3.00 per tree would be $15,000.[5] As a one kilometre length of a water course with a 40 metre riparian corridor would encompass 8 ha of land, the estimated cost of establishing this area with native trees would be approximately $120,000. However, it is unrealistic to assume that within a one kilometre length of river all of the potential riparian zone would require complete re-establishment of trees. It is more likely that a part would be fully vegetated, a part would be partially vegetated and require rehabilitation, some parts may never have had vegetation and other parts may require re-establishment.

Table 5.1 Assumptions Underlying Cost Estimates for Vegetating a Riparian Zone

Cost Component	Cost Assumption	Range of Estimate
Extent of Vegetation Required	a) Total re-vegetation (5,000 trees per ha)	3,000 – 5,000 trees per ha
	b) Some re-vegetation and Rehabilitation (2,000 trees per ha)	1,000 – 3,000 trees per ha
	c) Minor tree planing (500 trees per ha)	100 – 1,000 trees per ha
Cost of planting and maintaining trees	$3.00 per tree	$2 - $4 per tree
Width of buffer zone	40metres	15 - 40metres

An estimate of the length of major water courses (the Herbert and Stone Rivers) in the lower Herbert River catchment (from Abergowrie) is approximately 105 km, 85 km along the Herbert River and 20 km along the Stone River. Petroeschevsky (1997) estimates that 7 per cent of the riparian vegetation of the stream bank of the Herbert and Stone River's are badly degraded requiring extensive revegetation. The estimated cost of re-establishing vegetation along 7.35 km of river would be approximately $882,000. A further 19 per cent of the Herbert River and 22 per cent of the Stone River water courses (20.55 km) are estimated to require 50 per cent of the area

[5] This estimate compares favourably with Bell (1996) who gives an estimate of $12,000 per ha and the Johnstone Shire $26,600 per ha.

re-vegetated (Petroeschevsky, 1997). This is estimated to cost an additional $1m. In addition, 22 per cent of the riparian zone along the Herbert River and 52 per cent of the Stone River requires minor revegetation (encompassing 29.1 km) (Petroeschevsky, 1997). This work is estimated to cost a further $173,100. In all, the cost of planing trees along the Stone and Herbert Rivers, assuming a 40 metre riparian zone, would be approximately $2m. Geographic Information surveys (GIS) would provide more detailed information about the extent to which the riparian vegetation in these areas required rehabilitation.

Riparian vegetation in cane growing areas including Trebonne Creek, Cattle Creek, Palm Creek, Victoria Creek and Ripple Creek, has been rated by DNR (1996) as very poor. Clearing of vegetation and infrastructure location is cited as contributing to the poor rating. Substantial rehabilitation of riparian zones might be required in areas where the current mean width of riparian vegetation is estimated to be between 12 and 19 metres (DNR, 1996). Insufficient information is available at this stage to estimate the area around the tributaries of the Stone and Herbert Rivers requiring revegetation or rehabilitation.

Estimates of the value of the potential loss of production (assuming that sugar cane is grown on farms riparian to rivers in the lower catchment) requires estimates of the area of land potentially effected and of the quantity and value of cane lost. The assumptions underlying these estimates are provided in Table 5.2.

Table 5.2 Assumptions Underlying Estimates of Loss of Production

Component of Cost	Estimate of Cost	Range of Estimate
Proportion of riparian zone under cane	40% of riparian zone	20 – 50
Cane yield	90 tonnes per ha harvested per annum	80 – 100
Farm gate price of cane	$27.00 per tonne	24 – 30
Cost of cane production	$13.00 per tonne	11 – 16

Along a one kilometre length of river requiring complete revegetation, an area of 8 ha could be potentially taken out of production. Assuming that 40 per cent of the riparian zone would normally be under cane, and assuming the cane yield is 90 tonnes per ha harvested per annum (Australian Sugar Year Book, 1998), then 288 tonnes of cane per annum would be lost. Assuming that the farm gate price of cane is $27.00 per tonne, then the gross value of lost production along a kilometre stretch of river would be $7,776 per annum. The net income loss, deducting the cost of production which is assumed to be approximately $13.00 per tonne, could be approximately $4,032 per annum. The net income loss along 105 km of the Stone and Herbert Rivers (assuming 7 per cent of the total area required revegetation, and adopting all previously stated assumptions) could be approximately $27,165 per annum.

The estimated income loss, expressed as a proportion of total income from the growing of sugar cane, across the entire cane growing district is relatively small (approximately 0.5 of one per cent per annum).[6] However, if the income loss is expressed as a percentage of an individual farmer's total income, the loss can be shown to be significant. A number of scenarios have been developed to show the magnitude of the estimated relative income loss to cane farmers according to the size of their cane assignment. Three sizes of cane assignment have been considered. The first reflects the financial position of farmer who is marginally viable (40 ha assignment); the second, a farmer who has a slightly larger assignment and is able to absorb some of the income loss (65ha assignment), and third, a farmer who has a 100 ha assignment and is able to achieve economies of scale and where the income loss is likely to be absorbed. If these individual farmers had a one kilometre length of their farm riparian to the Herbert or Stone River and were required to vegetate a 40 metre zone which was currently under cane, they would incur a loss of their

[6] This assumes that the gross value of sugar production from the Herbert District is $209m (Sugar Year Book, 1998).

annual income. The results are provided in Table 5.3. Table 5.3 shows that if a cane farmer with a 40ha assignment to grow cane was to take 4ha out of production to revegetate a riparian zone, then his/her income loss would be 10 per cent of his/her total income from cane production per annum. On the other hand, a cane farmer with a 65ha assignment would incur an income loss per annum of 6 per cent and for a farmer with a 100 ha assignment, the per annum income loss is estimated to be 4 per cent of total income from cane.

Table 5.3 Likely Farmer Income Loss to Re-vegetate 4ha of Riparian Zone

Size of Cane Assignment	Percentage of Income Loss
40 ha	10 per cent
65 ha	6 per cent
100 ha	4 per cent

The net income loss per annum to an individual cane farmer would be determined by the area of land he/she would need to take out of production. The point made here is that the costs to farmers of taking the riparian zone out of cane (that is, the opportunity cost of the land) is not equitably distributed across all growers, some farms have none of their property riparian to a watercourse whereas others may have a relatively substantial riparian zone. At the same time, the potential benefits associated with management of riparian vegetation cannot be enjoyed exclusively by those who incur the costs.

5.1.4 The Estimated Value of Benefits

Valuation of most of the potential benefits from vegetating riparian zones is difficult. Estimates of the catchment community's willingness-to-pay for these areas is the subject of a much more comprehensive study of riparian zones currently being undertaken (Blamey *et al.*, 1999). Although a number of potential benefits are cited, all areas of riparian vegetation do not offer the same magnitude of benefits. These will vary according to the location of the site and the particular attributes of the site. Benefits such as pest and weed management, improved drainage, water quality and fish habitats as well as visual and aesthetic improvements in the catchment are largely unquantifiable. However, information is available from previous studies or from reports of damage incurred in the catchment which might have been reduced or avoided if appropriate areas of riparian vegetation had been in place.

Reduction in Damage to Cane from Rats (*Ratus sordidus)*

One potential benefit resulting from establishing vegetation in riparian zones is the reduction in damage to cane from rats. Establishment of appropriate vegetation in riparian zones is consistent with integrated pest management (IPM) programs which have been encouraged by the HRCCC and the HCPPB over several years.

Riparian zones, planted with trees that have a good canopy, eradicate the harborage areas for cane rats (*Ratus sordidus* and *Melomys burtoni)* leaving them more vulnerable to natural predators such as birds. By increasing shade areas, weed and grass growth is reduced. Without grass seeds, rats are denied access to a valuable source of protein. This reduces their ability to breed and subsequently leads to a reduction in the rat population.

Any estimates of the value of avoided costs of rat damage requires assumptions to be made about the value of lost production due to rat damage and the area of cane which might benefit from the potential protection offered by appropriate vegetation of riparian zones. Information supplied by the HCPPB (1998) shows that rat damage in the Herbert River District has been declining since 1993. In 1993, approximately 28,265 tonnes of cane were lost compared to 6,576 tonnes in 1997. This apparent reduction has been attributed to an increased awareness on the part of farmers to the benefits from IPM programs, to poor seasonal conditions for rats as well as to a reduction in visible damage recorded as being caused by rats as a result of trash blanketing. For the purpose of

this analysis, it is assumed that the potential benefits from reduced rat damage are realised on an annual basis rather than being dependent on seasonal conditions.

If it is assumed that a one kilometre length of a watercourse with an 8ha area of riparian vegetation protects a further 48ha of cane land from rats which would destroy 30 per cent of the cane in that area, then the potential value of protection from rat destruction would be $23,328 per annum. For the purpose of this evaluation, these potential benefits have been phased in over a period of five years.

In addition to this potential benefit, there are a number of previous studies which estimate an avoided cost of baiting rats as a potential benefit of riparian vegetation (Canegrowers, 1996). As there is no longer a registered available chemical to control rats, IPM, which involves harborage eradication and field hygiene, is the only course of action available to farmers. In so saying, however, it is likely that a suitable bait may be available in the future. Given the present situation, the avoided cost of baiting is no longer a relevant benefit. However, it is likely that farmers may incur reduced costs associated with grass cutting in riparian zones when trees are well established.

Water Quality

Vegetation of riparian zones provides a buffer between terrestrial and aquatic ecosystems which reduces nutrient and insecticide run-off into watercourses. Fish kills, defined by the Department of Environment (DOE) (1998) as a "significant and sudden mortality of fish or other aquatic animals such as crabs or prawns" (p.1), resulting from deterioration in water quality including oxygen deprivation, excessive nutrient run-off or low pH levels of the water, are evidence of the damage which can be caused if excessive run-off from agricultural land or industrial waste enters a watercourse. Fish kills are generally characterised by large numbers of aquatic animals dying over a relatively short period of time, usually within a clearly defined area (DOE, 1998, p.1). Scientific research (Nowak, 1996) shows that a large proportion of fish-kill events in Australia are due to natural causes. However, there are some fish-kills which can, at least partially, be attributed to human impacts on the natural environment. Fish-kills attributable to industrial discharges or spillages of toxic chemicals provide obvious examples of human impacts on fish. However, a more common cause of fish-kills due to human impact is degradation of natural waterways by interference in natural flows, the build-up of excessive nutrients and drainage of acid sulfate soils.

In addition to reducing agriculture related contamination of water courses, riparian vegetation can inhibit the growth of exotic plants and weeds. Hogan and Graham (1994) report that juvenile barramundi are virtually absent from many of the floodplain drainages, including Cattle, Palm and Trebonne Creeks. They suggest that a possible causal factor is the extensive infestation of these areas with exotic aquatic weeds including *Salvia molesta* (salvina), and *Eichhornia crassipes* (water hyacinth). It is claimed that these weeds reduce the amount of photosynthesis that can occur within the water body, thereby contributing to oxygen deprivation. This situation is particularly prevalent during the onset of the wet season or following significant rainfall events when large amounts of organic matter are flushed into the water courses.

Hogan and Graham (1994) recorded large numbers of freshwater species of fish in the Herbert River floodplain. The habitat of freshwater fish in tropical floodplain lagoons is recognised as being the most threatened within the Wet Tropics region (Pusey and Kennard, 1994). Pusey and Kennard claim that this is due primarily to "ecological impacts associated with agricultural development including: the draining and filling of swamps, the clearing of vegetation, nutrient enrichment from farm runoff, and the use of pesticides and herbicides".

Cane farmers use organic fertilisers, including fly-ash, a byproduct from the sugar mills, to fertilise the soils after harvesting. After heavy rains this could enter watercourses, reducing the oxygen level of the water which could potentially contribute towards fish kills. By providing a

buffer between agricultural land use and aquatic ecosystems, riparian vegetation may reduce the incidence and magnitude of fish kills. That fish numbers in the watercourses is an issue of some concern to the catchment community is supported by the results from a survey of the Herbert River catchment community (Butterworth *et al.*, 1997). The results show that more than half of the respondents to the survey indicated that they were personally affected by lower fish numbers.

Barramundi (*Lates calcarifer (Bloch)*), a native Australian freshwater fish species common in the Herbert River catchment water courses, is intolerant to oxygen deprivation. Following prolonged rainfall in the Herbert River catchment, barramundi fish-kills which may be due to oxygen deprivation, resulting from excessive plant growth (including algae), run-off high in organic debris, nutrients, pesticide and acid from acid sulfate soils, are not uncommon. DOE records show that a number of large fish-kills are reported and investigated in the Herbert River catchment each year (Hogan and Graham, 1994). For the most part, investigation into the possible cause of the fish deaths is inconclusive.

Estimating a monetary value for a fish-kill is difficult because fish-kills do not necessarily involve a single species with an equal value in the aquatic ecosystem. However, DPI Fisheries estimate the value of barramundi for restocking of dams at $50 for recreational fishermen and at $25 for commercial fishermen. In addition, it is estimated that approximately one third of the barramundi are caught by recreational fishermen. (Rutledge *et al.*, 1990).[7]

A recent fish-kill (September, 1998) in Palm Creek resulted in over 1,000 barramundi deaths. This fish-kill could have had a value of $31,500 assuming that one third of the fish would have been caught by recreational fishermen and the remainder by commercial fishermen. The Department of Environment (DOE) has records of several fish-kills of this magnitude per annum in the Lower Herbert catchment. If it is assumed that over 3,000 barramundi are killed each year as a result of agriculture related contamination of watercourses in the Herbert River catchment and that appropriate management of riparian vegetation could contribute towards preventing 20 per cent of these deaths, then the estimated value of improved water quality to the fishing community would be valued at $19,500 per annum. As was the case for reduced rat damage, these potential benefits have been phased in over five years.

Inhibit the growth of exotic plants and weeds and act as a buffer between aquatic and terrestrial ecosystems
Cane loss in the Herbert catchment, attributable to inundation of exotic aquatic weeds following flooding can be significant also. For example, on one farm in the lower catchment with poor riparian vegetation, inundation of cane following a medium size flood in February 1998, is estimated to have destroyed over 400 tonnes of cane valued at nearly $10,000. Across cane land in the lower catchment, the cane loss from such events is estimated to be over 2,000 tonnes, valued at more than $54,000. These avoided losses have been modelled in this analysis as having a 1: 7 year probability of occurrence.

In addition, exotic weeds such as *Brachiura mutica* (paragrass), and hymanachne which were introduced in the catchment by cattle producers with the objective of increasing the feed from water logged areas of their farms, prevent tree recruitment and exclude native sedge communities from ephemeral wetlands. In addition, these exotic weeds invade cane land and reduce productivity. Appropriate vegetation along water courses in these situations can reduce the prevalence of these exotic weeds and reduce the possibility of reduced cane yield.

Some protection of river or creek banks from erosion and protection of farmland from scouring and sediment deposition is possible in the Herbert River catchment if riparian zones are suitably vegetated (Kinhill, Cameron McNamara (1991). Canegrowers (1996) estimates the potential value

[7] Recent net closure in the Hinchinbrook Channel may lead to an increased proportion of Barramundi being caught by recreational fishermen.

of the avoided loss of cane resulting from scouring, which has a probability of occurring during a major flood event (1:10 years), to be $1,000 for a 100ha farm. These benefits are not necessarily enjoyed by all cane farmers but by those located in susceptible areas such as the Halifax Washaway and Anabranch where washaways and scouring have historically been a problem.[8] For the purpose of this analysis, it is assumed that the area of caneland in the catchment potentially afforded some protection by vegetation of a riparian zone from major erosion, scouring and deposition of sediments for a 1:10 major flood event is 400ha. The magnitude of the cane loss following a major flood event would be determined by the period over which the cane is waterlogged and the maturity of the cane. The avoided loss of production is assumed to be 1per cent of production over the total area ($97,200). For the purpose of this evaluation, this estimated avoided loss has been modelled as having a probability of occurring 1:10 years.

5.1.5 Net Benefits of Investment in Vegetation of a Riparian Zone

A cane farmer who currently experiences loss of income resulting from damage to cane by rats, scouring and sediment deposition as well as inundation of cane by exotic weeds following flood events, may need to invest $60,000 to revegetate 4ha of land riparian to a water course. In addition, some of the area requiring revegetation may be under cane. The farmer would need to make a trade-off. He/she would need to invest in revegetation and incur a loss in income in order to avoid a possible substantial loss of income in the future. The estimated value of avoided lost production for a farmer in this situation offsets the cost of revegetation and lost production resulting from land being removed from production. Specifically, a farmer in this situation would need to invest around $60,000 on vegetating the area as well as incur the cost of reduced on-farm production (approximately $2,016.00 per annum). Over a 20 year period the net present value (NPV) of this investment using a discount rate of 6 per cent would be approximately $6,712. However, the extent to which the costs might be recovered by farmers is dependent on the degree to which damage to cane due to rat damage, scouring and inundation from exotic weeds is avoided. If a farmer did not expect to benefit from prevention of scouring or weed inundation, then the return on his/her investment in riparian vegetation is estimated to be -$5,315.

For the catchment community however, additional benefits would be likely, including those resulting from improved water quality (such as reduced fish-kills) and aesthetic improvements to the catchment environment.

The return on the investment over a period of 20 years to revegetate and rehabilitate the vegetation along a 4ha corridor along the Herbert and Stone Rivers (a 40 metre riparian area) is estimated to be approximately -$97,132, at a discount rate of 6 per cent. Calculation of this return includes the potential benefit of improved water quality to the fishing industry as well as the potential benefits to cane farmers which would be realised gradually over a period of 5 years.

Summary information about the magnitude of potential costs and benefits to the catchment community of re-establishing or rehabilitating riparian vegetation along the Herbert and Stone Rivers is provided in Table 5.4.

[8] There are areas where specific structural work to stabilise the river bank may be required.

Table 5.4 Summary Estimates of Potential Costs and Benefits of Riparian Vegetation along the Herbert and Stone Rivers

Costs		Benefits	
Component of Cost	**Estimated Value**	**Identified Benefits**	**Estimated Value**
Re-vegetation (105 km)	$2,055,100	IPM – reduced rat damage to cane	$171,460 per annum
		Improved water quality – reduced fish kills	$19,500 per annum
		Reduced cane loss from scouring	$97,200 (1:10 year)
Loss of cane production	27,165 per annum	Reduced cane loss from weed inundation	$54,000 (1:7 year)
		Aesthetic benefits including increased owl population	Not valued

The estimated NPV over a period of 20 years, at 4, 6 and 8 per cent discount rates, of the investment in managing riparian vegetation along the Herbert and Stone Rivers is provided in Table 5.5.

Table 5.5 The Estimated NPV of Managing Riparian Vegetation Along the Herbert and Stone Rivers

Discount Rate (%)	Estimated NPV ($'s)
4	195,329
6	-97,132
8	-308,608

The estimated NPV is positive only when the discount rate is set at 4 per cent or below. At more commercial rates, 6 per cent and above, the NPV is not positive. In short, to the extent that investment in managing riparian vegetation is sourced from private sector funding, where a competitive return would be expected on investment (a discount rate of over 8 per cent would be required), the investment is not economically efficient. However, if investment were sourced from the public purse, where a discount rate of 4 per cent might be argued to be appropriate, then the investment is estimated to be economically efficient. The point made here, is that the distribution of the costs and benefits associated with managing riparian vegetation is an important consideration in determining the efficiency of the investment.

5.1.6 Sensitivity and Risk Analysis

The two most commonly used methods for measuring the impact of uncertainty on project outcome are sensitivity analysis and risk analysis. Sensitivity analysis is carried out by varying one element or a combination of elements and determining the effect of that change on the project outcome, measured as project worth or performance. Sensitivity analysis is a valuable tool to identify specific variables that could have a significant impact on project outcomes. Risk analysis is variously described as an analytical technique in which probabilities of occurrences are determined for a number of significant project variables which are modelled as varying simultaneously over a specified range over the life of a project. Risk analysis calculates the probability distribution of the performance of a project, providing information about the performance of a project in terms of the probability of an outcome.

Both sensitivity and risk analysis are employed in this analysis.

Sensitivity Analysis
Estimation of the costs and valuation of the benefits associated with the management of riparian vegetation is subject to a number of simplifying assumptions. For example, cost estimates are, for the most part, based on subjective estimates including the area requiring revegetation and the proportion of this area estimated to be under cane. Valuation of the potential benefits to cane farmers is reliant on estimates of avoided loss of production due to scouring or weed inundation and the time it would take for the newly established vegetation to become established to reduce rat damage.

Table 5.6 shows the sensitivity of the estimated NPV (at a discount rate of 6 per cent) to a change in the width of the riparian area and to the proportion of the area requiring revegetation assumed to be under cane.

Table 5.6 Sensitivity of the NPV (at 6% Discount rate) to Change in the Width of the Riparian Area and to the Proportion of the Riparian Area under Cane for a 1 Km Length of River ($'s)

Proportion of Riparian Area under Cane	Width of Riparian Area		
	20 metres	**30 metres**	**40 metres**
30 per cent	31,517	31,631	31,746
40 per cent	25,974	23,317	20,659
50 per cent	20,431	15,002	9,573

The analysis shows that the NPV is particularly sensitive to the proportion of the riparian area under cane. When the riparian area is set at 40 metres wide, and it is assumed that 40 per cent of the area is under cane which would be removed from production, the NPV is estimated to be $20,659. However, when the proportion of the area under cane is assumed to be 50 per cent, the NPV is estimated to be less than half at $9,573. The sensitivity of the NPV to the proportion of the riparian area under cane is important. It indicates that additional incentives may need to be offered to cane farmers if they are likely to lose substantial areas of cane.

Table 5.7 shows the sensitivity of the estimated NPV (at a discount rate of 6 per cent) to a change in the period it would take for potential reduction in rat damage and reduced fish kills to take full effect. Predictive estimates of reduced loss of production due to rat damage are uncertain, subject to seasonal conditions rather than dependent solely on farm management practices.

Table 5.7 Sensitivity of the NPV (at 6% Discount Rate) to Delayed Realisation of Reduced Rat Damage and Fish Kills for the Herbert and Stone Rivers ($'s)

Delayed Benefits of Reduced Fish Kills	Delayed Benefits of Reduced Rat Damage		
	3 years	**5 years**	**10 years**
3 years	40,972	-83,029	-390,184
5 years	23,780	-97,132	-401,372
10 years	1,408	-192,169	-435,973

Table 5.7 shows that the estimated NPV (6% Discount rate) is sensitive to delays in the realisation of the benefits of riparian vegetation, specifically reduced rat damage and reduced fish kills. The estimated NPV is shown to be particularly sensitive to delays in the realisation of reduced rat damage. A positive NPV (at a discount rate of 6 per cent) is shown to be possible only if these benefits are realised over a period of 3 years.

Risk Analysis

In the absence of data to estimate a probability distribution for values of uncertain variables, the value of the variables included in the risk have been assigned a triangular probability distribution (minimum, mode and maximum value). These variables are modelled to vary randomly (using Monte Carlo sampling) consistent with the assumed triangular distribution. The variables included in the risk analysis and the values assigned to them are presented in Table 5.8.

Table 5.8 Variables and Values Included in the Risk Analysis

Variable	Values Assigned
Width of Riparian Area	20, 30 and 40 metre zone
Number of trees planted per ha	1,500, 3,000 and 6,000
Per cent of riparian zone currently under cane	20%, 40% and 50%
Gross value of cane per tonne	$24, $27 and $30
Percentage of cane in area of impact protected from rat damage	20%, 30% and 40%
Number of fish kills per annum	2, 5 and 10
Number of fish per kill	100, 600 and 800

The estimated NPV from the risk analysis, resulting from1,000 iterations, are provided in Table 5.9. The results from the risk analysis show the probability distribution of the estimated NPV for each discount rate.

Table 5.9 Probability Distribution of the Estimated NPV for 4, 6 and 8% Discount Rates ($'s)

	Discount Rate		
	4%	**6%**	**8%**
Minimum value	-$493,156	-$658,019	-$771,220
Maximum value	$1,023,317	$578,519	$249,649
Mean	$213,177	-$82,294	-$296,106
Standard Deviation	$279,784	$228,137	$188,348
Mode	$336,285	-$207,438	-$399,248
95% Confidence level	-$240,896	-$452,782	-$602,183

The results show that there is a substantial difference between the estimated minimum and maximum values for the NPV for all discount rates. The probability distributions indicate that the minimum value and the value at the 95 per cent confidence level are negative for all discount rates. The estimated NPV is positive for the mean and mode values, only when the discount rate is 4 per cent.

5.1.7 Implications

The implications arising from these estimates, which it is stressed are based on a number of simplifying assumptions, are that there are considerable costs associated with the establishment of vegetation in riparian zones. The estimated performance of this project is shown to be especially sensitive to the assumptions about the costs involved with managing these areas, including the width of the riparian area as well as to the assumptions underlying the loss of production. In addition, the principal benefit associated with managing riparian areas is the reduction in damage to cane caused by rats. As a result, the estimated performance of the project and the ability of farmers to recover their investment in vegetating these areas is shown to be sensitive to the assumptions about the area which would benefit from reduced rat damage as well as the time it would take for improved production to take effect.

The cost to individual landowners to establish riparian areas is potentially significant. The benefits arising from re-vegetating these areas are not contained solely on an individual farm and an individual farmer cannot prevent others from enjoying the benefits from these areas. In particular, benefits including improved fish habitats and reduced fish kills are not confined to an individual investing in riparian vegetation. It would therefore appear to be appropriate for authorities wishing to encourage the establishment of vegetation in riparian zones to offer incentives to individual farmers.

5.2 Preservation of Natural Habitats

5.2.1 Endangered Species

Mahogany Glider

The most significant of the native mammals of conservation interest in the lower catchment is the Mahogany Glider (*Petaurus gracillis).* This species is thought to be endangered (Van Dyck, 1993). Suitable habitat for the mahogany glider is claimed to be primarily within two scheme areas, Lannercost and Mandam. Its status as "endangered" is due to its diminished habitat and to the fact that most of the remaining suitable habitat occurs on freehold and leasehold land which has been classified as having a high to medium suitability for agriculture (Blackman *et al.,* 1994). Two conservation and management issues for the species identified by Blackman *et al.,* are the retention of as much of the remaining habitat as possible as well as the maintenance of a continuous habitat or corridor between habitat areas. Cooperative management between landowners, Local government, and the Departments of Environment, Lands and Primary Industries is acknowledged as a requirement for successful management (Tait, 1994). More specifically, land-use planning for the catchment is identified as necessary to avoid the loss of endangered flora and fauna in the future. The HRCCC, in its role as coordinator and disseminator of information has the potential to influence and encourage appropriate land-use planning in the catchment to preserve natural habitats of this nature.

5.2.2 Integrated Pest Management

Owl Boxes

Closely associated with activities to manage vegetation in riparian zones have been activities to encourage farmers to engage in ecologically sustainable pest management practices. A specific activity undertaken by the HRCCC has been the establishment of approximately 55 owl boxes throughout the lower catchment. Not only was this activity undertaken with the objective of promoting ecologically sensitive farming practices by cane farmers, it also represents a coordinated effort between the HCPPB, DNR, local wildlife enthusiasts and landholders. Approximately $1,500 of the cost of the project was sourced from the HCPPB, covering the cost of a cherry picker required to place the boxes.

Owl populations on the Ingham coastal lowlands have dropped noticeably over the last five years. Reduced populations have been attributed to the clearing of native vegetation to accommodate the expanding sugar industry resulting in the destruction of nesting habitats and hunting perches. In addition, the possibility of secondary poisoning linked to rat baits has been suggested.

By establishing nesting boxes for owls in areas which have virtually been cleared of native vegetation, hunting perches have been provided which has increased their hunting range and increased their chance of survival in a changed habitat.

Owls offer an opportunity to promote ecologically sensitive pest control. Halvorsen (1998) reports that "a single owl family can eat over 2,000 rats per year" (p.6). Aside from the number of rats an owl family can physically remove from the environment, there is some potential for owls to disrupt the breeding cycle of rats, further reducing their population.

Rat damage to cane in the Herbert River District has been estimated by the HCPPB to range from 28,265 tonnes in 1993 to 6,576 tonnes in 1997. The farm-gate value of the damage to cane in the Herbert District is estimated to have been $763,155 in 1993 and $177,552 in 1997.

The estimated cost of an owl box is approximately $80.00. The estimated cost of establishing 55 owl boxes across the lower catchment is approximately $4,000 (HRCCC meeting notes). Contributions towards the cost have been made by the HCPPB as well as DNR. In addition, contributions have been made in the form of voluntary labour by individual landowners and local wildlife enthusiasts (no cost has been estimated for this labour).

The value of reduced rat damage to cane production does not need to be significant to show a return to the initial investment to establish owl boxes. Specifically, the value of the avoided cost of lost cane production in the catchment would need to be approximately $350 per annum over a 20 year period to offset the initial establishment costs and periodic maintenance work (assuming a discount rate of 4 per cent). Possibly the real value of establishing owl boxes around the cane growing district, however, is that they have raised the awareness of the catchment community of the advantages of encouraging farming practices to manage native vegetation as a wildlife habitat and which aids pest control.

5.3 Management of Drainage

5.3.1 Drainage as an Issue in the Herbert River Catchment

The main feature of the lower Herbert River catchment area is the Herbert River Delta or floodplain. The delta covers an area of approximately 500km^2. Cameron McNamara (1984) describes the delta as a "typical landform of natural levees bordering river channels, backed by low lying and sometimes swampy depressions" (p.2-1). Due to the flat and low-lying nature of the delta and the high intensity of rainfall in the area, appropriate drainage systems are necessary to satisfy agricultural drainage requirements. Principal land-use in this area is sugar cane production for which drainage is claimed to limit horizontal as well as vertical expansion in the catchment.

Numerous reports have been commission by the Herbert River Improvement Trust (HRIT), Water Resources and/or the Hinchinbrook Shire Council on drainage and flood management for the catchment. Few, if any, of the recommendations made in these reports have been implemented successfully. More recent redevelopment of grazing properties in the lower catchment for sugar cane has highlighted the need for a coordinated approach to developing drainage systems through cane lands. Coordination and amalgamation of existing drainage boards has been an essential component of the area's submission for funding by the Commonwealth Government for the provision of infrastructure to assist the sugar industry under the Sugar Industry Infrastructure Package (SIIP).

Inadequate drainage is cited by DNR (1998) as a major factor limiting agricultural productivity along the wet tropical coast. Drainage problems may be the result of insufficient capacity in natural drainage paths, poorly planned modifications to natural drainage systems, or a combination of these problems. DNR (1998) recommends that drainage systems be planned on a catchment basis. Poor drainage, where drainage works are defined as "those works directed at the reduction of standing water or groundwater levels during and after local rainfall, or after major flood flow has ceased" (Cameron McNamara, 1980, p.4-1), impacts on both cane yield as well as

restricting expansion onto low-lying areas of the flood plain. In this regard, Cousens and Kirby (1979) suggest drainage to be the main drawback to bringing the available land under cane production. They acknowledge that individually, farmers are improving drainage on their individual farms but that most problems are encountered because drainage systems between adjoining farms are not integrated. Cousens and Kirby suggest that these problems may become more pronounced as cane production extends onto more marginal land. Although these comments were proffered almost 20 years ago, they are still particularly relevant, and have not been adequately addressed in 1998.

A number of factors are cited in various reports (for example Cameron and McNamara, 1980; Cameron McNamara, 1984) as contributing to the drainage problems in the lower catchment.

These include:

- Frequency of high intensity rainfall events
- Herbert River flood spillage
- Inadequate surface and subsurface farm drainage works
- Indiscriminate private construction of levee banks and drains which can aggravate river spillage and hinder drainage works which relieve pooled run-off.
- Poor integration of drainage works undertaken by individual drainage boards within the delta
- Location of infrastructure including road, bridges and rail or tramway facilities which has obstructed natural drainage creeks and floodplains.

Estimates of loss of productivity in the Herbert District resulting from a major flood event in 1991 indicate that cane production was down by almost 33 per cent on a five year district average (Sugar Year Book, 1996). BSES research (Dick, 1982) shows that sugar cane yields decline significantly when water tables are less than 0.5m below the soil surface for more that approximately 50 days of a growing season. Loss of cane yield in these situations is estimated to be 0.5 tonne of cane each day. Such situations would be likely to arise in areas fringing freshwater or estuarine wetlands.

Local drainage problems within the lower catchment have reduced the productivity of a number of cane farms. In order to increase production farmers have adopted laser levelling to improve surface drainage, and where waterlogging is severe they have been encouraged to construct artificial lagoons or wetlands. In some instances, individual farmers have constructed levee banks to redirect flood water away from their cane land. For the most part, these levee banks are claimed to have exacerbated drainage problems elsewhere (Cameron McNamara, 1980).

5.3.2 HRCCC Activities

Uncoordinated drainage systems on canelands have been a long term issue creating social conflict in the catchment (McDonald and Bellamy, 1996). Information about the problems in the lower catchment and possible measures to address the problems has been sought through studies commissioned by the Herbert Shire Council in conjunction with the Herbert River Improvement Trust (Cameron McNamara, 1980; Cameron McNamara, 1984; Kinhill and Cameron McNamara, 1991; and Drummond and Associates, 1993). One outcome from these studies has been the proposed amalgamation of a number of drainage boards into one combined body to support a coordinated and consistent approach to drainage. In addition, the HRCCC has been active in securing the recent appointment, by DNR, of a technical drainage expert for the catchment. This officer provides advice on drainage issues and attempts to resolve technical issues about drainage problems associated with planning approvals, required by the town planning scheme. The appointment of a person to provide this service is a move towards a coordinated approach to drainage management in the lower catchment.

Improved coordination and consistency in decision-making could improve the cane yield of cane farmers currently experiencing problems with waterlogging and reduce the possibility of inappropriate subsurface drainage through areas considered to be prone to acid sulfate soils. These activities have the potential to result in an increased area of land developed for sugar cane production, to reduce negative externalities imposed on others as a result of inappropriate farm management and to reduce possible transaction costs associated with protracted negotiation over drainage management.

The HRCCC has not tackled drainage problems in the catchment in a holistic sense. Instead, indirect approaches have been adopted which address specific issues as they arise and encourage appropriate farm management practices. One approach has been to encourage cane farmers to manage drainage problems on-farm, specifically to establish or restore wetland areas. Another approach has been to adopt the role of coordinator, addressing local drainage problems which have been identified as threatening productivity by coordinating the efforts of the organisations and agencies involved and identifying an appropriate course of action. These approaches are consistent with the stated objectives of the organisation: to coordinate government agencies and the community to pursue common goals, to promote the wise use of all natural resources within the catchment and to encourage the retention of significant natural habitats within the catchment.

One of the benefits from an ICM approach to resource management to address drainage problems in the catchment is primarily associated with the increased collaboration between stakeholder groups. Section 4.2 suggested that the potential reduction in transaction costs associated with negotiation over the use or management of resources over which there are no clear property rights as a major economic benefit from the process. The HRCCC activities, in relation to drainage issues, have been largely directed towards reducing transaction costs. The HRCCC has been instrumental in ensuring that appropriate information about drainage problems in the catchment has been made available and that the appropriate organisation or agency to deal with drainage problems is identified.

Levee Banks

The construction of levee banks to protect property from damage resulting from flooding is regarded as appropriate over limited sections of the Herbert River to protect particular areas (Cameron McNamara, 1980, p.4-5). A flood management study (Cameron McNamara, 1980) recommends that the construction of levees to protect property from flood damage be considered carefully. Levees may reduce spillage at one point but will tend to increase spillage elsewhere. In short, although one farmer may protect his/her property from inundation by flood water following a minor flood or local rain event, he/she could well be exacerbating a problem elsewhere. There is an identifiable conflict of interest between individual farmers over this issue which could lead to prolonged and expensive measures being undertaken to define property rights.

The role of the HRCCC in relation to the construction of levee banks has been to provide a forum for discussion about property rights to construct levee banks and to identify the body; drainage board, Shire Council or state government agency which has the authority to take action to regulate their construction. These activities potentially contribute towards a reduction in transaction costs, especially if a lengthy process was required to clarify these issues.

The issue of levee banks, and in particular those constructed along the Halifax Washaway, has been dealt with at some length in a drainage study undertaken by Kinhill, Cameron McNamara (1991) for the Water Resources Commission and the HRIT. In that study it is reported that individual landowners have constructed a large levee (1.8 km in length and approximately 1m high) at an estimated cost of approximately $3,000. The levee was constructed to reduce damage to their property and associated cane loss resulting from scouring by high velocity water,

deposition of large quantities of sediment and increased periods of inundation following flood events. Crop damage for an individual farmer following the 1991 floods was estimated to be $70,000 (Kinhill, Cameron McNamara, 1991). Claims and counter claims about the impact of the levee on neighbouring properties and about responsibility for damage suggest that a coordinated approach to this and other levee bank construction issues might reduce transaction costs.

By providing a forum for discussion, the HRCCC has the potential to contribute towards identification of a solution which would be economically efficient.

A recent HRCCC meeting (July, 1998) demonstrated how a specific drainage issue, in this case the construction of a levee bank by a cane grower, required the identification of an appropriate agency with legislative power to deal with the issue.

The case in question involved the possibility of a farmer constructing a levee bank on his/her property to protect his/her property from flooding. The impact of this action was anticipated by farmers in the area to increase drainage problems on their properties with subsequent loss of cane yield. The HRCCC acted to identify the authority (Drainage Board, DNR (Water Resources) or Local Government) who had the authority to act to prevent the construction of the levee bank. Such action by the HRCCC has the potential to avoid litigation costs as well as the costs of prolonged negotiation to determine the legality of levee banks.

To some extent the management of drainage in the catchment requires the clear definition of farmers' property rights to construct levee banks or construct drainage channels across their property. Involvement of the HRCCC in the issue of construction of levee banks demonstrates an important step towards a coordinated approach to decision-making. A coordinated approach towards addressing this issue could lead to a reduction in transaction costs.

Wharps Holding Sub-division
The HRCCC has been directly involved in addressing perceived drainage problems and also with encouraging cooperation with government agencies to ensure that the possibility of the same problems arising in the future is reduced. Two specific activities in which the HRCCC was involved actively were the drainage of the Wharps Holding sub-division and the development of the Pomona Wetlands. The HRCCC adopted the role of coordinator, organising funding and a cooperative course of action to deal with problems.

Wharps Holding sub-division, in the Upper Stone area of the lower catchment (Upper Cattle Creek), is a 1,000 ha sub-division from an existing grazing property (Wharps Holding) to provide a number of farm allotments. These allotments were regarded as suitable for the production of sugar cane. The initial drainage design was found to be inadequate for the development and potentially could have contributed towards excessive erosion, damaged existing wetlands in the area as well as contributing to waterlogging of cane farms downstream of the development. These impacts would possibly have resulted in reduced cane production and protracted discussion about property rights and management of the drainage problem.

The HRCCC undertook the task of coordinating government agencies and industry support organisations to implement necessary drainage works to reduce these potential adverse impacts. The Hinchinbrook Shire Landcare Group took up the drainage issue with assistance from the HRCCC Coordinator.

5.4 Management of Wetland Areas

5.4.1 The Issue

The expansion of intensive agriculture in the lower catchment has impacted on areas of natural wetlands. *Melaleuca* (paper-bark) wetlands once covered large areas of coastal floodplains (Tait, 1994).[9] Wetlands provide a similar function in maintaining the biological health of ecosystems as riparian areas. Raison (1995) describes wetlands, swamps, billabongs and waterholes as providing important wildlife habitats and as forming an integral part of a hydrological regime. Changes to the hydrological regime of swamps and wetlands through drainage systems are claimed to severely alter the vegetation and habitat of these areas. Wetlands are described as providing an important habitat for wildlife including birds, amphibians and fish (Raison, 1995).

More recent development of land for the production of sugar cane, which requires well-drained land, has reduced the area of wetland in the catchment. Laser levelling, where land is levelled to remove natural contours to provide good drainage across farms, has removed many areas which were natural wetlands. Expansion of the area under sugar cane in the lower catchment is estimated by Johnson *et al.*, (1997) to have resulted in the area of *Melaleuca* communities being reduced by 40 per cent between 1943 and 1996.

Aquatic habitats have been severely threatened by agricultural development which has drained and filled wetland areas and has led to increased nutrient and pesticide run-off. A number of recommendations with regard to the management of wetland areas and ecologically appropriate drainage are made by Hogan and Graham (1994). Their suggestions include the preservation of remaining wetlands, control of exotic weeds which infest wetlands, the creation of artificial wetland areas and increased attention to avoiding drainage works that obstruct fish migration.

A key problem is that the definition of a wetland is problematic and has resulted in inappropriate action or lack of action, on the part of planning authorities in the Hinchinbrook Shire to regulate or manage the development of wetland areas. Vella (1997) cites a number of problems encountered in defining a wetland, including, the differentiation between terrestrial environments and wetlands and between wetlands and aquatic and marine environments. The *Local Government Planning and Environment Act (1994)* defines a wetland as an area "whether fresh, brackish or marine, including coral reefs, mangrove areas, mudflats, sandflats, sandy beaches, seagrass beds and tidal marshes". Vella contends that this definition is inadequate because it does not "refer to wetland indicators such as the permanency of the wetland system, the frequency of inundation, predominant vegetation type, or soil characteristics" (Vella, 1997, p.46). More recently, wetlands have been defined by the Department of Environment (1996) as areas of permanent, periodic or intermittent inundation, whether natural or artificial, static or flowing, fresh, brackish or saline and including areas of marine water the depth of which does not exceed six metres. Wetlands are described as typically including areas which show evidence of adaptation of soil or vegetation to waterlogging.

The HRCCC has undertaken a number of activities to encourage farmers to either retain natural wetlands on their properties or to create artificial wetland areas as a means to improving the drainage on-farm without placing additional strain on the capacity in natural drainage paths. These activities are consistent with the stated objectives of encouraging the retention of significant natural habitats within the catchment, preventing and reducing natural resource degradation and also to promote the wise use of all natural resources within the catchment.

[9] *Melaleuca* communities are considered to be indicative of the vegetation typical of wetland areas.

Pomona Sub-division
The sub-division of a grazing property at Pomona facilitated the development of an area for cane which encompasses some marginal land including ephemeral wetland areas. This development raised the issue of indiscriminate clearing and destruction of natural wetlands in the lower catchment. Re-development of the property resulted in farmers changing the hydrology of the natural habitat in the area which could adversely impact on the biodiversity of the area. A permanent water hole as well as ephemeral wetlands were filled and levelled to provide drained caneland.

The controversy over the development raised the awareness of government agencies and local council about the inadequacy of the definition of wetland areas by the *Water Resources Act (1989)* and the *Local Government (Planning and Environment) Act (1990)* and the deficiencies of existing government agencies to deal with issues of this nature. Lack of a more precise definition has reduced the capacity of the local authorities to act to prevent or manage the development.

The appointment of an officer from DNR to resolve development issues and associated planning approvals in the future is regarded as an achievement of the HRCCC.

Artificial Wetlands
The construction of artificial wetlands on-farm has the potential to create similar positive externalities to those associated with the establishment of riparian zones. Specifically, these areas could capture silt as well as nutrient and insecticide run-off before it reaches major watercourses. They have the potential to provide a habitat for fish and wildlife which has a positive ecological and aesthetic impact. In addition, artificial wetlands provide a means to drain areas of land which cannot be put under crop or which have poor productivity because of waterlogging. Rather than draining low lying land into existing creeks and streams which could already be at full capacity, farmers have been encouraged to manage the drainage problem on their own properties and capture or internalise many of the benefits for themselves.

A retention basin is described as an area of water that is designed to retain silt and nutrient inputs from surface water runoff. An example of a retention basin is an irrigation tailwater dam. The benefits from construction of a detention basin are primarily to retain surface runoff for recycling purposes. Environmental benefits do not extend to providing flora or fauna habitats. Encouraging the restoration of wetlands or the creation of an artificial wetland is a specific activity undertaken by the HRCCC.

As was found to be the case for vegetation in riparian zones, there are number of costs associated with the establishment of these areas which require careful consideration. There are also number of risks associated with the development of these areas. Specifically, acid sulfate soils that might be exposed during excavation need to be appropriately dealt with – either by avoiding areas where they are likely to occur or by neutralising the soils. In addition, soil excavated from these areas must be disposed of sensitively so that destruction of valuable habitat areas through soil being used to build up areas which would otherwise have remained as shallow wetlands, does not occur.

5.4.2 Identification of the costs and benefits of establishing artificial wetlands or restoring wetlands

Nature of costs for construction or restoration of a wetland
The costs associated with establishing or restoring wetland areas vary according to the size and nature of the wetland area to be constructed and the siting of the wetland and the availability of suitable areas for disposal of the soil.

Components of cost include excavation and removal of soil and planting of appropriate vegetation. DNR recommends that an appropriate lagoon area be no less than approximately 0.3ha. The costs associated the establishment of 0.3ha of lagoon which is no more than 3 metres deep are estimated to range from $15,000 to $20,000 (DNR, 1996).

Potential benefits

1. Provide a valuable source of water during a dry season
2. Act as a silt trap and nutrient sink by reducing the movement of nutrients and soil off the farm
3. Help to recharge underground water aquifers
4. Serve as a breeding habitat for fish, birds and water plants
5. Provide on-farm drainage which enables areas to be put under crop or to increase production from water logged areas.
6. Aesthetically attractive

It is worth pointing out at this stage, that artificial or restored wetlands are not expected to prevent flood damage resulting from medium or major flood events. In these situations, caneland is still likely to be inundated by floodwater and crop losses would be a likely outcome resulting from scouring and waterlogging. In these situations, a wetland is not expected to prevent crop losses, but may reduce the severity of crop damage by reducing the period of inundation.

For the most part, the benefits arising from establishing or restoring a wetland are unquantifiable. However, studies have been undertaken which show the magnitude of sugar cane crop loss resulting from prolonged periods of waterlogging following inundation by floodwater (Dick, 1982; Cameron McNamara, 1980). Damage from floodwater can also result from the velocity of the floodwater as well as from the silt load and deposition of debris. The construction, or retention of wetland areas has the potential to reduce crop losses resulting from prolonged water logging and from flood related crop damage.

Consideration to the extent to which potential benefits to farmers might be realised is dependent on seasonal conditions and, in particular on the susceptibility of the sugar cane to damage.

The distribution of floods through a year as well as the period of inundation influence the magnitude of crop losses due to floodwater inundation. These are the important considerations. The whole of the Herbert River catchment is in a cyclonic and intense rainfall area. Meteorological records about the frequency of cyclones in the area, which may cause flooding in the catchment, suggest a frequency of approximately one per year. In addition to cyclones, the area experiences intense local rainfall events which are responsible for localised flooding. The most common time of the year for cyclones and intense rainfall events is shown to be between December and February. This coincides with the period following harvesting when young plant cane is particularly susceptible to damage if waterlogged for extended periods.

5.5 Management of Acid Sulfate Soils

5.5.1 The Issue

Drainage of coastal wetlands or disturbance of soils which were formerly coastal wetlands and contain sulfur compounds may lead to degradation of land and water resources. Acid sulfate soils (ASS) are the name commonly given to soils containing iron sulfides. When exposed to air, the sulfides oxidise to produce sulfuric acid which can drain off into water courses following rainfall or tidal inundation. In addition, the acidic conditions may dissolve metals such as aluminium and iron as well as potentially toxic heavy metals such as cadmium from the sediments, resulting in fish deaths from metal toxicity (DOE, 1998, p.20).

ASS occur in low-lying areas, coastal embayments and estuarine floodplains. These soils are generally located in areas where the surface elevation is less than five metres above sea level. The problem of sulfuric acid formation and run-off arises when these areas, which are frequently waterlogged in their natural state, are drained for agriculture or other development (DOE, 1998, p.20). GIS mapping of the Herbert River catchment of areas which could potentially have ASS shows that approximately 24,000ha of the catchment could be involved.[10]

Although fish-kills are the most widely recognised impact of acidification of water courses (Brown *et al.,* 1983), the issue of ASS is a primary concern for the ecologically sustainable development of Australia's coastal zone. The effects of poorly managed ASS are felt across the community including farmers, fishermen, planners engineers and people involved in land resource management in local councils and government agencies. ASS are unique in that the impacts of drainage can be so severe that they can affect engineering works, agricultural productivity and the water quality of estuarine systems.

Marked impacts on estuarine receiving habitats have included major fish kills, probable displacement of fish population, degradation and destruction of benthic food chains, and changes in riverine and estuarine planktonic structures (Crossland, 1996, p.15). Such degradation of estuary ecosystems has far-reaching implications. Degradation impacts directly on food chains and eco-system function and indirectly on coastal habitats and fisheries resources (National Working Party on Acid Sulfate Soils, 1998).

The accession of ASS products into the groundwater can severely modify and change vegetation, usually reducing productivity. As well, potable water supplies can be degraded. In addition, concrete and steel pipes and other engineering infrastructure are susceptible to acid attack.

The problem with management of ASS arises from the erratic distribution of risk areas and the lack of knowledge about their impacts. In the respect, Crossland (1996) contends that:

> our knowledge of the distribution and extent of potential pyrithic sediments, and the impacts resulting from coastal development which leads to their exposure to air, provides compelling argument for maintaining a high level of concern about ASS processes and management options (p.17).

An additional problem for management arises from spatial factors where those responsible for disturbing ASS are frequently not the recipients of the resulting impacts. The responsibility for appropriate management of ASS lies with landowners or land managers. However, it is frequently estuarine environments and sectors of the community, including the fishing industry, which depend on these environments that bear the cost of acidic discharge. Remedial action, usually at the cost of the landowner, to lessen the possibility of acidic discharge can be expensive and impact on farm productivity.

It is claimed (National Working Party Acid Sulfate Soils, 1998) that ASS underlie significant areas of coastal Australia where the majority of Australians reside. The development of coastal Australia, including urbanisation, industrialisation, agriculture and aquaculture development, requiring infrastructure and utility supply, dredging as well as sand and gravel extraction in these areas, have all disturbed ASS. The impacts of ASS threaten these industries whose estimated value is $10 billion (National Working Party ASS, 1998).

[10] The acid sulfate risk area was initially indicated by a 2km buffer strip along the coast. More detail was indicated using soil values. The following areas were shown as having a high potential towards acid sulfate soils: Brae, Mandam, Mangroves, Orient and stream channels and swamps. A number of areas were excluded as having a negligible or low potential towards acid sulfate soils: beach ridge soils, Ingham, Hamleigh and Macknade. In addition, urban areas were excluded. (Johnson and Smith (1996)

The estimated cost of the impact of ASS is suggested by the National Working Party ASS to include:

- The economic costs associated with avoidance costs incurred as a result of transferring or relocating developments to non-ASS areas. Avoidance costs include items such as reduction in the value of land and the future loss of production from industries located in ASS areas.
- Treatment and rehabilitation of infrastructure affected by ASS would include replacement of iron, steel, aluminium and concrete structures.
- Prevention of acid discharge resulting from coastal urban development in Queensland is estimated to cost over $100 million annually.
- Loss of production, resulting from land and water degradation, includes losses from fishing industries as well as agriculture.

Increased understanding of ASS, coupled with better and more available information on their management, has enabled land managers to take greater responsibility for the consequences of their farm management practices. In many instances, avoidance of ASS through careful site selection can be the most economic and environmentally sound planning decision (Blunden and Rudd, 1996).

Blunden and Budd (1996) describe coastal zone land management in the past to have been primarily concerned with agricultural production, resource extraction or for residential development. They suggest that the management of ASS should be "integrated with the management of land in a holistic and comprehensive strategy that marries productivity and environmental outcomes" (p.264). It is recommended that the management of ASS should be a part of a comprehensive management plan for land generally and should not be treated as a separate issue.

The complexity of the environmental, social and economic impacts of ASS management is regarded by the National Working Party on Acid Sulfate Soils, 1998, to require :

- Effective coordination of limited government resources and policies at all levels.
- Effective regulation by government and compliance by industry.
- Effective planning and development controls.

(National Working Party ASS, 1998, p.5)

The HRCCC has actively participated in programs supported by DNR, DOE, BSES and Canegrowers to increase the awareness of farmers to the potential problems of ASS. The HRCCC has specifically targeted a number of farms identified as "high risk". HRCCC activities in relation to the management of ASS are consistent with the stated objectives of identifying and rectifying natural resource degradation, promoting ways to prevent and reduce natural resource degradation, and promoting the wise use of natural resources within the catchment.

5.5.2 Estimated costs of preventing the disturbance of ASS

The estimated costs associated with educating the catchment community considered at risk from the disturbance of ASS are primarily associated with distribution of literature. These costs are minimal relative to the potential benefits enjoyed if these areas are undisturbed or avoided. Costs to farmers to avoid disturbing acid sulfate prone soils are likely to be in the nature of the opportunity cost of land which would remain as grazing land rather than being redeveloped for cane.

There are, potentially, 24,000ha of the catchment affected by ASS. In 1996, 790ha of this area was under sugar cane, 1,969ha was classified as grazing or grassland (which could potentially be drained and developed for sugar cane) and over 13,200ha was classified as mangroves (providing a valuable fish habitat). If it is assumed that 40 per cent of the grazing and grassland (approximately 787ha) would, in the future, have been redeveloped for cane, then the

opportunity cost of that land is the difference between the income potential of the land under cane and the income earned from this land from grazing production. As grazing land, net income per ha per annum is estimated to be approximately $900 (Ramsay, pers com., 1998). The cost to redevelop grazing land for cane is estimated to be approximately $4,000 per ha. The net income per annum from this land if redeveloped for cane production is estimated to be $1,260 (assuming cane is valued at $27.00 per tonne). The estimated opportunity cost of not developing acid sulfate prone land which is currently classified as grazing or grassland for cane is estimated to be approximately $1,772,100 per annum.

5.5.3 Estimated Benefits

The estimated potential benefits associated with managing ASS in the Herbert River catchment are in the nature of avoided costs. In particular, avoidance of fish kills and degradation of the estuarine fish habitat are of primary concern. The avoided loss of production from agricultural land resulting from deterioration of land afected by run-off from ASS is an additional benefit..

The Hinchinbrook Channel area is claimed (Coles *et al.,* 1989) to have the highest number of fish and crab species and the highest fish and crab species diversity between Cairns and Bowen. Mangroves in the Herbert catchment were also found to have abundant populations of juvenile fish and crustaceans and to have significant populations of commercially important prawns. Fish and crustacean habitats provided by a one hectare area of mangrove is estimated to be worth over $100,000 per annum to fisheries production in Queensland (Crossland, 1996, p.15). Fish kills, valued at $35,000, in the lower catchment streams have been reported (DoE, 1998). However, the cause of the fish kills has not been identified with certainty.

It would be an exaggeration to claim that the total area under mangrove in the catchment was under threat from drainage of ASS. It would also be an exaggeration to claim that the total area of land in the catchment currently under sugar cane production, or which could potentially be put under cane in the future, would be at risk if land use, and in particular subsurface drainage (open drains), was inappropriate.

Insufficient information is available to determine the area of mangrove likely to be at risk or to attribute fish-kills in the catchment to the flushing of ASS. However, GIS mapping of the potential ASS in the catchment suggests that cane is currently grown on areas of potential ASS at the outlet to Victoria Creek. Farm land with open drains in this area would drain into Victoria Creek. This area is surrounded by mangroves which could, potentially, be adversely affected by deterioration of water quality destroying the estuarine fish habitats in the area.

In addition to avoided losses to the Queensland fishing industry, there are also potential losses to the sugar industry if ASS are not appropriately managed. A 1 per cent reduction in sugar cane production currently produced on land in the ASS prone area could be valued at around $20,000 per annum.

To offset the opportunity cost of land remaining under grazing or grassland, the potential value of protection of fish habitats in mangrove areas would need to be substantial. For example, an area of 10ha of mangroves affected by runoff from ASS potentially destroying 50 per cent of the fish habitats would need to be valued at $500,000 per annum to the Queensland fishing industry to offset the opportunity costs of not redeveloping the land for cane. The estimated NPV of managing ASS prone areas by not redeveloping is presented in Table 5.10. Table 5.10 provides the estimated NPV using discount rates of 4, 6 and 8 per cent and with the value of cane varying from $24.00 per tonne up to $30.00 per tonne and the value of the mangroves to the Queensland fishing varying between $200,000 per annum to $800,000 per annum.

Table 5.10 Estimated NPV of Managing Acid Sulfate Soil Prone Areas Under a Number of Assumptions

NPV ($'s) Discount Rate 4%			
Value of fish habitats ($'s)	**Value of cane/tonne ($'s)**		
	30.00	**27.00**	**24.00**
200,000	-11,285,919	-6,571,655	-1,857,391
500,000	-7,208,821	-2,494,557	2,219,707
800,000	-3,131,723	1,582,540	6,296,804
NPV ($'s) Discount Rate 6%			
Value of fish habitats ($'s)	**Value of cane/tonne ($'s)**		
	30.00	**27.00**	**24.00**
200,000	-7,991,221	-4,232,562	-473,903
500,000	-4,550,245	-791,586	2,967,073
800,000	-1,109,269	2,649,390	6,408,049
NPV ($'s) Discount Rate 8%			
Value of fish habitats ($'s)	**Value of cane/tonne ($'s)**		
	30.00	**27.00**	**24.00**
200,000	-5,553,753	-2,520,406	512,940
500,000	-2,608,309	425,037	3,458,385
800,000	337,134	3,370,481	6,403,829

For investment in the management of ASS, by not developing these areas, to show a positive NPV, either the opportunity cost of producing cane on these areas would need to be low (value of cane below $30.00 per tonne) or the value of fish habitats would need to be valued at greater than $500,000 per annum.

As was the case for establishing riparian vegetation, distribution of the potential benefits from appropriate management of potential ASS cannot be attributed to specific individuals or groups of individuals within the community. However, the disbenefits, if ASS are not appropriately managed, have the potential to impact on the wider community.

5.6 Strategic River Bank Protection

The HRCCC has been instrumental in coordinating the endeavours of the HRIT and the Shire Council to undertake substantial river bank protection of sites identified as a major erosion threat when the river is in flood. One specific activity undertaken by the HRCCC is at the Long Pocket site. This project was undertaken to protect infrastructure, including rail and road structures from a break-through or cut-off of the Long Pocket bend of the Herbert River. It is claimed (HRIT) that a cut-off would have resulted in substantial deepening and widening of the Herbert River upstream and considerable siltation downstream which could adversely impact on the river environs. The social, economic and environmental impacts of a cut-off are identified as:

- Loss of a road bridge linking Abergowrie and Ingham
- Loss of cane railway link between Victoria Mill and the Abergowrie District
- Isolation of a number of houses located within the river loop
- Major river bank erosion upstream, resulting in the loss of remaining riparian vegetation and adjacent agricultural land
- Siltation of lower sections of the Herbert River and associated marine areas.

The project required stabilising the potential cut-off path using vegetation, rock protection and changes to land use in the area adjacent to the site.

Although this project was identified previously in reports about flood mitigation in the catchment, neither the Shire Council nor the HRIT had acted on the recommendations. The HRCCC was instrumental in coordinating both organisations to work together to apply for external funding to undertake the required stabilisation work.

5.7 Mining Dams in Herberton Shire

Mining dams, north of the township of Mt. Garnet, constructed when tin was extracted from the area (abandoned in the late 1980's) are regarded by Herberton Shire Council as a threat to the surrounding community and to the downstream quality of water in the Herbert River. (Report to the Herberton Shire Council following an inspection by Council members and officers from the Department of Lands and the DPI together with a number of landowners, April 1993). Concern arises from the lack of maintenance of the earth-filled dams and the possible increasing risk of failure through erosion. Crook's dam has been described as being undermined and needs extending into the bank to improve its stability. Other dams, including Butler and Coolgarra are leaking and in need of repairs. Sediment or settlement dams in the area, are reported as containing "highly undesirable substances, and are of great concern to all water users downstream, including domestic, agricultural, recreational and wildlife habitats. These dams are at risk of failure if failure of the water storage dams occurs.

The HRCCC action with regards to the dams meets its stated objectives of coordinating government agencies and the community to pursue common objectives, identifying and rectifying natural resource degradation as well as promoting the wise use of all natural resources within the catchment.

The HRCCC identified the need for coordinated action between government agencies and the community and obtained National Landcare Program funding of $21K per annum for three years to undertake an inventory about the state of the dams, the possible costs associated with rehabilitation of the dams as well as the current land tenure. In addition the inventory identified habitat conservation and the recreation potential of the dams. To facilitate the use of the water storage dams to supply water to properties and/or urban users as well for recreational and habitat or nature conservation, property rights over the dams might need to be renegotiated with landholders. This would reduce the costs of negotiating responsibility for repairs and access to the dams, resulting in lower transaction costs. It is proposed that the Herberton Shire Council takes up a lease over the dams from landholders on whose properties the dams are located.

5.8 Summary

The present value of the costs associated with the establishment and on-going administration of the HRCCC over a period of 20 years is estimated to be approximately $974,000. The HRCCC has undertaken a number of specific activities in the catchment to meet its stated objectives that offset these costs. These activities have been funded from both the public purse as well as from the catchment community. Evaluations have been undertaken of a number of activities relating to the preservation of natural habitats, management of vegetation in riparian areas, management of floodplain drainage, management of wetlands, management of acid sulfate soils, strategic river bank protection, and stabilisation of mining dams in the upper catchment. Most of the HRCCC activities have been aimed at awareness raising, creating a forum for cooperative solutions, influencing a range of planning processes influencing the Herbert River catchment or brokering fund-raising (eg. Bellamy and Johnson 1999; Bellamy and McDonald 1999). If the activities undertaken did result in changed resource management practices, the estimated costs and benefits incurred are summarised in Table 5.11.

Table 5.11. Summary of potential costs and benefits of HRCCC activities.

Issue	HRCCC Activity	Potential Costs of Activity	Potential Benefits
Management of vegetation in riparian areas	• Mapping of riparian vegetation • Raising community awareness of restoration and retention of riparian vegetation • Organising a Community Riparian Forum with guest speakers	*Individual landowners:* • Cost of revegetation/restoration of riparian areas varies with width required along watercourse and extent of revegetation (eg. 40m buffer corridor costs $120K/km) • Opportunity cost of land which varies with cane assignment/farm size (eg. a 4ha riparian area, with 40% normally under cane would incur a net income loss of $4,000 per annum. This would represent 4% per annum of the net income for a farm with 100ha assignment but 10% per annum net income loss for a farm with 40ha assignment)	*Individual landowners:* • Reduced rat damage to cane crop (eg. value of protection of 8ha area of riparian vegetation is $23K per annum) • Avoided cost of baiting control (where applicable) • Reduced damage to cane resulting from aquatic weed inundation • Improved drainage • Stabilisation of river bank leading to reduced risk of cane loss due to stream bank collapse and scouring *Catchment Community:* • Improved water quality downstream • Improved habitat for fish and crustacea leading to reduced fish kills • Improved natural habitat and source of nutrients for riverine plants and wildlife • Aesthetic benefits (eg. Native wildlife habitat)
Preservation of natural habitats	• Owl box program in support of an integrated approach to pest management	*Individual landowners* • Cost of building owl nesting box and hunting perches ($80/box) *Catchment Community:* • Cost of hire of cherry picker of $1500	*Individual landowners* • Reduced rat damage to cane (see above) *Catchment Community:* • Adoption of ecologically sensitive pest control • Aesthetic benefits
Management of drainage	• Lobbying for technical drainage expert extension officer • Fostering of Landcare group to resolve Wharps Sub-division drainage problems	*Catchment Community:* · Cost of drainage reparation works	*Individual landowners* • Reduction in loss of cane production due to poor drainage *Catchment Community:* • Reduction in adverse impacts of inappropriate drainage infrastructure on other land-owners and habitats • Reduced social conflicts and reduction in

Issue	HRCCC Activity	Potential Costs of Activity	Potential Benefits
			litigation and transaction costs associated with negotiation over drainage management
Management of wetlands	· Raising awareness of ecological importance of retaining natural wetlands on farm · Fostering the development of artificial wetlands on cane farms	*Individual landowners:* • Opportunity cost of land • Construction costs of wetland vary according to size and site of area to be constructed and availability of suitable areas for disposal of soil (eg. Cost of 0.3ha lagoon up to 3m deep range from $15K to $20K) *Catchment Community:* · Contribution to salary and on-costs for DNR extension officer	*Individual landowners:* • Improvement to on-farm drainage • Source of water in dry periods • Aesthetic attraction of habitat etc. *Catchment Community:* • Retention of significant natural habitats on the Herbert floodplain for fish and wildlife • Providing a retention basin for nutrients and sediments in wetland leading to improved water quality downstream • Improve recharge of groundwater • Aesthetic benefits
Management of acid sulfate soils	· Raising farmer awareness of potential problems of acid sulfate soils	*Individual landowners:* · Estimated opportunity cost of land (eg. decision not to convert grazing land to caneland) for area 'at risk' in catchment (approx. 787ha) is approx. $1,772K per annum. *Catchment Community:* · Costs of media releases and distribution of literature to "at risk" farmers	*Individual landowners:* · Avoided costs of loss of cane production (eg. 1% reduction in yield on current caneland in ASS prone areas is approx. $20K per annum) varies with size of area of potential impact *Catchment Community:* · Avoided costs (eg. Avoidance of fish kills and degradation of estuarine habitat)) varies with size of area of potential impact
Strategic river bank protection	· Joint project with Herbert River Improvement Trust at Long Pocket	*Catchment Community:* · Cost of works (eg. bank stablisation using vegetation and rock protection as well as land use changes)	*Individual landowners:* · Avoided costs of loss of cane production *Catchment Community:* · Protection of existing infrastructure (eg. cane railway link to mill and road bridge across river) · Prevention of river bank erosion upstream causing loss of riparian vegetation and adjacent productive cane land · Reduction in siltation downstream

Issue	HRCCC Activity	Potential Costs of Activity	Potential Benefits
Stabilising relict mining dams in the upper catchment	· Inventory of derelict tin dams in upper catchment to assess risk and prioritise work needed · Fostering of coordinated action between government agencies and landowners	*Individual landowners:* · In-kind contribution of time and earth moving equipment *Catchment Community:* · NLP Project grant of $21K p.a. for dam wall stabilisation	*Individual landowners:* · Improved water supply to property owners *Catchment Community:* · Improved water quality downstream · Avoidance of risk of dam failure

Overall, it was found that these activities have the potential to significantly improve or preserve the condition of natural resources in the catchment. It was found also that, for the successful implementation of a number of these activities, notably management of riparian vegetation, management of acid sulfate soils and management of wetlands, private property owners would incur considerable financial expense. In addition, it was found that, all of the potential benefits resulting from investment in these activities were not equitably distributed among farmers incurring the cost and that those who do not contribute to the cost could not realistically be excluded from enjoying the benefits. In an economic climate where the financial viability of farmers is generally deteriorating, the ability, and therefore the willingness, of farmers to invest in improved resource management is considerably reduced. Community-based organisations, which rely on the voluntary cooperation of individual resource managers, may need to take this into consideration to improve the effectiveness of their strategies.

6.0 CONCLUSION

This report presents an economic evaluation of the ICM organisation in the Herbert River catchment. To a large extent, the problems encountered in this evaluation might be encountered for similar studies of similar organisations. In particular, CBA is conducted to evaluate investment in a particular project or program. In this regard, identification of the "without" project or program scenario is important. Because ICM organisations do not operate in isolation from existing government agencies, industry support agencies and community organisations, it is difficult to isolate the impact of the activities of a specific ICM organisation on the state of the environment from the impact of other organisations researching and working in the area. To overcome this problem, assumptions are required about the extent to which organisations of this nature can realistically claim responsibility or ownership over both potential and realised improvements in the condition of natural resources. A number of activities undertaken by the HRCCC to meet its stated objectives have been evaluated in this study using CBA methodology. Detailed description has been provided about these activities identifying potential benefits and costs associated with their implementation. For the most part, causal relationships between the activities of the HRCCC and an improvement in environmental attributes such as water quality are not quantifiable. Indeed, improvements in specific environmental attributes are not, or have not to date, been measured. In order to quantify or value potential outcomes from the activities of the HRCCC, a number of simplifying assumptions have been made.

The results from the evaluation show that the activities undertaken by the HRCCC have the potential to bring about substantial improvements in the quality of the land and water resources in the catchment. However, in the majority of cases, successful implementation of these activities requires significant costs to be incurred by individual landholders in the catchment. Many of the potential benefits, however, are shown to be enjoyed by both the landholders as well as the community as a whole, and further, landowners cannot internalise all of the benefits to which they contribute or exclude others from enjoying them.

The real issue the HRCCC and other organisations of this ilk need to address, is how to encourage farmers to take on farm management practices that could result in improvements to the land and water resources, particularly when to do so could result in a shortfall in their income. The HRCCC seems to have adopted the strategy of educating people in the expectation that this will bring about a change in their behaviour. This approach may prove to be lacking in effectiveness, particularly when farmers are being asked to bear the costs and in an economic climate for agriculture, and the sugar industry in particular, which is characterised by increasing costs and lower returns.

There are a number of limitations underlying this study which may provide an opportunity for further research. Specifically, many of the simplifying assumptions which were adopted to

facilitate the quantification of costs and benefits of activities undertaken by the HRCCC need to be reconsidered and refined. For example, estimates of riparian areas requiring revegetation and the extent to which an area requires revegetation or how much of this area is currently used for cane, has been undertaken in this analysis using simplifying assumptions. These assumptions require substantiation, perhaps by employing GIS techniques the validity of the results could be increased. Also, with additional data, more sophisticated modelling could be undertaken to improve estimates of potential reduction in rat damage and fish kills.

Previous reports on community-based organisations (Sloane, Cook and King, 1997; Stone and Assoc, 1995) suggest the need for indicators to be identified which would provide a means to measure improvements in the condition of natural resources. This report concurs with those suggestions.

The Draft Herbert River Catchment Management Strategy (HRCCC, 1996) identifies three desired outcomes from the implementation of their strategy. These are:

1. An understanding by land managers of the inter-relationships between land, water and biological resources, and the effects their decisions and actions have on these resources.
2. A co-operative and co-ordinated approach to natural resource management.
3. Primary industries which are economically viable and ecologically sustainable.

(HRCCC, 1996, p.i)

Without the identification of indicators to measure these outcomes which largely rely on behavioural change on the part of the catchment community, behaviour which would demonstrate a change in the sustainability of agricultural land, neither the desired nor the apparent achievements of the HRCCC can be measured and valued with confidence. This problem is not confined to the evaluation of the HRCCC but to all organisations of this nature.

1.0 INTRODUCTION

CSIRO are conducting research on the evaluation of Integrated Catchment Management (ICM) in a wet tropical environment. The objectives of this five year program are to:

1. monitor and document the process of implementation of ICM in the Herbert River catchment and identify the social, economic, and institutional factors that facilitate or hinder this process;

2. evaluate the key impacts of the implementation of the ICM process in terms of attitude and behaviour changes in the community and changes in the severity or tractability of the resource use conflicts for the Herbert River catchment;

3. assess the specific technical and related information needs that are relevant to an effective ICM implementation process in a wet tropical environment; and

4. develop a framework and related methods for evaluating the process of ICM implementation that will facilitate the development of more effective catchment management programs in Australia.

As the success of ICM by definition depends on communication between stakeholders to ensure coordination of inputs, the research included a pilot study on measuring and evaluating communication between significant stakeholders of ICM. Prior to this, very little research had been conducted to measure the degree of communication between stakeholders of ICM and the effectiveness of the communication.

2.0 METHODOLOGY

2.1 Structure of the questionnaire

2.1.1 Introduction

A brief introduction was read to respondents at the start of their telephone interview which explained what the study was investigating.

2.1.2 Involvement in ICM

The first questions related to respondents' involvement in ICM: whether or not they had been involved; reasons for involvement; length of involvement; and if the respondent was not involved, awareness of ICM in the Herbert River Catchment or elsewhere in Queensland. Everyone was also asked about any concerns they had regarding environmental management in the Herbert River Catchment.

2.1.3 Communication

To clarify which communications would be included, respondents were advised that communications may have been:

- formal (eg. a letter or e-mail) or informal (eg. a conversation or meeting at a social occasion);
- for one particular reason or for a number of reasons;
- personal (ie. individuals representing themselves) or official (ie. individuals representing their organisation); or
- 'one off' or a 'group' of communications with the same contact.

The following categories of 'contacts' were used throughout the questionnaire:

- state government in Brisbane;
- state government in Townsville or northern Queensland (regional state government);
- local government;

- Herbert River Catchment Coordinating Committee;
- industry or an industry group;
- individual basis; and
- other contacts.

Respondents were asked firstly how often they had communicated with each of these categories about ICM/environmental issues and secondly, with whom they had communicated. Up to six separate answers were permitted and depending on the category, they may have been departments, organisations or individuals. This was recorded by interviewers on a separate "Communications Sheet".

Originally it had been hoped to assess the nature and function of the eight communication dimensions identified for large corporations by Roberts and Reilly (1974). These dimensions were not appropriate for ICM and a more open-ended approach was developed. The key dimension, influence, was retained for this study.

The questionnaire (see Appendix A) therefore measured the following aspects of communication reported by respondents about their communication with each of the categories of contacts:
- frequency of communication with contacts over the past year;
- the topics of communication;
- who initiated the contact;
- whether respondents represented themselves or an organisation;
- the outcomes;
- the degree of satisfaction;
- any resultant change in the respondent's outlook; and
- the respondent's opinion about resultant change in the contact's outlook.

The terminology 'contacts' and 'categories of contacts' will be used throughout the report.

Interviewers referred back to the responses on the Communications Sheet to ask these questions. To prevent order biasing, interviewers used a different order for each interview. To make the administration of this easier, each category was printed in a different colour in the questionnaire and corresponding colours were written next to the categories on the Communications Sheet.

2.2 Pre-testing

Eight pre-tests were conducted with people familiar with ICM issues either in the Herbert River Catchment or elsewhere in Australia. The feedback was used to alter the questionnaire.

2.3 The Sample

The categories of respondents were:
- state government public servants (Brisbane);
- state government public servants (Regional);
- regional participants in ICM in nearby catchments;
- researchers;
- Herbert River Catchment Coordinating Committee (HRCCC) members;
- landholders and general community; and
- people active in the local community (eg local government, community/industry organisations).

Contact details for people in most of these stakeholder categories were obtained from members of the HRCCC and CSIRO researchers in Queensland. Landholders and general community were selected randomly from the telephone book and landholder lists. In categories for which

more respondents were needed, more names were gathered using the "snowball" sampling technique (see Fife-Shaw, 1995).

A total of seventy one people were telephoned to ask if they would participate in the study. Sixty individuals agreed to participate, a response rate of 84.5%. Those people were either interviewed by telephone at that time or at an arranged time. The table below shows the number of people telephoned, the number interviewed, and reasons for not participating. The actual refusal rate was very low by normal survey standards.

Response rate and reasons for not participating

	Contacted	Interviewed	Moved	Retired	Away/not available	Refused
HRCCC	17	16				1
Regional SG	14	9	1		4	
Local people	13	12		1		
SG Brisbane	6	3	2			1
Other ICM	5	5				
Researchers	4	4				
Active locals	12	11			1	
TOTAL	71	60	3	1	5	2

Interviewers were provided with the following definition to read to respondents who asked what ICM meant: "Integrated Catchment Management is a management system that attempts to integrate key resource management issues in a way that enables all stakeholders to work together towards the goal of balancing economic development with environmental protection".

3.0 RESULTS

3.1 Background

Are you involved either personally or because of other reasons in Integrated Catchment Management (ICM) in the Herbert Catchment?
Participants were asked whether or not they were involved, either personally or for other reasons, in ICM in the Herbert River Catchment. Of the sixty participants, 45 were involved in ICM. Those fifteen people not involved in ICM in the Herbert were from the following groups: local people (8), regional state government (4), and regional ICM (3).

From this point forward, those involved in ICM were asked about their communication concerning ICM and those not involved were asked about communication concerning environmental issues.

Which of the following are reasons for your involvement?
Those 45 people involved in ICM were then asked to indicate which of eight reasons were appropriate to explain why they were involved, shown in the table below. More than one answer was permitted.

Reason for involvement	% (n = 45)
Personal interest	75.6
Job related	64.4
Interest in the sugar industry	64.4
Member of a community group	57.8
Because I'm a landholder	48.9
Interest in other primary production	48.9
Live on the catchment	46.7
Scientific research	31.1
Other reasons (eg common sense, interest in a particular issue)	28.9

Three quarters of the sample agreed with *personal interest* as a reason for their involvement in ICM in the Herbert. *Job related* and *interest in the sugar industry* were selected by nearly two thirds of the sample.

Those involved in ICM were asked how long they had been involved. The mean length of involvement for each group of respondents is shown in the following table. The number of respondents is shown in brackets.

Category of respondent	Mean (years)
Researchers (n = 4)	7.2
SG Brisbane (n = 3)	6.3
Local people (n = 3)	6.0
Other ICM (n = 2)	5.5
HRCCC (n = 16)	4.9
Active local people (n = 10)	4.6
SG Townsville (n = 5)	4.4

As the HRCCC was formed in 1993 it is not surprising that the mean length of involvement in ICM for members of the HRCCC was 4.9 years and the modal response was 5 years. Of interest is the fact that researchers had been involved in ICM longer than any other category of respondent.

Before this interview were you aware of the ICM program in the Herbert Catchment and elsewhere in Queensland?

Those people who were not involved in ICM were asked whether they were aware of the ICM program in the Herbert Catchment and elsewhere in Queensland. Ten of the fifteen people not involved were aware of ICM. When asked what they knew about ICM, 5 mentioned previous involvement in ICM, and the remainder were either unfamiliar with the details of ICM, mentioned that it tackled erosion and chemical run-off or that it was related to a review of the Hinchinbrook canals.

Do you have any concerns about environmental management on the Herbert Catchment? If yes, what are your major concerns?

All participants were asked whether they had any concerns about environmental management in the Herbert Catchment and if so, to list their major concerns. For the 55 respondents who did mention concerns, the table lists the frequency of the concerns stated, separately for those people involved, and not involved, in ICM.

Concern	Involved (n = 45)	Not involved (n = 15)
Environment in general (inc biodiversity loss)	18	3
Ineffective decision making processes and communication	15	0
Water quality	10	1
Flooding, drainage and their management	8	5
Vegetation (eg clearing, revegetation and mangroves)	6	0
Impact of industry	4	0
Weeds and weed control (eg arsenic weed, lantana)	3	2
Over use and over allocation of water	3	1
Natural resource management	3	1
Other	11	7

The larger degree of concern by those involved in ICM about *ineffective decision making processes and communication*, *water quality*, and *vegetation* issues may reflect the insight gained to these issues through close involvement with government departments and attempts to address sustainability issues.

The order of concerns expressed by the HRCCC reflected the priorities of people involved in ICM except that *flooding, drainage and their management* rated much lower for the HRCCC.

3.2 Overall communication (Recorded on Separate Communications Sheet)

Over the last year, how often have you communicated with anyone from … about ICM OR environmental issues?

1	2	3	4
Frequently	Occasionally	Once or twice	Never

This question was asked for the following categories of contacts:

A. state government in Brisbane
B. state government in Townsville or Northern Queensland
C. local government
D. the Herbert River Catchment Coordinating Committee
E. industry or an industry group
F. individual basis (ie. communicating with the person as an individual, and not necessarily as someone representing an organisation).

This question was asked separately for each different contact in the 'other' category at the end of the questionnaire. The following table shows the overall frequency of communication with each of the categories of contacts, with median responses indicated with a tick.

	SG Brisbane	Regional SG	Local Govt	HRCCC	Industry	Individual	Other	Total	%
Frequently					✓			123	38
Occasionally		✓	✓	✓			✓	68	21
Once/twice	✓					✓		37	11
Never								96	30

The overall totals indicate that much of the communication that did occur was fairly frequent. The most frequent communication, on average, was with industry, which reflects the emphasis that ICM groups place on close communication with industry and industry groups.

Who did you communicate with? (Up to six responses permitted)
As mentioned above, respondents were asked to specify who they had spoken to from each category of contact. The sixty respondents reported a total of 348 different contacts they had communicated with about ICM and related issues.

For a detailed list of the different specific contacts for each category of respondent, see Appendix B. A table showing the number of different contacts for each group of respondents with each of the categories of contacts can be found in Appendix C.

Below are the various organisations or departments spoken to from each category, using names current at the time of the survey. Although names of individuals were mentioned by respondents, only the number of different individuals spoken to has been listed. Each of the contacts may have been communicated with any number of times by each respondent.

State government in Brisbane
Department of Natural Resources
Department of Local Government and Planning
Department of Environment
Department of Primary Industries
Department of Fisheries
Queensland Rail
Members of coordinating groups

Regional state government
Department of Environment
Department of Natural Resources
Department of Primary Industries
Queensland Transport
Dept of Local Government and Planning

Cattleman's Union
Members of coordinating groups
Colonial Sugar Refineries (CSR)
Fruit and Vegetable Producers Association
Horticulture
Queensland Commercial Fisheries Organisation
Landcare
Individuals
Tropical Fruit Group

Other
CSIRO
Landcare
6 different individuals
CSR
Aboriginal and Torres Strait Islander Commission (ATSIC)
local group

The table below lists the mean number of different contacts reported per respondent over the last year with the different categories of contacts.

Categories of contacts

Respondents	SG Brisbane	Regional SG	Local govt	HRCCC	Industry	Individual	Other	TOTAL	Overall mean
Researchers (4)	1.5	1.0	2.0	2.8	1.0	1.5	0.3	40	10
SG Brisbane (3)	2.3	1.3	0.3	1.7	0.7	0.0	0.7	21	7
HRCCC (16)	1.3	1.6	1.3	n/a	2.0	0.4	0.5	114	7.1
Active locals (11)	0.9	1.2	1.1	0.8	0.8	0.7	0.8	70	6.4
Other ICM (5)	1.2	0.4	1.8	0.2	2.2	0.6	0.0	32	6.4
Regional SG (9)	0.7	1.2	1.0	1.0	1.6	0.3	0.0	52	5.8
Local people (12)	0.3	0.3	0.3	0.2	0.2	0.3	0.1	19	1.7
Overall mean	8.2	7.0	7.8	6.6	8.4	3.9	2.3		

On average, researchers had communicated with the highest number of different contacts (10 per person). This was to be expected as they were selected because of their research on ICM issues and therefore had a great deal of contact with others about ICM.

HRCCC members had made an average of 7.1 different contacts per person overall. However, while some members of the HRCCC listed a relatively high number of different contacts (maximum = 26), other members had very few different contacts (minimum = 2). Overall, the number of different contacts for the HRCCC was very high considering the voluntary nature of members' involvement, unlike state and local government respondents and researchers.

State government representatives in Brisbane had a very similar number of different contacts to HRCCC members (7 per person).

The highest number of different contacts within a specific category was reported by researchers with the HRCCC (2.8 per researcher). Researchers also communicated with local government to a relatively high degree (2 per researcher).

The second highest number of different contacts with a specific category was reported by Brisbane state government respondents with other Brisbane state government representatives (on average, 2.3 contacts).

The relatively high number of different contacts that the HRCCC had in industry (2 contacts per person) and that other ICM groups had in industry (2.2 per person) again reflects the emphasis ICM groups place on close communication with industry and industry groups and industry representation on ICM committees.

Active local people had the most even distribution of communication with the different categories of contacts. This places active local people in an ideal situation to assist in coordination efforts.

The low mean number of different contacts reported by local people about ICM or environmental issues (1.7 per person) may indicate a relatively low involvement of the general community in ICM. At this stage, there are no baseline figures of this nature available. In addition, communication with people on an individual basis was very low.
The only linkage completely missing in this matrix of communications was between Brisbane state government respondents with people on an individual basis. Very low numbers of different contacts were reported by other ICM representatives with local government, regional state government and the HRCCC and by local people with all categories of contacts.

3.3 Characteristics of communication

What were the main reasons for the communication?
All respondents were asked to explain the main reasons for each communication with the different contacts they had listed. The table below shows those reasons mentioned in over 4% of responses by each of the seven groups of respondents. The total number of responses mentioned by each group of respondent is shown in the first row. For each different reason, the percentage of the total number of responses for each group of respondents is shown. For example, 33 responses were mentioned by local people and 9.1% of those responses were *policy/planning/decision making*. It is important to note that 'reasons for communication' have not been analysed by 'who initiated the contact'.

Reasons for communication (by groups of respondents)

	Respondents							
	Local people	Local active	HRCCC	Other ICM	Regional SG	SG Brisbane	Researchers	OVERALL
Number of responses	**33**	**79**	**176**	**50**	**90**	**35**	**69**	**532**
Reasons	%	%	%	%	%	%	%	%
Policy/planning/decision making	9.1	10.1	9.7	4.0	11.1	5.7	10.1	9.2
Environmental issues	21.2	12.7	5.7	12.0	14.4			8.6
Research/project work			5.1		4.4		30.4	6.4
Follow up on catchment /strategy issues		5.1	4.5		5.6	11.4	10.1	5.3
Meeting/seminar		6.3	5.7	6.0	6.7			4.7
Exchange information	9.1		8.5		5.6			3.8
Drainage action	9.1							3.4
Information collection and follow up		8.9				5.7	5.8	3.0
Funding				4.0		14.3		2.8
Departmental/local issues							10.1	2.6
Understanding			4.5				18.8	2.4
General discussion	3.0			4.0				2.3
Advice on water licencing/allocation issues					7.8			2.1
Gain support or interest in ICM				6.0				2.1
Marine permits					10.0			2.1
Coordination/conflict resolution	6.1			4.0	6.7			1.9
General advice		8.9						1.9
Land use or management	6.1			4.0				1.5
Death of fish or fish habitats								1.3

Overall, the most frequent responses were: *policy/planning/decision making* (9.2%); *environmental issues* in general (8.6%); and *research project work* (6.4%).

The most frequent reasons for communication mentioned by specific groups of respondents were:

- *research/project work* by researchers (30.4%);
- *environmental issues* by local people (21.2%), regional SG (14.4%), local active people (12.7%), and other ICM groups (12.0%);
- *understanding* by researchers (18.8%), mainly in communication with people on an individual basis; and
- *funding* by Brisbane state government (14.3%).

The following table lists the frequency of the same reasons for communication with each category of contact. Again, only reasons mentioned in over 4% of the responses are listed. However, as the number of responses was very low for 'Other' contacts, only reasons given in over 5% of responses are listed for this group.

The total number of responses for each category of contact is shown in the first row. The percentage indicates how often each response was mentioned in communication with each category of contact. For example, for communications with Brisbane state government contacts, a total of 88 responses were listed and 12.5% of these were *policy/planning/decision making*.

Reasons for communication (by categories of contacts)

	Categories of Contacts							
	SG Brisbane	Regional SG	Local govt	HRCCC	Industry	Individual	Other	OVERALL
Number of responses	**88**	**96**	**86**	**69**	**123**	**45**	**25**	**532**
Reasons	%	%	%	%	%	%	%	%
Policy/ planning/ decision making	12.5	4.2	12.8	8.7	9.8	4.4	12.0	9.2
Environmental issues	4.5	8.3	16.3	4.3	7.3	8.9	16.0	8.6
Research/ project work	6.8	4.2		15.9	7.3			6.4
Follow up on catchment / strategy issues	8.0		7.0	13.0				5.3
Meeting/ seminar			9.3		4.9	6.7	8.0	4.7
Exchange information	4.5					8.9		3.8
Drainage action	4.5					9.0		3.4
Information collection and follow up		6.3				8.9		3.0
Funding	5.7	4.2						2.8
Departmental/ local issues				11.6				2.6
Understanding						6.7		2.4
General discussion						6.7		2.3
Advice on water licencing/ allocation issues					4.9			2.1
Gain support or interest in ICM				4.3				2.1
Marine permits					4.1			2.1
Coordination/ conflict resolution				4.3				1.9
General advice	4.5						8.0	1.9
Land use or management		4.2				4.4		1.5
Death of fish or fish habitats		4.2						1.3

Frequent reasons mentioned by respondents for communication with particular categories of contacts were:

- *environmental issues* with local government (16.3%) and other contacts (16%);
- *research/project work* with the HRCCC (15.9%);
- *follow up on catchment/strategy issues* with the HRCCC (13%);
- *policy/planning/decision making* with local government (12.8%), state government in Brisbane (12.5%) and other contacts (12.0%).

Unique reasons for communication to particular respondents and contacts

Some responses were unique to particular groups of respondents (still using the 4% cut-off). *Drainage action* was mentioned only by local people, in their communications with state government representatives in Brisbane and with people on an individual basis. This result reflects the degree of community concern about drainage in the Herbert River Catchment. *General advice* was only mentioned by local active people, and was in communications with state government Brisbane and 'other' contacts, indicating that these groups are presently viewed as the best contacts for general advice.

Similarly, some responses were unique to communications with particular categories of contacts. For example, *death of fish or fish habitats* was only mentioned in communications with regional state government representatives. *Understanding* was unique to communications reported with people

on an individual basis and was mentioned by HRCCC members and researchers. This may indicate the importance of communication on an individual basis when trying to gain an in depth understanding of certain aspects of ICM.

General discussion was only mentioned in communications with people on an individual basis and was mentioned by local people and other ICM representatives. *Advice on water licensing/allocation issues* and *marine permits* were unique to communications between regional state government respondents with their industry contacts.

HRCCC communication

The following reasons were reported by HRCCC respondents in their communications with the categories of contacts shown.

- *Policy/planning/decision making*: with all categories.
- *Exchange information*: on an individual basis; with SG Brisbane.
- *Environmental issues*: with all categories.
- *Meeting/seminar*: with local government; other contacts; individual basis; industry.
- *Research/project work*: with HRCCC; industry; SG Brisbane; regional SG.
- *Follow up on catchment/strategy issues*: with SG Brisbane; local government.
- *Understanding*: on an individual basis.

By comparison, communication reported with the HRCCC was mainly for the following reasons and was reported by the groups of respondents shown.

- *Research/project work*: by researchers; regional SG.
- *Follow up on catchment/strategy issues*: by SG Brisbane; researchers; regional SG; local active people.
- *Departmental/local issues*: by researchers.
- *Policy/planning/decision making*: by all groups.
- *Environmental issues*: by local people; regional SG; local active people; other ICM.
- *Gain support/interest in ICM*: by other ICM.
- *Coordination/conflict resolution*: by regional SG; local people; other ICM.

Four of the reasons for communication by HRCCC respondents matched the reasons reported for communication with the HRCCC, although in different orders of frequency.

HRCCC respondents mentioned *exchanging information; meeting/seminar;* and *understanding* whereas other respondents did not mention these in their communication with the HRCCC.

Other respondents mentioned *departmental/local issues; gain support/interest in ICM;* and *coordination/conflict resolution* as reasons for their communication with HRCCC members but these were not mentioned by HRCCC respondents. These particular differences are important in light of two HRCCC key objectives (1998), to "coordinate government agencies and the community to pursue common goals" and to "seek community involvement in catchment management".

Who made contact first?

For each communication reported, respondents were asked who made contact first. The table below shows the percentage of contacts for each group of respondents made in each direction:

- outward – the respondent initiated communication with the contact;
- mutual – initiated through a mutual contact, meeting or other event; or
- inward – the contact initiated communication with the respondent.

Groups of respondents (number of communications)	Outward %	Mutual %	Inward %
Local people (19)	47.4	42.1	10.5
Local active people (60)	38.3	50.0	11.7
HRCCC (108)	27.8	49.1	23.1
Other ICM (32)	53.1	40.6	6.3
Regional SG (51)	31.4	58.8	9.8
SG Brisbane (18)	38.9	50.0	11.1
Researchers (39)	23.1	43.6	33.3
TOTAL (327)	111	160	56
Overall %	33.9	48.9	17.1

Overall, approximately half (48.9%) of the communications were reported to be mutual, which illustrates the high degree of initial contact made through previous contacts or at meetings and other events. This result will be important to utilise in any attempts to improve communication between stakeholders of ICM or environmental issues.

Researchers were the only group contacted more often by others (inward) than they initiated communication (outward). The HRCCC also received a large degree of inward communication which may reflect their central role in providing information on ICM.

For details of the direction of communication between each of the groups of respondents and the categories of contacts, see Appendix D.

Were you primarily representing yourself or an organisation or both?
For each communication, respondents were asked whether they had primarily represented themselves, their organisation, or both. The table shows the frequency of each response for the categories of respondents.

Groups of respondents **(number of contacts)**	Self %	Organisation %	Both %
Local people (19)	47.4	47.4	5.3
Local active people (65)	13.8	72.3	13.8
HRCCC (113)	12.4	65.5	22.1
Other ICM (32)	6.2	93.8	0
Regional SG (45)	2.2	95.6	2.2
SG Brisbane (21)	0	100.0	0
Researchers (40)	17.5	82.5	0
TOTAL (335)	42	257	36
Overall %	12.5	76.7	10.7

Overall, approximately three quarters (76.7%) of respondents represented their organisation in communication with others about ICM or environmental issues. Members of state government in Brisbane, regional stage government, other ICM groups and researchers predominantly represented their organisations.

Local active people and HRCCC members were more likely than other groups to represent both themselves and their organisation in their communication with others.

What was the outcome?
Respondents were asked to list the outcomes of each communication they had mentioned. The following table shows the main outcomes of communication with each of the categories of contacts. (The number of responses is indicated by n).

	SG Brisbane	Regional SG	Local govt	HRCCC	Industry	Individual	Other	Overall
	n = 76	n = 75	n = 70	n = 40	n = 87	n = 31	n = 20	n = 399
Outcome	%	%	%	%	%	%	%	%
Progress	18.4	28.0	25.7	27.5	24.1	19.4	20.0	23.8
Understanding of issues	22.4	12.0	31.4	15.0	25.3	16.1	15.0	21.1
Information exchange	17.1	22.7	12.9	5.0	12.6	35.5	30.0	17.3
Unsuccessful	13.2	17.3	7.1	7.5	13.8			10.8
Resolution of issues/ decision	7.9	8.0	7.1	5.0	4.6	6.5	10.0	6.8
Gained information	7.9	4.0	2.9	10.0	6.9	6.5	5.0	6.0
Specific action taken	3.9	1.3	4.3		3.4	3.2	5.0	3.0
Other	3.9	1.3	4.3	5.0	3.4		5.0	3.0
Changed their outlook				15.0	1.1	12.9		2.8
Coordinate/ collaborate	2.6	1.3	1.4	7.5	1.1		5.0	2.3
Coordination needed	3.9	1.3					5.0	1.3
Benefit to industry		1.3	1.4	2.5	1.1			1.0
Gained involvement in project		1.3	1.4		2.3			1.0

The results of this question were generally very positive, with the highest responses being *progress* (23.8%), *understanding of issues* (21.1%), and *information exchange* (17.3%). Overall, however, 10.8% of communications were said to have been *unsuccessful*.

The highest responses (over one quarter) for communication with specific contacts included: *information exchange* with people on an individual basis (35.5%) and other contacts (30.0%); *understanding of issues* with local government (31.4%) and industry; and *progress* with regional state government (28.0%), the HRCCC (27.5%) and local government (31.4%).

Considering the HRCCC's role in coordination, it was encouraging that 7.5% of the unprompted responses regarding outcomes of communication with the HRCCC were classified as *coordination or collaboration*, higher than with any of the other categories of contacts.

Overall, how satisfied were you with this communication?

1	2	3	4	5
Very satisfied	Quite	Somewhat	Slightly	Very dissatisfied

In this question, respondents were asked to rate their satisfaction on the scale shown above. The mean satisfaction for communication with each of the categories of contacts are shown in the following table. Scores were re-coded, giving a higher score to a higher rating of satisfaction (5 = *very satisfied*; 1 = *very dissatisfied*, etc).

Contacts	Mean
SG Brisbane	3.37
Regional SG	3.56
Local Govt	4.00
HRCCC	4.11
Industry	3.83
Individual	3.71
Other	3.95
OVERALL	3.79

Overall, the mean satisfaction score was 3.79, the modal response was 4 (*satisfied*) and 8.6% of communications resulted in the response *very dissatisfied*. These results indicate a fairly high degree of satisfaction with communications although an examination of the reasons for those who were very dissatisfied may be useful. High mean satisfaction scores were assigned to communications with the HRCCC (4.11) and local government (4.00).

Do you feel that this communication changed your outlook on …ICM OR …environmental issues?

1	2	3	4	5
Very much	Quite a lot	Somewhat	Very little	Not at all

For each communication, respondents were asked firstly whether it had changed their outlook on ICM or environmental issues, on the five point scale shown above, which was also recorded for the analysis. They were also asked whether they felt it had changed the contact's outlook. The mean responses to the two questions are listed in the table below.

Contacts (number of contacts)	Change in outlook of respondents	Change in outlook of contacts
SG Brisbane	2.02	2.13
Regional SG	2.15	2.26
Local Govt	2.42	2.57
HRCCC	2.78	2.79
Industry	2.14	2.71
Individual	2.75	2.88
Other	1.74	2.24
OVERALL	2.27	2.51

Overall, there was a tendency for respondents to feel they had changed the outlooks of others more than they believed their outlook had changed due to the communication. On average, respondents rated the most change in outlook, both for themselves and the contact, in communication on an individual basis or with the HRCCC.

How?

When asked how their outlook had changed, and how the outlook of the contact had changed, the frequencies of the main responses (mentioned three or more times) were as follows.

Change in outlook	Respondents	Contacts
Greater awareness	38	40
Understanding/knowledge	34	50
Share what is happening/ideas	31	
Positive impact	16	
Too early to tell	10	
Disappointed at lack of resources/commitment to ICM	9	
Issue too politicised and too big	7	
Accept/aware of ICM		13
Learned what is happening		12
Aware of environmental problems		8
Changed views		8
Hard to get acknowledgment of problems		7
Encouragement to keep going		5
Hard to explain concepts		5

The positive nature of many of these changes in outlook of both respondents and their contacts is promising for the communication occurring on ICM and environmental issues on the Herbert River Catchment. Negative changes in outlook mentioned by some respondents were: *disappointed at the lack of resources or commitment to ICM* and *politicised, very big issues*. A couple of difficulties were mentioned: *getting acknowledgment of problems by some contacts* and *explaining concepts to contacts.*

Finally, now that we've talked about some of the different groups that you communicate with about …ICM OR ..environmental issues, are there any suggestions that you'd like to make on how these communications could be more effective?

The most frequent responses are shown below.

Response	Frequency
Seminars, workshops, field days	7
Media coverage to sell ICM	5
More regular meetings	3
More communication/involvement within government departments	3
Greater access to information	3
Better communication at local level with ICM	3
Improved communication to the general public	3
Coordinate/one vision	3
More funding	3

Very few suggestions were made on how communication could be improved, less than an average of one response per respondent. This perhaps indicates that respondents felt that few improvements were required or that they found it difficult to suggest improvements on the spot. For those respondents who had a very large number of contacts to report, fatigue may have been a factor in the low number of responses to this question.

4.0 DISCUSSION AND CONCLUSIONS

4.1 Involvement in ICM

For those respondents involved in ICM in the Herbert River Catchment, the major reasons indicated for their involvement were:

- *personal interest*;
- *job related;* or
- *interest in the sugar industry.*

Researchers had been involved in ICM for the longest period of time (on average 7.2 years) whereas HRCCC members had been involved on average for five years (when the group was formed). Two thirds of those not involved in ICM in the Herbert Catchment had heard of ICM, five of whom had been involved in the past.

4.2 Concerns about environmental management

Major concerns for those involved in ICM were:

- *the environment in general;*
- *ineffective decision making processes and communication;*
- *water quality;* and
- *flooding, drainage and their management.*

For those not involved in ICM, however, *flooding, drainage and their management* was of greatest concern. This issue may therefore need more attention by the HRCCC.

4.3 Overall communication

A matrix of contacts revealed that there was direct contact between most of the groups of stakeholders. The most frequent communication about ICM or environmental issues overall was with industry, particularly mentioned by respondents from other ICM groups, the HRCCC and regional state government. This reflects the close linkage that the HRCCC has with industry, in particular canegrowers.

The only complete gap was between Brisbane state government respondents in communication with others on an individual basis. Brisbane state government respondents also had a relatively low number of different contacts within local government. Local people and active local people reported the least number of different contacts within Brisbane state government than other categories of respondents. These results suggest that Brisbane state government personnel received information about ICM from others more closely involved with the local area and community. While this may be necessary for efficiency, it may prevent parties receiving accurate information.

4.4 Specific communication

The greatest degree of communication between specific groups was reported by researchers with the HRCCC and local government; and by Brisbane state government with Brisbane state government. While this communication, or coordination, between various organisations and agencies is very important to the success of ICM, the results suggest that communication with the general community and community involvement have been given a lower priority.

Local people reported the lowest degree of communication about ICM or environmental issues. This is not surprising as local people were chosen randomly whereas other representatives were selected due to their involvement in ICM.

4.5 Characteristics of communication

The predominant reasons supplied by respondents for their communication, and the primary contacts associated with those reasons, were:

- *policy/planning/decision making* with local government and Brisbane state government*;*
- *environmental issues* with local government*;*
- *research/project work* with the HRCCC*;* and
- *follow up on catchment/strategy issues* with the HRCCC.

Answers to the question "who made contact first?" were categorised into *outward* (the respondent initiated the communication), *mutual* (through a mutual contact, meeting or other event) and *inward* (the contact initiated communication with the respondent). Most communication was categorised as "mutual" which indicates the importance of mutual or informal ways of meeting to the functioning of ICM.

Respondents reported having initiated the communication (outward communication) more than contacts initiated the communication (inward communication). This may be true but the result may have more to do with the tendency people have to describe their own activities more positively than they describe others, in other words, 'self-others biasing' (Kurman & Eshel, 1998).

Outcomes from communication were generally very positive, the most frequent being:

- *progress;*
- *understanding of issues;*
- *information exchange;*
- *resolution of issues/decision;*
- *gained information;*
- *changed their outlook;*
- *specific action taken;* and
- *coordinate/collaborate.*

Two negative outcomes were also mentioned, which may need to be addressed:

- *unsuccessful;* and
- *coordination is needed.*

With the exception of local landholders, most perceived their communications in relation to ICM to be satisfactory. Satisfaction was highest, however, for communication with the HRCCC and local government which indicates a greater satisfaction when communication was with local bodies. It is a very encouraging result for the HRCCC.

There was a tendency for respondents to report that they had influenced the outlook of others more than others had influenced them. This may be due to self-others biasing (Kurman & Eshel, 1998) and others therefore were perhaps not changing their outlooks as much as perceived by respondents.

Respondents reported the most change in outlook (for themselves and the contact) in communications with the HRCCC and with people on an individual basis, which will be an important result to utilise in situations where attitude change is seen to be important.

The main ways in which respondents reported that their outlook had changed were: *gaining greater awareness; understanding or knowledge*; or *to share what is happening and ideas*. Difficulties mentioned were: *disappointed at the lack of resources/commitment to ICM* and *issues are too politicised and too big.* The main ways in which respondents felt the outlook of contacts had changed were:

understanding/knowledge; greater awareness; and *accept/aware of ICM.* Different difficulties were mentioned in the change of outlook of the contacts: *getting acknowledgment of problems by some contacts* and *explaining concepts to contacts.*

All respondents were asked for their suggestions on ways in which communication on ICM could be improved. Although there were very few responses, some of these were:

- *seminars, workshops, field days;*
- *media coverage to sell ICM;*
- *more communication with government departments;*
- *greater access to information;*
- *better communication at the local level and to the general public;*
- *coordinate – one vision*; and
- *more funding.*

4.6 Conclusions

This pilot study was conducted primarily to determine the feasibility of measuring the quantity, and various characteristics, of communication occurring on ICM and environmental issues in the Herbert Catchment. It is also possible to make some initial conclusions about communication between stakeholders of ICM.

The survey illustrated that linkages exist between almost all major groups of stakeholders and that most people feel satisfied with their communication about ICM and environmental issues. There were mainly positive outcomes of communication with others, including *greater awareness*, *understanding,* and *knowledge* for both respondents and perceived in contacts, and respondents *sharing what is happening and sharing ideas* and contacts *accepting or becoming more aware of ICM.*

The results of the survey indicate that it may be important for ICM to:

- communicate more with the general community;
- strengthen communication between state government in Brisbane and local government;
- strengthen communication between other ICM groups and regional state government;
- strengthen communication between other ICM groups and the HRCCC, if necessary;
- build on the 'mutual' communication occurring by creating opportunities for mutual contact allowing stakeholders to meet;
- be cautious about the perceived influence on others;
- carry out the major suggestions by respondents to improve communication in ICM: seminars, workshops, field days, and meetings;
- address the difficulty some people find in gaining acknowledgment of the problems by others and in explaining concepts to others.
- pay more attention to the issues of drainage and flooding;
- addressing the two negative outcomes of communication, generally *unsuccessful* communications and the *need for coordination.*

While it is therefore clearly possible to measure the quantity of communication occurring between stakeholders of ICM and other characteristics of that communication, there were some lessons to be learned from this pilot study.

- Respondents found it difficult to categorise their contacts correctly so in future it will be important to brief interviewers more thoroughly on the possible departments and organisations that may be mentioned.
- Interviews with those respondents who had a large number of contacts were relatively long and repetitive. One suggestion would be to allow a break in the interview to prevent fatigue and possible biasing of responses.

- Although respondents were restricted to six different contacts for each category, some people who are heavily involved in ICM may have more than six different contacts within some categories.
- The time frame used for communications may need to be shortened as some respondents found it difficult to remember communications as long as one year before the survey.
- Administration would be easier if respondents are provided a copy of the scales used in the questionnaire to refer to during the telephone interview.

INTEGRATED CATCHMENT MANAGEMENT COMMUNICATIONS STUDY

February 1998

Respondent Details

Name: _____

Occupation _____

Gender: M .... 1 F 2

Lives on the catchment: **Yes 1**
Nos 2

Good morning/afternoon. I'm _____ from the CSIRO.

We're speaking with people in the Herbert River Catchment about communications.

☞ **Read to respondent**

A questionnaire has been developed by the CSIRO to try to understand the characteristics of communications between the different agencies involved in Integrated Catchment Management in Queensland, and in particular, the Herbert River Catchment.

By answering the following questions, you will help us to put together a comprehensive picture of communications in this area. For example:

- who people communicate with
- the main reasons for these communications
- as well as the main outcomes.

Would you like to speak with me now?

OR

Could I call back at a more convenient time?

1. Are you involved either personally or because of other reasons in Integrated Catchment Management (ICM) in the Herbert Catchment? (Circle the number).

YES …. 1 **NO …. 2**

↓

Go to Question 4

☞ **If YES - Read 'ICM' in later question**
☞ **If NO – Read 'Environmental issues that concern you' in later questions**

2. Which of the following are reasons for your involvement?

☞ **Tick as many boxes as nominated**

Live on the catchment	❑
Member of a community group	❑
Personal interest	❑
Scientific research	❑
Interest in the sugar industry	❑
Interest in other primary production	❑
Job related	❑
Because I am a landholder	❑
Other,	❑

↳ please explain _____

_____

_____

3. How long have you been involved with ICM? _____ years

↓

Go to Question 5

4. Before this interview, were you aware of the ICM program in the Herbert Catchment and elsewhere in Queensland?

YES …. 1 **NO …. 2**

↓

Go to Question 5

If **YES**, what do you know about ICM?

_____

_____

_____

_____

5. Do you have any concerns about environmental management on the Herbert Catchment?

YES …. 1 **NO …. 2**

↓

Thank you for cooperating. (END)

If **YES**, what are your major concerns?

_____

_____

_____

_____

_____

_____

☞ **Read to respondents**.

We are interested in who you have communicated with about **ICM/environmental issues** over the last year.

Communications may have been:

- **Formal** (e.g. a letter or e-mail) or **informal** (e.g. a conversation or meeting at a social occasion)
- For **one particular reason** or for **a number of reasons** (in which case, I'll ask you to tell me
- about each one)
- **Personal** (i.e. individuals representing themselves) or **official** (i.e. individuals representing their organisation)
- **"one off"** or a **group of communications** (these can be mentioned together).

******* Now, go to separate communications sheet and ask questions.

COMMUNICATIONS SHEET

NAME: _____

❑ A. Over the last year, how often have you communicated with anyone from **state government in Brisbane** about …. ICM OR …. environmental issues?

☞ **Circle the correct number.**

APPENDIX E:

Individual Comments

Individual Comments

- Communication slower than expected. Lack of progress. The result is less satisfying.
- Place in crisis, so many things to do, not because of bad communication.
- The Information Centre is an informative provider. [Name withheld] has wide contact. Individuals to organisations in many cases general except as indicated.
- Because of expansion there could have been an impasse on land but council has taken on more responsibilities: a major one has been that cane land expansion has been stalled for one or two years which helps to buy time for development control.
- Senior bureaucrats have a good rapport.
- Need real laws, real ICM that's consistent in its decision making, eg they're letting cane be grown on marginal land.
- No-one is doing anything constructive, sugar industry is destroying the land and water. Must protect the environment.
- Silt is coming from cattle/mining – collapsing River Banks. Need to open up river to public and let them have it (eg silt).
- But we have formed a bit of an alliance through adversity.
- No leadership has ICM/Landcare trying to combine. Nothing personal. Don't know who is the coordinator of ICM at state level. Not much contact in last year.
- Individuals – involve them to do something, develop plan for their property, environmental outcome on farms, etc, etc.
- Groups develop projects, information, talk, extension.
- Useful, most things done changing outlook or bringing people up to speed.

As a member on Local Assignment Committee – representing local growers, I have particularly wide contact with individuals but main interaction with government departments is via this committee. Thus I contribute to Committee deliberations and they are communicated through committee members. Members include representatives from various government departments – Environment; Resources; Primary Industry; Local Government; and those involved with property management as well as the wide responsibilities and information provided through Bureau of Sugar Experiment Station. Other organisations such as Resource Information Centre and Herbert River Canegrowers Executive are reference points to which inquiries are referred. The questions as posed do not cover, in this case, the meeting communication breadth, which I see as an integral part of input.

Chapter 4

Natural Resource Management Issues and Integrated Catchment Management as Reflected in the Herbert River Express 1990-1998

Dr Alison Cottrell and Ms Katherine Rowbotham

Tropical Environment Studies & Geography, James Cook University, Townsville, 4811

Originally Published as:
Cottrell, A. and Rowbotham, K. 1999. Natural Resource Management Issues and Integrated Catchment Management as reflected in the *Herbert River Express* 1990-1998. CSIRO Tropical Agriculture, Brisbane

Introduction

The evaluation of the Integrated Catchment Management program (ICM) conducted in the Herbert River catchment[1] was in need of some indication of the social context in which the Herbert River Catchment Coordinating Committee was operating. One method of assessing this local social context was to consider how natural resource management issues in general and integrated catchment management in particular were presented in the media.

In a survey of the catchment conducted by Butterworth *et al.* (1997) various media were found to be important sources of information about land and water resource issues. *The Herbert River Express,* the local newspaper was used more frequently than any other source of information (60%), including friends and colleagues (54%) and personal experience (39%). In the lower catchment it was the source of information for 84% of those surveyed. The Australian Broadcasting program, *Landline,* was mentioned by 44% of those surveyed. The most reliable sources of information identified in Butterworth's *et al.* were *Landline* (88%), personal experience (82%) and *The Herbert River Express* (74%). Even though an analysis of the content of Landline programs might be useful to assess the content of messages considered reliable it could not be claimed to be clearly indicative of the local social context within which integrated catchment management was placed. Preliminary analyses also indicated that integrated catchment management was not frequently presented in either *The Australian* or *The Courier Mail.* An analysis of *The Herbert River Express* therefore appeared to be a reasonable course of action to assess the social context of integrated catchment management, particularly because it was such a frequently mentioned source of information and considered reliable. In addition, it was important to use an unobtrusive research method such as a content analysis because over-surveying in the catchment was becoming an issue (Bellamy, 1997).

It is important to be clear at this stage that this research is not an evaluation of the Herbert River Catchment Coordinating Committee (HRCCC). It is an examination of how natural resource management issues were presented in *The Herbert River Express* between 1990 and 1998 to provide an assessment of the social context within which the HRCCC is/was operating. Because of other events occurring over the time period, it would not be possible to singularly assess the impact of the HRCCC though media coverage. For example, the HRCCC was established in June 1993 and other significant studies and events included:

1993: Interim Guidelines for Floodplains, Herbert River Management Plan
1994: Herbert River Workshop on the Plan
1995: Mahogany Glider Issue arose
1996: Mahogany Glider Conservation Plan, Water Infrastructure Task Force, State of the Rivers Report, and the Sugar Industry Infrastructure Package.

This study takes a social constructionist perspective of the media and its representation of environmental and natural resource management issues. That is, we are concerned with how the media assign meaning to the world and then how the world is then presented to the audience. We take the view that the media shapes as well as reflects social values (see Altheide & Snow 1979; Burgess & Gold, 1985; Hannigan, 1995; Bignell, 1997; Waitt, 1995). The aim is to examine articles on environmental and natural resource management issues in *The Herbert River Express* to provide a view of local perspectives on integrated catchment management in particular. *The Herbert River Express* is a paid tabloid with a circulation of approximately 3,200 and published on Tuesday, Thursday and Saturday of each week (AIS Media Brisbane: 1998).

[1] LWRRDC Research Project CTC7: Evaluation of Integrated Catchment Management in a wet tropical environment (Bellamy *et al.* 1999).

The framework for analysis of the content of the newspaper articles is similar to that of Xu and Bengston's (1997) study measuring forest values in the news media. Xu and Bengston (1997) distinguished four distinct ways in which people value forests – economic/utilitarian, life support, aesthetic and moral spiritual value. Figure 1 summarises the relationships between the value systems which were used to categorise the data in this study.

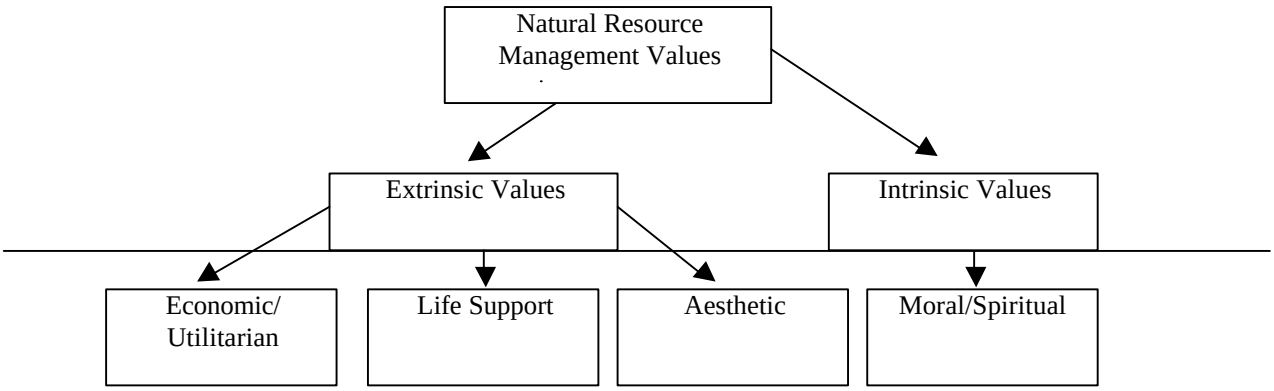

Figure 1: Natural resource management and environmental value trends (after Xu & Bengston,1997).

In this study, economic values, life support values and aesthetic values all fall under the category of extrinsic values of natural resources and the environment in general. This differs to Xu and Bengston's (1997) categorisation where aesthetics fell under the category of intrinsic values. Callicott (1989), in contrast to Xu & Bengston (1997), argues that an object may be valued for itself and not for the sake of any subjective experience such as pleasure, knowledge or aesthetic satisfaction. Economic/utilitarian value stems from the economic 'utility for achieving human ends, where the ultimate end is preference satisfaction' (Xu & Bengston, 1997:45). Life support values occur where human well-being is seen to depend on the situation. These values differ from economic values in that they are not measurable by an 'aggregation of peoples preferences or willingness to pay for an environmental service' (Xu & Bengston, 1997: 46). Aesthetic values are based on perceptions of beauty in the landscape. Moral or spiritual values relate to an affection, or reverence or respect for something

Research Methods

The specific questions we wanted to answer were:

1. **How does the Herbert River Express represent natural resource management issues over the time frame of 1990 to mid-1998?**
2. **Has there been a change in the treatment of integrated catchment management issues in the Herbert River Express over that time frame?**

This research addresses these questions through a content analysis (Gregory and Williams, 1981; Krippendorf, 1980; Rosengren, 1981; Waitt, 1995; Weber, 1985; Xu & Bengston, 1997) of the *Herbert River Express*. Because analysing newspapers is not a trivial exercise, a realistic time frame needed to be set to address the research questions. We needed a time frame for analysis which would allow us to assess the manner in which natural resource management issues were being presented in the newspaper overall, as well as prior to and subsequent to the establishment of the HRCCC. This would allow us to make an assessment of the treatment of natural resource management issues in general, and integrated catchment management in particular. Consequently, the mid 1990 to mid 1998 time frame was chosen.

The Hinchinbrook Library houses the historical collection of *The Herbert River Express*. These archives were accessed to identify articles from 1990-1998 concerned with natural resource management issues to develop a description of how natural resource management, and in particular integrated catchment management were presented. Unlike Xu and Bengston (1997) and Bengston *et.al.* (1999) who were not able to access an 'on-line' database of media articles and because this newspaper is not available on line or on microfiche, it was necessary to physically handle each issue of the newspaper to assess the content. It took eight weeks to construct a population of articles, which included 'Letters to the Editor,' on natural resource management issues and to identify the major themes. An additional two weeks was required to scan news articles into a computer database to allow a qualitative analysis to be conducted by using the NUD*IST© program. Copies of *The Herbert River Express* in this time frame were analysed broadly for articles covering natural resource management issues to form a population of articles. These were summarised into an EXCEL© database (Figure 2, and Cottrell and Rowbotham 1999.)

Data Field	Description
Date	Date of newspaper
Title	Title of article
Author/Journalist	If applicable
Category	Economic/utilitarian; life support; aesthetic; moral/spiritual
Section	Letters to the editor; rural report; etc.
Page Number	Page number on which article/letter occurs (pg).
Pages Total	Total number of pages in that issue
Title Size	In mm.
Article Position	Position on page. (RT = top right of page)
Number of Columns	Total number of columns in article
Width of columns	In mm.
Col 1	Width of each individual column in article

Col 3	
Col 4	
Col 5	
Col 6	
Col 7	
Picture Dimensions	In mm, size of any pictures included with the article
Description	General description of article context

Figure 2: Data collected for the population of articles on natural resource management

From an initial theme analysis, with the broad theme of natural resource management in mind, 2956 articles including 'Letters to the Editor' were extracted to form the population of newspaper articles from which a sample would later be extracted (see Cottrell and Rowbotham 1999). We included 'Letters to the Editor' because once a letter was accepted into this section of the newspaper it was rarely edited to change views presented. Indeed, local informants suggest that articles and press releases submitted to the newspaper, providing they are accepted, were changed very little. For the purposes of manageability, a random sample of 351 articles (12%) was generated using SPSS© and included articles addressing the HRCCC over the time frame of the study (see Cottrell and Rowbotham 1999). Newspaper articles and letters concerned with natural resource management issues (excluding advertising, weather forecasts and photographs not directly related to any article) were then quantified under 15 theme categories using Gregory & Williams (1981) point score scheme.

Under this scheme, each article's surface area is measured in square centimetres, including the headline and any photographs. This measure was then weighted by multiplying the area in sq mm:

- By 5 if one the front page
- By 4 if continued from the front page
- By 3 if only on the second page and,
- By 2 if on any other page.

If there was any photographic material included in the article 15 points was added and according to the headline size the following points were added:

- 15 points if headline >15 mm
- 10 points if headline 10-15 mm
- 5 points if headline <10 mm

To ensure consistency of coding one coder was employed to assess the content of the sample of 351 articles from June, 1990 to June, 1998. The coding was then checked by another coder. Categorisation on the basis of each article (Gregory and Williams, 1981) was chosen rather than on the basis of words used (Waitt, 1995; Xu and Bengston, 1997) because we wanted to retain the overall context of each article. Each article was scored and categorised using the above-mentioned scheme, according to the predominant theme of the content. The following is a concise list of the themes used at the early stage of the study:

- Sugar industry
- Forestry industry
- Tourism industry
- Land resources
- Waste management
- Fisheries
- Pests/Feral species
- World heritage
- River/Stream management
- Soil conservation
- Flora/Fauna issues
- Government initiatives
- Coastal development
- Political issues/controversies
- Other

All the totals for each theme was then compiled for each year and the total number of articles for each category was counted as a percentage of the total articles. These findings are summarised in Tables 1, 2 and 3.

Natural Resource Management Topics in The Herbert River Express

Over 36% of all the articles sampled from *The Herbert River Express* dealt with river/stream and water resource management. It could be said, subsequently that these issues are of great importance to the community that this paper circulates. Figure 3 shows that river/stream and water resource management theme occurs more frequently than other themes. Other themes of note were political issues or controversies (19.5%) and pest/feral species management (14.3%).

From the broad categorisation of articles, it was discovered that River/Stream and Water Management themes were the most predominant. The 42 articles on this theme were subsequently extracted to conduct an in-depth qualitative analysis of their content to provide a view of the community's perspectives on issues fundamental to integrated catchment management in the region.

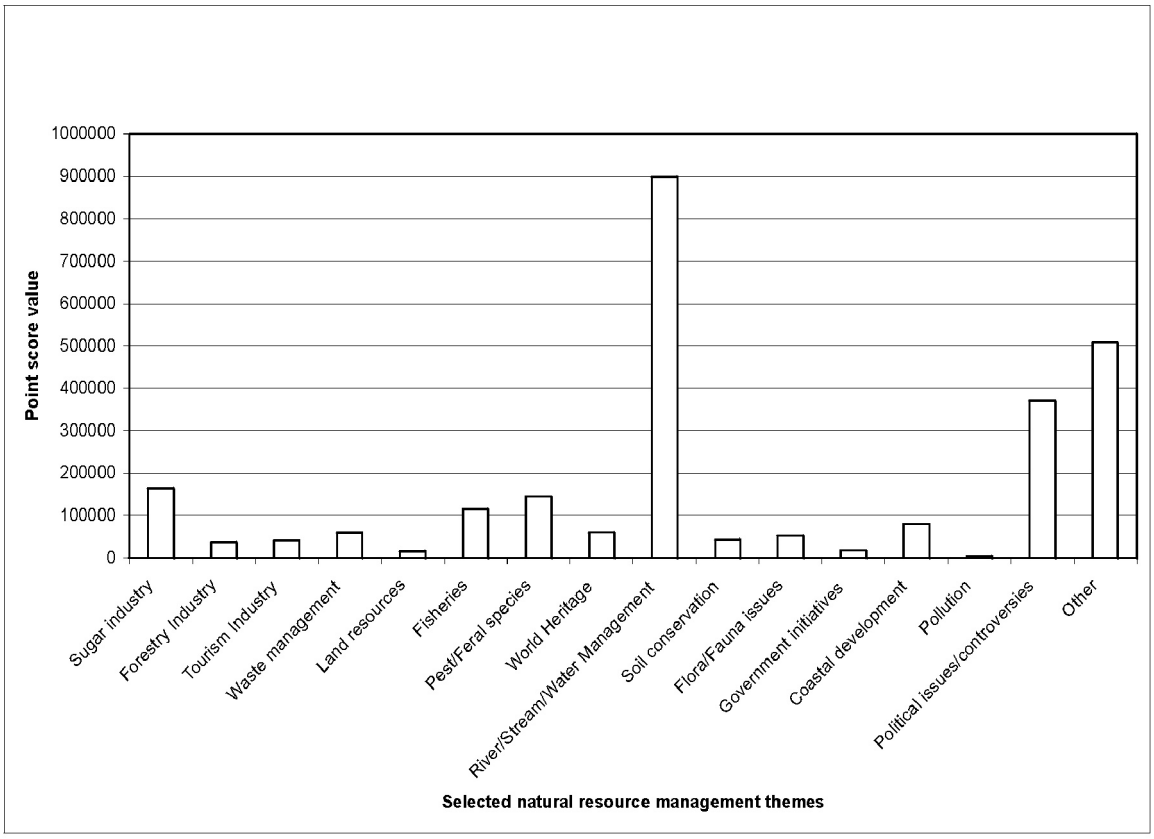

Figure 3: Point score values for selected natural resource management issues in The Herbert River Express 1990-1998.

It is not surprising that river and stream management issues would be important in the community served by *The Herbert River Express*. The community is located in a catchment subject to high intensity rainfall and subject to flooding on a regular basis. The main industry is sugar cane production which is reliant on water management.

The occurrence of articles with the theme of river, stream and water management clearly changed over the 1990-1998 time frame. As indicated in Figure 4, the total number of articles with the predominant theme of river, stream and water management increased over time. Analysis of trends over time for the other themes can be found in Appendix 1 to this report.

Although the trend over the period under consideration indicates an increase in the number of articles on this theme, the prominence of the articles as indicated by the point score values does not appear to have a consistent pattern of increase. What appears to have happened is that since 1993 there has been an increase in the prominence of articles on this major theme. Even though there have been fluctuations in the number of articles in some years, lower frequency of numbers of articles appears to have been counteracted by the prominence of those articles as indicated by the point score values. Alternatively, even if articles on river, stream and water management are not prominent in size or emphasis this seems to be offset by an increased frequency in occurrence of articles on these topics.

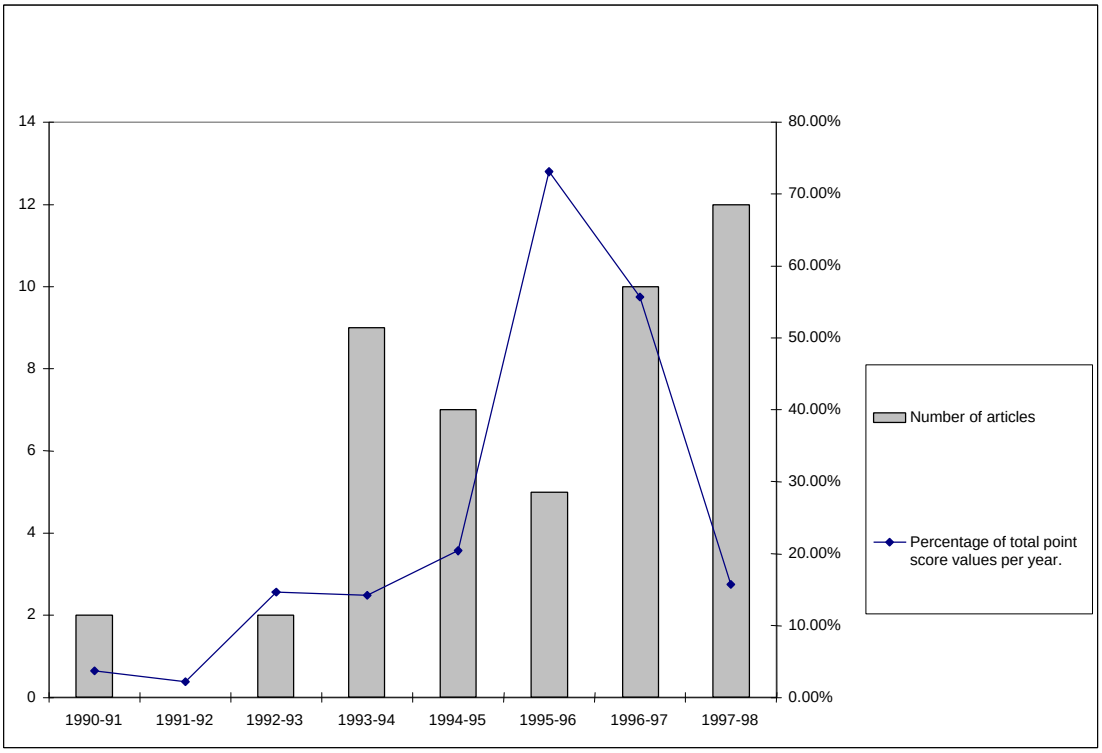

Figure 4: Change in the number of articles with the predominant theme of river, stream and water resource management in The Herbert River Express 1990-1998.

Values presented in the articles

In order to understand the newspaper's presentation of what we are taking to be the community's perception of these issues that appear to be important to them, it is necessary to consider the 42 articles addressing river/stream/ water management in depth. Intrinsic values (moral and spiritual) were not found in any of the sampled articles on river, stream and water management in the *Herbert River Express*. Therefore, extrinsic values became the focus of analysis in this study. As indicated in figure 5, *aesthetic* values were the dominant theme in 9% of the articles, *economic or utilitarian* values were dominant in 26% and *life support* values were dominant in 65% of the articles. Analysis of the values expressed for other themes are summarised in Appendix 1.

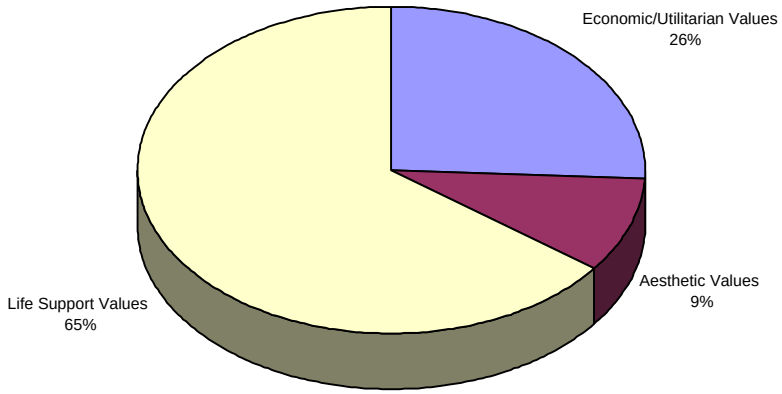

Figure 5 : Extrinsic values as expressed in River/Stream and Water Management articles in The Herbert River Express : 1990/1-1997/8

Aesthetic values

There were two articles where the predominant values were aesthetic. Under the header "Creek Bank Goes Natural" (21/10/93:3), was a report on a tree planting program which would remove 'unsightly garbage and waste on the banks of Palm Creek" and bring with it the "aesthetic benefits of a rainforest in the middle of town". The second, much longer article "Eco Park Plan for Palm Creek" (19/10/95:1) discussed the conversion of a "grass infested area" into "an oasis of high quality". This article also discusses the "Integrated Catchment Management Group" and quotes the Catchment Coordinator of the time, Rob Hunt, on the value of the project which was to create a wetland area.

Economic/Utilitarian Values

Twelve articles were categorised under an economic theme as they contained ideas and philosophies directed towards satisfying human preferences to meet human ends of an economic kind. Drainage was a key issue, this is because the focus community is located on a flood plain and good drainage is essential to such an agricultural community. As some articles emphasized 'about 11 000 tonnes of cane was lost last year because of poor drainage' (*Mangroves upset drains*, 14/2/91:3). 'Excess water is conservatively estimated to have wiped out at least 80 000 tonnes of sugar production for each of the 1990 and 1991 seasons, worth at least $45 million over two years (*Water management needs more funding*, 4/6/91:3). Drainage however, does not seem to be consistent throughout the sample of newspaper articles under the economic theme. Drainage only appears as being economically significant in these early two articles. One topic that is consistent through the economic articles is community consultation. This is where the HRCCC becomes significant. The HRCCC is presented to the community as the auspicing body for community consultation for issues relating to water, river and flood management in the Herbert River region. There are several articles which also indirectly call for such an auspicing body to be the liasing unit between the government (State, Commonwealth and Local) and the public to manage funds, disperse information and consider community interests in developments.

Other articles in the economic category seek funding from the State government to create new managerial positions at local authorities such as the HRCCC, to repair river bank reinforcements, sugar industry infrastructure projects and management strategies for the region. Economic articles emit an anthropocentric view of good management of river and water resources. For instance, one article (*Trust targets river islands*, 5/12/95:1) places emphasis on the notion of good stream management by 'bulldozing heavily vegetated sand islands which have built up due to prolonged dry seasons and relatively inactive wet seasons'.

Other articles are less focussed on the economic theme but still emit values that suit to satisfy a preference of some kind and therefore are categorised under economic values. One article (*Wetland built to improve farm drainage*, 21/8/97:8) is typical of this trend when discussing the benefits of wetlands. This article categorises the benefits of wetlands to be, in order of priority, economic (to open up low lying cane land), ecological (for species preservation) and for land and water management (as a more logical drainage line).

Life Support Values

Economic values of natural resources were not the dominant theme, however life support values of natural resources were, with 28 articles in comparison to economic (12 articles) and aesthetic values (2 articles). It is life support values of natural resources and the environment that are of priority to the newspaper. The domination of the agricultural industry, in particular the sugar industry, in the Herbert River region means that the population depends on the health and sustainability of their natural resources. As we have argued earlier, it is not surprising for articles

in the local newspaper to reflect this dependence on natural systems and resources. What is interesting is that this dependence is not presented in purely economic terms.

In an article regarding the release of a report by the HRCCC to the Minister Primary Industries, major issues confronting the catchment including the immediate appointment of a full time catchment coordinator were outlined (*Casey told full time coordinator needed*, 4/5/93:8). It was noted that the 'catchment has particular infrastructure needs for sustainable growth', with flooding and drainage (including river sedimentation) recognized as having major bearing on sustainable agriculture (*Casey told full time coordinator needed*, 4/5/93:8). Sugar cane crop yields are used as a justification for sustainable sugar production practices where it states that: 'since the floods of 1991 where sugar cane crop yields declined in the 1991 crop year by about 33% from the district's five year average, there has been major focus on the principles of integrated catchment management and near coastal zone' and 'land and water resource management is a major issue in the Herbert River Valley, particularly as the sugar industry continues to expand' (*Casey told full time coordinator needed*, 4/5/93:8). The following quote from this article encapsulates the essence of problems that the people and therefore the paper are concerned with:

> *'drainage in the lower Herbert flood plain delta is critical to crop production. It is perhaps the main limitation on much of the land which has potential for future sugar cane production and yields'.*

The mobilisation of integrated catchment management in the community via the HRCCC was presented as a solution to many of the problems that the community would have with this major river system (*Casey told full time coordinator needed*, 4/5/93:8).

In a later article, the release of a stream control plan for the Herbert River by the Herbert River Improvement Trust was to 'set the trust on track' to control the river system for the future (*River strategy plan released*, 19/8/93: 1). Management is central to this article with the Chairman of the Herbert River Improvement Trust stating the 'committee welcomed the plan and looked forward to a positive future of river management in the Herbert River district'. The front page positioning of this article and its heavy weighting (18380) emphasizes its significance to the community in general.

Tully and Murry River Reports Out (19/8/93:4) reports on the 'environmental health of the catchments'. What was considered as 'environmental health' is quite surprising in that it included:

- expansion of cane growing lands,
- levee banks
- stream bank erosion
- gravel and sand extraction

The 'management of burgeoning cane land expansion' was presented as the 'most urgent issue requiring attention' by the newly established Tully Murry Catchment Coordinating Committee. Ensuring 'controlled', 'ecologically sustainable', 'cooperative' and 'orderly' development took place, essential and 'vital' to local and state economies (*Tully and Murry River Reports Out* 19/8/93: 4).

Catchment body active, (24/3/94: 10) presents the announcement of the inception of the Herbert River Catchment Coordinating Committee (HRCCC), it scope, functions, membership and duties. This article is primarily a piece of community information containing valuable information about the HRCCC in a succinct and effective form of communication. 'The (HRCCC) are already tackling problems ranging from rehabilitation of tin mining dams to coordinating drainage for the Herbert River flood plain'. The goals of the HRCCC were also outlined in this article, further adding to its informative qualities. 'Preliminary identification of

the major issues for the catchment has been done, the first step towards developing a management strategy'. The importance of this program is also placed in the context of the communities wider agenda of community development which, through these articles, is apparently of prime importance to the target audience of the newspaper.

It is clear through such articles that the HRCCC has a profile in the community. The article – *River group heralds major breakthrough*, (21/4/94: 1) is a good indicator of the framework that the committee operates within to improve productivity without prejudicing environmental values' and where 'the Coordinators role was to find out the concerns of represented'. Funding is presented as important. However, once again, the importance of the community in the management of the catchment was stressed by the Coordinator where there 'was an opportunity for people to bring their issues and concerns together to find the solution instead of just taking what appears to be the best option'. The article – *Body coordinates focus on catchment*, (23/3/95) once again introduces the HRCCC to the community by providing the broader context in which the committee operates, an outline of their basic principles and involvement to date on particular projects. It too provides an account of these characteristics but in no different form than previous articles.

As in the articles on the *economic* theme, community consultation is presented as highly important. *Catchment body offers link in communication*, (26/5/94:6) primarily is concerned with the consultation of the community. The HRCCC is presented in this article as the solution to this problem. This consultation occurs as a system checking the State Government's activities in the Herbert River Catchment, particularly the lower catchment. 'People have had concerns over infrastructure works on the floodplain for a number of years. With the recent works they're seeing an opportunity to voice their concerns', 'the main thing is a lot of landholders are seeing new infrastructure but don't know what's really going on… we want to get (state government departments) to liaise with us and get some meaningful feedback from them; get them to tell us what they're doing' (*Catchment body offers link in communication*, 26/5/94: 6). Communication between governments and the public appear to be of great importance to this community due to its expression in the media. The HRCCC is presented as the key community representative group to "run" projects through before they commence. This is exemplified in the following: 'Mr. Hunt said the committee, a community based group suitable for conveying information between government and the general community, was willing to assist issues concerning the catchment future development'. It was stated in a letter to the editor from the chairman of the HRCCC that: 'More communication will help to bring calmness and local thinking into discussion regarding water management and drainage issues that have been featuring in the local media' *(Full water management briefing due*, 23/3/95: 6). Once again, this acts as a brief on the roles and functions of the HRCCC in the community and in the representation of all major stakeholders in the catchment area. The letter also aims to settle an issue involving a local water management issue and suggests communication is the key to managing such resources effectively.

Other players in resource management arise in this category of articles, including the Herbert River Improvement Trust. (*River trust to have more important role*, 15/10/94: 5). The wide reaching nature of catchment management is highlighted as 'everyone lives in a river catchment and river trusts will continue to have a very specific and specialised role to play for the community as the "doers" of river management, getting things done under various conditions'. This article emphasizes the role that river trusts must take in the management of the states rivers in the implementation of the 'new' integrated catchment management initiative. This article also provides an outline of River Trusts, their role and principles, origins and representativeness.

The term *Integrated Catchment Management* only begins to be emphasised around 1996 in the sample of articles. An article refers to the threat of a shortcut along the Herbert River which would reduce it in length by up to six kilometers, and cause 'increased bank erosion upstream and siltation downstream' (*River shortcut a concern*, 25/4/96: 5). This venture is termed the "Long Pocket project" and encapsulates many of the phases connected to Integrated Catchment Management and its practices. Erosion, bank stabilization scouring, native vegetation and floods were all mentioned in this article and are concepts integral to integrated catchment management. The fear of flooding for the community is evident in this article, 'many of them (landholders) have lived through floods in the area and have first hand experience with what the water does'. Informing the public, moreover, the landholders with the intricacies of the project also appears to be important in this and the other articles. This article also places river and flood management in the context of integrated catchment management. The HRCCC Chairman states 'the project was an example of how the local community could benefit from Integrated Catchment Management'.

Integrated Catchment Management

From mid 1996, Integrated Catchment Management takes some focus with many articles mentioning the principles of integrated catchment management generally and such as the article, *River trust work funded* (30/07/96:2). The Herbert River Improvement Trust and the HRCCC had secured funding from the 'government' for works that would avoid 'enormous economic and environmental impacts'. Once again, integrated catchment management is the integral component or type of management but takes another form of what could be termed, river management. The revegetation solution was not chosen for the integrity of habitat that it encourages but because 'revegetation was also much cheaper than rock work which enabled river trust funds to be used to treat greater areas'. The intention is positive, and underlines the entire process of river management, however the philosophy or paradigms in which the managers operate can not be described as "green".

River degraded, (22/10/96:1) is a large headline article with front page coverage and pictures. The focus of this article is integrated catchment management. The article refers to the State of the Rivers report for the Herbert River and tributaries and summarises the findings of the report and what this means for the region. The river was given 'eight out of ten' by the Herbert River Catchment Coordinator, Rob Hunt, thus feeding the need to quantify the state of the catchment. The article refers to riparian vegetation, fish habitat degradation and river bank erosion as the major problems facing the catchment as a whole. Once again, the problem is quantified, 'the condition (of the river) is pretty well reflected in fish catches'. This includes fisheries as a stakeholder in successful integrated catchment management. This article fits the category of 'life support values' where the river is portrayed as the life blood of the economy of this region with comments such as 'narrow riparian vegetation can create the potential for erosion, weeds and pests, which in turn reduces the environmental and financial value of land for farmers'. The emphasis is on the importance of planning development as 'people are starting to realise we need to be more careful with our creeks and rivers… there was not an endless supply of water … and there is always potential for drought.' It was also stated in this article that there were aesthetic values to be had in this catchment. "The eye is often a good indicator of the condition and health of a catchment".

Community Consultation

Community consultation is also important. (*Consult before clearing land*, 21/8/97: 9) Issues that 'will never go away' regarding river, water and flood management were reported to have split the community into a 'them or us situation concerning land use issues and natural resource management'. This article is full of information regarding integrated catchment management and the HRCCC, the life supporting nature of the environment is evident in this article. For

example, 'It was possible to have the best of two worlds… we need sugar production currently worth more than $230 million annually to the Ingham district but we also need tourism, fishing, cattle and forestry industries… we need jobs for our children, but we also need our natural resources such as streams, wetlands, lagoons, beaches and forests… these bring in tourists and makes it a pleasing region of Australia to live in'. This quote exemplifies the perspectives of the regions managers and management committees. Protection of the environment occurs to meet human ends, not to increase the integrity of that habitat or for the intrinsic value of the environment in question. Information is present regarding the HRCCC, although it is not once explicitly mentioned by name, it is however called the Integrated Catchment Management Committee who were 'currently looking for solutions on how to manage issues such as riparian areas, drainage, wetlands and roads in the Herbert River catchment'.

There is no evidence of intrinsic value of the environment. For example, *Dam study funded* (18/9/97: 11) indicated 'There could also be some environmental values' as the closing comment regarding a quarter of a million dollars allocated to a study of the effects of a local dam in the Herbert River Catchment.

Conclusions

The Herbert River Catchment Coordinating Committee was established in 1993. The issues of river, stream and water management increase in frequency in the newspaper from 1996. This suggests a time lag between the inception of the HRCCC, the Herbert River Management Plan and an increase in coverage of issues related to integrated catchment management. In addition, *Integrated Catchment Management* specifically appears from mid 1996 and is stressed as an important issue for the community. The HRCCC is portrayed as a contributor to achieving the goals of productivity, development and sustainability of the local community. The media representation of the HRCCC is positive and is clearly linked with integrated catchment management in almost all articles involving the HRCCC.

Extrinsic, 'life support' values were the predominant values presented in natural resource management issues in *The Herbert River Express*. This seems fitting as the community in the Herbert River region is agriculturally based and located on a flood plain. The community's identity and well being is dependent on the health and sustainability of their natural resources, and is clearly evident from the manner in which the local newspaper presents issues. Intrinsic values were not apparent.

An important issue here is that it seems that *The Herbert River Express* editorial policy appears to operate in a manner that excludes views that do not adhere to the dominant social values locally. However, once an item is accepted for publication there appears to be so little editorial interference that the material can be accepted as representing the dominant values held.

The use of a media as an unobtrusive source of data for research on the social context is becoming more popular as the data is becoming more readily available in 'on-line' data bases. For national media this provides a useful perspective on changing attitudes to environmental issues (Bengston *et. al.*, 1999). On the basis of the results of this research we suggest that despite the difficulties of data collection and analysis, local newspapers such as *The Herbert River Express* are rich sources of data for social context on resource management issues.

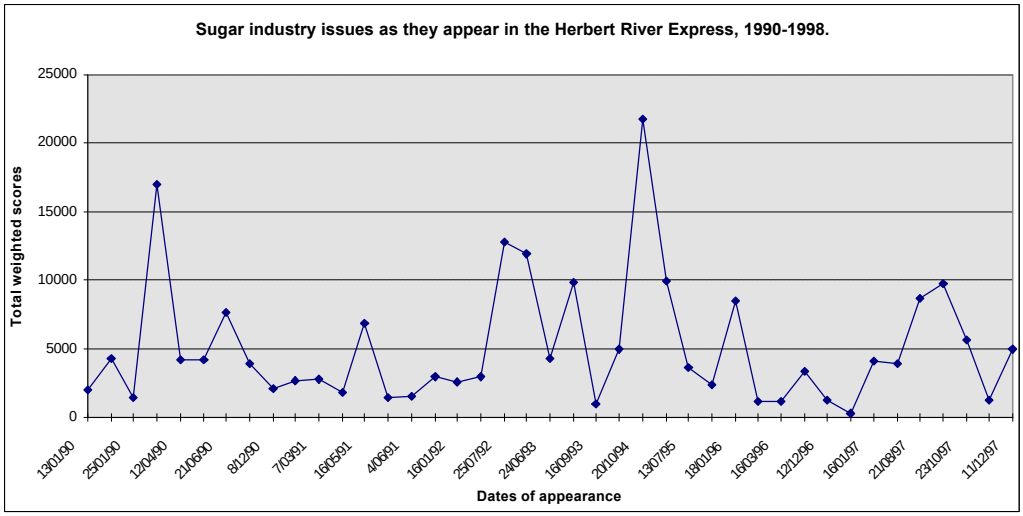
APPENDIX 1

TRENDS OVER TIME AND ANALYSIS OF VALUES PRESENTED IN ARTICLES ON KEY NATURAL RESOURCE MANAGEMENT THEMES OTHER THAN RIVER, STREAM AND WATER MANAGEMENT

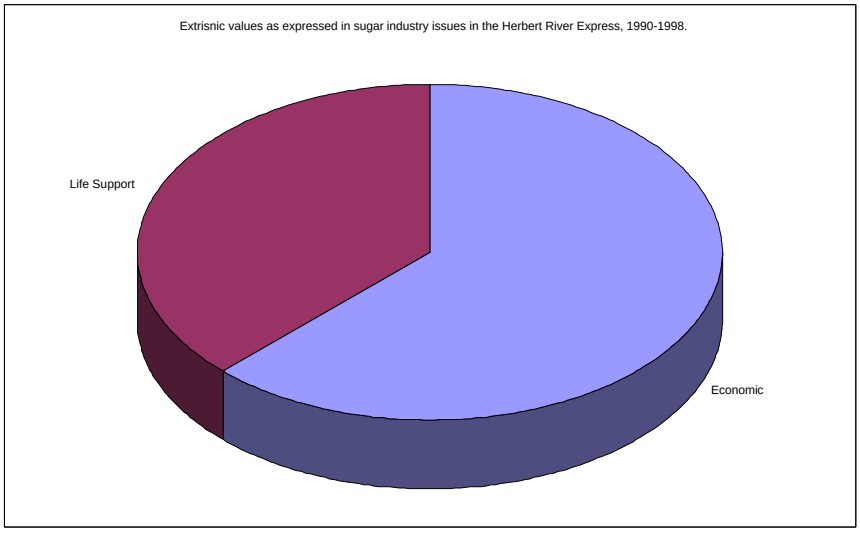
1. Sugar Industry



To unstack sugar industry issues, 4 articles, each of which exceed 10000 points on the Gregory & Williams (1981) point score scheme. Each of these articles will be looked at in turn.

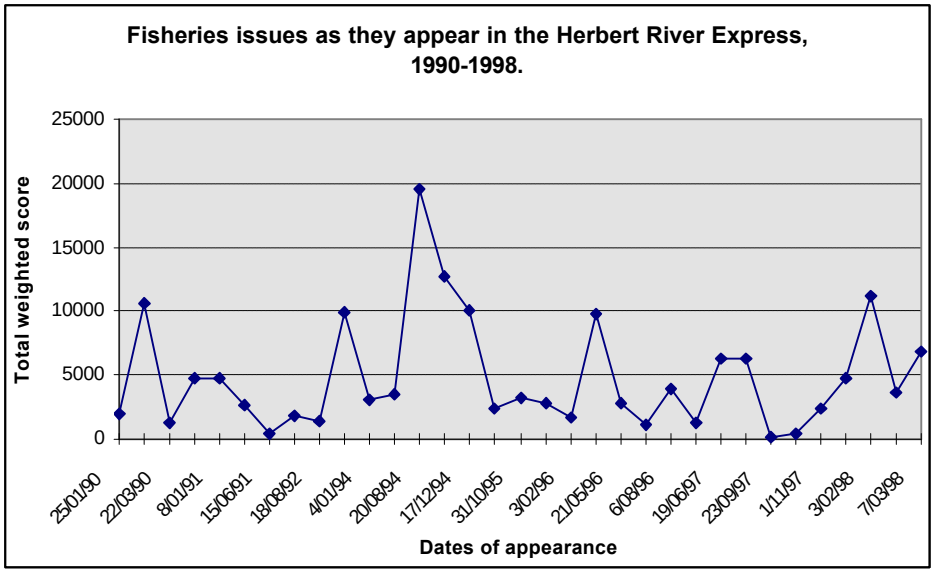
Bulk white sugar exports the 'next logical step' (1/3/90) is the first of these articles to appear over the 10000-point mark. Categorised as an article displaying a life support theme this article discusses the move for the sugar industry to push for bulk exports of white sugar from a northern refinery as 'one of the most logical next steps in exports'. With the demand in overseas, particularly Asian, markets the demand for sugar to be exported in its white form made the need for proper infrastructure to be developed accordingly.

Wharps project shelved (25/07/92) discusses the proposal for the expansion of the sugar industry in the Herbert River District being shelved due to lack of government funding for the project. This is a large article categorised as having economic themes of natural resource management summarising the issue as it expecting "to cost the district $1.5 million annually in lost revenue".



Sugar industry issues dominate the economic theme of articles consisting of 29% of all articles in that theme. 62.42% of all sugar industry articles indicated characteristics of economic values of the environment and natural resources while 37.58% of the same set of articles were associated with a life support theme with sugar industry related articles consisting of only 6% of all articles under the life support theme.

2. Fisheries



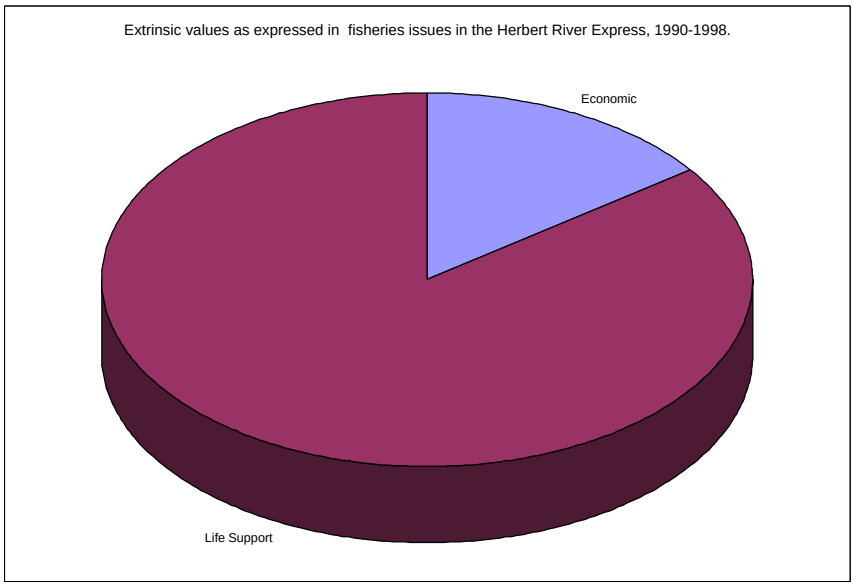
Fisheries articles appear more frequently over the time frame, 1990-1998, and the range of points they receive are varied. These articles range from the small notice about fisheries restriction infringements to major fisheries resource management issues. Many articles are major reports measuring above 10000 points on the Gregory & Williams (1981) point score scheme. *The Brambles Reef dilemma – scientists favour extended closure* (20/08/94) is a full page article with photographs. This article addresses the possibility of an extended closure of the areas closest mid-shelf reef, Bramble Reef, to bottom line fishing for fish stock replenishment after research findings suggest it to be best option for the well being of local fisheries. Pros and cons and options of reef closures and their impact on local fisheries are discussed.

Cardwell operation goes from strength to strength (01/03/90) is a large article (10680 points) with pictures featured as part of "This week in Cardwell" section of the Herbert River Express categorised in the economic theme. It focuses on the aquaculture giant, *Seafarms,* productivity and cash benefits for the local economy.

Huge fish dump is another large article (12765 points) featured on the front page of the 22/09/94 issue of *The Herbert River Express* as its headline story. This article covers the results of a huge fish stock dump allegedly done by professional fisheries in the local area. It was categorised as an article expressing life supporting values of the environment and natural resource management due to the impact this issue had on the local population's well being and state of the environment.

Pros sweat it out on payout scheme (03/02/98) is an articles that appears towards the end of the 1990-1998 timeframe. It is a front page headline story dealing with the possibility of a $5 million government commercial license buyback scheme. "It is not going to cripple the area because sugar is the mainstay but we'll end up a one company town and that is unhealthy" surmises the importance of the issue to the local area and thus its categorisation in the life supporting values. The diversity of issues dominating the fisheries issues covered by *The Herbert River Express* is important to emphasize, however, their importance (life supporting role) is also to be recognized.

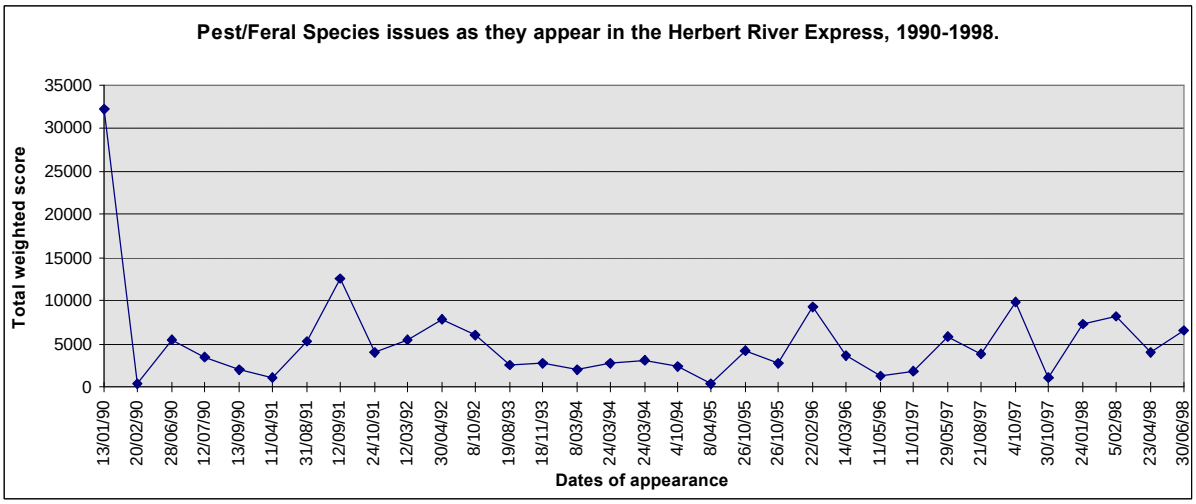
The impact of less weighted stories is not to be underestimated. Many small, less emphasised issues such as fishing authorities announcements and notification of licence infringements is also to be recognised.



Fisheries issues were a substantial component of articles in the Herbert River Express comprising of 9.7% of the life support articles and 5.45% of all economic articles. 85.06% of the articles discussing fisheries issues presented a life support theme. 14.94% of the fisheries issues articles displayed an economic theme. 33 articles discussing fisheries issues were presented in the sample.

3. Pest/Feral species

Issues concerning the threat of pest or feral species into the local area are of great importance to this community.



This is reflected in the way these issues are presented in the Herbert River Express. The topics that these articles cover vary from the immediate threat of pest invasion to the notification of new pesticides or herbicides for better productivity protection. One major article acts as a good example of the content of the articles categorised under the pest/feral species banner. *Rats on the move – canegrowers told to 'starve them'* (10/01/90) is a relatively small but front page headlining article calling for Herbert River district cane growers to take immediate action to prevent crop damage from rats.

> "At the present, conditions are favoring the rats," the spokesman said. "And we don't want to start the new decade with a rat plague. "It may be too late to eliminate grasses and weeds inside some paddocks, but it's not too late to spray out margins. "Slash headlands, keep them wide and clean from tall grass. Rats think twice about crossing bare ground or open areas." He said by keeping harborage areas such as drains, swamps and especially grasslands slashed or sprayed, food supply would be greatly diminished, resulting in the rats starving to death.

Not only were animal species of pests indicated as a concern, the threat of weed invasion also proved to be an important issue to the local area. *Weed control to protect profits* (12/09/91) was another highly weighted article (12637 points) calling for the protection of production.

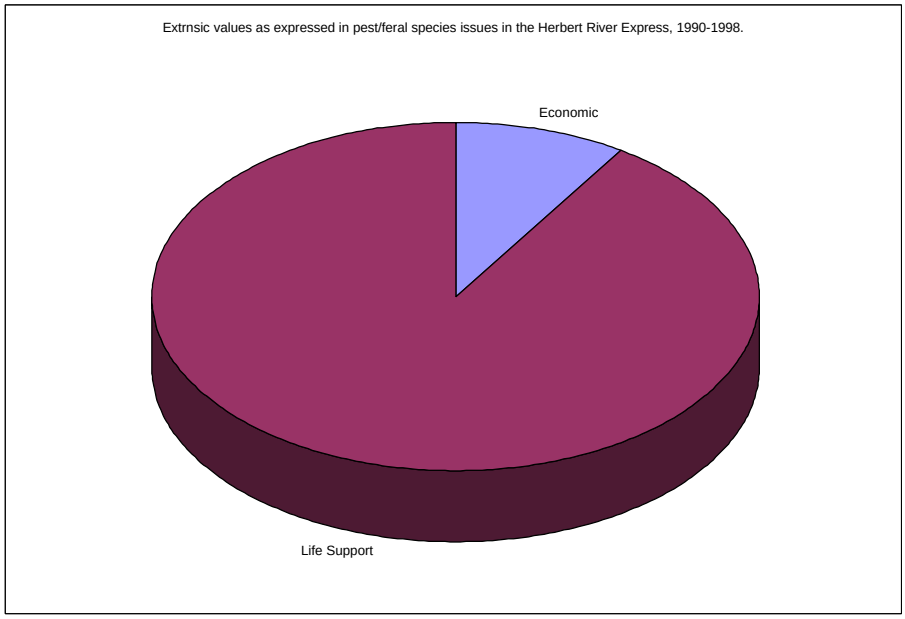
> THE RECENT downturn in the sugar price, combined with a reduction in crop just harvested, means that good management is required now to make certain the next crop is given the best possible chance of success and ensure improved incomes.

This article is a hidden promotion for Gramoxone, a herbicide found to be productive for the local area.

> Gramoxone is definitely the ammunition for your weed control strategy - it's easy on your pocket and tough on weeds. The lowest cost option remains Gramoxone, leaving other knock-down herbicides and cultivation way behind. Gramoxone is reliable, versatile and knocks down grasses and broadleaf weeds quickly.

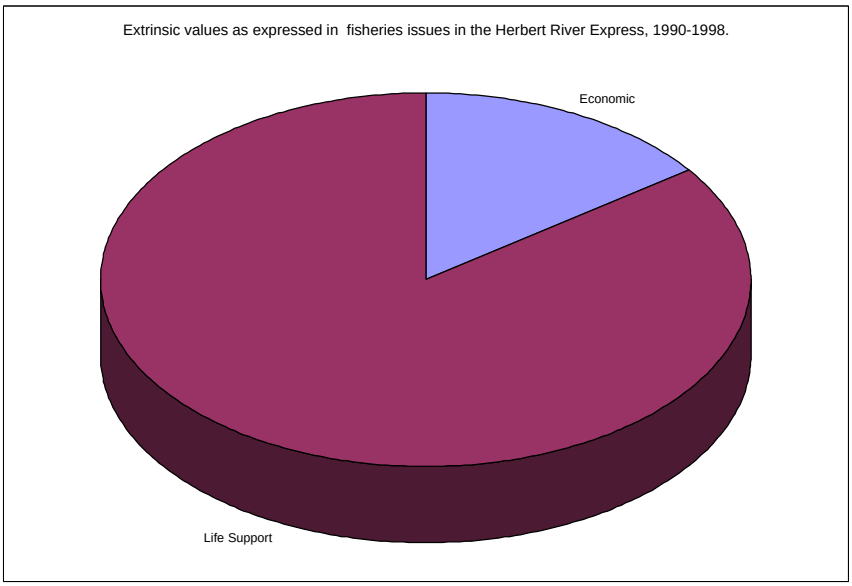
Locusts prove to be another threat to this area with an article addressing the issue ranking 7835.5 points on the Gregory & Williams (1981) point score scheme. *Farmers warned 'look out for locusts'* (30/04/92) is such an article.

The threat of the papaya fruit fly appears towards the end of the timeframe in early 1996. Many articles address this threat as it was a major event for this area. Papaya fruit fly battle enters its third phase (22/02/96) deals with this major event for the Herbert River district with the distribution of canite blocks to the local people with fruiting trees on their property to lure and kill male papaya fruit fly.



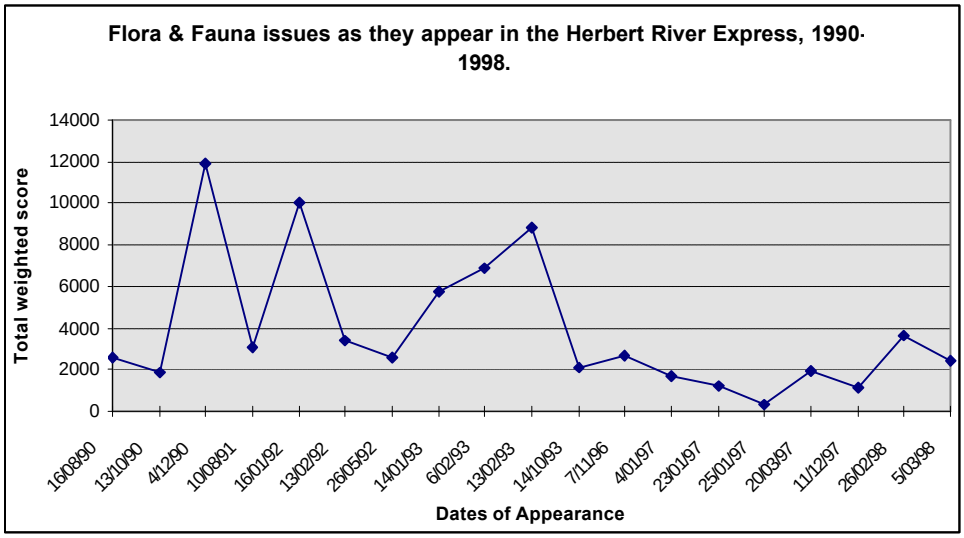
Articles presenting issues regarding pest and feral species were dominated (90.84%) by life supporting values of the environment. The remaining 9.16% of the articles expressed economic values of the environment. These issues featured highly in the life supporting, 11.10% of the articles in this category were pest and feral species issues and only 3.58% of economic articles covered this issue.

4. World Heritage



Articles of *The Herbert River Express* dealt with issues regarding world heritage predominantly with life supporting values of the environment held to heart (?) 90.75% of these articles were categorised under the life support theme. 9.25%, the remaining articles, were classified as indicating aesthetic values of the environment and natural resources. World heritage issues ranked fairly amongst the value categories consisting of 9.43% and 4.52% for aesthetic and life support values respectively.

5. Flora and Fauna Issues

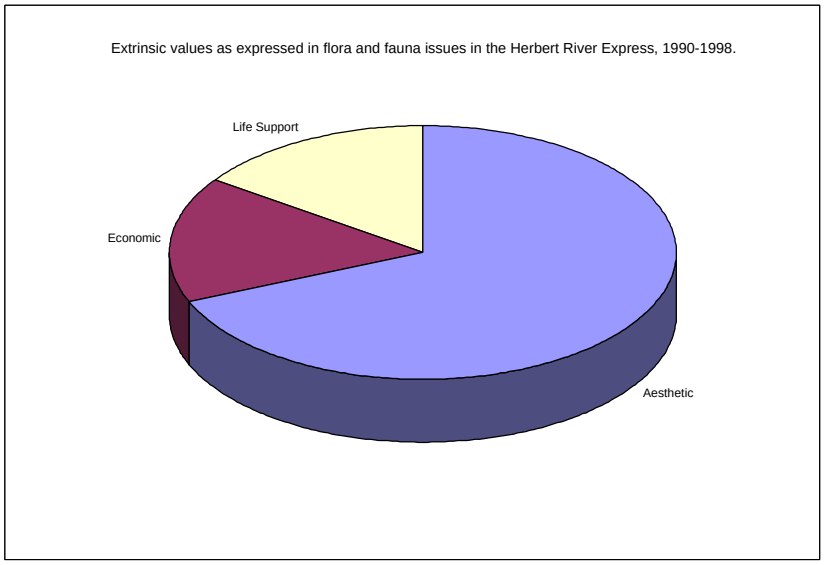


Flora and fauna issues included articles that focussed on specific species of animal or plant and gave the details of their makeup, breeding, diversity, eating habits etc. These were usually small to medium sized feature articles providing general information on various species of plants and animals. Some of these feature articles proved to gain much space in the newspaper for attention to be paid. A number of these articles scored above 6000 points on the Gregory & Williams (1981) point score scheme, including:

Spawning time on Orpheous Island (14.12.90) –
Two unique Australian monotremes (16.01.92
Kingfishers – Jewel of the rainforest (13.02.93)
Birds of prey hunt during the day time (06.02.93)

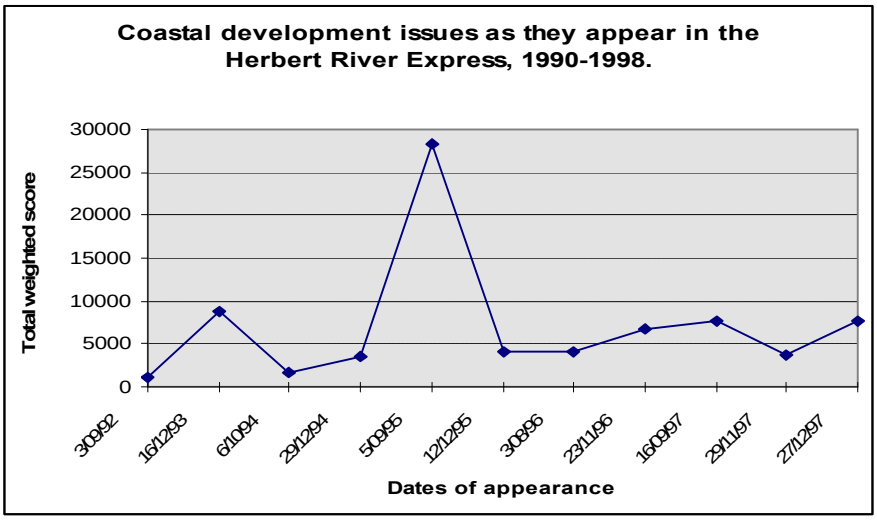
Most of the remaining articles covering issue of flora and fauna in the local area ranged between 300 and around 4000 points on the Gregory & Williams (1981) scheme. Some examples from this group of stories includes:

Herbert Valley is rich in beautiful wildlife (14/01/93)
Watch out for wasps in ants clothing (04/01/97)
Nighttime fun with owl spotting tour (11/12/97)

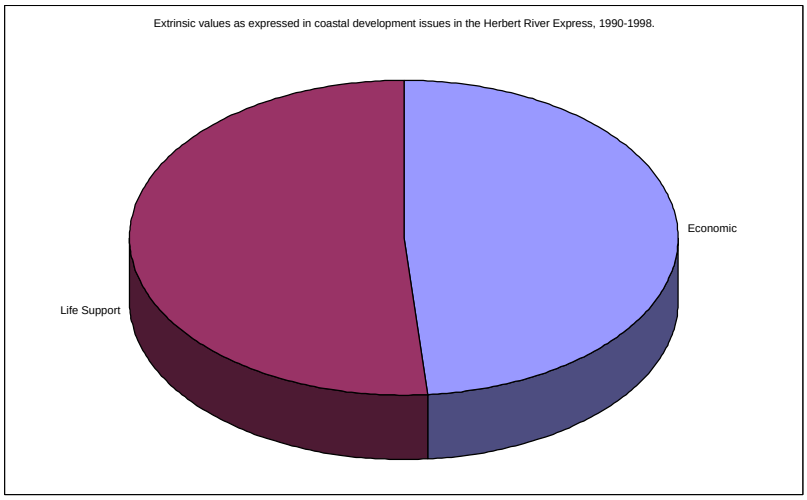


Flora and fauna issues were dominated with an aesthetic value theme towards natural resource management with 68.67% of the articles being classified under this theme. This issue was almost equally treated under the life support and economic theme with 15.27% and 16.06% respectively of the articles being dealt amongst these two themes. Flora and fauna issues consisted of 74.32% of all articles categorised under the theme of aesthetic values. These issues ranked lowly amongst the themes of the majority, that is, economic and life support values of the environment. Flora and fauna issues consisted of 2.72% of the economic theme and 0.81% of the life support values of the environment.

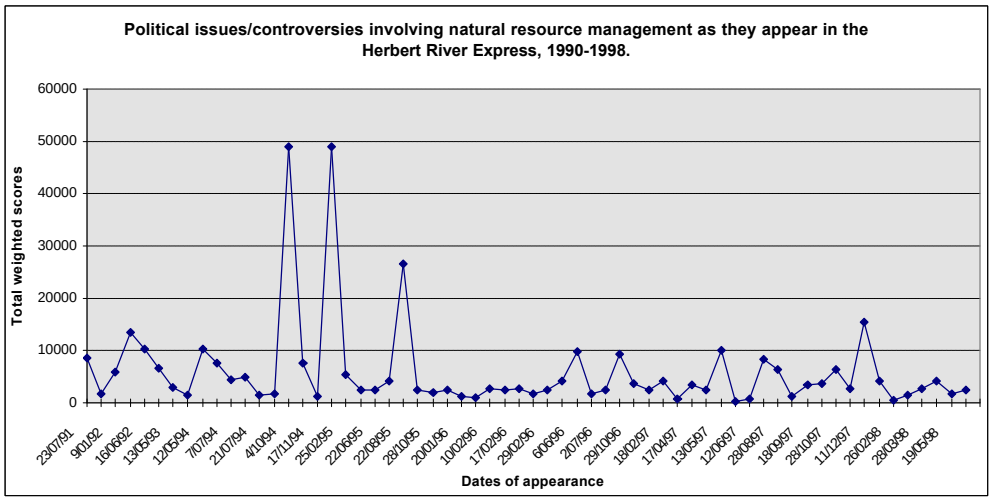
6. Coastal Development



Coastal development issues are predominantly between approximately 1000 and 9000 points on the Gregory & Williams (1981) point score scheme with the exception of one article *"Step closer to permanent Dungeness marina facility"* (05.09.95) which is a front page headlining article with pictures discussing the Hinchinbrook Shire Council's efforts for a permanent commercial waterfront facility. The article addresses the claim of some water front land, the details of the transaction and the impact the transaction will have on local development. This article was categorised under economic theme of the environment for the financial focus of the article with the council "weighing up its options on the type of development and facilities they believe will best serve the shire". The weighting of these articles remains fairly consistent over the time frame and appear sporadically through this period. Only 1 or 2 articles a year appear with relatively little emphasis on them. Coastal development articles appear not until 1992 then are fairly consistent after this time.
Coastal development issues consisted only a small part of the sample with only 11 articles in total. However, this issue was almost evenly split with 51.4% of these articles indicating a life support theme or value. 48.6% of these articles indicated an economic theme. This small category only comprised of 8.65% of all economic articles and 2.86% of all life support articles.



7. Political Issues



Political issues and controversies was a specially designed category to cover particularly contensios and complex issues for the local area. This category cover a select few issues which have proven to be of great media interest in the local area. These issues include:

- The Port Hinchinbrook/Oyster Point debate
- The mahogany glider habitat issue
- The Tully Millstream proposal

8. The Port Hinchinbrook/Oyster Point debate

This is a very decisive issue, it is a case in this community that you either are for it or against it, and this community is for it according to the local media. The local area sees it as the light at the end of the tunnel for the local economy. With headlines such as:

Dredging debate won't stop Williams (12/05/94)
Williams starts at Oyster Point (04/10/94)
Molly's folly to be revegetated (18/01/96)
Williams to pay for water (27/11/97)
Oyster Point: Rowell attacks agitators (25/06/94)
The battle for Port Hinchinbrook - Oyster Point row hots up (29/11/94)
Chamber is confident of Williams resort approval (03/08/95)
Environmental bigots (29/02/98)
Williams say 'genuine'greenies were conned (18/02/97)
The hard sell begins for controversial resort (11/12/97)

It is difficult to say that the paper overtly sides on the development side of the controversy as they "should" be non-biased reporting. Place comments from the articles to support this claim - from the major articles...

Williams starts at Oyster Point (04/10/94) is a major article (48870 points) on the Gregory & Williams (1981) point score scheme and features as major voice peice on the Port Hinchinbrook debate. This appears around the middle of the timeframe in late 1994 but by no means marks any less of a milestone for the development site and the local area.

The initiation of development works at the Oyster Point site obviously was met with protests from lobby groups concerned about the project as another major article hits the newstands, The battle for Point Hinchinbrook: Oyster Point row hots up (29/11/94) with a major 48865 points.

Later in the timeframe of 1990-1998 another prominent article concerning this particular debate arises, *The hard sell starts for controversial resort* (11/12/97) marking another milestone for the debate.

The mahogany glider habitat debate

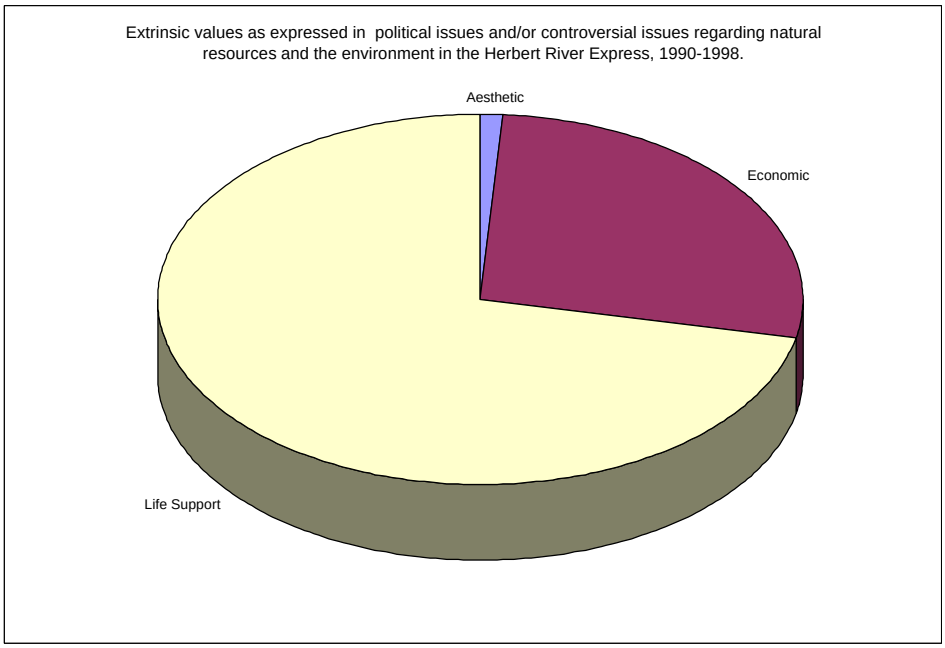
This birth of this debate coincides with an article that appears in the Herbert River Express, *Rare possum sighting puts plan on hold* (16/06/92) and culminates with *Buy back of mahogany glider habitat discussed with landholders* (22/08/95). Other headlines read:

Prawn farms lose to gliders (28/10/95
Minister committed to mahogany glider conservation plan (20/7/96)
Mahogany glider gets $1.6m home (01/03/97)
Aquisition of mahogany glider habitat just a rumour (19/04/97)
Gliders on the run (31/05/97)

Tully-Millstream hydro electric plant proposal

This is the third issue that dominates the headlines in the political issues/controversies category. Still a contentious issue and despite its lower weighting scale in the paper, this issue remains of importance to the Herbert River district. Headlines read:

Wet tropics chief 'cops flack' over Tully hydro (30/11/91)
Katter backs hydro (1605/92)
Millstream scheme 'on the backburner' (13/05/93)
Councils push for Tully-Millstream hydro by 2000 (25/02/95)
Promise to build Tully Millstream hydro scheme (08/04/95)



Political issues and controversies were dominated by a life supporting value of the environment and/or natural resource in question. 1.18% of these issues were for expressed aesthetic values and 21.02% were for expressed economic values. The sample produced unsurprising results with 22.89% of the economic articles were covering political issues/controversies as were 19.21% of life supporting articles and 6.41% of aesthetic values articles.

Abstract
This paper reviews the role of riparian and wetland areas in ensuring ecosystem function and briefly assesses the status of riparian and wetland areas in catchments immediately adjacent to the Great Barrier Reef Marine Park. We also report in detail on the results of a study undertaken on the floodplain of the Herbert River catchment, that assessed both spatial and temporal changes in the area of riparian and wetland zones. We demonstrate that there has been significant reduction in the riparian and wetland area since European settlement and provide a range of measures to show that landscape diversity and quality have also declined. In response, we introduce and discuss a range of policy, planning and management options that can contribute to more sustainable resource management in coastal environments.

INTRODUCTION

The Great Barrier Reef Marine Park (GBRMP) covers an area of approximately 350000 km^2 and spans almost 2000km of the east-coast of Queensland. Fifteen catchment divisions, covering an area of approximately 375000 km^2, drain directly into the GBRMP (Figure1) (Anonymous, 1993). Since the mid-1980's, many coastal and catchment areas adjacent to the GBRMP have experienced strong economic growth, underpinned predominantly by solid performance by their agricultural and tourist sectors (ABS, 1995). While the long-term performance of these sectors will reflect the quality of their supporting natural resource base, current environmental trends suggest a decline in terrestrial and riverine systems, and on the adjacent marine environment (Anonymous, 1993; Arthington *et al.,* 1997).

Many of the catchments adjoining the GBRMP have been extensively cleared (Russell and Hales, 1993; Sattler, 1993) since European settlement. *Melaleuca* (paper-bark) wetlands once covered large areas of coastal floodplains which are now used for intensive agriculture (Tait, 1994). Prior to clearing, these wetlands would have provided extensive buffer strips protecting coastal river systems, estuaries and shorelines. Clearing, notably for sugarcane cultivation, has left only remnants of this ecosystem (Russell *et al.,* 1996). Riparian and wetland zones in many of these catchments are frequently narrow and sparsely vegetated and have been invaded by exotic weeds, particularly para grass (*Brachiaria mutica*) and *Hymenachne*, which suppress the process of natural revegetation (Johnson *et al.,* 1997). It is likely that riparian and wetland zones in such poor condition have suffered a corresponding degradation of their intrinsic ecological values (Arthington *et al.,* 1997).

The aim of this paper is first, to briefly outline the extent of change of riparian and wetland areas in catchments adjacent to the GBRMP, and second to examine in detail, changes in space and time of riparian and wetland areas on the Herbert River floodplain. While the focus of the paper is not on impacts of these changes on terrestrial, riverine and marine environments *per se*, we discuss significant issues that are central to the maintenance and function of riverine and marine resources. In so doing, we hope that readers can make the obvious connection between land, water and marine resource management. We conclude by outlining both a broad policy and planning framework, and some simple management options, that provide significant potential in addressing fundamental resource management challenges in the region.

What Role for Riparian and Wetland Areas?

Riparian and wetland areas play an important role in maintaining the biological health of the aquatic and terrestrial ecosystems associated with watercourses (Raisin, 1995). Wetlands, swamps, billabongs and waterholes are important wildlife habitat areas and form an integral part of a hydrological regime. Changes to the hydrological regime of swamps and wetlands (eg. drainage), alter both the habitat and the vegetation. Wetlands are important habitat for birds, amphibians and other wildlife. They are also important as nursery areas for several species of commercially important fish such as barramundi. Maintenance of these values is dependent upon annual

flushing and recharge during wet season floods. Important ecological functions of riparian and wetland areas include (Bunn, 1993; Campbell, 1993; Catterall, 1993; Cummins, 1993):

- *Assisting in maintaining bank stability*. The roots of riparian plants bind stream bank materials and help to reduce slumping. This constrains the width of stream channels and may allow banks to become under-cut without collapsing, thus creating habitat for aquatic organisms (Bunn, 1993). Clearing of riparian vegetation increases the chances of stream channels migrating (Barling and Moore, 1994);

Figure 1. Catchment areas draining into the Great Barrier Reef Marine Park.

- *Providing a filter strip to reduce sediment input into a watercourse*. Riparian and wetland areas form a buffer between streams and surrounding systems which can filter nutrients, pesticides and suspended sediment in runoff water. The mechanisms of this filtering function are both physical and biological including deposition, vegetative uptake and conversion by micro-biological processes such as denitrification (Lowrance *et al.,* 1984). In a similar manner, riparian and wetland areas can act as a sink for nutrients carried in solution via overland flow during floods. Clearing and draining riparian and wetland areas prevents water from being filtered as it enters stream systems or the marine environment;
- *Creation of habitat for fish and other aquatic organisms*. Riparian vegetation provides shade and reduces both light and heat reaching the stream (Arthington *et al*., 1997). Riparian shading also alters the wavelength of light reaching streams, filtering out much of the ultraviolet spectrum and favouring green in the visible spectrum. Water temperature increases in unshaded streams (Pearson and Penridge, 1992), and this is frequently associated with a reduction in dissolved oxygen levels in the water and the progressive death of sensitive aquatic organisms. This can be particularly significant in north Queensland during the dry season when natural biological oxygen demand can be high (Arthington *et al*., 1997). An increase in water temperature at this time may eliminate some taxa from a stream (Pearson and Penridge, 1992). In unshaded streams with dense growth of aquatic plants, trophic status may fluctuate between production and respiration depending on cloud cover; several overcast days in succession may result in anoxia in such streams (Bunn and Davies, 1996; Bunn *et al.,* 1997). Shade also renders fish less visible to predators such as birds and thus provides them with some protection (Koehn, 1992). This may be especially important in streams with little structural in-stream cover. The deposition of leaf litter into the watercourse is a major component of the food chain. Riparian vegetation contributes woody debris which has an integral and often profound influence on stream morphology and ecological processes in most natural streams (O'Connor, 1986). The surface of the wood also provides habitat for invertebrates (O'Connor, 1991). This is particularly significant in large silty and sandy rivers where woody debris can be the major invertebrate habitat and is consequently also very important as feeding habitat and shelter for fish (Arthington *et al.,* 1997);
- *Provision of habitat for terrestrial birds, mammals, reptiles and amphibians and insects*. Riparian and wetland areas may also act as critical refuges for the maintenance and replenishment of wildlife populations during times of drought or after fire (Catterall, 1993). Riparian and wetland habitats provide important corridors for wildlife movement and dispersal, especially in catchments cleared for human use, where areas of riparian vegetation link bushland remnants (Catterall, 1993). Remnant wetland habitats in the coastal lowlands of catchments, such as bulkuru sedge swamps in the Tully-Murray catchment, are important as nursery areas for silver barramundi (*Lates calcarifer*). Waterfowl species are also dependent upon these wetlands. Further clearing of riparian and wetland areas on the coastal lowlands should be examined carefully, considering the generally low agricultural suitability of these areas and their important functional and habitat roles. Tait (1994) suggested that these areas be conserved and incorporated into farm drainage systems. In practice, however, there are few operational examples of such approaches.
- *Benefits for agricultural systems*. Benefits to agricultural production systems can also be gained from conserving and restoring riparian vegetation. Riparian zones, particularly riparian wetlands, play a key role in regulating the natural hydrological cycle, particularly in minimising flood peaks following heavy rainfall. They help reduce soil loss from bank erosion (Moss *et al.,* 1996) and from runoff. Riparian areas also increase the abundance of beneficial insects in adjacent crops (Lowrance *et al.,* 1985). Recent research has also clearly demonstrated that rat damage to sugarcane crops can be significantly minimised by establishing closed canopy vegetation in harbourage areas (riparian areas, drainage lines and hillsides). Shade trees impede grass and weed growth, providing a long-term solution to rat control (Tucker, 1996; Brodie, 1996).

Status of Riparian and Wetland Zones In Catchments Adjacent the GBRMP

The status of riparian and wetland areas in catchments adjacent to the GBRMP has been reviewed by a number of authors (eg Arthington and Hegerl, 1988; Anonymous, 1993; Blackman *et al.,* 1996). Accounts of these areas have increasingly confirmed their outstanding biological richness, diversity, geographical extent, and importance as habitat for a similarly rich and diverse biota. Of the 19 Queensland wetlands identified as having national importance (Blackman *et al.,* 1996), 8 are located in areas immediately adjacent to or within the GBRMP. Tables 1 and 2 provide summary information on the catchment areas that drain into the GBRMP and include an overview of the dominant tenure, land use and disturbance patterns for wetland and riparian areas.

Wetland areas adjacent to the GBRMP are only partially protected from development and specific protection is frequently restricted to the coastal fringe via the *Fisheries Act 1994* or Marine Parks legislation. In most cases, existing wetland areas are in a sound condition, however most are also threatened by competing uses and many protected wetlands are impacted upon by activities in surrounding areas. Protection for riparian areas is very poor and is almost solely confined to National Parks or Reserves. Accordingly, with the exception of areas in the vicinity of Shoalwater Bay, Townsville and NE Cape York, substantial losses of riparian and wetland areas have occurred since European settlement.

The principle causes for this decline have been: the development of intensive agriculture, mainly sugarcane and horticulture production from Sarina to the Daintree River; urban and industrial development in Mackay, Townsville and Cairns; and the introduction of grazing systems based on the use of improved and ponded pasture (particularly in the southern catchments). Of these, clearing of wetland and riparian areas for sugarcane production has had the most profound impact, particularly on areas from the Burdekin to Mossman.

Table 1. Estimated extent of coastal wetland and riparian areas and their relative conservation significance in catchments adjacent the GBRMP (Adapted from: Anonymous, 1993; Blackman et al., 1996).

Catchment	Catchment Area (km^2)	Wetland Area (km^2)	Significance

On the Wet Tropical Coast (Rollingstone to the Daintree River), expansion of agricultural industries has seen widespread destruction of riparian and wetland areas. In the Johnstone River catchment, the area of wetlands has decreased by approximately 60% since 1951 (Russell and Hales, 1996). The most significant losses have been of freshwater wetlands, particularly *Melaleuca* communities. *Melaleuca* forests, notably those to the south of the Johnstone estuary have been reduced by approximately 78%. There have also been significant reductions in other wetland categories, including a 64% reduction in palm and pandanus dominated wetlands and a 55% reduction in freshwater reed swamps. Freshwater wetlands to the north and west of the confluence of the North and South Johnstone Rivers have also almost entirely disappeared during this period. In contrast, the area of mangrove patterns has remained almost stable. Of the riparian areas assessed, 72% of the coastal lowland zones were in poor or very poor condition (Russell and Hales, 1996).

In the Tully-Murray catchment, less than 20% of land systems with a high suitability for agricultural production remain under native vegetation (Tait, 1994). Large areas of freshwater wetland have been lost or degraded by clearing, draining and exotic weed invasion. The fish habitat values of remnant floodplain wetlands have been severely reduced as a consequence of agricultural drainage. Riparian vegetation of the Tully- Murray catchment has also been degraded due to clearing, erosion and exotic weed invasion. Infestation of watercourses with para grass has resulted in the prevention of establishment of riparian vegetation and a severe reduction in the value of aquatic habitat (Tait, 1994). Similar phenomena are manifest in the Herbert, Russell-Mulgrave, Barron and Mossman-Daintree catchments, and from increasing expansion in the extent of the Burdekin River Irrigation Area (Congdon and Lukacs, 1995). Unless limitations to the continued expansion of agriculture are imposed, these trends are unlikely to alter.

Catchments in the NE of Cape York have, in comparison to the Wet Tropical Coast, remained largely undisturbed (Anonymous, 1993). Cattle grazing, exotic weeds, feral animals and mining activities have all had some impact on riparian and wetland areas. It is likely that these areas will remain in a sound condition in the short to medium term. However, increasing pressure from tourism and mining pose a significant threat to the regions riparian and wetland resources. Mining and tourism also represent a threat in the Shoalwater Bay area, which remains in outstanding condition following many years of management by the Australian military (Anonymous, 1993; Blackman *et al.*, 1996).

While the current extent of riparian and wetland resources is well documented, the extent of wetland loss since European settlement is in general, poorly understood in most catchments adjacent to the GBRMP. In the sections that follow, we report on a study conducted in the Herbert catchment that quantifies the distribution of coastal riparian and wetland areas since European settlement.

Spatial and Temporal Distribution of Riparian and Wetland Zones in the Herbert River Catchment

The Herbert River Catchment drains an area of approximately 10000 km^2 to the Coral Sea and is the largest of the river systems located in Australia's sub-humid to humid tropical north east (lat. 15-19^0 S, long. 145-146^0 E) (Figure 2). Large areas of the catchment remain under natural vegetation, although approximately 35 to 40% of the coastal lowland area has been cleared for crop production or improved pastures. Agricultural and pastoral activities are the largest users of land (in area) in the catchment. The catchment has two major population centres and a population of approximately 18000 (1993 Census), of which 75% are located in the lower catchment.

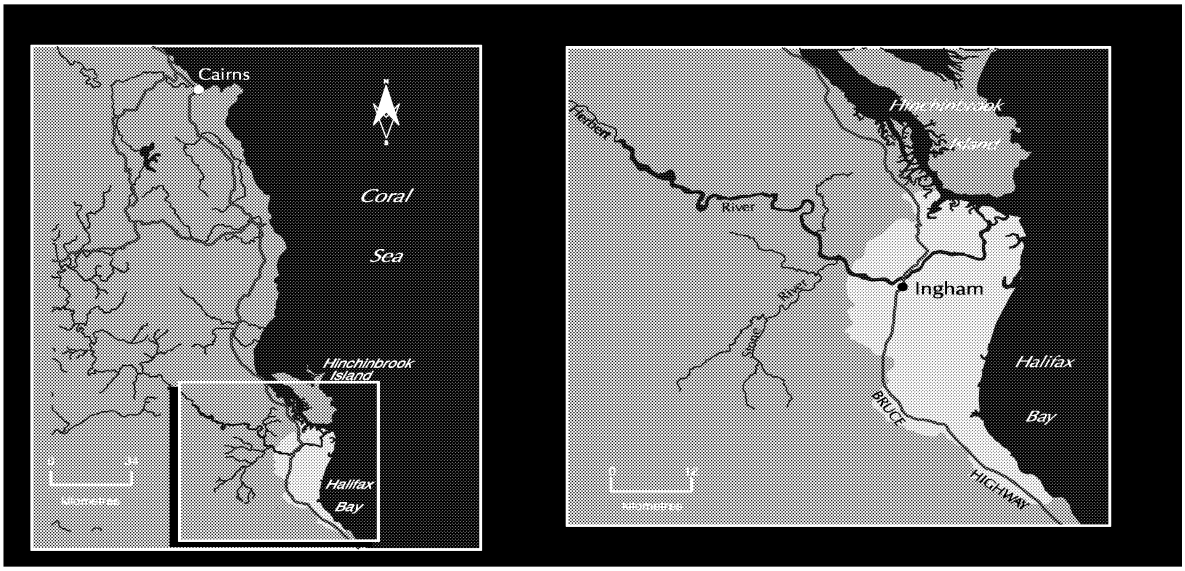

Figure 2. Location of the study area in the Herbert River catchment.

METHODS

Land cover of the lower Herbert River catchment was mapped from aerial photography acquired in 1943, 1961, 1970, 1977, 1988, 1992, 1993, 1994 and 1995. SPOT Panchromatic and MSS imagery were used to map land cover in 1996. Land cover boundaries were mapped onto a geo-referenced digital base. Classification drew heavily on previous vegetation (Tracey, 1982; Perry, 1995) and soil surveys (Wilson and Baker, 1990; Heiner and Grundy, 1994) in the region. Wetland areas were classified using the method of Blackman *et al.* (1992). Ground truthing of mapping units and mapped boundaries was conducted by vehicle and foot traverses. Classification of units and boundaries not inspected was undertaken by extrapolation from equivalent photographic units.

In addition to mapping observed land cover, an estimate of land cover prior to European settlement (early 1860's) was derived from observed relationships between remaining stands of native vegetation and the known distribution of soils, topography, relief, hydrology and rainfall. Although mapping was conducted for the entire Herbert catchment, this paper only reports on land cover on the coastal lowlands below an elevation of 13m AHD (Australian Height Datum) ie the zone of seasonal inundation with direct influence on coastal wetlands and the adjacent marine environment.

A time series was developed to elucidate spatial and temporal change in land cover, with a focus on measurement of interaction within riparian and wetland areas. An analysis of floodplain landscape pattern, emphasising the dynamics of riparian and wetland areas. Tables 3 and 4 detail mathematically the analyses performed and Figure 3 illustrates the derivation of 2 key spatial parameters. The usefulness of these measures and indices is as follows:

- Edge:area ratio quantifies the amount of irregularity in the shape of remnant stands of vegetation;
- The forest island dissection index, DI, compares the amount by which any one island is more dissected than another and, therefore, would have a greater edge to interior. Any index greater than 1 is a measure of such irregularity in comparison to an index of 1, which is circular in shape.

- Since 'edge effect' can influence vegetation composition and structure, total edge was calculated from individual edges measured for each island. The landscape dissection index (DL) measures the edge:area ratio and is cumulative for the entire landscape in which the island exists;
- The island distribution index (IDI) measures aggregation and is similar in logic to the nearest neighbour statistic. IDI emphasises the pattern of islands in the landscape. IDI = 1 in a randomly distributed population, < 1 in an aggregated population and approaches uniformity if the value is close to 2.1491, where islands would have maximum spacing, in which case they are regularly distributed in a hexagonal pattern;
- Diversity and Evenness indices compare changes in richness and landscape apportionment;
- Number and density of islands, and cover class as a % of total area, measure landscape pattern.

Table 3. Measurements and indices used to describe spatial patterns in riparian and wetlands zones in the Herbert River floodplain (Adapted from Moss and Davis, 1994 and Medley et al., 1995).

Description of individual riparian areas and wetlands
- Measurement of area (*a*) and measurement of edge (*p*)
- Edge-to-area ratio using island dissection index (DI)

Description of interactions between riparian and wetland areas

- Nearest neighbour centroid-to-centroid distance r_c

Description of floodplain landscape pattern
- Landscape dissection index (DL) and distribution index (IDI) for land cover types
- Frequency of number of wetland and riparian areas
- Diversity and Evenness Indices to compare changes in richness and floodplain apportionment

Table 4. Equations used in quantifying landscape pattern and spatial relationships for land cover/use.

Forest island dissection index

$$DI = \frac{p}{\left(2\sqrt{p\ a}\right)} \qquad \text{(Equation 1)}$$

where DI = forest island dissection index
p = island perimeter (metres)
a = island area (ha)

(*Source*: Sharpe *et al.* 1981: 111)

Landscape dissection index

$$DL = \sum_{i=1}^{n} \frac{p}{\left(2\sqrt{p}\sum_{i=1}^{n} a\right)} \qquad \text{(Equation 2)}$$

where DL = landscape dissection
p = total perimeter (metres)
a = total area of the forest island (ha)

(*Source*: Sharpe *et al.* 1981: 111)

Island distribution index

$$IDI = 2\bar{r_c}(lp) \qquad \text{(Equation 3)}$$

where IDI = island distribution index
$\bar{r_c}$ = mean centroid-to-centroid distance from a forest island to its nearest neighbour (Fig.3)
λ = density of forest islands (number per ha)

(*Source*: Bowen and Burgess 1981)

Shannon-Wiener Diversity Index

$$H' = -\Sigma P_i \ln P_I \qquad \text{(Equation 4)}$$

where P_i represents the proportion of of total area in category *i* of each land cover/use type
(*Source*: Medley *et al.,* 1995)

Evenness Index

$$E = H' / \ln s \qquad \text{(Equation 5)}$$

where s = total number of land cover/use categories
(*Source*: Medley *et al.,* 1995)

RESULTS AND DISCUSSION

Description of riparian and wetland areas

Figure 4 shows changes in space and time of key land cover classes on the lower Herbert floodplain since European settlement. It can be seen that prior to settlement, the area was dominated by grassland, lowland rainforest, mangrove and *Melaleuca* communities. However, by the 1940's significant losses of riparian (ie rainforest patterns) and wetland (ie *Melaleuca* dominated patterns; open water) areas had occurred and much of the native grassland had been converted either to grazing or sugarcane. Land cover remained relatively stable throughout the 1960's and early 1970's, however the period between 1977 and 1996 saw a rapid expansion in the area of sugarcane. The consequences of this expansion have resulted in a 60% decrease in the area of *Melaleuca* dominated patterns (40% decrease between 1943 and 1996) and a 50% decrease in the areas of rainforest patterns when compared to pre European estimates of area. In contrast, the area of mangrove communities has remained relatively stable since 1943, while the area of sugarcane has more than tripled between 1943 and 1996.

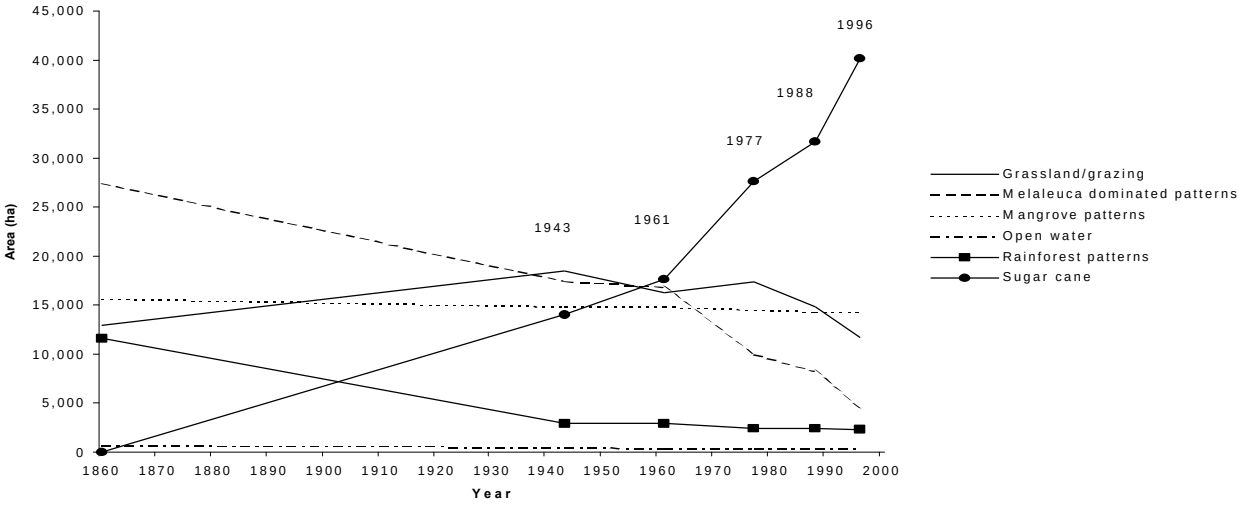

Figure 4. Spatial and temporal distribution of key land cover classes on the Herbert River floodplain.

Figure 5 shows changes in the island dissection index (DI), an index of the ratio of edge:area for land cover units. DI for wetland and mangrove areas decreased (ie > area:edge) in the period

between first European settlement and 1943 and remained relatively stable between 1943 and 1996. In contrast, DI for riparian areas increased (ie > edge:area) with time, indicating that riparian areas were increasingly becoming longer and thinner.

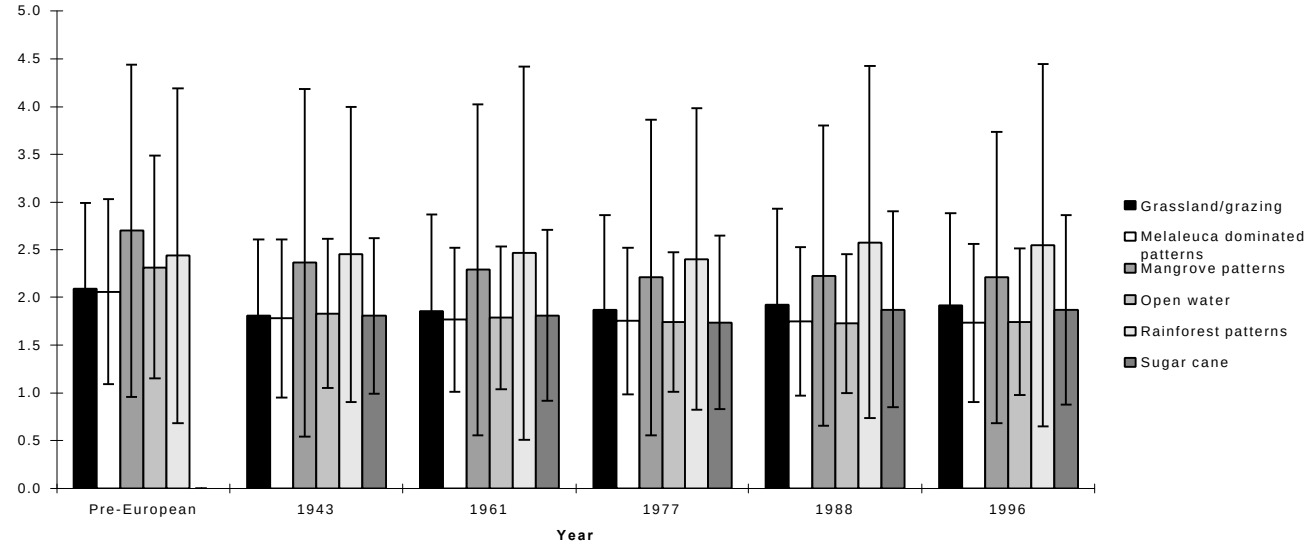

Figure 5. Mean and standard deviation of DI for key land cover classes with time.

Description of floodplain landscape pattern

Data at this level showed that although the number of riparian and wetland islands remained relatively constant since European settlement (Figure 6), mean island size for both land cover classes decreased significantly. Mean island size for riparian islands decreased from 128 ha pre-settlement to 28 ha in 1942 and 24 ha in 1996. Similarly, mean Melaleuca island size decreased from 135 ha pre-settlement to 82 ha in 1943, 46 ha in 1977 and 22 ha in 1996.

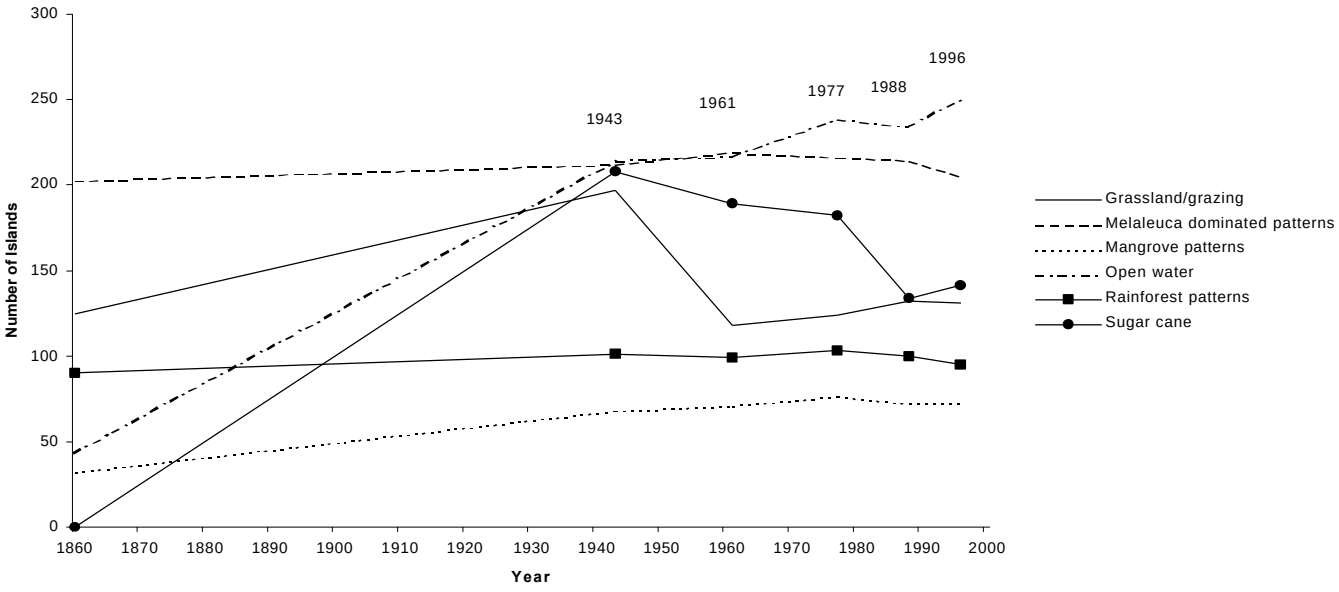

Figure 6. Changes in the number of islands for key land cover classes with time.

Island Dissection indices (IDI) for riparian and wetland areas (Figure 7) remain unchanged from pre-settlement to the 1970's, but decrease gradually after this, indicating a pattern of island aggregation. One might conclude this to be contradictory to previous results presented, however it is not unexpected given that in an ever increasing "sea" of agricultural land, remnant areas tend to occur as clusters. They appear aggregated or clumped, when land cover over the entire floodplain is considered, although as previously discussed, the mean size of each cluster is also

decreasing. Similar results were also obtained from the Landscape Dissection Index (Figure 8). The patterns observed in the IDI are supported by results obtained for measures of Diversity and Evenness, where a decline has occurred as the area of sugarcane has increased and the floodplain became less evenly apportioned (Figure 9).

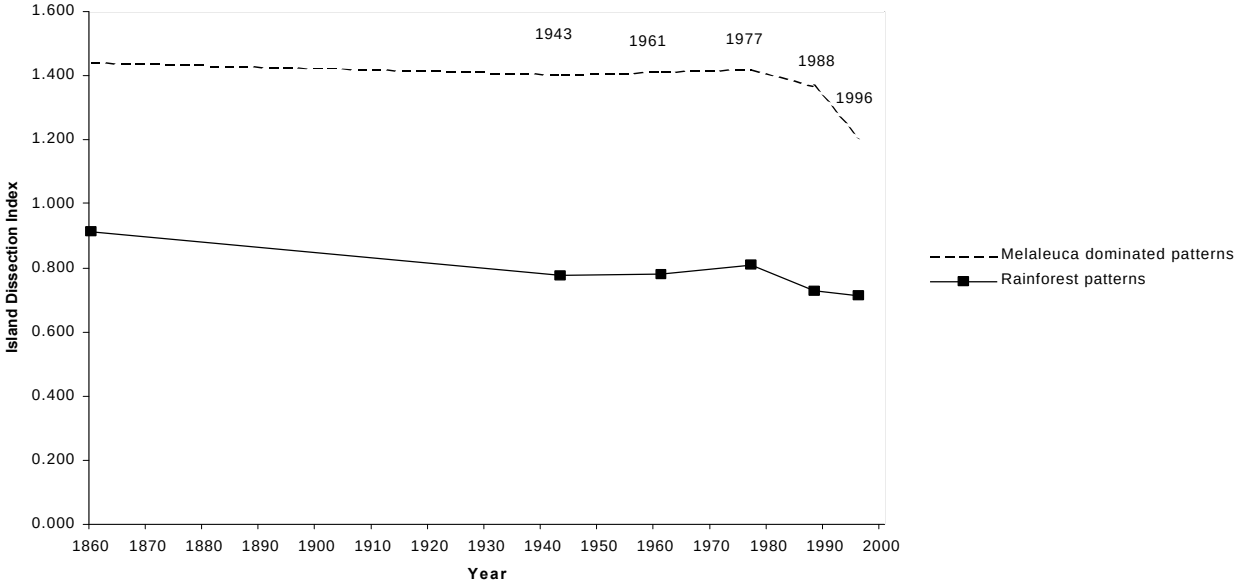

Figure 7. Changes in the Island Dissection Index for Melaleuca and rainforest dominated patterns.

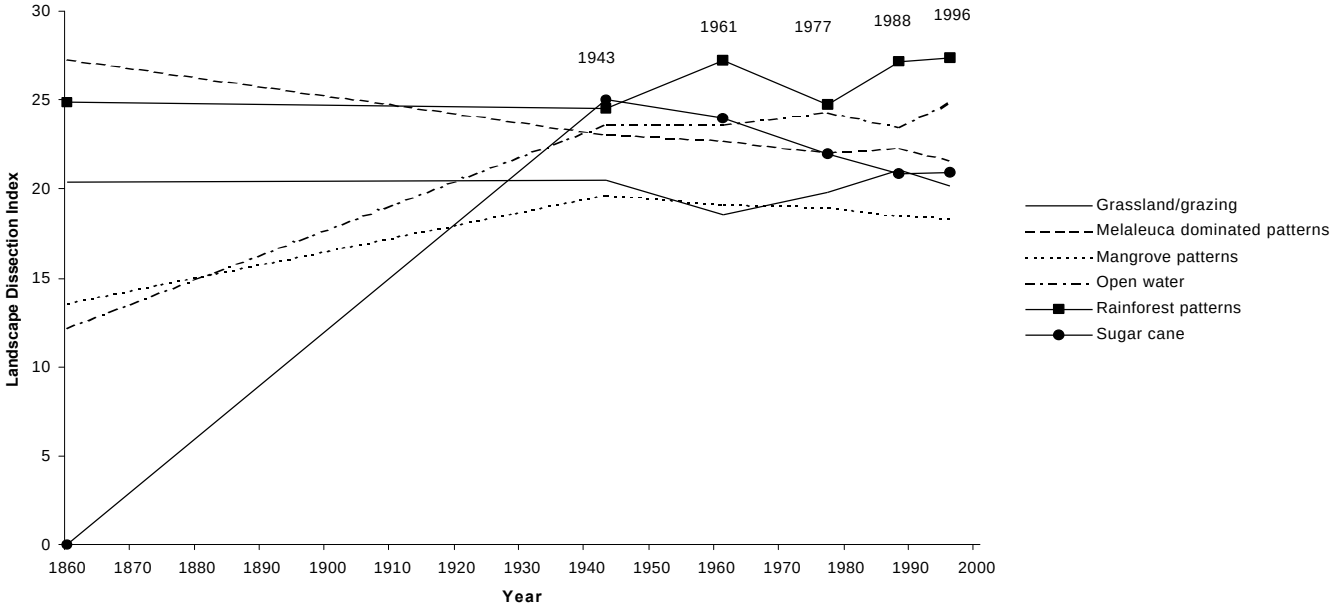

Figure 8. Changes in Landscape Dissection Index (DL) with time

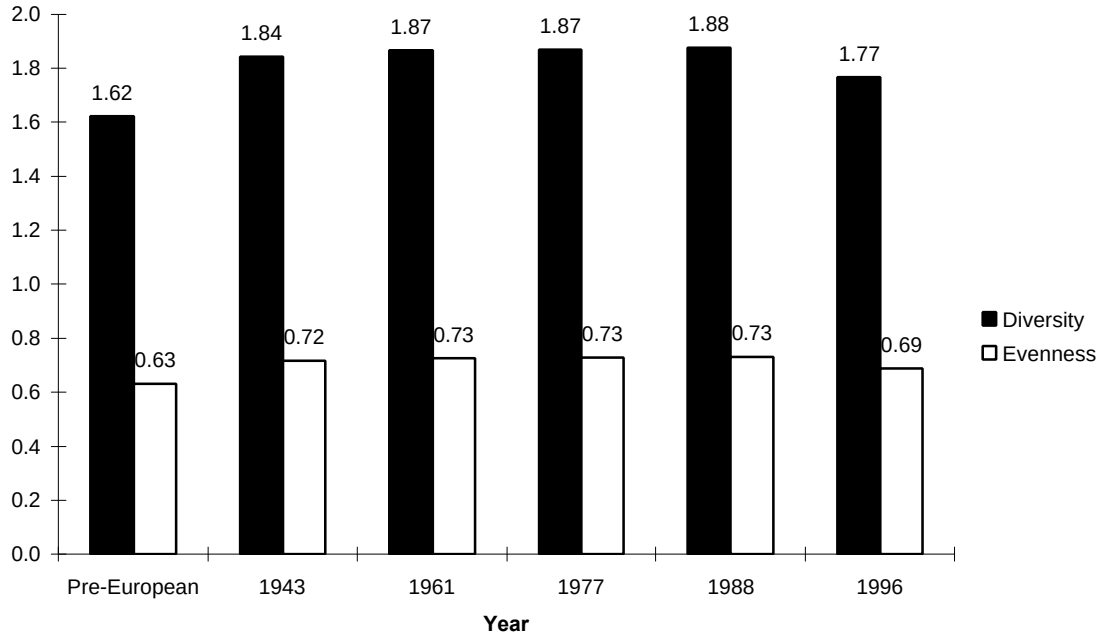

Figure 9. Measures of Diversity and Evenness for land cover on the Herbert River floodplain

Given the results presented here, it is clear that unless a change in current land management practices occurs, then the area of riparian and wetland zones on the Herbert River floodplain will be reduced to a very low level. However, it could be argued that the individual area of remnant stands of riparian and wetland vegetation are already less than is required to perform as an effective and functional biological unit. Indeed, it could be argued that rehabilitation and restoration activities are required.

In this paper we have made no attempt to evaluate the habitat status of remaining riparian and wetland areas on the floodplain. Results from the recent "State of the Rivers" analysis conducted by Moller (1996) show that the condition of remaining riparian vegetation was poor to very poor and the condition of wetland habitat moderate to poor. The trends observed on the Herbert River floodplain are not unique. Similar trends are apparent in the Tully-Murray (Tait, 1994), Johnstone (Russell and Hales, 1996), Russell-Mulgrave, Mossman-Daintree and, to a lesser extent, Burdekin-Haughton catchments. In the section that follows we attempt to introduce and discuss a range of policy, planning and management options that can contribute to the sustainable use of floodplain resources.

Opportunities for Improvement in the Management of Wetland and Riparian Zones

In detailing the opportunities for improving natural resource management in catchment areas adjacent to the GBR Marine Park, it is instructive in the first instance to provide a broader framework for future development. In so doing it is possible to draw heavily from the landmark work of Young *et al.* (1996) and place it in the context of the riparian and wetland management.

In terms of a broad policy framework, we believe that it is incumbent on industry, government and the broader community to work towards ensuring that the following objectives are fulfilled:

1. Riparian and wetland management in coastal regions is undertaken as a fundamental part of and necessary precondition for ecologically sustainable development and the implementation of the precautionary principle.
2. Responsibility for riparian and wetland management is shared between government, community and industry in a transparent manner.

3. Appropriate incentives are put in place to encourage the protection of riparian and wetland areas and to encourage their use only in ways which are ecologically sustainable.
4. Appropriate mixes of incentives are developed and appropriate weighting given to motivational, voluntary, property-right, price-based, and regulatory instruments in ways which are context sensitive and responsive to local, regional and social characteristics.
5. The Australian community as a whole - as well as users and beneficiaries of riparian and wetland areas - contribute towards the provision of incentives to industry (particularly the sugar industry in the context of coastal Queensland), whose primary responsibility is for the protection of the environment.

For this framework to be implemented, it is essential that governments at all levels develop the necessary supporting institutional capacity. Accordingly, governments at all levels must develop structures that empower local communities and industries to protect and manage riparian zones and wetlands and provide access to instruments necessary for their operation. Conversely, governments must address problems where local initiatives fail or are incomplete and importantly, must give consistent signals to resource users and consumers about the importance of riparian and wetland areas within the broader context of ecologically sustainable development.

In order to overcome some of these problems, we suggest that the appropriate boundaries for government decision making on riparian and wetlands management are bioregional. However, local government and industry, whose boundaries are rarely consistent with bioregional boundaries, have close and identifiable ties with the community, and provide an appropriate base for implementation. Hence, riparian and wetland management needs to be integrated into decision making at all levels of government, community and industry. Furthermore, stakeholders must be involved in the establishment (where they don't already exist) and operation of relevant decision making and advisory bodies (eg ICM). Improved participation of local government in the cane assignment process is also necessary. This should be done through the appointment of a local government representative(s) to Local Assignment Boards (to be known as Cane Production Boards).

Stakeholders, particularly canegrowers, also have a responsibility to ensure that their own internal processes allow real opportunities for the involvement of those at a "grassroots level". There is potential for self-interest and local needs to dominate important resource management issues. Conflict within decision-making fora represents a major potential threat to improved practice. Visible monitoring and accountability mechanisms are therefore essential pre-requisites for increased community and industry involvement, as are the development of appropriate and effective conflict resolution and facilitation processes. This is especially the case for the operation of the cane assignment system. We believe that it is more efficient to build on and adapt existing administrative and institutional structures, where possible, to address management of riparian and wetland areas rather than to create new structures. Suggested improvements in the assignment process include (Johnson *et al.,* 1996; Shrubsole, 1997):

- Reviewing the present referral process for cane assignment;
- Establishing and applying locally based conflict resolution mechanisms before requiring the formal involvement of the Queensland Sugar Corporation or Sugar Tribunal. These mechanisms should be codified in new sugar industry legislation;
- Local Boards should provide for the earlier consideration of environmental factors in the cane assignment process through existing mechanisms such as "Continuous Crushing Agreements" and corporate policies. In so doing, Local Boards can reduce the perceived need for pre-emptive clearing by adjusting the timing of the assignment process. In the Herbert River district, for example, this would see the announcement of awards in the February-March period.

Motivational and voluntary incentives

Incentives aimed at increasing levels of knowledge and understanding or requiring voluntary action, are premised on the belief that environmentally responsible behaviour is far more likely to result when people have a basic knowledge of the issues at stake, and /or a commitment to the principles of ESD (Young *et al.,* 1996). Motivational and voluntary incentives encourage all stakeholders to share information and contribute to improved management. Motivational and voluntary incentives have already been used in coastal catchments adjacent to the GBRMP, and include activities such as ICM and the Herbert Resource Information Centre (Johnson and Walker, 1996). Hence motivational incentives must be a core mechanism for improved riparian and wetland management. Two examples of a potential application would include:

- The identification of agreed wetland and riparian areas in coastal catchments to underpin negotiated agreements between landholders, government and the broader community on buffer setback widths. This activity would preferably be embedded and implemented within a broader catchment planning exercise undertaken as a partnership between government, industry and the community. In evaluating catchment resource use alternatives, stakeholders should consider existing and projected patterns in resource use and land tenure, supply and demand relationships for outputs produced, resource availability, regional and national economic indicators, environmental impacts, and community goals and expectations. Importantly, any catchment plan must include a bio-regional approach to habitat protection (Johnson and Cramb, 1992; Tait, 1994); and
- The establishment of voluntary conservation agreements between landholders and government under the *Nature Conservation Act (1992).*

For motivational and voluntary incentives to succeed, it is crucial that both the content of the information presented and the method of transferring information is appropriate and well targeted.

Property-right incentives

Two alternative types of property right incentives - covenants or management agreements, which cannot be separated from a specific resource, and those like licences to use water, which can be moved from one location to another (Young *et al.,* 1996) - are relevant in this context. Management agreements can be used to reimburse people for the costs of resource management which are not able to be recovered through normal market mechanisms. An example would be to encourage canegrowers to undertake specified management activity on private land adjacent to public conservation reserves or wetlands.

Conservation covenants are particularly effective in protecting remnant vegetation or wetlands, and can be use to underpin approaches such as management agreements. The use of conservation covenants can also be linked to other incentives, for example, the local government rating systems (for rate relief purposes), to recognise the value of uncleared land. They have direct applicability to the Burdekin, Herbert and Tully-Murray catchments. Licence and permit systems are used where there is a need to link riparian and wetland management with an economic activity, for example, pollution permits and land clearing. In the design of licence systems, there is a need to place emphasis on the dependability of the licence to protect riparian and wetland areas in an efficient and equitable manner. Central to this must be the establishment of effective monitoring strategies that not only assess specific activities (eg., cane assignment) but also general environmental performance.

Mechanisms are required which place more responsibility on developers and the sugar industry for determining the nature and extent of the serious environmental problems (eg acid sulphate soils) before review of an individual application. This may include developing and applying environmental impact assessment screening mechanisms that identify applicants who must more

adequately consider farm management and environmental issues with the submission of their assignment applications (Shrubsole, 1997).

Tradeable rights systems are frequently advocated by economists, but generally have a poor track record (Nelson, 1977). The benefit of transferable property rights are more apparent in areas where equivalent units (eg water) can be traded than where units traded may not necessarily be equivalent (eg wetland preservation schemes). Tradeable rights have a role but should never be seen as the sole solution. In virtually all cases, they need to be supported by an appropriate network of regulatory, financial and institutional measures (Young *et al.,* 1996).

Regulatory incentives

Despite advocating motivational, social and market based incentives, there remains an important role for regulation, because acting alone, non-regulatory instruments are not always effective (Napier, 1994). Regulations provide precautionary standards and an essential safety net to protect against the recalcitrant few not persuaded by other incentives. Each level of government needs to set such standards and no level of government should be able to undermine the standard set by another level of government, by a community or by industry itself. It is crucial that industry and the community be given the opportunity to contribute to the development of standards. As regulatory incentives provide protection against those who do not respond to other measure, they are particularly important when threats to riparian and wetland areas are likely to become irreversible, for example, in the case of land clearance on coastal floodplains.

Although some protection of riparian and wetland areas is currently afforded by planning controls embedded within the *Nature Conservation Act 1992*, *Coastal Protection* and *Management Act 1995*, *Fisheries Act* and *Local Government (Planning and Environment) Act 1992*, problems exist in areas subject to the provisions of the *Water Resources Act 1989* or on land with freehold tenure. An increasing regulatory role for Local Government (eg through the invocation of planning controls if consent is required for subdivision, zone change and drainage development) provides some opportunity for improved riparian and wetland management. Some of these issues are presently being addressed in the draft planning schemes of Hinchinbrook, Cardwell and Johnstone Shires. However, for improved management to occur, greater integration between local and state government, industry and the community must be a priority.

Financial Considerations

A fundamental consideration in the development and implementation of any policy or instrument mix is both the private and public cost implications. The cost of controlling and preventing damaging processes in coastal areas should be borne primarily by those who cause these problems. However, the Australian community as a whole should take financial responsibility for protecting the natural environment when the costs of doing so cannot be recovered by the use of market mechanisms. Hence, all those who benefit from non-market dimensions of protecting the natural environment, whether directly and indirectly, should contribute to the cost of its maintenance (Young *et al.,* 1996).

The tax system is an important area for reform, particularly when taxation incentives are recognised to be the most cost effective means of encouraging altruistic investments in resource conservation by the private sector (Davenport, 1995). Another method of ensuring that users pay, is the imposition of levies and charges. These have the additional benefit of making users of riparian and wetland areas aware of the cost of their activities (Young *et al.*, 1996). Acceptance of such levies is likely to be improved if the funds raised are clearly seen to be working towards resource management and protection, preferably by being placed in resource management funds administered by the local community. Opportunities also exist for the implementation of financial incentives for retention and management of high value habitat areas dedicated as Nature

Refuges or Coordinated Conservation Areas. Finally, government acquisition of riparian and wetlands of regional, national and international importance remains as an option.

CONCLUSIONS

It is difficult to judge the rate at which the first settlers on the Herbert River floodplain cleared the native vegetation and thus began to fragment riparian and wetland areas. However, in summary, the evidence presented in this paper clearly demonstrates the following:

- A rapid decline in the area of riparian and wetland zones;
- A 60% decrease in the area of *Melaleuca* dominated patterns (including a 40% decrease since 1943); triple the area of sugarcane since 1943;
- A 50% decrease in rainforest patterns;
- Riparian areas becoming narrower;
- While the number of riparian and wetland islands remained constant, mean island area decreased significantly;
- Aggregation of islands on the floodplain occurring since 1943;
- A significant decline in Diversity and Evenness measures; and
- A more uniform/less diverse landscape now exists when compared with historical patterns.

These trends measured in the Herbert are not unique and are manifest in most catchments adjacent to the GBRMP. In response to these trends we proposed a range of policy, planning and management options that can contribute to improved resource management.

It is clear that policy environment for natural resource management in coastal areas will continue to respond to changing political, economic, social and environmental considerations. While the manner in which riparian and wetland resources are managed will vary, public expectations for, and support of, effective management policies will remain. In this regard, the principles for ESD will likely form a general basis for the development of new, and hopefully improved initiatives in riparian and wetland management. The general trend of shifting management responsibilities to lower levels of government is likely to continue, although the extent will be guided by overriding state and federal government policies.

In this paper we have demonstrated that concerns relating to the decline in riparian and wetland resources in catchments adjacent to the GBRMP are justified and requiring of further attention. Given that agricultural industries in these areas are, like most other Australian agricultural industries, operating in the context of an ever-increasing community expectation for the preservation of riparian and wetland areas, conflict over the use of these scarce resources is likely to grow in the future.

We have demonstrated that the magnitude of the tasks facing stakeholders in catchments adjacent to the GBRMP, in terms of the way in which they manage riparian and wetland areas in the future, remain substantial. Accordingly, the challenge for these stakeholders, but especially landholders, is to embrace, rather than resist the inevitable trend toward greater public intervention in its affairs. The challenge facing government is to provide a stable environment in which locally relevant decision-making can occur and which is supported with appropriate and viable monitoring, cost-sharing and regulatory arrangements. Stakeholders in the region have the rare opportunity to have a significant say in their future directions. Agricultural industries in particular, need to develop their own policies and activities to guide their future developments within a wider context. In so doing, they must recognise that external pressures will evolve with time; hence planning must be a continuous activity rather than a singular exercise. Further, all stakeholders in partnership together, must develop a strategic view on where and how natural resources will be used. This view will be need to be based on the best available technical information and will occur at a regional, catchment and local level.

Acknowledgments

ABSTRACT
There has been considerable recent concern over the amount of vegetation clearance in the wet tropics of northern Australia. This paper reports on the results of a case study undertaken in the lower Herbert River catchment in north-east Queensland, that utilised remote sensing and Geographic Information Systems (GIS) to assess both spatial and temporal changes in land cover since European settlement in the mid 19th Century. We demonstrate that since European settlement, there has been a substantial reduction in the area of *Melaleuca*, rainforest and *Eucalyptus* dominated land cover patterns. We also provide a range of quantitative measures to show that the landscape diversity, integrity and quality of these ecosystems has also declined between the 1860's and 1996. We conclude that reform is required at policy, planning and enterprise levels if the ecological, economic and social values of these systems are to be maintained in the future.

INTRODUCTION

The land cover of many of the river catchments in north-east Queensland has been extensively modified since European settlement in the mid 19th Century (Russell and Hales, 1993; Sattler, 1993). *Melaleuca* wetlands, Eucalypt woodlands and rainforest once covered large areas which are now used for intensive agriculture and grazing (Tait, 1994). Clearing for agriculture has left only remnants of these ecosystems (Russell *et al.,* 1996). In addition, remnant vegetation in many of these catchments is frequently small in unit area and degraded through exotic weed invasion (Johnson *et al.,* 1997).

It is likely that systems in such poor condition have suffered a corresponding degradation of their intrinsic ecological values (Arthington *et al.,* 1997). In the Johnstone River catchment, for example, the area of wetlands has decreased by approximately 60% since 1951 (Russell and Hales, 1996). The most significant losses have been of freshwater wetlands, particularly *Melaleuca* communities. *Melaleuca* forests, notably those to the south of the Johnstone estuary, have been reduced in area by approximately 78%. There have also been significant reductions in other wetland categories, including a 64% reduction in palm and pandanus dominated wetlands and a 55% reduction in freshwater reed swamps (Russell and Hales, 1996). Freshwater wetlands to the north and west of the confluence of the North and South Johnstone Rivers have also almost entirely disappeared during this period. In contrast, the area of mangrove patterns has remained almost stable. Of the riparian forests assessed by, 72% were degraded.

In the Tully and Murray River catchments, less than 20% of land systems suitable for agricultural production remain under native vegetation (Tait, 1994). Large areas of *Melaleuca* wetland have been lost or degraded by clearing, draining and exotic weed invasion. The fish habitat values of remnant floodplain wetlands have been severely reduced as a consequence of agricultural drainage. Riparian vegetation of the Tully and Murray River catchments has also been degraded due to clearing, erosion and exotic weed invasion. Infestation of watercourses with para grass (*Brachiaria mutica*) has resulted in the prevention of re-establishment of riparian vegetation and a severe reduction in the value of aquatic habitat (Tait, 1994). Similar phenomena are manifest in the lower Burdekin, Herbert, Mulgrave-Russell, Barron and Mossman and Daintree River catchments (Congdon and Lukacs, 1995).

While the current extent of land cover in river catchments of north-east Queensland is generally known, the spatial and temporal distribution of land cover since European settlement is poorly understood. The aim of this paper is to describe changes in space and time of land cover in north-east Queensland, using a case study undertaken in the lower Herbert River catchment. While the focus of the paper is not on impacts of these changes *per se*, the results identify a number of significant issues that are central to the management, maintenance and function of natural resources in the region.

Study Area

The Herbert River catchment drains an area of approximately 10000 km2 to the Coral Sea and is the largest of the river systems located in Australia's sub-humid to humid tropical north east (lat. 15-19^0 S, long. 145-146^0 E) (Figure 1). The Herbert River rises at an elevation of approximately 1070 m and has a total length of 340 km. The catchment has three distinct geomorphic sections; the upper catchment (6000 km^2), the intermediate catchment (1000 km^2) and the lower catchment (3000 km^2). In the upper catchment, the topography ranges from level alluvial plains to rugged, deep incised ranges. In the western parts, the land is generally gently undulating while in the eastern portion of the upper catchment, the topography rises irregularly and reaches altitudes over 1000 m. The middle catchment consists of a deep gorge before entering the lower catchment. The lower catchment consists of a coastal plain flanked by mountains in excess of 1000 m high, but commonly at 600 to 900 m with steep slopes.

The catchment normally experiences warm humid to sub-humid summers and mild dry winters. Large rainfall and temperature gradients exist across the catchment and variability of rainfall is also very high. Mean annual rainfall is 1370 mm and ranges from in excess of 4000 mm in the coastal ranges to 750 mm in the extreme west. Approximately 74% of the mean annual rainfall occurs from December to March, decreasing to a minimum in the June to October period.

Agricultural and pastoral production are the largest users of land in the catchment. In terms of arable agricultural production, the sugar industry located in the lower catchment is dominant, with approximately 65000 ha of sugarcane under cultivation. Other important industries are plantation forestry, beef cattle and small crops such as pineapple, melon and pumpkin. Less important crops include paw paw, banana, lychee and mango. Lands not used for arable agriculture are mainly under native vegetation or improved pastures for beef cattle production. This is especially the case in the upper catchment. Small areas are utilised for mining (in the upper catchment only) and industrial activities, or are alienated for urban development. The catchment has two major population centres (Ingham and Ravenshoe) and a population of approximately 20758 (1996 Census), of which 66% are located in the lower catchment.

Methods

Land cover of the lower Herbert River catchment was visually interpreted from scanned and rectified 1:25000 aerial photography acquired in 1943, 1961, 1970, 1977, 1988 and 1992 (spatial accuracy ±7m) and 1:10000 digital orthophotography acquired in 1993, 1994 and 1995 (spatial accuracy ±1m). An unsupervised classification of SPOT Panchromatic and MSS imagery was used to map land cover in 1996 (spatial accuracy ±10m). Land cover boundaries were mapped onto a geo-referenced digital base (spatial accuracy ±10m) in ARCINFO GIS. Classification drew heavily on previous vegetation (Tracey, 1982; Blackman *et al.* (1992); Perry, 1995) and soil surveys (Wilson and Baker, 1990; Heiner and Grundy, 1994) in the region. Validation of 1996 mapping units and mapped boundaries was conducted by vehicle and foot traverses. Approximately 150 sites were visited during these inspections. Classification of units and boundaries not inspected in 1996 was undertaken by extrapolation from equivalent photographic units.

In addition to mapping observed land cover, an estimate of land cover prior to European settlement (circa 1860's) was developed from a simple rule base that related remaining stands of native vegetation and the known distribution of soils, topography, relief, hydrology and rainfall. A time series was developed to elucidate spatial and temporal change in land cover.

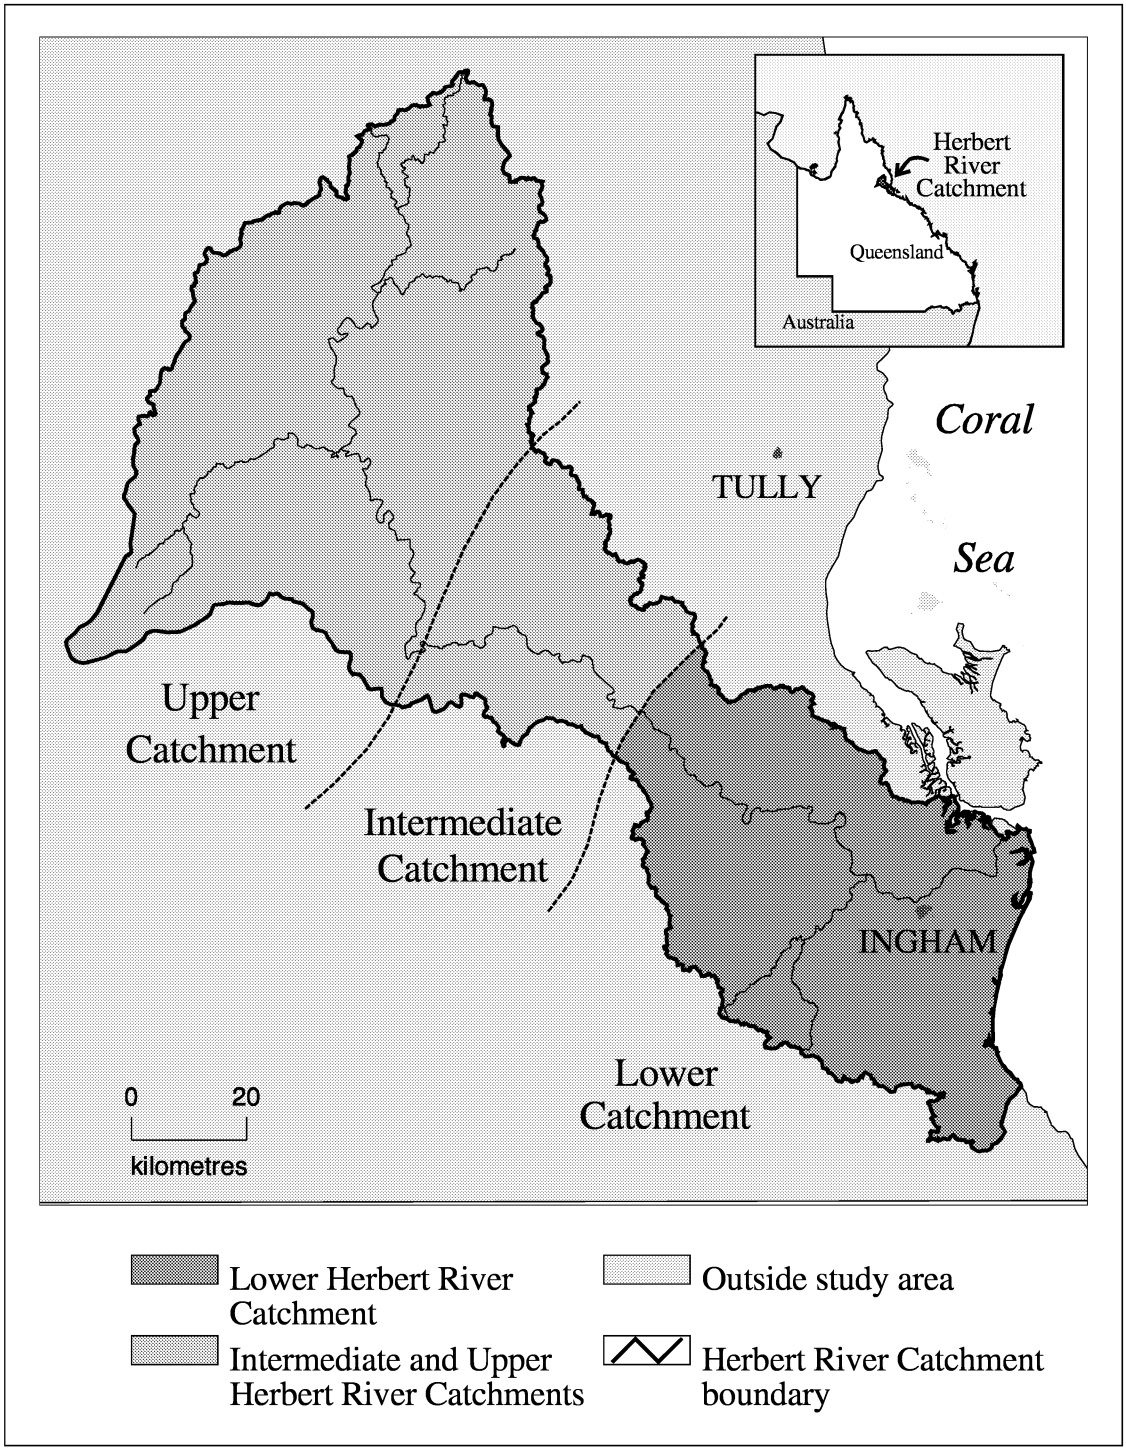

Figure 1. Location of the study area.

A spatial analysis of land cover in the lower Herbert River catchment was also undertaken. A number of key indices were calculated in ARCINFO to quantify changes in shape, size and spatial pattern of vegetation units. These indices have been successfully used in a number of similar studies:

- *Edge:area ratio*, which quantifies the amount of irregularity in the shape of remnant stands of vegetation (Sharpe *et al.*, 1981);
- *Forest island dissection index* (DI), which compares the amount by which any one "island" (or in GIS terms, polygon) of vegetation is more dissected than another and, therefore, would have a greater edge to interior. Any index greater than 1 is a measure of such irregularity in comparison to an index of 1, which is circular in shape (Sharpe *et al.*, 1981). DI can be represented by the following equation:

$$DI = \frac{p}{\left(2\sqrt{p\ a}\right)}$$

- where p = island perimeter (metres) and a = island area (ha)
- *Landscape dissection index* (DL), which measures the cumulative edge:area ratio for the entire landscape (Sharpe *et al.*, 1981). DL can be represented by the following equation:

$$DL = \sum_{i=1}^{n} \frac{p}{\left(2\sqrt{p}\sum_{i=1}^{n} a\right)}$$

- where p = total perimeter (metres) and a = total area of the forest island (ha);
- *Island distribution index* (IDI), which measures landscape aggregation and is similar in logic to the nearest neighbour statistic. IDI emphasises the pattern of islands in the landscape. IDI = 1 in a randomly distributed population, < 1 in an aggregated population and approaches uniformity if the value is close to 2.1491, where islands would have maximum spacing, in which case they are regularly distributed in a hexagonal pattern (Bowen and Burgess, 1981). IDI can be represented by the following equation: $IDI = 2\bar{r}_c(lp)$

  where $\bar{r}_c$ = mean centroid-to-centroid distance from a forest island to its nearest neighbour and λ = density of forest islands (number per ha)
- *Diversity* (H') and *Evenness* (E) indices which compare changes in richness and landscape apportionment (Medley *et al.*, 1995). H' and E can be represented by the following equations:

$$H' = -\Sigma P_i \ln P_I$$

  where P_i represents the proportion of total area in category i of each land cover/use type

$$E = H' / \ln s$$

  where s = total number of land cover/use categories
- *Number* and density of islands (ie number per unit area) and cover class as a % of total area measure landscape pattern.

Results

Land cover change in the lower Herbert River catchment

Land cover in the lower Herbert has changed substantially since European settlement. Figures 2 and 3 show changes in area with time of land cover in the lower Herbert catchment since the 1860's. It can be seen that prior to settlement, the area was dominated by open grassland, rainforest patterns, mangrove patterns, Eucalypt woodlands and *Melaleuca* communities. However, by the 1940's large losses of rainforest patterns and *Melaleuca* dominated patterns had occurred and much of the native grassland had been converted either to grazing or sugarcane. Land cover remained relatively stable throughout the 1960's and early 1970's, however, the period between 1977 and 1996 saw a rapid expansion in the area of sugarcane. The consequences of this expansion have resulted in a decrease of approximately 65% in the area of *Melaleuca* dominated patterns (comprising a 43% decrease between 1943 and 1996), a 60 % decrease in the area of beachside vegetation, a 20% decrease in the area of Eucalypt woodland

and a 10% decrease in the areas of rainforest patterns when compared to pre-European estimates of area. In contrast, the area of mangrove communities and open water has remained relatively stable since 1943, while the area of sugarcane has more than tripled between 1943 and 1996. As expected the area of urban and industrial land cover has increased since European settlement, however the total area alienated is small within the context of total catchment area (ie <1%).

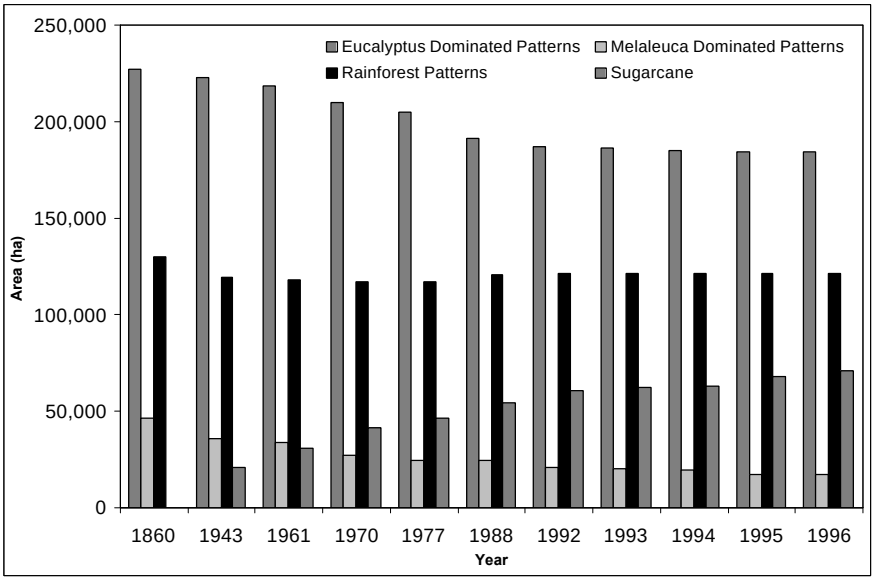

Figure 2. Changes in the area of 4 key land cover types in the lower Herbert River catchment since European settlement. The bars for each time period are from left to right: *Eucalyptus* dominated patterns, *Melaleuca* dominated patterns, rainforest patterns and sugarcane.

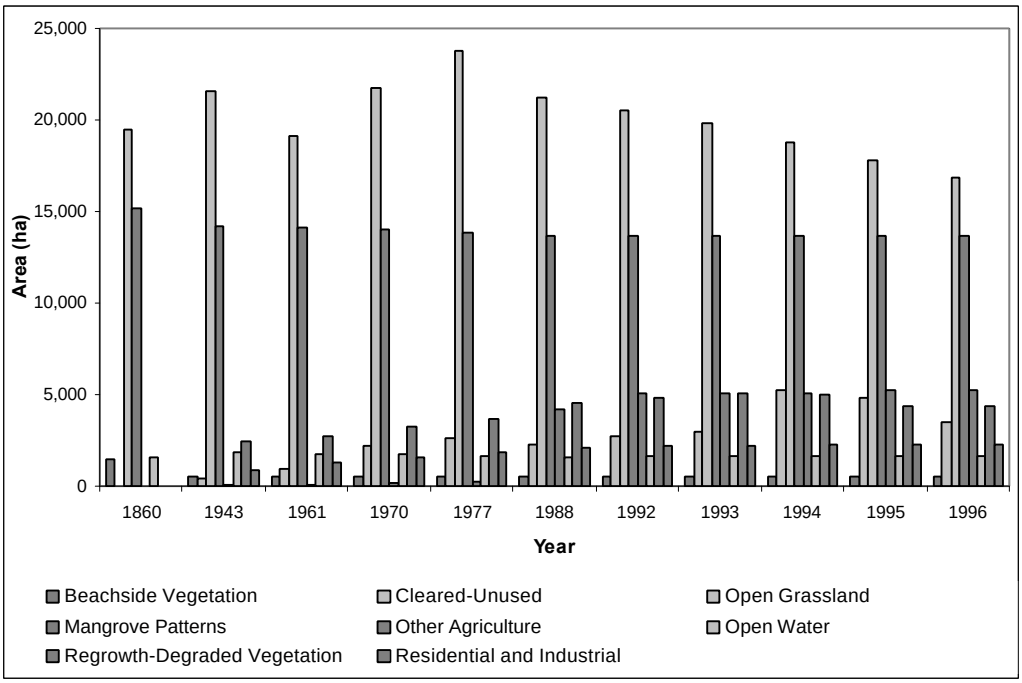

Figure 3. Changes in area of other land cover types in the lower Herbert River catchment since European settlement. The bars for each time period are from left to right: beachside vegetation, cleared-unused, open grassland, mangrove patterns, other agriculture, open water, regrowth-degraded vegetation, residential and industrial.

Landscape pattern in the lower Herbert River catchment

Figure 4 shows that with the exception of beachside vegetation, the number of *Melaleuca*, Eucalypt and rainforest islands has increased since European settlement. The number of sugarcane islands has remained relatively stable over the last 50 years, however island number peaked during major periods of sugar industry expansion in the 1970's and 1995/96. Although the number of islands increased for *Melaleuca*, Eucalypt and rainforest land cover, mean island size for these classes has decreased substantially over the last 50 years (Figure 5). For example, mean island size for *Melaleuca* forest islands decreased from 126 ha pre-settlement to 97 ha in 1942 and 43 ha in 1996. Similarly, mean island size for Eucalypt woodlands decreased from 818 ha in 1860 to 546 ha in 1943, 465 ha in 1977 and 392 ha in 1996. The number of islands of open grassland increased by 300% between settlement and 1996, although mean island area decreased by 75% over the corresponding period. In contrast, mean island area for sugarcane increased by 320% between 1943 and 1996 as sugarcane areas aggregated into larger production units.

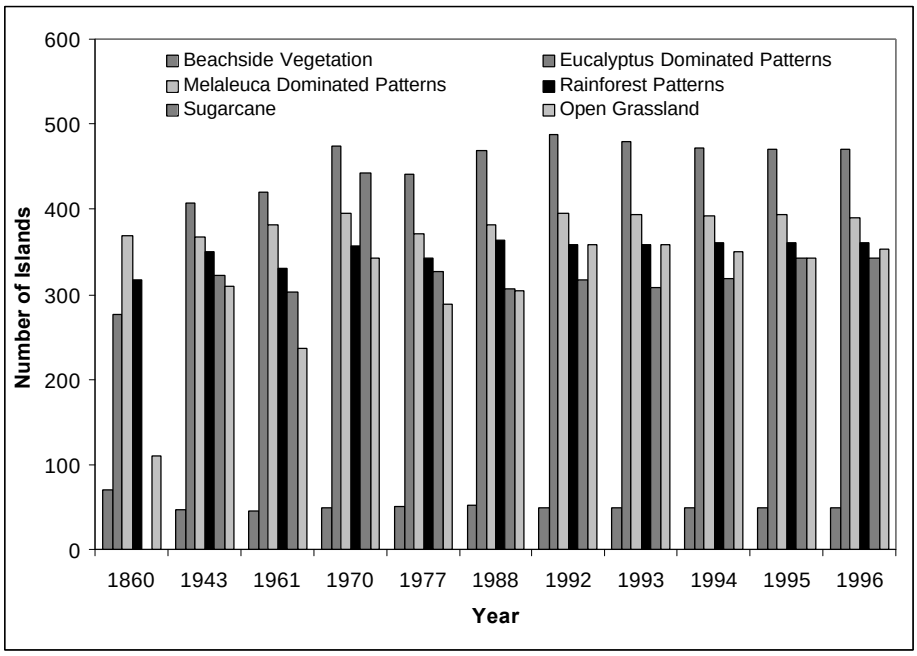

Figure 4. Change statistics for number of islands for key land cover classes in the lower Herbert River catchment. The bars for each time period are from left to right: beachside vegetation, *Eucalyptus* dominated patterns, *Melaleuca* dominated patterns, rainforest patterns, sugarcane and open grassland.

Island distribution indices (IDI) for rainforest and *Melaleuca* patterns (Figure 6) show contrasting island aggregation characteristics. Rainforest patterns show an increasing IDI, indicating that remnant cover is disaggregated, while IDI for *Melaleuca* patterns declines over time, indicating a pattern of island aggregation. It could be concluded that this contradicts results presented in Figures 4 and 5, although it is not unexpected given that in an ever increasing "sea" of agricultural land, remnant areas of *Melaleuca* tend to occur as clusters on the floodplain. However, as previously discussed, the mean size of each cluster is also decreasing.

Landscape distribution indices (DL) for rainforest patterns, *Melaleuca* patterns and sugarcane have increased since 1943, indicating that islands of these land cover classes have become longer and narrower over time (Figure 7). These results support those obtained for IDI distributions as shown in Figure 6. In contrast, DL index values for Eucalypt woodlands and beachside vegetation have remained nearly constant over the same period.

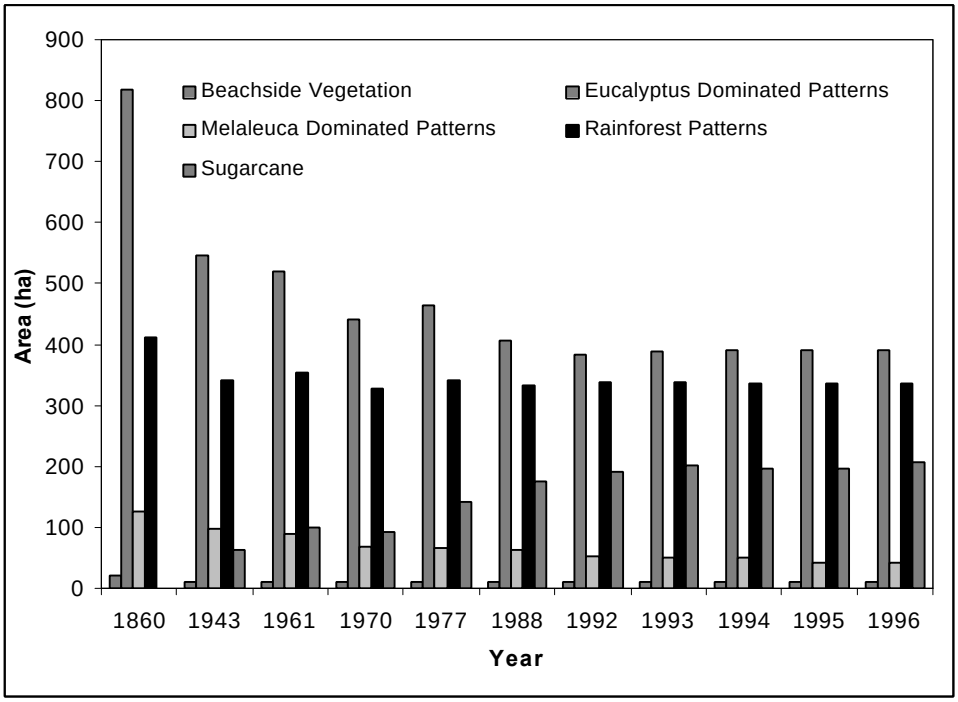

Figure 5. Change statistics for mean island area for key land cover classes in the lower Herbert River catchment. The bars for each time period are from left to right: beachside vegetation, *Eucalyptus* dominated patterns, *Melaleuca* dominated patterns, rainforest patterns, and sugarcane.

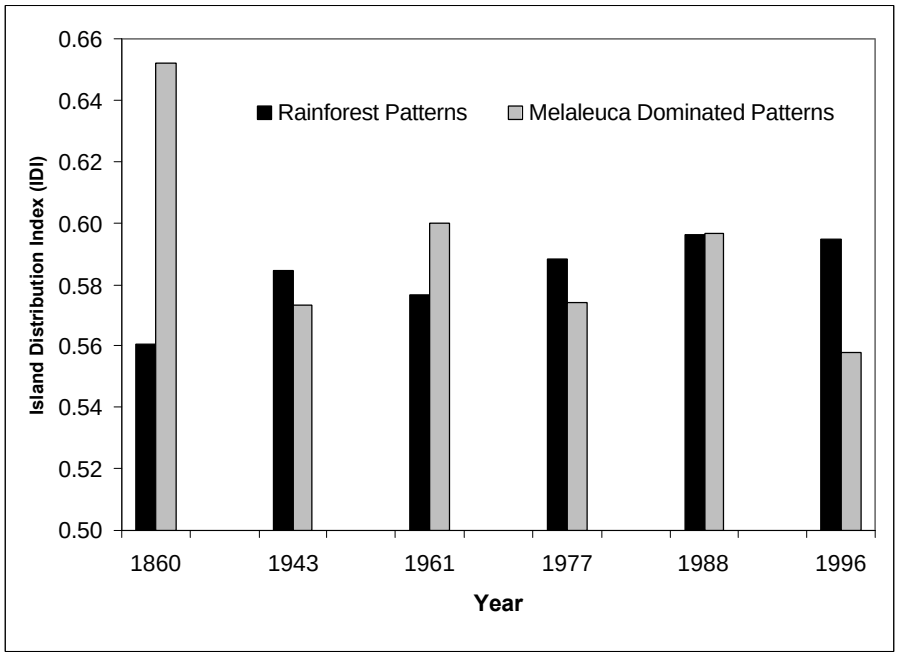

Figure 6. Change statistics for the Island Distribution Index for rainforest and *Melaleuca* patterns in the lower Herbert River catchment.

Measures of Diversity and Evenness show an increasing landscape richness and evenness in the lower catchment between European settlement and 1994, as the landscape became more evenly divided among component cover types. However both measures begin to decline post 1994, in response to the large increase in the area of sugarcane (Figure 8).

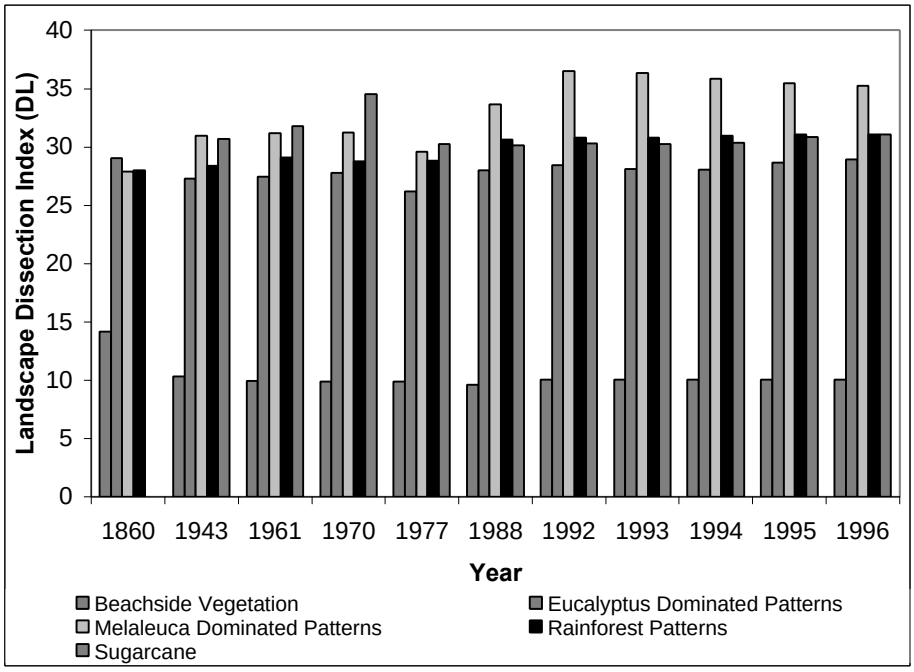

Figure 7. Change statistics for the Landscape Dissection Index for key land cover classes in the lower Herbert River catchment. The bars for each time period are from left to right: beachside vegetation, *Eucalyptus* dominated patterns, *Melaleuca* dominated patterns, rainforest patterns, and sugarcane.

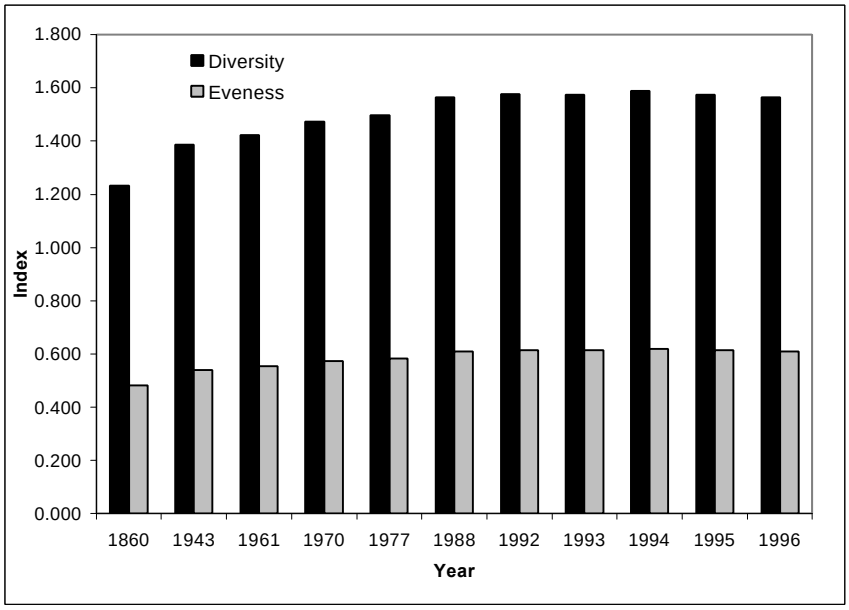

Figure 8. Change statistics for Diversity and Evenness measures in the lower Herbert River catchment.

DISCUSSION AND CONCLUSIONS

The extent and nature of vegetation clearance can provide a useful indicator of environmental quality in the Herbert River catchment. As well as providing a direct indicator of the impact of agricultural development on native vegetation, vegetation clearance can also act as an indicator of general ecosystem disturbance. Studies such as this can assist decision-makers in assessing

resource condition and addressing the broader requirements of natural resource policy development and planning. The evidence presented in this paper clearly demonstrates a substantial reduction in the area of native vegetation in the lower Herbert River catchment over the last 50 years. The significance of land cover change in the lower Herbert since European settlement can be summarised as follows:

- A 65% decrease in the area of *Melaleuca* dominated patterns (43% decrease between 1943 and 1996);
- A 60 % decrease in the area of beachside vegetation;
- A 20% decrease in the area of Eucalypt woodland;
- A 10% decrease in the area of rainforest patterns;
- No significant change in the area of mangrove communities and open water;
- A 300% increase in the area of sugarcane between 1943 and 1996;
- An increase in the number of islands of *Melaleuca*, Eucalypt and rainforest land cover;
- A large decline in mean island size for *Melaleuca*, Eucalypt and rainforest land cover;
- A 320% increase in mean island size for sugarcane;
- Rainforest areas becoming disaggregated and narrower with time;
- Aggregation of *Melaleuca* patterns between 1943 and the present;
- A recent decline in landscape Diversity and Evenness measures in response to recent large increases in the area of sugarcane ; and
- A more uniform/less diverse landscape now exists on the Herbert coastal floodplain when compared with historical patterns.

These results support those obtained in a companion study focussing on land cover changes in seasonally inundated areas of the lower Herbert floodplain (ie areas below 13m AHD) (Johnson *et al.*, 1997). This study showed that mean island size for rainforest islands decreased from 128 ha pre-settlement to 28 ha in 1942, and 24 ha in 1996. Similarly, mean island size for *Melaleuca* forests decreased from 135 in 1860 to 82 ha in 1943, 46 ha in 1977 and 22 ha in 1996. The trends observed in the lower Herbert River catchment are not unique. Similar trends are apparent in the Tully, Murray (Tait, 1994), Johnstone (Russell and Hales, 1996), Mulgrave-Russell, Mossman, Daintree and, to a lesser extent, Burdekin and Haughton River catchments (Johnson *et al.*, 1997).

Given the results presented, it is clear that ecosystem integrity in the lower Herbert has been altered substantially. Hence, unless a change in current land use policy, planning and management occurs, then the area of *Melaleuca*, Eucalypt and rainforest cover in the catchment (and indeed in other catchments in the region) will be reduced to a very low level. It is likely that the area of these classes on the floodplain proper are already less than is required to perform as effective and functional biological units (Johnson *et al.,* 1997). While we have made no attempt in this paper to evaluate the ecological status of remaining riparian and wetland areas on the Herbert floodplain, a recent ecological audit of river catchments in Queensland (Moller, 1996) has shown that the ecological condition of remaining stands of native vegetation outside of reserves and National Parks is poor to very poor. Our results have, however, served to identify those land cover types requiring priority management attention. In response to these trends we argue that improved policy, planning and management is required if areas of *Melaleuca*, Eucalypt and rainforest land cover are to be protected or maintained in the future.

In this paper we have demonstrated that concerns relating to the decline in riparian and wetland resources in river catchments in north-east Queensland are justified and requiring of further attention. Given that agricultural industries in these areas are, like most other Australian agricultural industries, operating in the context of an ever-increasing community expectation for the preservation of riparian and wetland areas, conflict over the use of these scarce resources is likely to grow in the future. Hence, the challenge facing government is to provide a stable environment in which locally relevant decision-making can occur and which is supported with appropriate and viable monitoring, cost-sharing and regulatory arrangements. In addition,

agricultural industries in particular, need to develop their own policies and activities to guide their future developments within a wider context and in so doing contribute to a reversal in the rapid historical decline of *Melaleuca*, Eucalypt and rainforest land cover in river catchments such as the Herbert.

For effective natural resource planning to occur in the wet tropics it will be important to acquire an accurate representation of land cover change in catchments other than the Herbert. It is also important that this understanding is preferentially acquired for coastal areas where serious concern exists over the ecological status of freshwater wetland and riparian areas (Johnson *et al.,* 1997). Finally, if the region is to move toward achieving sustainable development in the future, broad agreement needs to be reached between stakeholders in industry, government and the broader community as to what constitutes an acceptable level of landscape modification, or indeed if landscape rehabilitation is required.

SUMMARY
Because coral reefs are sensitive to land derived inputs of nutrient and sediment, there is concern worldwide for the effects of anthropogenic change in river catchments on reefs. Thirty-one river catchments drain directly into the waters of the Great Barrier Reef, NE Australia This case study was undertaken on the floodplain of the Herbert River catchment in north Queensland, utilising remote sensing and GIS to assess both spatial and temporal changes in freshwater wetlands and riparian forests. We demonstrate that there has been a very large reduction in the area of these ecosystems since European settlement in the mid 19th Century, with an 80% decline in their extent since 1943. We also provide a range of quantitative measures to show that the landscape diversity of these ecosystems has also declined. These changes are of importance in terms of regional, national and international trends. We argue that policy, planning and management reform is required if the remaining ecological, economic and social values of these systems and the adjacent Great Barrier Reef Marine Park are to be maintained.

INTRODUCTION

The Great Barrier Reef Marine Park (GBRMP) covers an area of approximately 350000 km^2 and spans almost 2000km of the east coast of Queensland, Australia. The GBRMP is a marine ecosystem that is recognised internationally for its unique biological and physical features. Thirty-one river catchments, covering an area of approximately 375000 km^2, drain directly into the GBRMP (Fig. 1). Current environmental trends suggest a decline in coastal terrestrial and riverine systems, and on the adjacent marine environment (Anonymous, 1993; Arthington *et al.,* 1997).

The vegetation of many of the river catchments adjoining the GBRMP has been extensively cleared (Russell and Hales, 1996) since the mid 19th Century. Freshwater wetlands and riparian forests once covered large areas of coastal floodplains which are now used for agriculture (Tait, 1994). Prior to clearing, these wetlands would have provided extensive buffer strips protecting coastal river systems, estuaries and shorelines. Clearing, notably for sugarcane cultivation, has left only remnants of these ecosystems (Russell *et al.,* 1996). Present-day wetlands and riparian forests in many catchments are frequently narrow and sparsely vegetated and have been invaded by exotic weeds (Johnson *et al.,* 1997). It is likely that wetlands and riparian forests in such poor condition have suffered a corresponding degradation of their intrinsic ecological values (Arthington *et al.,* 1997).

The status of freshwater wetlands and riparian forests in river catchments adjacent to the GBRMP has been reviewed superficially by a number of authors (eg Arthington and Hegerl, 1988; Anonymous, 1993; Blackman *et al.,* 1996). Accounts have increasingly confirmed their very high biological richness, diversity, geographical extent, their importance as habitat for a similarly rich and diverse biota, and fundamental role in ensuring the health of key GBRMP ecosystems. Of the 19 Queensland wetlands identified as having national importance (Blackman *et al.,* 1996), eight are located in areas immediately adjacent to or within the GBRMP. While the status of these ecosystems is broadly known, there have been no detailed assessments of historical changes in coastal wetlands and riparian forests in GBRMP catchments.

The aim of this study was to explore spatial and temporal changes of coastal riparian and wetland ecosystems adjacent to the GBRMP using a case study on the floodplain of the Herbert River catchment. While the focus of the paper is not on impacts of these changes *per se*, we discuss significant issues that are central to the maintenance and function of estuarine and marine ecosystems in the GBRMP.

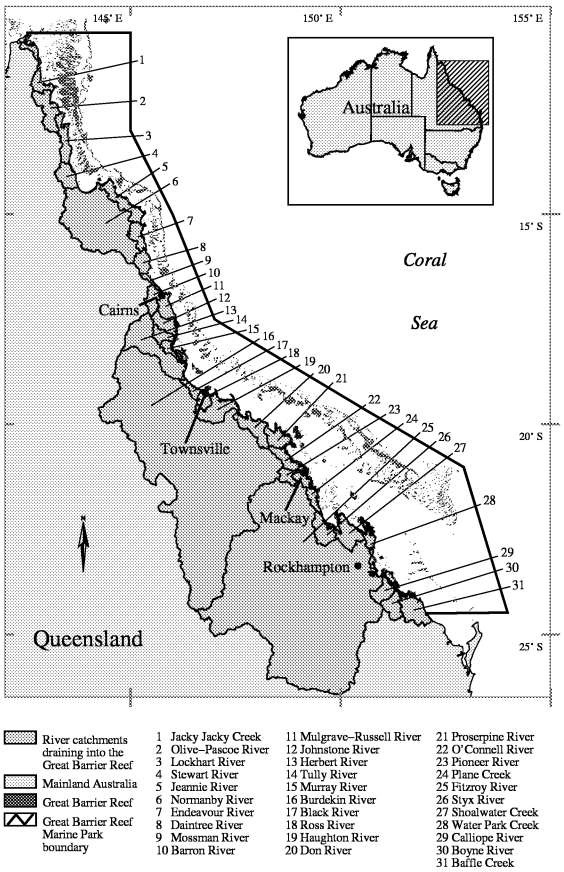

Figure 1. River catchments draining into the Great Barrier Reef Marine Park.

Spatial and Temporal Distribution of Freshwater Wetlands and Riparian Forests on the Coastal Floodplain of the Herbert River Catchment

The Herbert River catchment drains an area of approximately 10000 km^2 to the Coral Sea and is the largest of the river systems located in Australia's sub-humid to humid tropical north east (15-19^0 S; 145-146^0 E) (Fig. 2). Average annual rainfall is approximately 2500mm. Mean annual runoff for the catchment is 4991000 ML or 493 mm and the rainfall-to-runoff ratio approximately 37% (Hausler, 1991). Natural vegetation consists predominantly of open *Eucalyptus* and *Melaleuca* woodlands, with areas of open grassy plains and dense *Melaleuca* wetlands. Rainforest patterns occur on the creek and river levees. Large areas of the upper catchment remain under natural vegetation, although much of the lower catchment has been cleared for crop production or exotic pastures. Agricultural and pastoral activities effect largest area of the catchment. The catchment has a population of approximately 18000 (1993 Census), of which 75% are located in the lower catchment.

Methods

Land cover of the lower Herbert River catchment was visually interpreted from scanned and rectified 1:25000 aerial photography acquired in 1943, 1961, 1970, 1977, 1988 and 1992 (spatial accuracy ±7m) and 1:10000 digital orthophotography acquired in 1993, 1994 and 1995 (spatial accuracy ±1m). An unsupervised classification of SPOT Panchromatic and MSS imagery was used to map land cover in 1996 (spatial accuracy ±10m). Land cover boundaries were mapped onto a geo-referenced digital base (spatial accuracy ±10m) in ARCINFO GIS. Classification drew heavily on previous vegetation (Tracey, 1982; Blackman *et al.,* 1992; Perry, 1995) and soil surveys (Wilson and Baker, 1990) in the region. Validation of 1996 mapping units and mapped boundaries was conducted by vehicle and foot traverses. Approximately 150 sites were visited.

Classification of units and boundaries not inspected in 1996 was undertaken by extrapolation from equivalent photographic units. Although mapping was conducted for the entire Herbert catchment, this paper only reports on land cover on the coastal floodplain below an elevation of 13m (ie the zone of seasonal inundation with direct influence on estuarine ecosystems and the adjacent GBRMP).

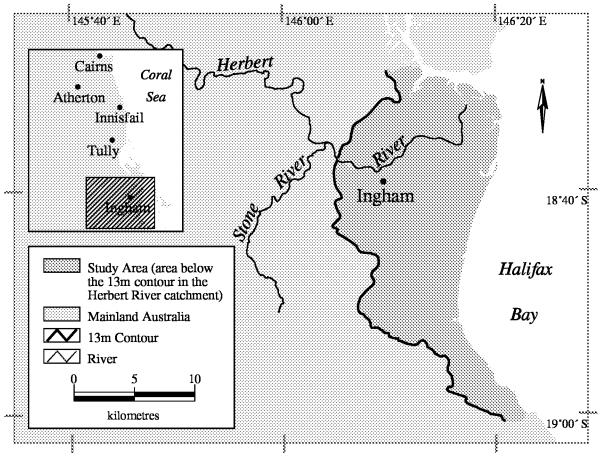

Figure 2. Location of the study area in the Herbert River catchment.

In addition to mapping observed land cover, an estimate of land cover prior to European settlement (circa 1860's) was developed from a simple rule base that related remaining stands of native vegetation and the known distribution of soils, topography, relief, hydrology and rainfall. A time series was developed to elucidate spatial and temporal change in land cover.

A spatial analysis of land cover in the lower Herbert River catchment was also undertaken. A number of key indices were calculated in ARCINFO to quantify changes in shape, size and spatial pattern of vegetation units. These indices have been successfully used in a number of similar studies:

- *Edge:area ratio*, which quantifies the amount of irregularity in the shape of remnant stands of vegetation (Sharpe *et al.*, 1981);
- *Forest island dissection index* (DI), which compares the amount by which any one "island" (or in GIS terms, polygon) of vegetation is more dissected than another and, therefore, would have a greater edge to interior. Any index greater than 1 is a measure of such irregularity in comparison to an index of 1, which is circular in shape (Sharpe *et al.*, 1981). DI can be represented by the following equation:

$$\mathrm{DI} = \frac{p}{\left(2\sqrt{\pi a}\right)}$$

  where p = island perimeter (metres) and a = island area (ha)
- *Landscape dissection index* (DL), which measures the cumulative edge:area ratio for the entire landscape (Sharpe *et al.*, 1981). DL can be represented by the following equation:

$$\mathrm{DL} = \sum_{i=1}^{n} \frac{p}{\left(2\sqrt{\pi \sum_{i=1}^{n} a}\right)}$$

  where p = total perimeter (metres) and a = total area of the forest island (ha);
- *Island distribution index* (IDI), which measures landscape aggregation and is similar in logic to the nearest neighbour statistic. IDI emphasises the pattern of islands in the landscape. IDI = 1 in a randomly distributed population, < 1 in an aggregated population and approaches uniformity if the value is close to 2.1491, where islands would have maximum spacing, in

which case they are regularly distributed in a hexagonal pattern (Bowen and Burgess, 1981). IDI can be represented by the following equation:

$$IDI = 2\bar{r}_c(lp)$$

where $\bar{r}_c$ = mean centroid-to-centroid distance from a forest island to its nearest neighbour and λ = density of forest islands (number per ha)

- *Diversity* ($H^/$) and *Evenness* (E) indices which compare changes in richness and landscape apportionment (Medley *et al.*, 1995). $H^/$ and E can be represented by the following equations:

$$H^/ = -\Sigma P_i \ln P_I$$

where P_i represents the proportion of total area in category *i* of each land cover/use type

$$E = H^/ / \ln s$$

where s = total number of land cover/use categories

- *Number* and density of islands (ie number per unit area) and cover class as a % of total area measure landscape pattern.

RESULTS

Description of wetlands and riparian forests

Figure 3 shows changes in area of key land cover classes on the floodplain of the Herbert River catchment since 1860. It can be seen that prior to settlement, grassland, riparian forests and freshwater wetlands dominated the area. However, by the 1940's significant losses in the area of riparian forest and freshwater wetlands had occurred and much of the native grassland had been converted either to grazing or sugarcane. Land cover remained relatively stable throughout the 1960's and early 1970's, however the period between 1977 and 1996 saw a rapid expansion in the area of sugarcane. As a consequence of this expansion, a 80% decrease in the area of freshwater wetlands (70% decrease between 1943 and 1996) and a 80% decrease in the area of riparian forest have occurred relative to their estimated pre-European extent. In contrast, the area of sugarcane has tripled between 1943 and 1996 (Fig. 3).

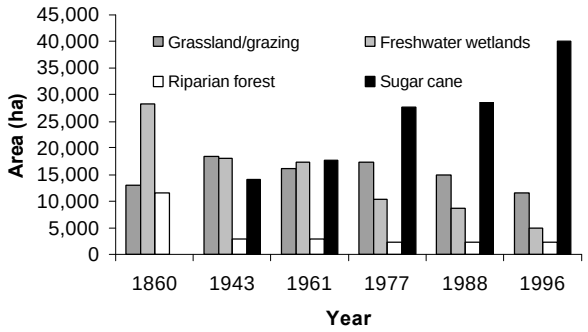

Figure 3. Area of key land cover classes on the Herbert River floodplain with time. The bars for each time period are from left to right: grassland/grazing; freshwater wetlands; riparian forest; and sugar cane.

Figure 4 shows changes in the island dissection index (DI), an index of the ratio of edge:area for land cover units. DI for freshwater wetland islands decreased (ie > area:edge) in the period between 1860 and 1943 and remained relatively stable between 1943 and 1996. In contrast, DI for riparian forest islands increased (ie > edge:area) with time, indicating that riparian forest islands were increasingly becoming longer and thinner.

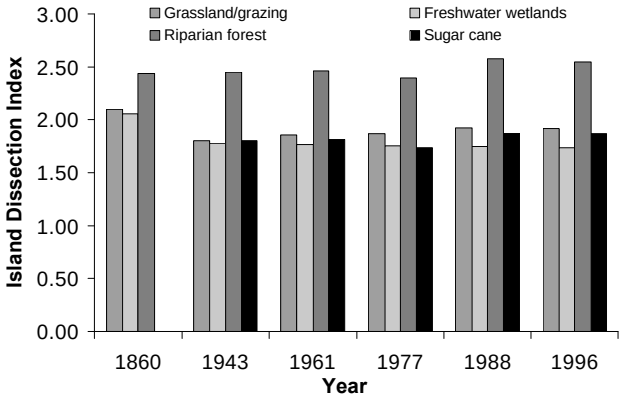

Figure 4. DI for key land cover classes with time. The bars for each time period are from left to right: grassland/grazing; freshwater wetlands; riparian forest; and sugar cane.

Description of floodplain landscape pattern

The data showed that although the number of riparian forest and freshwater wetlands islands increased since 1860 (Fig. 5), mean island size for both land cover classes decreased substantially. Mean island size for riparian forest islands decreased from 128 ha pre-settlement to 28 ha in 1942 and 24 ha in 1996. Similarly, mean island size for freshwater wetlands decreased from 135 in 1860 to 82 ha in 1943, 46 ha in 1977 and 22 ha in 1996.

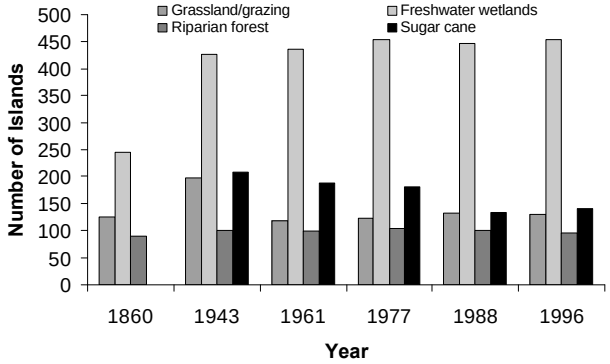

Figure 5. Changes in the number of islands for key land cover classes with time. The bars for each time period are from left to right: grassland/grazing; freshwater wetlands; riparian forest; and sugar cane.

Island distribution indices (IDI) for riparian forest and freshwater wetlands (Fig. 6) remained unchanged from pre-settlement to the 1970's, but decreased gradually after this, indicating a pattern of island aggregation. One might conclude this to be contradictory to previous results presented, however it is not unexpected given that in an ever increasing sea of agricultural land, remnant areas would tend to occur as clusters. They appeared aggregated or clumped, when land cover over the entire floodplain is considered, although as previously indicated, the mean size of each cluster was also decreasing. Similar results were also obtained from the Landscape Dissection Index (Fig. 7). The patterns observed in the IDI are supported by results obtained for measures of Diversity and Evenness, where a decline has occurred as the area of sugarcane has increased and the floodplain became less evenly apportioned (Fig. 8).

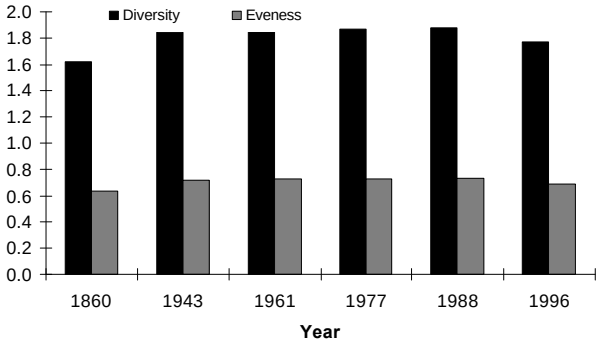

Figure 8. Measures of Diversity and Evenness for land cover on the Herbert River floodplain.

DISCUSSION

This study clearly demonstrates the following in terms of land cover change on the floodplain of the Herbert River catchment:

- A rapid decline in the area of freshwater wetlands and riparian forest since European settlement in the 1860's;
- An 80% decrease in the area of freshwater wetlands (including a 70% decrease since 1943);
- An 80% decrease in the area riparian forest since European settlement with riparian areas becoming narrower with time;
- The number of riparian forest and freshwater wetland islands increased after 1860, however mean island area decreased;

- Aggregation of freshwater wetland and riparian forest islands on the floodplain between 1943 and the present;
- Decline in Diversity and Evenness indices as the area of sugarcane increases; and
- A more uniform/less diverse landscape now exists on the Herbert coastal floodplain when compared with historical patterns.

The trends observed on the Herbert River floodplain are not unique. For example, in the Johnstone River catchment, the area of coastal wetlands has decreased by approximately 60% since 1951 (Russell and Hales, 1996). The most significant losses have been of freshwater wetlands, particularly *Melaleuca* communities. *Melaleuca* forests, notably those to the south of the Johnstone estuary, have been reduced by approximately 78%. There have also been significant reductions in other wetland categories, including a 64% reduction in wetlands dominated by palm and pandanus and a 55% reduction in freshwater reed swamps. Freshwater wetlands to the north and west of the confluence of the North and South Johnstone Rivers also disappeared almost entirely during this period. In contrast, the area of mangrove has remained almost stable. Of the riparian forests assessed, 72% were in poor or very poor condition (Russell and Hales, 1996). Similar phenomena are manifest in the lower Burdekin, lower Pioneer, Fitzroy, Boyne, Mulgrave-Russell, Barron and Mossman and Daintree River catchments (Congdon and Lukacs, 1995). In the Tully and Murray River catchments, less than 20% of coastal land systems suitable for agricultural production remain under native vegetation (Tait, 1994). River catchments north of the Daintree River and in the Shoalwater and Styx catchments have, in comparison, remained largely undisturbed either as a result of their isolation or status as a national park (Johnson *et al.,* 1997)

Given the results presented, it is clear that unless a change in current land use policy, planning and management occurs, then the area of freshwater wetland and riparian forest ecosystems on the floodplain of the Herbert River catchment, and indeed many other catchments adjacent the GBRMP, will be reduced to a very low level. It is likely that the area of remnant freshwater wetlands and riverine rainforest vegetation are already less than is required to perform as an effective and functional biological unit. While we have made no attempt to evaluate the ecological status of remaining riparian and wetland areas on the Herbert floodplain in this paper, a recent ecological audit of river catchments in Queensland (Moller, 1996) has shown that the ecological condition of remaining riparian vegetation is "poor" to "very poor" and the condition of freshwater wetlands "moderate" to "poor".

The losses of coastal freshwater wetlands and riparian forests observed on the Herbert floodplain and in other catchments adjoining the GBRMP are equivalent to or exceed losses in other parts of Australia. For example in Victoria, one-third of wetlands have been destroyed, including half the area of non-permanent freshwater wetlands (SEAC, 1996). Some 70% of wetlands on the Swan Coastal Plain, Western Australia have been lost since European settlement in the early part of the 19th Century. Similar trends can be observed in south-east Asia where reported losses are as high as 50% in Malaysia, Thailand and southern China (UNEP, 1998). What separates the north-east Australian experience from the rest of the country, large areas of south-east Asia and most of Europe and the USA, is that such a large proportion of these losses have occurred in the last 50 years and particularly in the last 20 years. In Europe and the USA, significant wetland and riparian zone restoration programmes were operational 20 years ago, a time when large-scale losses were occurring in Australia.

Current legislative protection for the environment within the GBRMP predominantly applies to ecosystems within the park boundaries. There is very little scope for direct management of adjoining areas such as coastal freshwater wetlands and riparian forests, even though fundamental linkages between these ecosystems and marine environments are known. Attempts by the Queensland government to address this deficiency through coastal planning provisions in the *Coastal Protection and Management Act (1995)* have been unsuccessful. In response, we argue

that a range of policy, planning and management reforms are required if remaining coastal ecosystems adjoining the GBRMP are to be protected or maintained. Hence, we believe that it is incumbent on agricultural industry, government and the wider community to work towards ensuring that:

- Broad, context-driven planning systems are implemented that are able to respond to the unique nature of each resource management problem and are underpinned by sound scientific input. These systems must also include areas that directly influence GBRMP ecosystems;
- Appropriate mixes of incentives (eg motivational, educational, property-rights based, regulatory) are provided to encourage the protection and use of riparian forests and freshwater wetlands only in ways which are ecologically sustainable;
- The community as a whole contribute financially towards the provision of incentives to industry (particularly the sugar industry in the context of coastal Queensland) for the protection of freshwater wetlands and riparian forests on freehold land. Hence, all those who benefit from non-market dimensions of protecting riparian forests and freshwater wetlands, whether directly and indirectly, should contribute to the cost of its maintenance.

For this framework to be implemented, it is essential that governments at all levels develop the necessary supporting institutional capacity by ensuring:

- Responsibility for riparian and wetland management is shared between government, community and industry in a transparent manner through the development of appropriately resourced bioregional management structures;
- These structures empower local communities and agricultural industries to protect and manage riparian forests and freshwater wetlands adjacent the GBRMP;
- Access is provided to instruments and resources necessary for operation of these structures;
- Intervention occurs where local initiatives fail or are incomplete;
- Clear and consistent signals are given to resource users and consumers about the importance of riparian forests and freshwater wetlands within the broader context of ecologically sustainable development; and
- Improved scientific underpinning and participation of local government in the allocation and management of agricultural land.

Stakeholders, particularly agricultural producers, also have a responsibility to ensure that their own internal processes allow real opportunities for the involvement of those at a "grassroots level". There is potential for self-interest and local needs to dominate important resource management issues. Conflict within decision-making fora represents a major potential threat to improved practice. Hence, visible monitoring and accountability mechanisms are essential pre-requisites for increased community and industry involvement, as are the development of appropriate and effective conflict resolution and facilitation processes. This is especially the case for the operation of the allocation of agricultural land on freehold tenure.

CONCLUSIONS

In this paper we have demonstrated that concerns relating to the decline in riparian and wetland resources in catchments adjacent to the GBRMP are justified and requiring of further attention. Given that agricultural industries in these areas are operating in the context of an ever-increasing community expectation for the preservation of riparian and wetland areas, conflict over the use of these scarce resources is likely to grow in the future.

We have demonstrated that the magnitude of the tasks facing policy makers and resource managers in catchments adjacent to the GBRMP, in terms of the way in which they manage riparian and wetland areas in the future, remain substantial. The challenge facing government is to provide a stable environment in which locally relevant decision-making can occur and which is supported with appropriate and viable monitoring, cost-sharing and regulatory arrangements.

In addition, agricultural industries in particular, need to develop their own policies and activities to guide their future developments within a wider context and in so doing contribute to a reversal in the rapid historical decline of riparian and wetland ecosystems adjacent the GBRMP.

Originally Published as:
Johnson, A.K.L. (1995). Quantifying current and historical inputs of fertiliser N and P to rural lands in the Herbert River Catchment. *Proceedings National Conference on Downstream Effects of Land Use*. Rockhampton, Queensland. Pp. 273-276.

Abstract
There is a need to develop practical tools to assist decision makers to evaluate the downstream impacts of changes in land use and management practices in river catchments. An understanding of historical events in a catchment is central to this activity. This paper quantifies current and historical nitrogen (N) and phosphorus (P) usage practices on rural lands in the Herbert River catchment in the context of changes in land use. It shows that since European settlement, the lower catchment has undergone 3 major phases of rural land use change while rural land use in the upper catchment has remained relatively constant. The area of rural land fertilised in 1994 is shown to be approximately 7% of the total catchment area. With increasing land area, fertiliser inputs of N (kg ha^{-1}) for sugarcane increased with time, reaching a peak in the late 1980's, while inputs of P (kg ha^{-1}) have also increased significantly over time. The area of improved pastures and associated inputs of N and P (kg ha^{-1}) have remained relatively constant. The area of exotic pine plantations has increased since the 1970's, although additions of N and P (kg ha^{-1}) have decreased since the late 1980's. The area of horticulture and small crops in the catchment has varied with time, although N and P usage (kg ha^{-1}) has remained relatively stable.

Introduction

The coastal zone of Australia is a major focus of competition between alternative uses of resources which poses serious threats to its future economic, environmental, social and cultural potential. Sustainable land and water resources management is best achieved through the informed action of individual users and managers of these resources. The existing knowledge base (e.g. data, expert knowledge, models) resides in a wide range of agencies and in a variety of data forms (e.g. raster, vector attribute, scanned). There is an urgent need to develop tools to integrate this knowledge base. It is essential that these tools operate at scales (e.g. catchment, sub-catchment) that can be used by a variety of resource users and managers to address major issues being raised by agricultural industries and the broader public. An understanding of historical events in a catchment is central to this activity.

A body of evidence (e.g., Yellowlees, 1991; Moss *et al.,* 1992) exists which shows that nutrient and sediment contaminant loads in Queensland coastal waters have increased since European settlement, although the origins of this increase are yet to be fully established and quantified.

An understanding of the nature and spatial distribution of land use and management practices in the Herbert River catchment over time is vital to the development of nutrient export budgets from different land uses in the catchment. The development of nutrient export budgets is essential for the calibration and validation of models and tools that evaluate the spatial distribution of nutrient loads in the catchment at several scales. This paper reports on the results of a study aimed at quantifying current and historical nitrogen (N) and phosphorus (P) usage practices on rural lands in the Herbert River catchment in the context of changes in land use.

Materials and Methods

Calculation of Nutrient Usage
Fertiliser usage data were obtained from the Bureau of Census and Statistics (pre 1972) and the Australian Bureau of Statistics (ABS). Information contained in these records included: land utilisation, employment, area and production of crops, fruit and vegetables, machinery, livestock numbers and production, areas irrigated and areas fertilised and quantity of fertiliser applied. Data for the period 1915-16 to 1950-51 was augmented from Pulsford (1993) and shows total crop area grown, crop area fertilised, tonnes of fertiliser used in Queensland in each year. All data pre 1915-16 were estimated from: data obtained from archives maintained by CSR Limited and the Queensland Department of Lands; and consideration of both crop areas grown and the changing proportions of fertiliser on each crop in each district. All ABS data were supplemented with records obtained from fertiliser companies operating in the catchment. All estimates post 31 December 1990 are based on fertiliser company sales records. Hence, in order

to calculate N and P it is necessary to combine data collected at three levels: statistical divisions and local government authorities; the original sales areas of fertiliser companies (these correspond in the Herbert to the sugar mill areas) and; individual dealer records for sales districts of fertiliser companies.

These estimates should be treated with caution, as complete information on changes in composition of the various fertiliser groups over time is not available. Furthermore, as Pulsford (1993) points out, the value of the results of such estimates and the calculations applied to them, depend on the accuracy of the original data. It is highly likely that census figures, in terms of areas fertilised and tonnages used, became less accurate as the complexity of the tables on the form increased and as local authority boundaries changed. This problem is reduced in the Herbert River catchment where local authority boundaries have remained relatively constant since Federation, and are closely associated with the boundaries of fertiliser company sales districts and of the river basin itself.

Allocation of Nutrients

Nutrient allocations were developed on a crop basis (i.e. the known area of each crop multiplied by the rate of usage), and then summed for the catchment over time. Allocations of sales area data to the catchments were confirmed in discussions with industry personnel and by visits to the area. While the 1991-1994 figures are likely to be the most accurate, it is believed that the earlier years sufficiently reflect previous practices. The regional totals for N and P for the 1950 to 1990 period have high accuracy, however in the 1910 to 1950 period there are no statistics available to check against individual areas of usage. The five year intervals used prior to 1960 infer average data for the particular period, rather than for the particular year. Given that the sugar industry is the dominant user of fertiliser products in the catchment, usage data are strongly correlated with changes in both the area of sugarcane and sugarcane management practices.

Results and Discussion

Since European settlement, the lower catchment has undergone 3 major phases of rural land use change. These phases are associated with expansions in the sugar industry (Figure 1) in the 1960's, 1970's and late 1980's - early 1990's and the establishment of large areas of exotic pine plantations in the late 1980's. In contrast, rural land use (predominantly grazing of unimproved pastures) in the upper catchment (areas upstream of Nash's Crossing) has remained relatively constant . Total fertiliser N and P (Figure 2) use in the catchment has increased with time, however it is important that these increases are placed in the context of changes in land use.

The total area of rural land fertilised in 1994 is shown to be approximately 7% of the total catchment area (approximately 10000 km^2), 5.5% of which is sugarcane cultivation (Figure 3). As the area of sugarcane cultivated has continued to increase, N fertiliser inputs (kg ha^{-1}) increased with time, reaching a peak in the late 1980's. Early indications are that this trend may be declining as sales of fertiliser post 1990 have declined and current BSES fertiliser recommendations for the Herbert River district advocate reduced rates of N (R. Beattie *pers comm*) (Figure 4). P fertiliser inputs (kg ha^{-1}) have increased over time as the area of cultivated land has increased (Figure 4), although both rates and total use declined for a period in the 1970's due to the removal of the government fertiliser subsidy and the energy crisis (M. Probert *pers comm*). The area of improved pastures increased until the late 1970's and remained constant until the early 1980's when pasture land was converted to sugarcane production. Inputs of N and P to pastures increased dramatically during the 1980's. The area of exotic pine plantations has increased since their establishment in the 1970's, although additions of N and P (kg ha^{-1}) have decreased since the late 1980's. The area of horticulture and small crops in the catchment has varied with time, although N and P usage (kg ha^{-1}) has remained relatively stable.

Conclusions

These data provide a valuable insight into the use of fertiliser in the context of Herbert River catchment land use. Quantifying the spatial and temporal variation of N and P usage is essential for the development of nutrient export budgets for different land uses in the catchment. These will play a major role in the future work aimed at calibration and validation of models and tools that evaluate the spatial distribution of nutrient loads in the catchment. Calculation of a nutrient mass balance will be finalised with the acquisition of nutrient output data.

Summary
There is a need to evaluate the downstream impacts of changes in land use and management practices in river catchments and associated marine environments. An understanding of historical events in a river catchment is central to this activity. This paper quantifies pesticide inputs on rural lands in the Herbert River catchment in the context of changes in land use over the last 100 years. It shows that since European settlement, 3 major phases of rural land use and land cover change have occurred on the coastal floodplain of the lower Herbert. In contrast, land use in the upper catchment has remained relatively constant. The area of rural land receiving regular inputs of pesticides is shown to be approximately 7% of the total catchment area. However, with increasing land area for agriculture, inputs of pesticides have increased significantly with time. These trends raise a number of significant challenges for agricultural industries in terms of their ability to comply with the principles of ecological sustainability.

Introduction

Fifteen river catchments, covering an area of approximately 375000 km^2, drain directly into the Great Barrier Reef Marine Park (GBRMP). The vegetation of many of the river catchments adjoining the GBRMP has been extensively cleared (Russell and Hales, 1996; Johnson *et al.,* 1999) for agricultural, horticultural and pastoral production since the mid 19th Century. Evidence also exists (e.g., Yellowlees, 1991; Moss *et al.,* 1992, Bramley and Johnson, 1995; Furnas *et al.,* 1995) which shows that nutrient and sediment contaminant loads in Queensland coastal waters have increased since European settlement. It is likely that pesticide and other contaminant loads have also increased (Hunter, 1992).

While there have been recent published estimates annual pesticide applications (eg Hamilton and Haydon, 1996), there are no published estimates of historical pesticide usage in eastern coastal catchments and only a few reports of investigations into pesticide residues in aquatic or marine environments (Hamilton and Haydon, 1996; 1997). This paper reports on the results of a study aimed at quantifying historical pesticide usage practices in the Herbert River catchment in the context of changes in land use. An understanding of the nature and spatial distribution of land use and management practices in the Herbert River catchment over time is vital to the development of contaminant export budgets from different land uses in the catchment. The development of contaminant export budgets is essential for the calibration and validation of models and tools that evaluate the spatial distribution of contaminant loads from the catchment to aquatic and marine environments.

Study Area

The Herbert River Catchment drains an area of approximately 10000 km^2 to the Coral Sea and is the largest of the river systems located in Australia's sub-humid to humid tropical north east (lat. 15-19^0 S, long. 145-146^0 E) (Fig. 1). The Herbert River rises at an elevation of 1070 m and has a total length of 340 km. Topographically, the catchment can be divided into three distinct sections. The upper catchment of approximately 6000 km^2 is bounded to the north and west by the Great Dividing Range and to the east by the Cardwell Range. In the intermediate catchment (1000 km^2) the river changes direction and flows south east for 70 km through a deep gorge before entering the lower catchment. The lower catchment (3000 km^2) is bounded to the north by the Cardwell Range and to the south by the Seaview Range.

The catchment normally experiences warm humid to sub-humid summers and mild dry winters. Mean annual rainfall for the catchment is 1370 mm and ranges from in excess of 3000 mm in the north-east of the lower catchment, to 750 mm in the extreme west of the upper catchment. Approximately 74% of the mean annual rainfall occurs from December to March. Mean annual runoff for the catchment is 4991000 ML or 493 mm and the rainfall to runoff ratio approximately 37%. Mean annual flow for the river is 3440610 Ml and highest monthly flows occur from November to May.

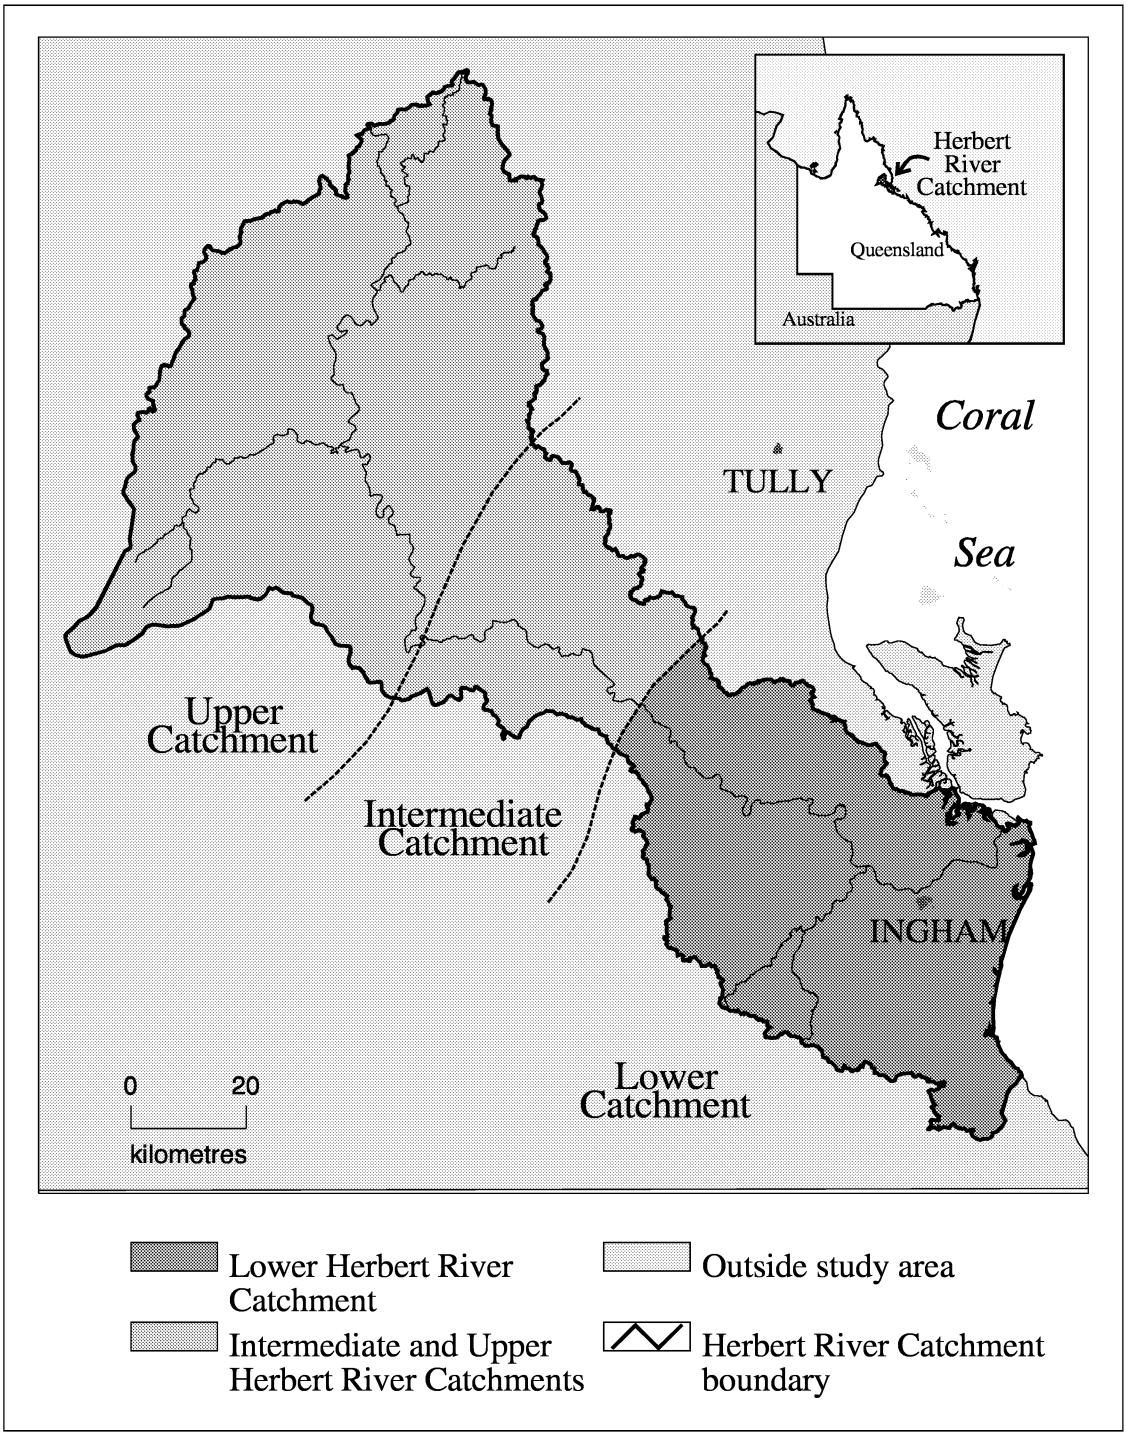

Fig. 1. Location of the study area.

In the upper catchment, the topography ranges from level alluvial plains to rugged, deeply incised ranges. In the west, the land is gently undulating while to the east, the topography rises irregularly and reaches altitudes over 1000 m. The lower catchment consists of a coastal plain flanked by mountains in excess of 1000 m high, but commonly at 600 to 900 m. The geology comprises Quaternary alluvium and beach sands, Cainozoic basalts, Carboniferous granites, Carboniferous acid volcanics and undifferentiated Paleozoic quartzite. Soils are closely related to geology and in the lower catchment heavily influenced by fluvial processes. Soils are mostly coarse textured in the upper catchment and fine textured clay/loam soils in the lower catchment. Agricultural and pastoral production are the largest users of land in the catchment. In terms of arable agricultural production, the sugar industry located in the lower catchment is dominant, with approximately 65000 ha of land supplying cane to two sugar mills. Lands not used for arable agriculture are mainly under native vegetation or used for extensive beef cattle production (especially in the upper catchment). The catchment also supports a substantial commercial and recreational fishery as well as exotic softwood plantations. Small areas are utilised for mining, industrial and urban activities. Approximately 18000 people reside in the catchment, of which 75% are located in the lower catchment.

Methods

Land Cover and Land Use

Land cover of the lower Herbert River catchment was visually interpreted from scanned and rectified 1:25000 aerial photography acquired in 1943, 1961, 1970, 1977, 1988 and 1992 (spatial accuracy ±7m) and 1:10000 digital orthophotography acquired in 1993, 1994 and 1995 (spatial accuracy ±1m). Land cover boundaries were mapped onto a geo-referenced digital base (spatial accuracy ±10m) in ARCINFO GIS.

Classification drew heavily on previous vegetation (Tracey, 1982; Blackman *et al.* (1992); Perry, 1995) and soil surveys (Wilson and Baker, 1990; Heiner and Grundy, 1994). Validation of 1996 mapping units and boundaries was conducted by vehicle and foot traverse. Approximately 150 sites were visited during inspections. Classification of units and boundaries not inspected was completed by extrapolation from equivalent photographic units.

Data on land use was obtained from the Bureau of Census and Statistics (pre-1972) and the Australian Bureau of Statistics (ABS), and was cross-referenced with the land cover data. This data was augmented (particularly for the pre-1948 period) from records held by the two local sugar mills and the Queensland Department of Primary Industries.

Pesticide Usage

Quantities of herbicide and insecticide used in infrastructure maintenance (eg roads, railways, drains, electricity poles) pest and weed control on government and leasehold lands, and government forestry plantations were obtained from historical records maintained by the relevant state or local government agency. Data for insecticide usage in the sugar industry was obtained from historical records held by the Herbert Cane Protection and Productivity Board (a statutory body responsible for the prevention of sugarcane pests and disease in the catchment). Insecticide usage for crops other than sugarcane, as well as herbicide and fungicide usage for all agricultural activities, was estimated by combining data collected at 4 levels: statistical divisions and local government boundaries (in the Herbert River catchment local government boundaries have remained relatively constant since 1900, and are closely associated with the boundaries of chemical company sales districts and of the catchment itself); the original sales areas of chemical companies (these correspond in the Herbert River catchment to the sugar mill areas); individual dealer records for sales districts of fertiliser companies; and interviews with individual agricultural producers. Chemical allocations were developed on a crop basis (i.e. the known area of each crop multiplied by the rate of usage), and then summed for the catchment over time. Allocations

of sales area data to the catchments were confirmed in discussions with industry personnel.

Results and Discussion

Land cover and land use in the Herbert River catchment has changed substantially since European settlement, particularly in the lower catchment. Figures 2 and 3 show changes in area with time of land cover in the lower catchment since the 1860's. It can be seen that prior to settlement, the area was dominated by open grassland, rainforest patterns, mangrove patterns, Eucalypt woodlands and *Melaleuca* communities. However, by the 1940's large losses of rainforest patterns and *Melaleuca* dominated patterns had occurred and much of the native grassland had been converted either to grazing or sugarcane. Land cover remained relatively stable throughout the 1960's and early 1970's, however, the period between 1977 and 1996 saw a rapid expansion in the area of sugarcane such that by the end of 1996 the area of sugarcane was approximately 65000 ha. The consequences of this expansion have resulted in a decrease of approximately 65% in the area of *Melaleuca* dominated patterns (comprising a 43% decrease between 1943 and 1996), a 60 % decrease in the area of beachside vegetation, a 20% decrease in the area of Eucalypt woodland and a 10% decrease in the areas of rainforest patterns when compared to pre-European estimates of area (Johnson *et al.,* 1999). In contrast, the area of mangrove communities and open water has remained relatively stable since 1943, while the area of sugarcane has more than tripled between 1943 and 1996. As expected the area of urban and industrial land cover has increased since European settlement, however the total area alienated is small within the context of total catchment area (ie <1%). Land cover and land use (predominantly extensive grazing of unimproved pastures) in the upper catchment has remained relatively constant.

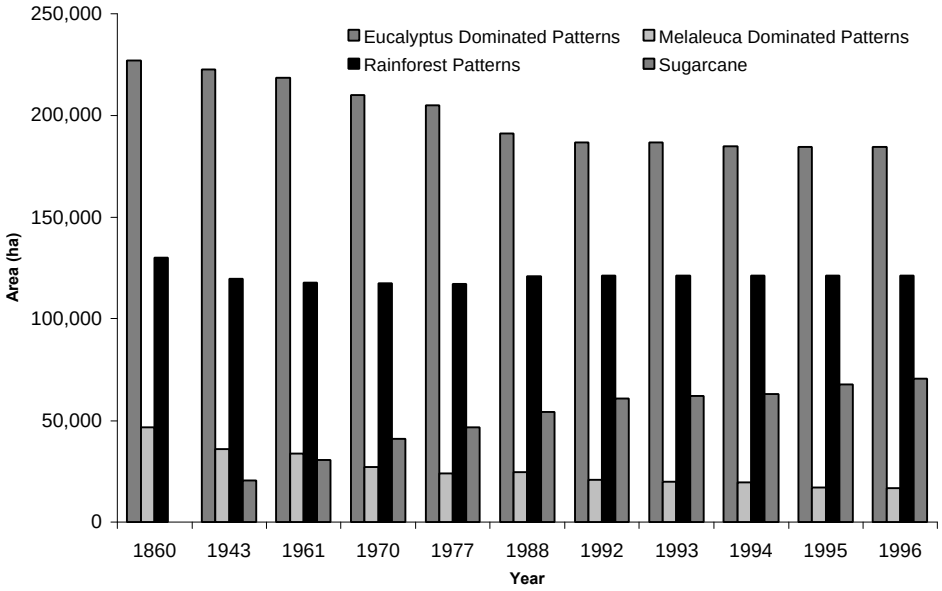

Fig. 2. Changes in the area of 4 key land cover types in the lower Herbert River catchment since European settlement. The bars for each time period are from left to right: *Eucalyptus* dominated patterns, *Melaleuca* dominated patterns, rainforest patterns and sugarcane (Source: Johnson *et al.*, 1999).

A large number of agrochemicals have been applied in the Herbert River catchment since European settlement. These include:

- *Organochlorines* (Aldrin, BHC, DDT, Dieldrin, Heptachlor, Lindane, Methoxychlor);
- *Organophosphates* (Chlorpyrifos, Ethoprophos, Fenaphimos);
- *Aliphatic acids* (Dalapon, Glyphosate, TCA);
- *Aromatic acids and esters* (Dicamba, Picloram);
- *Nitroanilines* (Trifluralin);

- *Phenoxys* (2,4-D (amine), MCPA, 2,4,5-T);
- *Triazines and triazoles* (Ametryn, Atrazine, Simazine);
- *Ureas* (Diuron);
- *Bipyridyliums* (Paraquat);
- *Mercurial Fungicides* (MMEC); and
- *Azoles* (Flusilazole, Prochloraz, Propiconazole).

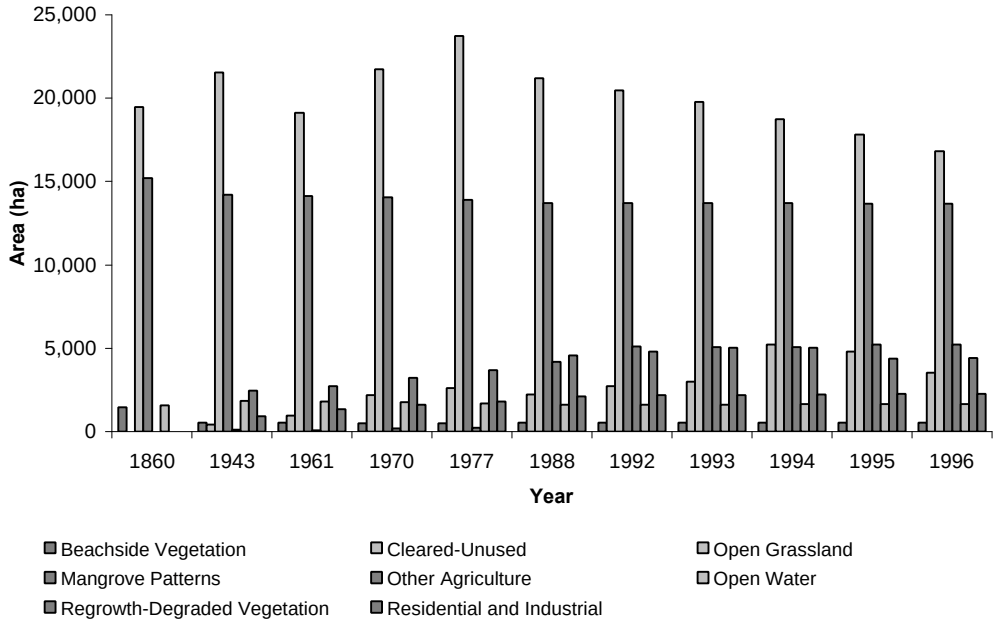

Fig. 3. Changes in area of other land cover types in the lower Herbert River catchment since European settlement. The bars for each time period are from left to right: beachside vegetation, cleared-unused, open grassland, mangrove patterns, other agriculture, open water, regrowth-degraded vegetation, residential and industrial (Source: Johnson *et al.*, 1999).

In 1995 approximately 7% of the total catchment area was receiving pesticide applications, with approximately 95% of total applications (by volume) occurring in cane growing areas of the lower catchment. With increasing land area of sugarcane and other crops (Fig. 4), inputs of pesticides have increased with time (Fig. 5-9).

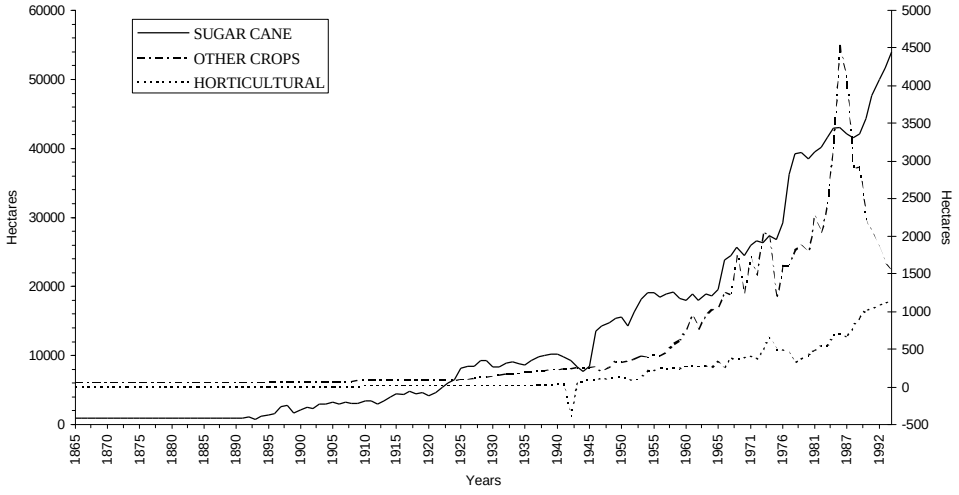

Fig. 4. Area of sugarcane and other crops in the Herbert River catchment 1865-1895. Sugarcane area is on the left side axis.

Significant quantities of organochlorine pesticide have been applied in the catchment (Fig. 5). In general these chemicals are highly persistent, sorb strongly to particulate matter, are toxic to aquatic and marine organisms and have a tendency to bioaccumulate. While many of these were withdrawn from usage in the late 1980's and early 1990's, their fate in aquatic and marine environments of the Herbert River and adjacent GBRMP are unknown (although work is in progress that examines the fate of organochlorines in the Hinchinbrook Channel).

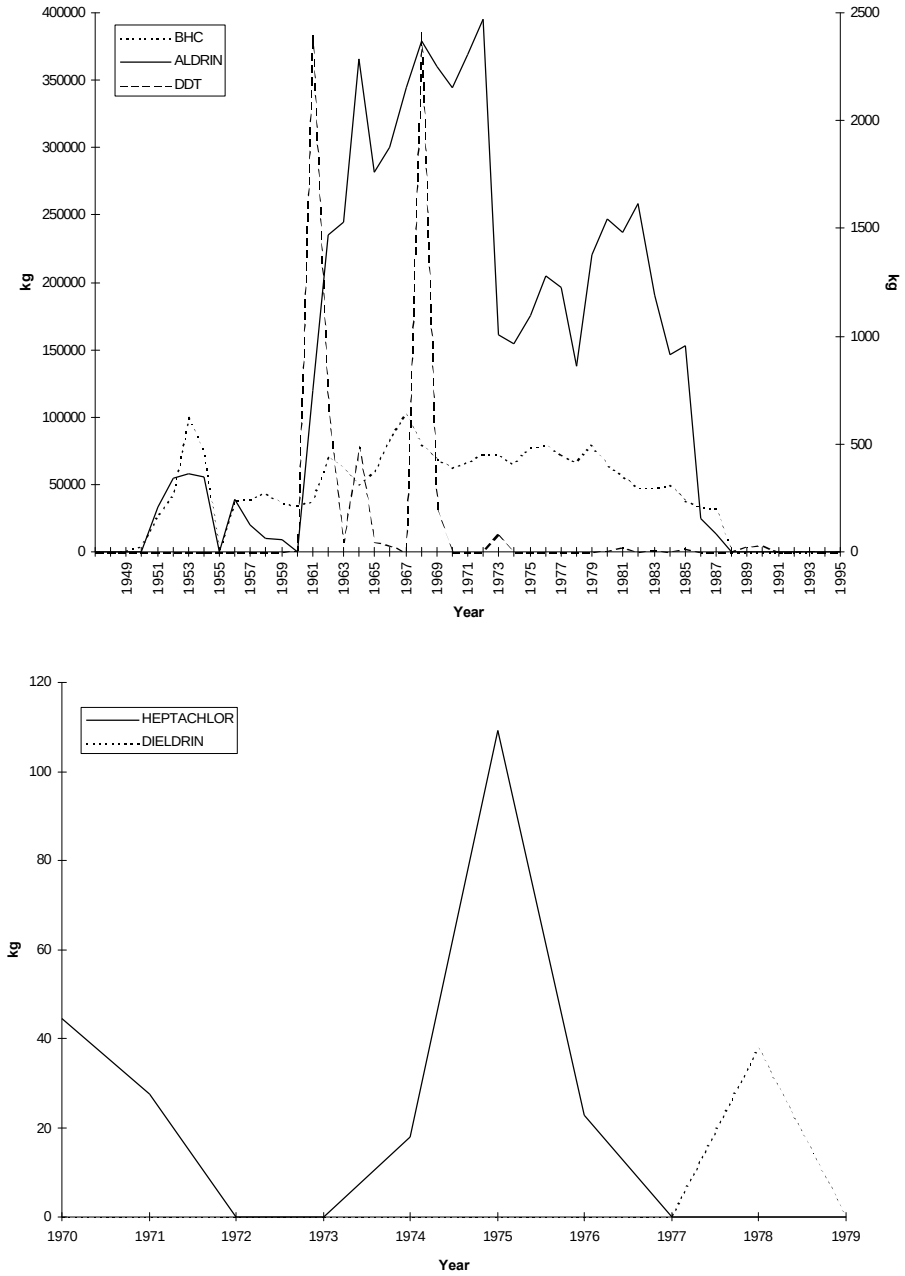

Fig. 5. Historical usage patterns (active ingredient) for selected organochlorine pesticides in the Herbert River catchment. DDT usage is on the right side axis.

Large volumes of the organophospate insecticide Chlorpyrifos continue to be applied in the catchment (Fig. 6). Chlorpyrifos has become the dominant chemical for control of cane grubs in the sugar industry. Recent increases in total volumes correspond closely in relative magnitude to the increasing area of sugarcane production. Given the significant impact that cane grub damage has on the sugar industry, this trend is likely to continue unless an effective substitute can be found. The large volumes of Chlorpyrifos applied in the Herbert are consistent with values (on a unit area basis) recorded in other catchments in which sugarcane is grown (Hamilton and

Haydon, 1996; 1997). Chlorpyrifos is persistent but effectively immobile in the soil, hence it poses little threat to ground water. However it does have the potential to contaminate aquatic and marine environments, particularly where soil erosion occurs.

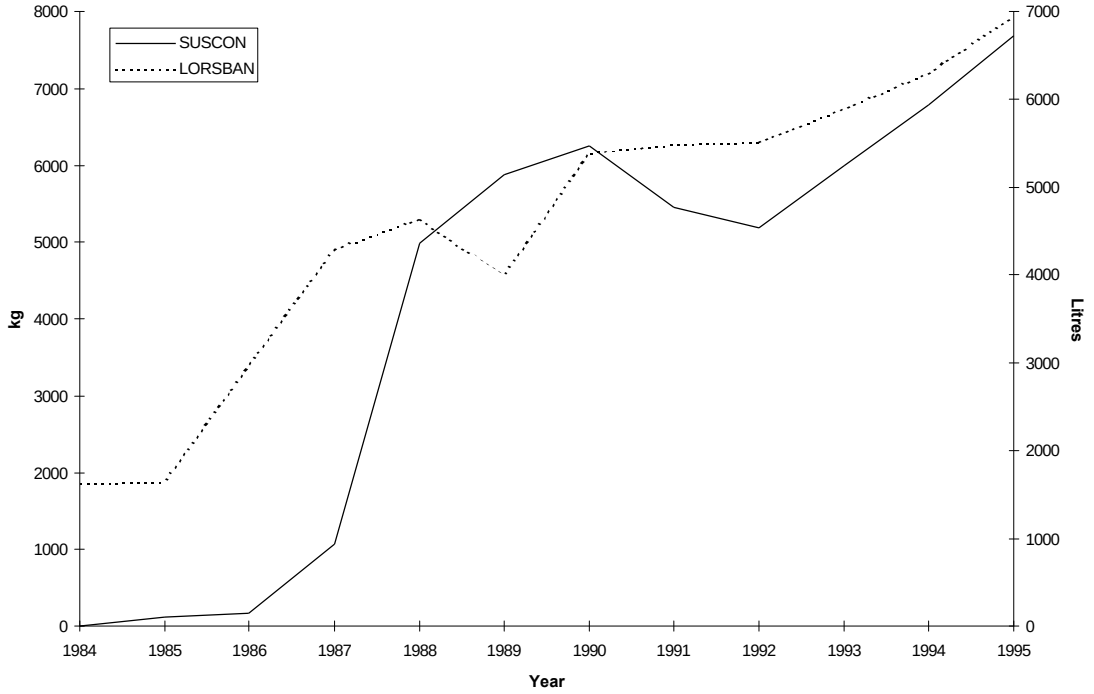

Fig. 6. Historical usage patterns (active ingredient) for the organophosphate pesticide Chlorpyrifos in the Herbert River catchment. Suscon is the trade name for Chlorpyrifos granules (kg) while Lorsban is the liquid form of the chemical (l).

The volume of the herbicides Atrazine, Diuron and 2-4,D applied in the Herbert has also increased rapidly in the last 15 years (Fig. 7). Similar trends have also been observed in neighbouring coastal catchments in which the sugar industry is a large user of land (Hamilton and Haydon, 1996). Very little is known of the residual behaviour of Diuron and 2-4,D under north Australian conditions and no information is available in terms of their persistence in ground or surface waters in NE Queensland catchments and adjacent GBRMP waters. Diuron is persistent but not highly mobile while 2-4,D is less persistent but more mobile. Given the large volumes applied of both Diuron and 2-4,D, they do have ecotoxicological potential. Atrazine, which is both highly persistent and mobile, has been detected in ground water in the Burdekin River delta (Brodie *et al.*, 1984) and similarly, has a high ecotoxicological potential.

Usage of Azole group fungicides has increased rapidly since 1982 as cane growers used these products as a substitute to Mercury based fungicides (Fig. 8). However, the small volumes used mean that a low ecotoxicological potential exists. Large volumes of methoxymethylmercury chloride (MEMC) have been applied in the catchment since 1953. MEMC has the longest continuous record of known pesticide application in the Herbert catchment (Fig. 9). Farmers perceptions of the greater efficacy of MEMC in comparison to Azole group fungicides has meant that its use has increased in the 1990's following a period of declining use in the 1980's. The environmental fate of MEMC is not well documented in the literature (Semu *et al.,* 1986), however recent studies have shown a close correspondence between known history of MEMC application, and its subsequent appearance in the Herbert River estuary and associated coastal embayments of the GBRMP (Johnson and Brunskill, 1999).

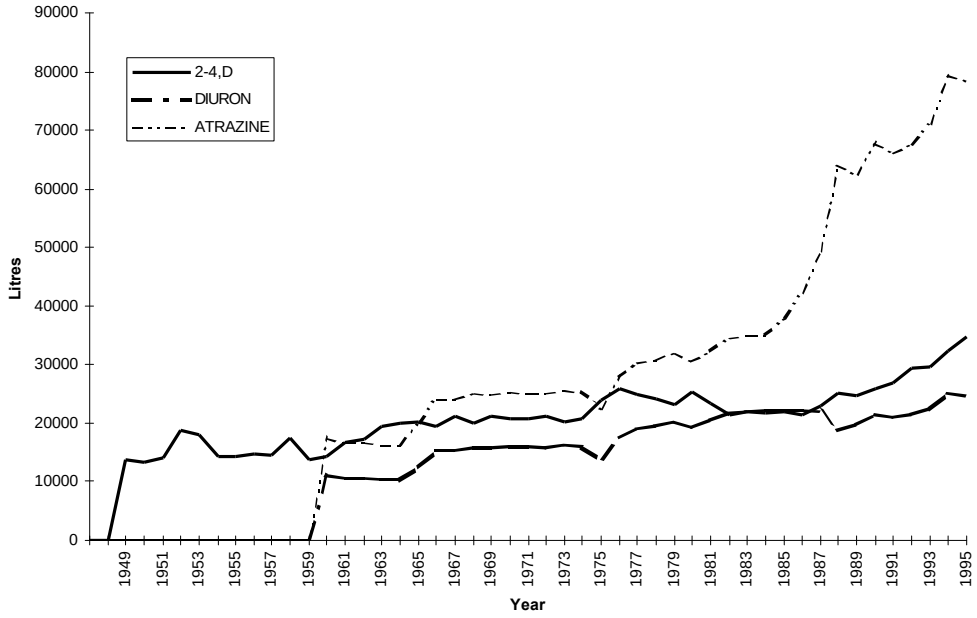

Fig. 7. Historical usage patterns (active ingredient) for selected Phenoxy, Triazine and Urea group herbicides in the Herbert River catchment.

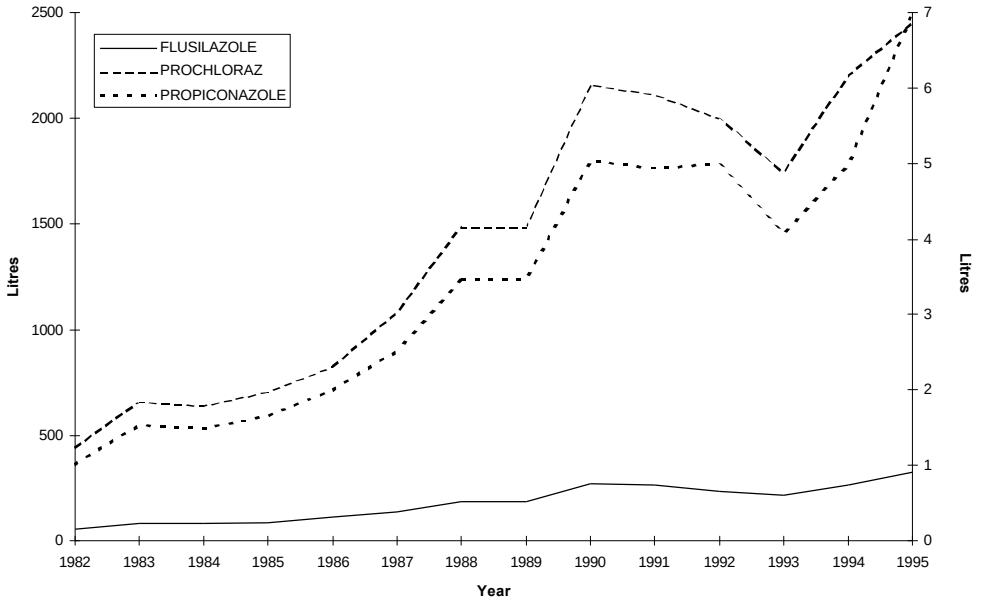

Fig. 8. Historical usage patterns (active ingredient) for Azole group fungicides in the Herbert River catchment. Propiconazole volume is indicated on the right side axis.

Fig 9. Historical usage patterns (active ingredient) for mercurial fungicide (MEMC) in the Herbert River catchment.

Conclusions

These data provide a valuable insight into the historical use of pesticides in the Herbert River catchment and hence potential sources of contaminants to the GBRMP. Total agrochemical use in the catchment has increased with time, however it is important that these increases are placed in the context of changes in land use. Given that the sugar industry is the dominant user of chemical products in the catchment, usage data are strongly correlated with changes in both the area of sugarcane and sugarcane management practices. Even though sugarcane farm management practices vary along the Queensland coast, the trends obtained from this study are representative of cane growing catchments adjacent the GBRMP. These trends raise a number of significant challenges for agricultural industries in terms of their ability to comply with the principles of ecological sustainability.

While this case study has focused on quantifying the spatial and temporal distribution of agricultural land use and management practices, it is important to understand the extent to which increasing agrochemical usage can be identified in ecological and biogeochemical signals in the adjacent Herbert river estuary and nearshore GBRMP embayments. This history is contained in the annual growth bands of fringing reef corals, and in fine mud trapped in mangrove associated mudbanks (Hopley, 1982; Belperio, 1983; Wolanski *et al.*, 1990; Carter *et al.*, 1993) and can be dated with radiochemical tools.

The biogeochemical and ecological consequences of land use changes to the GBRMP cannot easily be determined by present day monitoring of rivers or ecological studies on biota. Past episodes of natural and anthropogenic inputs to the GBR lagoon are uncontrolled experiments still in progress, and some understanding of what has happened to date can facilitate the development of predictive models for the future. From a natural resource management perspective, models that relate the known history of catchment land-use change to observed changes in coral and sediment cores in the GBR are required if future contaminant inputs and dispersal patterns are to be estimated and a management response developed.

Acknowledgments

ACKNOWLEDGEMENTS

The authors wish to acknowledge the financial support of the Land and Water Resources Research and Development Corporation over a five year period, which made this research possible.

The authors wish to express their extreme gratitude to all those people with have an interest or who are actively involved in the implementation of Integrated Catchment Management in Queensland and who gave time from their busy schedules to complete interviews or questionnaire survey forms that were fundamental to the success of many project activities. Of special note are the following people and agencies who willingly co-operated and provided valuable assistance to this five-year research project:

- The members of the Herbert River Catchment Coordinating Committee who actively participated and contributed their valuable time, views and knowledge.
- Dave Horsley, CSR Herbert River Mills, who was an invaluable source of information on natural resource management and related activities in the Herbert River catchment, provided substantial advice to the researchers and contributed actively to many of the research activities of this project.
- The Herbert River Catchment Coordinators, Rob Hunt and subsequently Andrew Petroeschevsky, who provided valuable comment and information as well as facilitating interactions with HRCCC members.
- Ray Quabba, Chair of the HRCCC, who gave his time, knowledge, invaluable assistance and encouragement to the researchers over the life of the project.
- Philip Rowland, Mike Merrin and Don Begbie, Department of Natural Resources, Queensland who have actively supported the project since its commencement and provided valuable assistance and access to information to the researchers involved.
- Luis Laredo, CSIRO Tropical Agriculture, Brisbane, who has provided valuable general computing assistance to the researchers involved and contributed actively to database development and management for some key research activities.
- Kathy Mitchell and Leesa Austin, CSIRO Tropical Agriculture Brisbane, for invaluable assistance in the preparation of this publication.

INTRODUCTION

There is growing recognition of a class of resource use issues whose identification and management have not been effectively addressed by conventional science-based disciplinary approaches to their solution (e.g. Lange 1990a; Mitchell 1990; Resource Assessment Commission 1993; Syme *et al.* 1994). These resource use issues characteristically arise in those situations (Lang 1990a):

> *where problems are highly complex, interests and objectives are numerous and in conflict, information and knowledge are quite incomplete, ends and means are ambiguous, control is fragmented and the external environment is in flux.*

The complexity and long-term nature of many of these emerging issues requires new and integrated approaches to their management if they are to be dealt with effectively. Included in this class of issues are many which fall within the scope of integrated resource management. Integrated resource management is an approach to planning and management that attempts to place resource use problems and opportunities in a systemic or holistic framework with an aim to finding integrative solutions by addressing resource use problems and their management in the broader context of their associated land, water, social, economic and institutional attributes (Lang 1990b; Resource Assessment Commission 1993).

Conventional science-based disciplinary approaches to Research and Development (R&D) as a means to support integrated resource management and related planning activities may lead to ad hoc decision making and piecemeal action, aimed more at treating symptoms while systemic effects and emergent properties may be overlooked, long-term changes masked, and/or cumulative effects ignored (Lang 1990a; TASQUE 1992; Brown and McDonald 1993). Adoption of integrated approaches, however, requires shifts in attitudes, a longer time frame and acceptance of new approaches to resource management issues.

Catchment care programs, such as Integrated Catchment Management (ICM) on which this chapter is focussed, are a special case of integrated resource management. Such programs are being implemented in several Australian states (e.g. Queensland Department of Primary Industries 1993; Syme *et al.* 1994). The philosophy underlining these programs is an acknowledgment that there are no simple solutions, nor a single disciplinary perspective that can provide and appropriate course of action to deal with complex resource use issues within a catchment context. What contribution can science-based R&D make to ICM principles and practice? Most importantly, how should we evaluate the contribution of an R&D intervention for ICM? These questions are explored in this chapter.

The evolution and scope of integrated resource management and ICM in Australia is first explored in further depth. We then consider some key characteristics of resource use problems falling within the ICM domain, and contrast these with the problems and approaches that have been typically addressed by science-based R&D. The need for an evaluation of the effectiveness of science-based interventions in catchment care programs is addressed and potential approaches to evaluation are explored.

Integrated resource management in Australia

Characteristics of integrated resource management

Integrated approaches to resource management and land use emerged in the 1980s in Australia against a background of increasing pressure on natural resources, growing public awareness of natural resource issues, and increasing community expectations for influences in land use

decision making. At the broadest level, integrated resource management procedures involve the integration of both environmental and economic consideration at management, planning and policy levels, which is argued to be an effective means of implementing the principle of sustainable development (e.g. Lang 1990b; Resource Assessment Commission 1993).

An important characteristic of integrated resource management is that it commonly focusses on multiple objectives. For example, Mitchell and Hollick (1993) and the Resources Assessment Commission (1993) have defined five generic objectives of integrated resource management, as follows:

1. *Systems components*: to manage resources with regard to the interactions among the component parts of natural and human systems and the linkages between those systems.
2. *Balanced components*: to ensure that economic development, protection of the environment and social values are considered in all major decisions concerning resource use.
3. *Strategic components*: to emphasise key (rather than all) issues, to be adaptive to changing conditions and to set indicators against which performance is evaluated.
4. *Partnership component*: to involve individuals, non-government organisations and all levels of government in decision making, as well as in increasing awareness and understanding of resource use issues, identifying management objectives, determining the responsibilities and powers of all parties, developing mechanisms for effective communication and cooperation, and establishing conflict resolution mechanisms.
5. *Jurisdictional components*: to ensure that measures applied under several jurisdictions that cover a single system are streamlined through exchange or sharing powers or coordinated by consultation.

Lang (1990b) proposes that integrated resource management and planning needs to be strategic, interactive and adopt multiple perspectives, that is, to advance beyond technical rationality to encompass perspectives that are personal, organisational and political. Such strategic approaches have been recommended in several resource management contexts including the management of coastal resources (Resource Assessment Commission 1993), local government environmental management (TASQUE 1992; Brown and McDonald 1993), land use planning (Douglas 1990), and importantly in the context of this chapter, catchment management (e.g. Hollick and Mitchell 1991). Davis and Weller (1993) define a 'strategic approach' as one that establishes broad objectives, and identifies a process by which they may be achieved, that is, one that integrates goals, policies and strategy into a cohesive whole. In the more traditional approaches to program management, policy formulation precedes implementation. In the strategic model, Davis and Weller (1993) point out that 'an implementation process which eventually generates its own goals may be as legitimate, and as strategic, as one which follows the traditional management model of plan, implementation and control'.

The potential contribution of integrated resource management to positively influence resource use practices is seen to arise through opportunities associated with its various attributes. For example, Mitchell (1990) proposes that integrated resource management be viewed as a vehicle to positively enhance economic and social change. Syme *et al.* (1994) suggest that an integrated approach to catchment management will provide a more diverse range of means to manage resource use issues, as well as broader motivation for land managers and other stakeholders to deal with them, particularly through changes in both attitudes and behaviour.

Catchment care programs in Australia

Catchment care programs, including ICM and its close relation, Total Catchment Management (TCM), have been adopted as policy by some Australian states for catchments where there are conflicting and competing resource use problems and/or multiple institutional responsibilities.

These programs aim to achieve balanced and sustained use of land, water, vegetation and other biological resources through the coordinated and cooperative actions of individuals, community groups, industry and various levels of government. The argued need for ICM is due to environmental, economic, social and institutional factors (e.g. Laut and Taplin 1989; Syme *et al.* 1994), including:

- continuing degradation of land, water and related resources;
- conflicting government policies;
- different agencies with statutory responsibilities leading to non-complementary programs; and
- increasing public expectations for involvement in decision making.

There are no simple short-term solutions to these issues. The clear implication is that there is a need for programs that provide the attributes identified as being common to ICM strategies in Australia by the Resource Assessment Commission (1993), namely:

- management of interrelated resources with regard to ecological processes and the maintenance of environmental quality;
- involving community participation in natural resource management; and
- coordinating government, non-government and community natural resource management policies and activities.

Benefits that are generally attributed to the application of ICM processes include the development of catchment management strategies, and the planning and implementation of resource use practices on a catchment-wide basis that can lead to sustainable use, management and conservation of natural resources (e.g. Mitchell and Hollick 1993; Queensland Department of Primary Industries 1993; Syme *et al.* 1994). The implementation of such programs in Australia, however, is in its infancy, and is largely experimental. As practices, they have been primarily used as vehicles for community awareness programs (Syme *et al.* 1994). The actual approaches that have been adopted vary between states (e.g. Laut 1992; Mitchell and Hollick 1993; Queensland Department of Primary Industries 1993; Syme *et al.* 1994) but are essentially focussed on the application of science-based knowledge to resolve concerns over land and water management on a catchment basis through both community action and statutory change. The evaluation of the effectiveness of the ICM process itself in resolving land and water management problems in Australia, however, is one of the most neglected areas of resource use management.

Can science-based research and development contribute to catchment care programs?

The nature of information needs of integrated resource management is characterised by its context of complex problem settings, multiple stakeholders, divergent interests and scales of relevance and relative urgency. This seems to contrast with the characteristics of information derived from traditional R&D endeavours focussed on single, specialised disciplines, namely repetitive trialling, limited scale and medium to longer-term focus for information delivery. Moreover, traditional R&D approaches are highly analytical rather than systemic (Patton 1987). This may restrict their capacity to usefully contribute to decision making within an ICM context. The trend to more participative models of R&D management (e.g. see Chapter 7) with an increasing focus on system multi-disciplinary teams addressing complex resource management problems is a significant move away from this position (MacLeod and Van Beek 1993). The flexibility of this new approach to R&D would seem to be more closely aligned to the nature of the problems being addressed by ICM.

Given this background, three are four important issues relevant to the potential contribution of science-based R&D to ICM, as follows:

- a common mismatch between research and decision-making needs in policy-related areas, including the gap between R&D that is immediately feasible and the information needed for urgent decisions (Kaimowitz *et al.* 1990; Chelimsky 1991);
- uncertainty is integral to the biophysical, socio-economic and institutional aspects of resource management and planning (Funtowicz and Ravetz 1990; Costanza *et al.* 1992);
- ICM may require resource managers (e.g. individual landholders, industries, conservationists) to adopt practices or production systems which provide no direct or immediate economic or social benefit to themselves or the local community (Hollick 1992); and
- much science-based R&D ignores the context (i.e. political, technical, organisational, economic, social) within which its outputs will be evaluated and potentially applied and, therefore, this affects the use and relevance of the R&D (e.g. Kaimowitz *et al.* 1990; Mitroff 1993; Ormala 1994).

We ask the question of how science-based R&D might enhance the effectiveness and efficiency of ICM. The four issues are discussed in the following subsections.

Limited synchrony between R&D information and decision-making needs

The complexity of ICM issues and the immediacy of decision-making information needs will commonly lead to policy makers having to handle and synthesise information of vastly different qualities and types. Such information usually represents a mixture of qualitative (or "heuristic") and quantitative data, the later fitting more closely within the comfort zone of traditional R&D practitioners (Patton 1987). For example, hydrological data have traditionally been provided by R&D projects in a quantitative form for specific situations. However, as the scale being addressed and the type of information required to resolve land use problems becomes more complex, the ability of R&D to produce models capable of generating reliable quantitative estimates is reduced. Grayson *et al.* (1993) argue that under these circumstances, reliance on quantitative estimates should be replaced by qualitative descriptions of the pattern of hydrological response and that this information should be combined with simple reasoning to assist decision making. This relatively pragmatic approach is consistent with both the availability and quality of so-called "hard" data and the ability of R&D practitioners to represent complex natural and human systems.

Uncertainty

An important characteristic of the decision-making environment associated with ICM applications is the high level of uncertainty associated with the parameters underlying the biophysical, socioeconomic and institutional components of the managed system and their linkages. That is, there are both large degrees of uncertainty and many sources of uncertainty associated with the ecological system as well as with human behaviour. This compounds the complexity inherent in catchment resource management issues.

In many instances, problems facing decision makers may be sufficiently advanced or developed to be rendered irreversible, at least in an economic sense. Under these circumstances, Funtowicz and Ravetz (1990) suggest that the practical considerations become restricted to those of coping, presumably within the constraint of vastly changed and inferior environmental conditions. Alternatively, while a resource quality issue is not definitely known or recognised to be irreversible, it may still be considered to be too complex to resolve in a sufficiently short time, or the uncertainty surrounding its status may swamp the relevant facts that are known (Funtowicz and Ravetz (1990).

Uncertainty needs to be managed and effectively communicated so that it becomes a recognised input to decision making (Funtowicz and Ravetz 1990; Costanza *et al.* 1992). The performance of

the science-based R&D community in this area has been relatively poor (Keeney and Van Winterfeldt 1986; Hance *et al.* 1989).

Three categories are uncertainty have been distinguished by Lang (1990b) with respect to integrated resource management.

1. Uncertainty concerning 'the problem' and its context. This creates a demand for more R&D, better data, improved predictions and tools such as risk assessment.
2. Uncertainly concerning what to do about the problem, with respect to both 'ends and means'. This raises a call for better policy guidance and innovative solutions.
3. Uncertainty concerning what 'others' in related field of choice may do. This requires collaboration and coordination.

The perception of risk may be different for the R&D specialist, land managers and other stakeholders. This is, for example, consistent with the findings of MacLeod and Taylor (1992) who highlighted major differences between perceptions of land degradation problems held by a rang eof groups with an interest in sustainable management of grazing lands in Queensland. Similarly, there was a wide divergence, both between and within the groups studied, in perceptions of the solvability of sustainable resource use problems and the potential role of formal R&D in finding such solutions.

However, with the possible exception of the third type of uncertainty, there would seem to be considerable scope for science-based R&D to assist decision makers by removing some of the underlying sources of uncertainty. While it is unlikely that R&D will ever deliver a definitive solution to a given complex land resource management problem, by removing some of the uncertainty associated with resolving such problems, it should be able to make a contribution in terms of moving to a more certain position.

Non-immediacy of payoffs to ICM

Conflicts and problems arising from both single and multiple uses of natural resources within catchment areas may be non-source point in nature (e.g. Chisholm 1987a). That is, the so-called 'sources' and 'sinks' of some resource problems, including land and water degradation and the loss of other attributes of environmental amenity, may be both spatially and temporarily separated. The creators and recipients of such pollution rarely meet on a voluntary basis to seek socially beneficial solutions. Moreover, there may be little reward for individuals and groups taking independent action, in the sense that private costs and social benefits of the action may be non-coincident (Hollick 1992). These classic externalities of the economic literature commonly defy solution through market-based instruments (e.g. fiscal policies including taxes and subsidies) and require social or institutional resolution (Chisholm 1987b). Science-based R&D can offer decision makers insight into the nature of the trade-offs, particularly the technical elements of the decision problem of interest.

Contextual relevance

It has been claimed that much science-based R&D effort, including that at the 'applied' level, is conducted in apparent ignorance of the context within which potential stakeholders and policy decision-makers will have to judge its ultimate relevance 9e.g. Kaimowitz *et al.* 1990; Mitroff 1993). That is, problem definitions are commonly set in context-neutral terms or, at best, set in terms relevant to the context of only a subset of the 'identified' stakeholders. Unhappily, our personal observation would confirm this.

However, more recent work in the field of agricultural extension and knowledge systems and technology transfer has highlighted the importance of stakeholders' real and perceived circumstances, as well as the decision context, to the successful meshing of R&D ouputs and the demands for them (e.g. Van Beek 1991; Ison 1993). For example, Ison (1993) has proposed that behaviour is determined not only be attitudes, but also by its context. Different individuals will 'see' the same situation as different systems and will, therefore, perceive change and what constitutes an 'improvement' somewhat differently. Van Beek (1991) argues that stakeholders are participants in arrays of communication networks or knowledge information systems through which they exchange information and obtain knowledge relevant to their decision-making context and needs. Formal R&D bodies are only one player in the relevant knowledge information systems and their importance for a given decision problem will depend on context, which is transient.

Integrated catchment management: an environmental, social or institutional problem?
The effect of rural land use on catchment environments is frequently viewed as an environmental management problem for which technical solutions can be found through science-based R&D and farmers/resource managers adopting the appropriate technologies. While this 'technical rationality' approach has allowed specialist R&D professionals to focus on well-defined problems, it has also led to many resource management issues being examined from the narrow perspective of an individual discipline and the associated institutional clientele (Resource Assessment Commission 1993). Mitchell (1990) argues that, in so doing, it has often overlooked other societal values and interests. Lange (1990b) observed that 'conventional' resource management has several undesirable outcomes including: piecemeal action aimed at treating symptoms while systemic effects and real needs may be overlooked; being oriented to the status quo rather than being innovative; promising only limited results without realising the full potential of resource use; and omitting interests without power.

The foregoing is consistent with the findings of Thompson and Warburton (1985) who, in examining the management of environmental problems in the Himalayas, found that although the key management problem was uncertainty, it extended beyond 'technical uncertainty'. Rather, a major factor was 'structural uncertainty" relating particularly to institutional factors. They concluded that 'when the problem is to know what the problem is, we need more than one perspective'. This applies to both science-based disciplines, as well as different groupings of stakeholders.

Syme (1992) views ICM as a problem of institutional change in coping with a redefinition by the community of the problems of environmental management and the government's ability to cope with these 'new' problems. He concluded that ICM should be viewed primarily as a social rather than an environmental problem (Syme *et al.* 1994):

> *The social dynamics operating within rural communities may act to facilitate or impede efforts to sustainable approaches to resource management. As a logical extension of physical planning research, research of community nature can enrich the information and knowledge about communities, including constraints to change and factors that may facilitate change.*

There is wide recognition that sociocultural, economic and institutional factors will affect the acceptance and adoption of resource management practices (e.g. Young 1992). Some examples include the following:

- Attitudes influence farmer's decisions about whether to adopt certain farming techniques to prevent water pollution (e.g. Napier *et al.* 1986). For example, if farmers did not value the physical environment highly, they were less likely to adopt conservation technologies.

- The perception of land condition and the nature of change in land/ecosystems can be different for scientists and land managers and will affect the emphasis and values that they place on certain concerns (Ison 1993).
- The perception of risk is also significant in the adoption of 'sustainable' management practices. For example, Napier and Brown (1993) concluded that the perceived threat to family health was a significant motivation to take action to prevent contamination of groundwater resources.
- Napier and brown (1993) have found that farmers will not change production practices to protect groundwater from contamination, if the adoption of new farming systems threatens the economic well-being of the farm enterprise.
- Economic constraints, including commitments to previous investments in fixed assets and the level of farm debt, are common barriers to adoption (Hooks *et al.* 1983; Napier and Brown 1993).
- Multiple or overlapping jurisdictions of institutions, and related difficulties in collecting and disseminating information have been found significant in risk communication (Hadden 1989).

The foregoing points highlight that while science-based R&D might offer a key role and a potential contribution to complex catchment management issues, it will do so as only one of the source of information. Clearly, there is a range of important perspectives and interests that need to be recognised in any endeavour to promote enhancement in both individual and social welfare through more holistic approaches to catchment care. Nevertheless, we believe that science-based R&D will continue to be recognised as a significant contributor to ICM, and that ICM decision makers will continue to look to R&D for solutions to specific aspects of resource-use problems.

Evaluation in science-based research and development for integrated catchment management

Although there has been a considerable amount of R&D focussed on many biophysical processes and other technical issues that are relevant to ICM, there has been little research on the social, economic and institutional aspects of its implementation. There has also been little objective evaluation of the effectiveness of science-based R&D to the ICM process in resolving land and water management problems in Australia.

Evaluation is 'the act or result of judging the worth or value of something' (Prinsley 1994). The specific practice of evaluation research has been defined by Patton (1986) as:

> *the systematic collection of information about the activities, characteristics, and outcomes of programs for use by specific people to reduce uncertainties, improve effectiveness, and make decisions with regard to what those programs are doing and affecting.*

Given the uncertainty associated with the complex natural and social systems that catchment care programs operate within, barriers to adoption of 'sustainable' technologies, and the gaps between research and decision making, evaluation of R&D designed to support ICM programs is essential.

However, to be worthwhile, evaluation is not an activity that can be tacked onto the current research management process, but must be developed in conjunction with this process so that it becomes an integral part of it (Prinsley 1994). Evaluation, therefore, should be an ongoing and integral part of both the process of ICM implementation and of any specific R&D intervention in that process.

Evaluating research and development intervention in ICM

In a review of R&D evaluation, Prinsley (1994) defined the purpose of evaluation as 'providing a basis for informed decision-making in the initiation, selection, direction and termination of R&D'. How might policy makers and other ICM stakeholders assess the value of a particular R&D program as a contributor to ICM?

Georghiou (1989) argues that evaluation of R&D is a social process, and that the organisation of that process is critical to the outcome of evaluations. Catchment care programs, like ICM, are long-term and evolving processes in which the needs of the program and the perception of those needs by stakeholders within the community, industry, government and R&D agencies will also change over time. Therefore, in any R&D program it is essential for catchment care that those evolving perceptions and changing needs are assessed and monitored as an ongoing process over the duration of the program to ensure relevance of the R&D. The R&D evaluation process, therefore, also needs to be an iterative process.

Research on program evaluation (e.g. Crane 1988; Pancer and Westhues 1989) has found that the critical factors affecting program implementation will vary depending upon the particular stage of development of the implementation process. Therefore, the criteria or methods for evaluating an R&D intervention in an ICM program or process need to be flexible and vary according to the stage of implementation, as well as the nature of the particular resource problems and issues being addressed. Moreover, attempts to solve one problem may actually sow the seeds of other problems because of adverse and unforeseen consequences of actions (Ingram 1990). When dealing with complex and/or conflicting resource use issues, the most appropriate evaluation criteria may not be whether specific problem-related objectives are achieved, but rather, whether the resulting problems are more 'tractable' or manageable than the initial ones.

The role and success of an R&D intervention in an ICM process are likely to be affected by different factors in different regions. For example, the key factors in rangelands will always vary significantly from those relevant to intensive tropical cropping. The factors may be environmental, economic, social or institutional, with different weightings appropriate to the specific circumstances. Any evaluation, therefore, should focus on the opportunities, as well as the constraints of the environmental, socioeconomic and institutional context that influences the potential of that region to change and adapt to the demands of catchment management needs. In some areas, for example, there may be no financially viable solutions to existing problems. Therefore, even when new technologies or practices have been extensively researched, and even adopted, their effect needs to be monitored and evaluated within the context of their application.

The importance of involving decision makers and other information users (i.e. stakeholders) who represent a wide range or diversity of perspectives in the evaluation process is widely recognised (e.g. Patton 1986; Greene 1988; Mitchell and Hollick 1993; Prinsley 1994; Chapter 7). The major benefits claimed for stakeholder participation and utilisation are enhanced understanding of the program and evaluation findings, including how the program works, a broader view of the key issues, and acceptance or ownership of the program and its results.

A participatory evaluation approach to R&D in ICM, in which the evaluation process is an integral part of the R&D methodology, will provide opportunities for enhancing the effectiveness and efficiency of the R&D. That is, the evaluation needs to be an iterative and ongoing part of the science-based R&D methodology. Consequently, the evaluation will influence the effect of the R&D in an ongoing way. The program's goals and baselines for observing change (e.g. in attitudes and behaviour, or the effect on the environment) will evolve and, therefore, need to be

reassessed frequently. Participatory approaches are discussed in detail elsewhere (e.g. see Chapter 7; Chapter 8).

Approaches to evaluation of research and development for catchment care

Evaluation research emerged in the late 1970s within the public administration and social policy fields, with the emphasis on program evaluation. Several approaches and frameworks for evaluation that are relevant to science-based R&D programs for catchment care are briefly described below.

Some of the most comprehensive research on program evaluation has been undertaken in the context of policy science. Mazmanian and Sabatier (1983) have comprehensively evaluated factors affecting policy implementation. In seeking to explain variation in implementation success across programs and organisations, they emphasised stakeholder attitudes and behaviour, role of agencies, technical tractability, statutory structures and behaviour change within a resource-planning framework. This evaluation approach has most commonly been applied in the final stages of a program to assess the outcomes or the product of the program, that is, the extent to which the original objectives were achieved. Sabatier (1986) proposes that this approach appears to be most useful in situations in which there is either a dominant piece of legislation, or where research funds are limited. However, a major difficulty arises if the evaluation results indicate that the policy objectives have not been met (Pancer and Westhues 1989) or were inappropriate to the current situation or context. Such 'top down' approaches have also been shown to be difficult to use in situations where there are a multitude of government policies and actors (Sabatier 1986).

Crane (1988) has proposed a set of five assessment criteria for evaluation of social policies which can be adapted for the context of science-based R&D in ICM, as follows:

1. *Inclusiveness*: the extent to which the policy as implemented takes into account all of the populations at risk.
2. *Adequacy*: the degree to which the policy accomplishes its qualitative goals, for example, reduction in poverty.
3. *Equitableness*: the extent to which the distribution of benefits and risks associated with the policy impact on the different groups of people affected by it.
4. *Effectiveness/efficiency*: the cost effectiveness of the policy, relative to other possible policies, in achieving the goals established for policy.
5. *Democratic involvement*: the degree to which persons directly served, or residents of areas in which the policy is in effect, or the general public, are empowered to contribute to the planning, implementation, improvement or termination of the policy.

Taking the problem of risk assessment, Crane (1988) illustrates how these criteria can be turned into broad evaluation principles to guide the development of a research program.

Evaluation research in social policy has recently placed more emphasis on evaluating the process of program implementation and development rather than the product or program outcome *per se*. For example, Dehar *et al.* (1993) have demonstrated the importance of the application of both formative and process evaluation in leading to: (a) better designed and more effective health promotion and disease prevention programs; and (b) improved understanding of the factors influencing program outcomes. Process evaluation documents and analyses the way the program operates to assist in interpreting program outcomes and to enhance future program planning. Its primary purpose is perceived to be understanding how a program achieves what it does. Formative evaluation, on the other hand, involves the ongoing collection and feedback of

information relevant to program planning and operation for use by decision makers in developing and improving a program as it is designed and implemented. It therefore necessitates collaborative working relationships between the evaluator and those planning and implementing the program. Dehar *et al.* (1993) identify the primary purpose of formative evaluation as generating information that can be sued by program decision makers to refine and improve the program on an ongoing basis from an early stage.

Given the more recent shift in focus of research and innovation from an emphasis on scientific progress to its effect on economic and social development, impact assessment has also been identified as an essential element of R&D evaluation. Ormala (1994) ahs argued that R&D effect cannot be measured directly, but should be explored in terms of a combined set of quantitative and qualitative impact dimensions. Xu (1994) emphasises the need to incorporate within program planning an assessment of how the distribution of impacts of a program affect the sustainability of development or resource use, as well as social welfare. Ormala (1994) points out because effects are highly dependent on the specific social and economic context, they may take considerable time to become visible, and the complexity of attribution of the impact to a program or R&D intervention increases with time.

Pancer and Westhues (1989) have proposed a 'developmental stage approach' to program planning and evaluation which emphasises a need to match the evaluation research techniques, if appropriately matched to the specific stage of development, can lead to more informed decision-making at each stage, and resolve the questions that need to be answered before proceeding to subsequent stages. Although they recognised that the course of program development may not be a linear one, Pancer and Westhues (1989) identified eight general stages of program development, as follows:

- the determination of societal values;
- assessment of social needs or problems;
- determination of goals;
- design of program alternatives;
- selection of an alternative;
- program implementation;
- program operation; and
- program outcome.

They perceived each of these stages as being characterised by a central question that defines its evaluation research function, and by which research techniques might appropriately be used. These evaluation research functions include: (a) assessment of needs; (b) evaluation of process; (c) evaluation of outcomes; (d) analysis of program values, goals and logic; (e) assessment of program feasibility; and (f) assessment of program implementation. The actual research techniques may include surveys, interviews, social indicators, cost-benefit analyses and the use of other research instruments such as indexes, scales or social impact assessment. Prinsley (1994) emphasised the importance of maintaining links between each stage of the R&D evaluation, both between techniques and criteria, as well as the people who are carrying out the evaluation.

Evaluation of a science-based R&D intervention in an ICM process will invariably need to integrate several evaluation techniques. For example, Syme and Sadler (1994) and Syme *et al.* (1994) have identified some general guidelines for regional water use issues that involve an interactive partnership approach conducted in association with the community. It has three methodological components, as follows:

1. *Formative evaluation*: allowing the results of each component of the evaluation to influence the development of the ICM process.

2. *Participation*: those involved in the ICM process have an input into the design of the evaluation process.
3. *Developmental*: utilising Pancer and Westhues (1989) logical staged-approach to program development as the starting point for the evaluation.

Although there are many techniques for program evaluation, actual methodology for R&D evaluation is still in a developmental stage. There is no simple 'black box' solution that can be tacked onto the current research management procedures. Most significantly, Prinsley (1994) proposes that 'it is the process of evaluation and focussed interactions and systematic thinking of users of the evaluation techniques that is its major benefit and not the number that comes out at the end'. In other words, the process of developing and using R&D is as important, if not more so, than the R&D product itself.

Problems in evaluation

Despite the advances that are being made in developing and testing program evaluation methods, several problems areas remain. Some key issues relevant to science-based R&D in ICM are discussed briefly below.

Perhaps, at the philosophical level, the major problem facing any ICM-related evaluation will remain the lack of clarity in articulating what the program is intended to achieve, and from whose perspective. Without this clarity, evaluation of the success of an R&D intervention is clearly problematic. Some progress might be made by considering the basic question set that Patton (1987) saw as fundamental to directing any program evaluation involving qualitative research methods. The question set, which can be generalised to the broader question of evaluation *per se*, is as follows:

1. *Who* is the information for and *who* will use the findings of the evaluation?
2. *What* kinds of information are needed?
3. *How* is the information to be used? For what purposes is the evaluation being done?
4. *When* is the information needed?
5. *What* resources are available to conduct the evaluation?

In the context of ICM, as described in previous sections, answers to these questions are not entirely clear-cut. Patton (1987) argues that the major challenge for evaluation is 'getting the best possible information to the people who need it – and then getting those people to actually use it for decision making'. In doing so, he argues that any evaluation design or procedure will necessarily be 'an interplay of resources, practicalities, methodological choices, creativity and personal judgements by the people involved'.

At a more specific level, it may be difficult to establish the precise nature of the relationship between an R&D intervention or an ICM process and actual changes in management practices, or in the broader ecological or socioeconomic environment, because of the dynamic nature, number and complexity of contributing factors (e.g. Ormala 1994). This problem remains a major one for social science-based research, especially that related to the so-called 'soft-systems' approaches to situation improvement in human systems (e.g. MacLeod *et al.* 1996).

The problem of how to determine appropriate indicators of change, and what to measure about them, is an equally difficult issue for both the 'hard' biophysical sciences and the 'soft' socioeconomic sciences. In all likelihood, some indicators and measurement techniques will be drawn from the hard sciences, but others from within the context of the wider community and

stakeholder groups. Consensus on the appropriate indicators and techniques will need to be negotiated between the 'who's' of Patton's question set referred to previously.

More generally, Mitchell and Hollick (1993) have observed that catchment care programs, like ICM, require a long-term perspective and one that reflects the concerns of the broader community. They also require an appreciation that many people and agencies need to move out of their 'current comfort zones'. As a consequence, Mitchell and Hollick (1993) warn that undoubtedly any ICM implementation may well encounter 'turbulence and debate'. This will invariably also be the case for any science-based R&D intervention in ICM.

Conclusion

Within the context of catchment care, science-based R&D is a part-player in a complex process. It is not useful to think of the socioeconomic dimension as a constraint to proper catchment care. The integration of the science-based and social perspectives offers opportunities for strategic management which cannot be generated by any one set of actors alone. Traditional discipline-based science has a good deal to offer catchment care programs, particularly in the context of fillings gaps where 'hard' knowledge is required. Moreover, it can make an important contribution to reducing the uncertainty that is common to the complex resource use problems generally associated with catchment management. However, the overall contribution of science-based R&D to the success of catchment care programs will be enhanced through evaluation being an integral part of the R&D process.

Increasingly the practice of science-based R&D is changing to encompass more participatory and flexible approaches, which are essential characteristics of catchment care programs. The key issue is for science-based R&D to take an objective view of what its real contribution can be to such programs, and the rate at which the R&D can be delivered. This will require a willingness on the part of policy makers to understand some of the reality of the R&D environment, and at the same time, for R&D practitioners to understand the decision-making environment of ICM stakeholders, in order to bridge the gap between the two.

1. INTRODUCTION

Most Australian states are promoting and supporting natural resource management programs as a means of implementing sustainable resource use objectives or policy. These programs are grounded on the assumptions that natural resource management and planning should be a coordinated government process conducted in partnership with the community and should take a strategic perspective at a regional or catchment scale. Operationalising these assumptions has proven challenging to both the government agencies and the communities concerned. These difficulties can be attributed in part to inadequate attempts to evaluate the efficacy of such approaches to integrated resource management. In particular, evaluation has generally been:

- fragmented in terms of reconciling the different perspectives in evaluation,
- insensitive to the socio-political context of program performance,
- hampered by an inherent lack of assessable goals and outcome measures, and
- conducted as a cross-sectoral snap-shot in time rather than a longitudinal study (Bellamy *et al.*In Press).

2. AN INTEGRATED EVALUATION FRAMEWORK FOR ICM

2.1 Evaluation Principles

Approaches to natural resource management and planning need to be evaluated as a system that links policy to on-ground action. In this context, the evaluation of Integrated Catchment Management (ICM) in the Herbert River catchment needs to be:

(a) conducted in terms of the fundamental assumptions and instrumental hypotheses that underpin natural resource management policy, planning and management action (assumptions or hypotheses may relate, for example, to: coordination, public involvement, partnership, integration, representativeness, ecosystem management, technical support, duty of care, cost sharing, or fairness and equity).

(b) grounded in the natural resource, institutional, economic, socio-cultural and technological contexts of program implementation in practice.

In principle, evaluation should not only allow for the assessment of *impact (*i.e. environmental, economic, social, institutional, and technological) but importantly it should also be implemented as a *process tool* that:

- supports purposeful and informative stakeholder participation;
- creates improved opportunities for the incorporation of on-going learning processes at individual, organisational and policy levels;
- facilitates negotiation and mediation processes; and
- supports the move towards the amelioration of, or improvement in, the tractability of regional resource use management and planning problems.

Fundamental to an evaluation that supports this approach are the underlying principles that an effective evaluation method needs to:

(i) provide a framework for the integration of the different perspectives on evaluation of regional resource use planning processes and support mechanisms (ie., social, economic, environmental, policy and technological perspectives);

(ii) recognise the underlying assumptions and hypotheses that underpin the ICM policy and its implementation as well as ICM activities, processes or products, or body of knowledge;

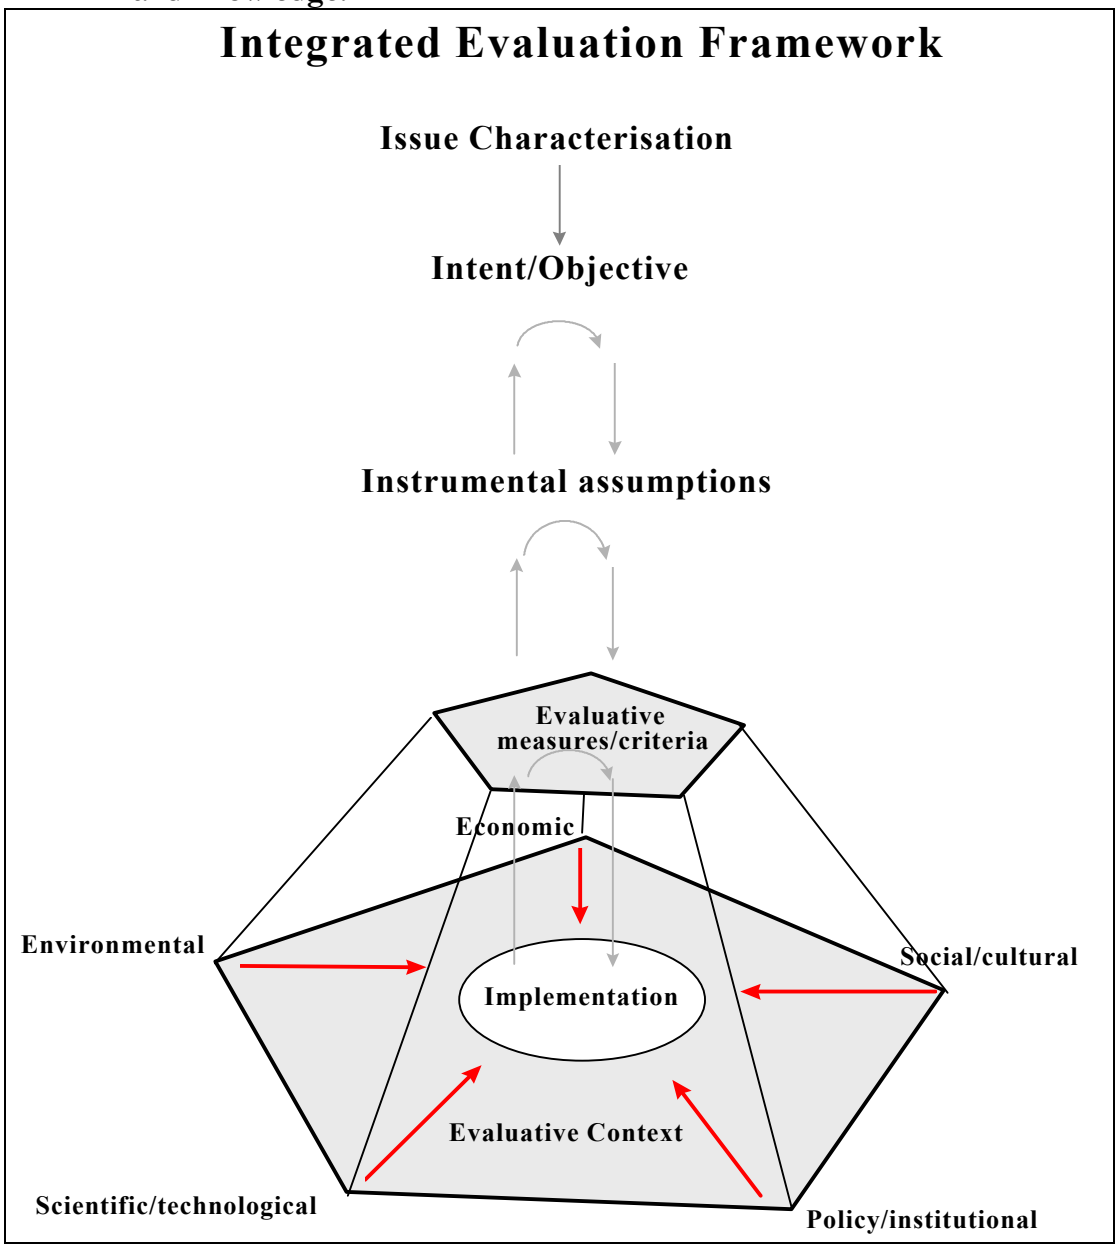
(iii) base performance assessment on the establishment of practical, valid and equitable evaluation criteria by which change can be monitored and assessed; and

(iv) ground the performance assessment within the natural resource, policy/institutional, economic, socio-cultural and technological contexts of regional resource use planning processes.

2.2 A Systems Approach to Evaluation

A multi-perspective systems framework that provides the basis for an integrated evaluation of the different perspectives (i.e. social, economic, environmental and institutional) on the natural resource management and planning process is developed to evaluate the Herbert ICM process (see Figure 1). This framework recognizes the multiple levels and nested nature of natural resource management policy, namely: problem characterization, policy formulation and intent, program logic, and on-ground implementation. It links the rationale of the IRM policy, process or tool to its implementation and impact on the ground. It also provides the basis for synthesising the multiple perspectives on the evaluation of the phenomenon or object of interest.

Figure 1. Integrated systems framework for the evaluation of IRM processes, products and knowledge.



The framework provides a systems approach to the evaluation of a IRM policy or program implementation, activity, process, tool or body of knowledge. The five key elements of this framework are defined in Table 1 and discussed below.

Table 2.1: Definition of elements of the IRM evaluation framework.

Element	Definition
Issue characterisation	The nature of the issue or problem underlying the object of evaluation (e.g. program or policy, activity, process, method/tool, body of knowledge), and the context in which the issue or problem evolved.
Intent	The objectives and intent of the object of evaluation, the expected outcomes and the key stakeholders and users of the outputs or process need to be clearly identified.
Instrumental assumptions	The underlying assumptions and instrumental hypotheses or rationality underpinning the implementation of the object of interest need to be made transparent.
Evaluative measures/criteria	Natural resource, economic, social, institutional and technical indicators which reflect on progress in achieving key objectives and outcomes, and which are interpreted within the context in which the object of evaluation is implemented and impacts.
Evaluative context	The contextual elements (e.g. environmental, economic, social, institutional, technological) that identify the constraints on performance and the factors that influence the implementation of the object of evaluation and its impact.

Issue/Problem Characterisation

The background to the object of interest being evaluated and the characterisation of the context in which it evolved.

Objective/Intent

The purpose(s) of the object of evaluation (e.g.policy, program, activity, process, method, tool, body of knowledge) need to be identified and clearly linked to the intended users and stakeholders of the research. These stakeholders will invariably be multiple including a range of government agencies, industry and community interests.

Theoretical Basis and Instrumental Assumptions

Theory describes the phenomenon of interest by identifying: (i) the boundary that defines the domain of interest, (ii) key constructs or "entities of interest" in that domain, (iii) the values or states these constructs or entities can take, and (iv) the relationship among the key constructs or entities (Eierman *et al.* 1995). Theory can be used in evaluation, for example, to propose and test links among key factors indicating the direction and degree of impact they have on IRM implementation and impact. An atheoretical research or evaluation approach may collect interesting facts but there is a danger that no unifying theme or predictable patterns or relationships emerge. Defining the construct space of a phenomenon provides the basis for establishing validity and ultimately sound measures that can be applied to a variety of contexts (Grover *et al.* 1996, p.187).

Each theory base brings with it different methodologies, assumptions and value systems. In evaluation, identifying the theory underpinning the implementation of the object of interest therefore will highlight the underlying assumptions and instrumental hypotheses, clarify what evaluation measures are needed, and contribute to an understanding of causal linkages (Bellamy *et al.* 1998). Significantly, it is necessary to make explicit and transparent the rationale of the

object of evaluation, that is the hidden or implicitly held assumptions, behaviours and motivations reflected in identified goals of that object and which influence decision-making and IRM implementation processes. Such underlying assumptions or instrumental hypotheses may relate to:

- program or policy logic;
- stakeholder involvement;
- collaboration;
- process;
- policy and institutional arrangements;
- technical information and support;
- communication;
- policy or process impacts; or
- project products and outcomes.

Purpose of an Evaluation

Clear identification of the purpose(s) of an evaluation (including its stakeholders and clients) is fundamental to planning an effective evaluation. The reasons for, and expected benefits from, undertaking an evaluation are invariably multiple. Although not necessarily mutually exclusive, five broad categories of purposes are identified in Table 2.3.

Bellamy *et al.* (1998) argue that research to evaluate approaches to integrated resource use management and planning are needed for a number of specific purposes, including:

(a) to evaluate public and private investment in alternative approaches;
(b) to develop an understanding of the most critical social, economic, institutional, environmental and technical factors that influence the implementation of a particular approach, as well as factor interrelationships;
(c) to develop appropriate performance criteria for assessing the potential impacts and influences of an approach not only on the management of natural resource systems, but also on institutional arrangements and society as a whole; and
(d) to establish guidelines and techniques for self-evaluation of progress towards the achievement of agreed objectives and planned outcomes, including consideration of equity and social justice issues.

Evaluative Measures and Criteria

The fundamental basis for evaluation is the establishment of practical evaluation criteria by which change in key evaluative measures can be monitored and assessed. They will also provide the basis for testing underlying assumptions and hypotheses relating to the policy, process, tool or activity of interest. Each evaluative measure may have one or more evaluation criteria. These criteria will be drawn from a range of disciplinary perspectives and therefore require synthesis.

The influence of the evaluative context on performance needs to be recognised and accounted for in analysing the findings. The evaluative context will be multi-dimensional having natural resource, economic, social, policy/institutional and technological elements. The relative importance of the influence of each of these elements will vary depending on the particular evaluation criteria. Importantly, each criterion will measure only a portion of the total construct space of the evaluative context.

Table 2.3. Purpose of an Evaluation.

Evaluation Purpose
Improving Program Management • Develop a common understanding of objectives and expected outcomes • Provide a basis for informed decision-making on research direction, resource allocation and attainable levels of performance. • Identify and focus attention on factors influencing program outputs and outcomes • Identify gaps in performance and insights on how they might be addressed • Facilitate a robust and integrated approach to program planning and implementation. Improving Transparency and Accountability • Evaluate costs and benefits of an investment of public or private resources • Improving efficiency and effectiveness of a project or process • Early identification of unanticipated outcomes Improving the Body of Knowledge • Identify impacts of a project, program or process • Identifying information pathways and processes and their role • Developing understanding of causal relationships • Identifying equity and social justice issues Fostering Learning • Influencing decision-making and policy development • Supporting on going information exchange, feedback and learning • Improving awareness of equity and social justice problems as they arise Improving Process • Facilitating continuous participation • Supporting the public consultation process • Building stakeholder capacity • Developing ownership of project outcomes • Providing information and a structural framework to underpin negotiations • Providing a platform for cultural change.

Evaluative measures should reflect the achievement of key objectives of the object of interest. In the context of natural resource management, evaluation measures may relate, for example, to:

- institutional structures or processes in the catchment;
- equity of resource use;
- stakeholder perspectives and behaviours on natural resource issues;
- state or tractability of natural resource management issues (social, economic, environmental, institutional; technological);
- stakeholder capacity to adapt and to undertake catchment management and planning;
- knowledge base on natural resource issues and their management;
- coordination or communication processes within and between stakeholder groups; and
- resource use and management policies, plans and practices of stakeholder groups.

Potentially there is scope for a whole suite of measures that will reflect the influences on and impacts of the IRM program, process, product or body of knowledge. For practical and efficiency reasons, each evaluation will need to focus on a selected number of critical evaluation criteria that are relatively readily measurable over time, yet rigorous and effective in reflecting change in a evaluative measure.

Evaluative Context

The implementation of approaches to integrated resource management are context-sensitive and a wide range of factors will make a difference to their implementation and impact. These influencing factors are:

(i) *environmental context*: e.g. the evolution of resource use and management systems in the region; the major resource use issues and their on-site and offsite implications and

impacts; attitudes and behaviour to natural resource management and environmental issues; nature and extent of behavioural change in resource use and management practices required across catchment stakeholders.

(ii) *economic context*: e.g. the nature and status of, and interdependencies within, the regional economy overall and on a sectoral basis; perceptions of future development and economic prospects; distribution of wealth and resources; economic vulnerability of the regional economy; financial viability of land managers.

(iii) *social/cultural context*: e.g. the regional demography and related sustainability issues; cultural diversity and related resource use issues; the nature and commonality in community expectations (both within and outside the region) regarding the catchment's environment and socioeconomic situation, as well as the catchment management and land use planning process; perceptions of equity and social justice; political and media support for catchment issues and ICM processes; social history and demographic change.

(iv) *policy/institutional context*: e.g. relevant policies and the organisational structures and processes for natural resource management across government, industry and community; resourcing and coordination characteristics of policies, plans and processes; stability and volatility of local and state political process.

(v) *scientific/technological context*:- e.g. the characteristics of the existing technology system; technical knowledge base and competencies to use advanced technologies across stakeholders; availability and feasibility of technical solutions; adequacy of scientific knowledge including appropriateness of scientific understanding and its ability to assist decision-making.

Mapping and characterising the environmental, social, economic, institutional and technological contexts that influence the implementation of the phenomenon, object or process of evaluative interest in achieving key objectives and outcomes is therefore necessary to account for the factors that influence implementation processes and their impact. The evaluative context will also impact on an evaluation and influence its analysis and interpretation.

3. AN APPLICATION TO R&D ON ICM IN THE HERBERT RIVER CATCHMENT

3.1. Problem Characterisation

Approaches to natural resource management based on the integration of community involvement, technical knowledge, and organisational structure and policy objectives are endorsed throughout Australia. The impetus for these integrated resource management (IRM) approaches has arisen from a number of factors including:

- Degradation of land, water and vegetation resources in many rural areas due to a combination of unrealistic expectations and inappropriate management over time (SEAC 1996; IC 1996);
- Federal government obligations as a signatory to a range of international treaties (e.g. Convention on Biological Diversity; United Nations Framework Convention on Climatic Change).
- Federal and state government commitment to a range of national agreements and strategies on the environment such as the National Strategy for Ecological Sustainable Development (Council of Australian Governments 1992b); National Greenhouse Response Strategy (Commonwealth of Australia 1992); National Strategy for the Conservation of Australia's Biological Diversity (DASET 1992); the National Weeds Strategy (ARMCANZ 1997) and the Intergovernmental Agreement on the Environment (Council of Australian Governments 1992a);

- Fragmentation of decision making and responsibilities for natural resource management across a number of public agencies (including all 3 tiers of government) and industry bodies;
- Trends in state and federal governments toward the devolution of responsibilities for environmental stewardship and management (e.g. land clearing and the protection of biodiversity) to the local community and municipal governance level (ANAO 1997);
- A move to greater diversification in the use of natural resource systems and increased recognition of the diversity of values placed upon these systems by stakeholders; and,
- Increasing community expectations for greater involvement and higher standards of accountability and transparency in decision-making on environmental protection and the conservation of biodiversity.

In practice, however, attempts at implementing comprehensive, integrated and flexible ways of promoting ecological sustainable development (ESD) through community-based approaches both in Canada and Australia (e.g. Dorcey 1986, 1991; Syme *et al.* 1994) have proven to be difficult; often resulting in inequitable outcomes. Such initiatives are posing enormous challenges for both rural communities and responsible government and industry agencies.

The implementation of IRM programs in Australia is in a formative and largely experimental stage. In essence, IRM is an evolving concept which lacks a well defined body of guiding principles capable of general application. Much of the conceptual development and experience relates to catchment management programs such as Integrated Catchment Management in Queensland and Western Australia, and Total Catchment Management in New South Wales. These programs vary significantly in terms of their scope and process but all involve experimentation with both the approach undertaken, and the organisational structures established (e.g. Mitchell and Hollick 1993; Syme *et al.* 1994).

To date, there has been little comprehensive evaluation of IRM in practice. Much of the focus of attention has been on the philosophy of IRM and its assumed product rather than IRM as a planning process (eg. Syme *et al.* 1994; AACM 1995). Previous evaluations have generally been limited because they have been:

(i) fragmented and conducted from the viewpoint of a single disciplinary perspective or sectoral interest rather than that of the general community (Syme and Sadler 1994; Bellamy *et al.* 1998);
(ii) rarely applied systematically to the sociopolitical framework within which decisions are made (Syme and Sadler 1994);
(iii) hampered by lack of concrete measurable goals and identifiable outcome criteria (AACM 1995);
(iv) focussed on the assessment and monitoring of 'engineering-type' biophysical or economic performance criteria, such as impacts on water quality, or soil erosion and productivity (eg. Laut and Taplin 1989), rather than more holistic social and political criteria such as attitudinal change, equity and social justice (eg. Syme *et al.* 1994), or policy learning (eg. Davis and Weller 1993); and
(v) for practical reasons, broad one-off overviews that provide a snap-shot in time rather than a systematic longitudinal analysis (Bellamy *et al.* 1998).

Significantly progress towards improvements in the natural resource base at a regional or catchment scale are yet to be systematically demonstrated. Evaluations of ICM processes may help in this context. In particular evaluation of IRM approaches is needed to:

(a) evaluate public and private investment in IRM;
(b) identify the most critical social, economic, institutional and technical factors that influence IRM;

(c) develop appropriate performance criteria for assessing the potential impacts and influences of such approaches not only on the management of natural resource systems, but also on but also on institutional arrangements and society as a whole; and
(d) establish guidelines and techniques for self-evaluation of progress towards the achievement of agreed objectives and planned outcomes, including consideration of equity and social justice issues (Bellamy *et al.* In Press).

3.2. Purpose

Policy Intent

The stated purpose of the Queensland ICM Strategy (QDPI 1991) is to integrate the management of land, water and related biological resources in order to achieve the sustainable and balanced use of these resources.

The goals identified in the ICM strategy are:

1. *Community understanding, coordination and cooperation:*
    - To have the community and government better understanding the interactions between land and water resources and related components of the ecosystem and the need to manage these resources on a catchment basis.
    - To have effective coordination within government, between government and the community, and within the community, of activities and policies relating to the management of Queensland's land and water resources.
    - To have effective cooperation between relevant government agencies, authorities, companies, industry and community groups, landholders and individuals involved in the management of Queensland's land and water resources.
2. *Common goals and priority action:*
    - To have all sectors of the community and government share common or agreed goals for land and water management.
    - To have all users or managers of land and water resources take account of the effects of their actions on these and other related natural resources.
    - To address interrelated land and water issues on a priority basis within catchments.
3. *Economic and ecological sustainability:*
    - To maintain economically viable industries within an ecologically sustainable framework.
    - To maintain, and where feasible, restore and improve the quality and productivity of land, water and related biological resources.
    - To maintain essential ecological processes, ecosystems and biodiversity.
    - To minimise detrimental environmental effects due to the development of land, water and related biological resources, within and beyond catchment boundaries.
    - To protect the wild, scenic and natural characteristics of rivers, lakes and the landscape.

Anticipated Outcomes of ICM in Queensland

As identified in the Queensland ICM Strategy (QDPI 1991), the adoption of the ICM philosophy and processes is expected to result in:

- All users and managers of land and water resources understanding and accounting for the interrelationships between these natural resources in their management decisions and activities
- All sectors of the community and government accepting their individual responsibilities for the sound management of land, water and related biological resources
- Integrated policies and programs for the management of land, water and relation biological resources

- Common goals, strategies and coordinated action by the community and government in addressing priority land and water management issues
- The sustainable use of land and water resources while providing for the material, residential, industrial, recreational and environmental needs of current and future generations
- The maintenance of essential ecological processes, ecosystems and biological diversity.

In essence, the outcomes of the successful implementation of the ICM strategy are expected to be:

- An understanding and accounting by all users and managers of land, water and related biological resources and of the effects of their decisions and actions on these resources;
- Cooperation and coordination between the community and government in their land and water resource management activities;
- Economically viable industries within an ecologically sustainable framework; and
- Clean water, fertile soil and ecologically diverse and productive ecosystems.

A more detailed ICM Strategy summary is provided in Appendix A.

3.3. Instrumental Assumptions

The fundamental assumptions and instrumental hypotheses underlying the implementation of the ICM policy initiative in Queensland relates to a number of elements which are identified below.

(i) *Policy Logic*: The underlying theory base for the Queensland ICM Strategy predominantly relates to systems theory (Ison *et al.* 1997); and the integrated resource management paradigm (Bellamy *et al.* 1998). A fundamental assumption of the ICM policy logic is the adequacy of the inferences of this theory base for achieving ICM Strategy objectives and desired outcomes/changes.

(ii) *Stakeholder or participant involvement*: The key underlying assumptions of participation or involvement in an ICM process relate to:
- expectations of the benefits and costs of a partnership approach to ICM implementation between government and the community (e.g. expectations of the role and influence of an ICM processes; development of synergies; value of informational exchange; prevention and resolution of conflict; development of understanding or learnings; acceptance and ownership of outcomes);
- inclusiveness (i.e. the extent to which the process as implemented takes into account all relevant stakeholder groups who have a stake in natural resource management);
- adequacy of the provisions/arrangements for access by stakeholders and the general public, including continuity of involvement;
- empowerment to plan and effect action; and
- the acceptability and ownership of the ICM process and its outcomes by the catchment community.

(iii) *Process*: The key underlying assumptions relating to an ICM process and its implementation are:
- the representativeness of stakeholder groups and peak bodies on the CCC;
- the degree to which persons directly influenced or the general public are empowered to be involved in ICM (i.e. its planning, implementation, improvement or termination);
- perceptions of appropriate roles, responsibilities and influence of catchment stakeholders;
- perceptions of community processes that need to be put in place;
- stakeholder perceptions and understanding of the ICM's objectives, process and outcomes;
- expectations on fairness and equity of processes;
- expectations of cooperation amongst stakeholders;

- perceptions of stakeholder needs and expectations of the process;
- adequacy and perceived value of public participation/involvement in an ICM process;
- responsiveness of policy formulation and institutional learning processes;
- adequacy and sufficiency of technical knowledge base or understanding to guide substantive action;
- acceptability of solutions identified.

(iv) *Policy and institutional arrangements*: The key underlying assumptions relating to policy and institutional arrangements are:
- the role and value of coordination across levels of decision-making; including all three tiers of government;
- alignment of objectives with government priorities and policy objectives;
- adequacy of guiding principles underlying government policy (such as for Landcare and ICM etc.) or statutory and regulatory controls: (e.g. water allocation, land management and control, local government planning schemes) or industry or voluntary standards (tree clearing, pest management, etc.) in accomplishing their goals/intent;
- clarity, understanding of, and consistency in, policy objectives and outcomes.
- existence or effectiveness of a complementary implementation process beyond strategy development;
- resourcing, commitment and skill of those responsible for implementation; and
- support of stakeholders and politicians for policy or arrangements.

(v) *Technical information and support*: The key underlying assumptions relating to the role and effectiveness of information in integrated catchment management processes are:
- the adequacy and accessibility of information or technology in practice;
- stakeholder information and knowledge needs; and
- the needs for information, technology and other technical support in an ICM process.

(vi) *Communication:* The key underlying assumptions relating to communication and interaction in integrated catchment management processes are:
- adequacy and effectiveness of feedback mechanisms to constituents;
- equity in access to information and other communication mechanisms; and
- the adequacy and effectiveness of the network of social interactions at individual and organisational levels and their linkages to decision-making.

(vii) *Outcomes:* The key underlying assumptions relating to the outcomes of an ICM process are:
- cost-effectiveness and efficiency of an ICM approach relative to other possible alternative approaches in achieving ESD goals;
- equitableness (e.g. the extent to which the distribution of benefits and risks associated with the impact of the ICM policy initiative on the different groups of people affected by it are fair and just);
- adequacy and effectiveness of expected outcomes in achieving ICM goals objectives;
- and behaviour as outcomes; and
  - alignment of outcomes with government priorities and policy objectives as well as community needs and expectations.

3.4. Evaluation Criteria

Evaluation Objectives

The purpose of this evaluation is:

1. To identify the social, economic, and institutional factors that facilitate or hinder the process of implementation of ICM in the Herbert River catchment.

2. To evaluate the key impacts of the implementation of the ICM process in terms of attitude and behaviour changes in the community and changes in the severity or tractability of the resource use conflicts for the Herbert River catchment.
3. To assess the specific technical and related information needs that are relevant to an effective ICM implementation process in a wet tropical environment.
4. To test an integrated framework and related methods for evaluating the process of ICM implementation that will facilitate the development of more effective catchment management programs in Australia.

Purpose of Evaluation

The principal reasons and expected benefits of the evaluation are to:

- support the accountability needs and communication requirements of R&D providers and funders and other relevant collaborators;
- contribute to the effectiveness of the ICM implementation process in the Herbert River catchment (through, for example, provision of information to, and support for on-going learning within the Herbert River Catchment Coordinating Committee (HRCCC); influencing decision-making and policy development processes of HRCCC member organisations);
- provide the basis for a multi-perspective synthesis and an evaluation of the Herbert River ICM process that is applicable to community-based catchment management programs in Australia;
- improve the effectiveness of the R&D process and synthesis of research findings across all project activities;
- early flagging of equity and social justice issues arising from the research project implementation;
- early identification of unanticipated outcomes so that they may be identified, and ameliorated or, if appropriate, capitalised to advantage; and
- contribute to the development of ownership of the evaluation and its findings by ICM stakeholders.

The evaluation of the Herbert River ICM process has a number of elements that provide the basis of an analytical framework for evaluation criteria:

(i) the tractability of resource use issues and tensions in the catchment;
(ii) institutional structural capacity to address natural resource issues at a catchment scale;
(iii) adequacy and equity of community processes; and
(iv) technical understanding and needs to support ICM implementation.

Evaluative measures will be broadly focussed encompassing a range of different criteria, including social, cultural, institutional, economic, environmental, and technical. A framework for evaluative measures and criteria is provided in Table 1 that clarifies their role in the evaluation.

3.5. Methods of Evaluation

A range of methods are required to measure and assess the ICM process in the Herbert. Each performance measure will require multiple methods to assess performance criteria. The principle methods will include:

1. On-going monitoring and document analysis of the ICM implementation process.
2. Bench-marking (e.g. of attitudes, perspectives and behaviour) through surveys with key stakeholders of the Herbert community.
3. Bench-marking (e.g. of attitudes, perspectives) through semi-structured interviews with the HRCCC members as well as key players in ICM implementation in Queensland
4. Interactive annual forums/workshops with HRCCC members and other Herbert ICM stakeholders.

5. Open-ended interviews with key players in ICM from implementing agencies.
6. Organisational studies of institutional arrangements for ICM in Queensland (including institutional mapping).
7. Characterisation of the natural resource, policy/institutional, social and technological context of ICM implementation in the Herbert,
8. Meta-analysis of other activity specific evaluations.
9. Economic analysis/valuation
10. Content analysis
11. Spatial analysis
12. Focus group studies

Proposed methods for each criteria for evaluating ICM in the Herbert River catchment are provided in Table 3.1.

Table 3.1: A framework of measures and criteria for evaluating the ICM process in the Herbert River catchment.

Evaluative Measures	Evaluation Criteria	Methods
1. The tractability of catchment resource use issues and tensions .		
1.1 External environment vigilance	Community ability to identify significant external economic and political influences and opportunities that impact on ICM: ♦ alertness to economic and political changes that influence ICM; ♦ Number of presentations, guest speakers, and HRCCC agenda items on changes in policy, etc.	• On-going monitoring and document analysis of the ICM process. • Content analysis of newspapers. • On-going monitoring and document analysis of institutional arrangements for NRM in the catchment.
1.2 Characteristics of the catchment's resource use context	Characterisation of natural resource use and management within the catchment including: ♦ the change in the nature and distribution of land cover/use in the catchment over time; ♦ the degree of community involvement and the role of institutions (eg. government, industry, and R&D organisations) in initiating an integrated approach to resource management in the catchment; and ♦ nature and level of disputes and degree of conflict on resource use. ♦ the change in economic signals that affect resource management. ♦ media support for natural resource issues and ICM activities.	• Spatial analysis of land cover/use in the catchment • On-going monitoring and document analysis of the ICM process. • On-going monitoring and document analysis of institutional arrangements for NRM in the catchment. • Content analysis of newspapers. • Economic assessment
1.3 Understanding of community attitudes and behaviour	Degree and direction of change in the community and the HRCCC member perceptions on natural resource management and the ICM process in the Herbert catchment including perceptions on: ♦ the key catchment resource management issues; ♦ agreed objectives for ICM; ♦ desirable outcomes for ICM ♦ the role and function of the HRCCC ♦ community/individual behaviour in respect of natural resource use and management, ♦ resource use and management responsibilities and influence. Change in attitudes (and behaviour) of resource users and managers to natural resource management in the catchment including: ♦ the nature of stakeholder understanding of key NRM issues/conflicts (e.g. importance; means and ease of resolution or management; impact; cause and responsibility for resolution).	• Benchmarking of attitudes, perspectives and behaviour through semi-structured interviews with HRCCC members. • Interactive annual forums/workshops with HRCCC members. • Open-ended interviews with key players in ICM implementation. • Benchmarking of attitudes, perspectives and behaviour through surveys of the Herbert community. • Benchmarking of attitudes, perspectives and behaviour through semi-structured interviews

Evaluative Measures	Evaluation Criteria	Methods
	♦ the compatibility or degree of conflict in community and stakeholder attitudes and perspectives amongst stakeholders ♦ Improved recognition of importance of a catchment perspective on resource management including an ICM process ♦ the cost/benefits of change in natural resource management practices to landholder and community/society at large ♦ Degree and nature of stakeholder participation in catchment management and land use planning	with HRCCC members. • Interactive annual forums/workshops with HRCCC members. • Economic assessment/valuation
2. Institutional capacity for catchment management		
2.1 Adequacy of community-based planning at the catchment level.	Community ability to plan and implement future initiatives including: ♦ evolution of ICM process in catchment; ♦ adequacy and continuity of communication within and between stakeholders represented on the HRCCC. ♦ stakeholder involvement in HRCCC meetings and activities. ♦ structures and mechanisms for negotiation on issues; ♦ opportunities for interactions across stakeholder groups; ♦ degree of enhancement/building of HRCCC linkages into regional development management and planning processes ♦ commitment and skill of implementing staff/agencies ♦ commitment of financial resources to support ICM. ♦ support from political and industry leaders. ♦ use of media.	• Benchmarking of perspectives through semi-structured interviews with HRCCC members. • On-going monitoring and document analysis of the ICM process. • Interactive annual forums/workshops with HRCCC members and other stakeholders.
2.2 Institutional processes for natural resource management and planning at the catchment scale	Policy frameworks and institutional arrangements for catchment/natural resource management including: ♦ clarity and consistency of roles and objectives of agencies ♦ adequacy of policy, plans and decision rules of implementing agencies. ♦ adequacy and diversity of representation of interests within government processes. ♦ coordination amongst responsible government agencies and industry bodies; ♦ the nature and degree of involvement of responsible government agencies; ♦ accessibility and availability of technical support and financial resources.	• On-going monitoring and document analysis of the ICM process. • On-going monitoring and document analysis of policy frameworks and institutional arrangements for NRM. • Benchmarking of perspectives through mail-out surveys of key players in ICM implementation. • Interactive annual forums/workshops with HRCCC members and other stakeholders. • Organisational mapping. • Open-ended interviews with key players in ICM implementation.

Evaluative Measures	Evaluation Criteria	Methods
2.3 Capacity to identify and address resource use issues at a catchment scale.	♦ opportunities for formal access by wider community. Scientific and other technical capacity to address catchment management issues including: ♦ the level of understanding of the causes and sources of technical problems across stakeholders; ♦ economic constraints to addressing issues. ♦ the level of technical understanding relating to the resolution or improved management of the problem; ♦ accessibility and use of technical/scientific information to conceptualise the problem and negotiate solutions); ♦ availability of, and equity of access to, body of knowledge relating to natural resource issues, their management and use. ♦ mechanisms and protocols for sharing of information across institutions and stakeholder groups.	• Benchmarking of perspectives through semi-structured interviews with HRCCC members. • Meta-analysis of other evaluations of NRM technologies and information needs • Focus group studies. • Benchmarking of perspectives through mail-out surveys of key players in ICM implementation.
3. Adequacy and equity in community processes		
3.1 Adequacy of Stakeholder involvement	Mechanisms for communication or interaction on catchment issues. ♦ Degree of interactiveness in catchment management and planning systems (including the desire for, trust in, and nature and degree of interactions amongst stakeholder groups). ♦ Perspectives on information flow (e.g. free flow of information or information as a power tool). ♦ Representativeness of stakeholder groups on the HRCCC. ♦ Level of strategic alliances/partnerships developed to exploit synergy; ♦ Presence of a sense of control of change (e.g. gaining realistic support) and meaningful involvement (e.g. practical outcomes) in natural resource management and planning process	• Bench-marking of attitudes, perspectives and behaviour through community surveys and semi-structured interviews of HRCCC members • Phone survey of key players in ICM. • Interactive annual forums/workshops with HRCCC members. • On-going monitoring and document analysis of the ICM process.
3.2 Equity of opportunity for involvement in resource use and management .	Perceptions of fairness in resource use management and planning systems and related decision-making processes including: ♦ Perceptions of sufficiency of allocation, and fairness in terms of distribution, of government and industry resources provided to address regional resource use issues. ♦ Feelings of being unfairly ascribed the blame for environmental problems. ♦ Degree of belief that decision-making processes have been fair to all. ♦ Degrees of tension relating to indigenous rights of use.	• Bench-marking of attitudes, perspectives and behaviour through community surveys and semi-structured interviews of HRCCC members • Interactive annual forums/workshops with HRCCC members. • On-going monitoring and document analysis of the ICM process. • Economic valuation

Evaluative Measures	Evaluation Criteria	Methods
	♦ Perceptions of trust in government and its acceptance of responsibilities. ♦ costs and benefits of use and management.	
3.3 Adequacy of opportunities for future collaboration and involvement	• Support/satisfaction of stakeholder with participation in ICM; • Degree and nature of involvement of stakeholders. • Emergence of local champions. • Vitality of cross-stakeholder collaboration in natural resource management projects. • Degree of enhancement of communication and coordination between stakeholders; • Degree of strengthening of institutional capacity at community level (including technical, financial, skills development and training) to support meaningful and viable participation/collaboration. • Endurance of collaborative mechanisms established. • Commitment of stakeholders to future collaboration/cooperation. • Perceptions of costs and benefits of participation/involvement.	• On-going monitoring and document analysis. • Benchmarking of attitudes, perspectives and behaviour through semi-structured interviews. • Interactive annual forums involving representatives of all stakeholders.

4. EVALUATIVE CONTEXT

The effect of contextual factors on a process and its impact are well recognised. The implementation of integrated approaches to resource management is context-sensitive and a wide range of factors will influence their implementation and outcomes. The key contextual factors influencing ICM are:

(i) *environmental context*: e.g. the evolution of resource use and management systems in the region; the major resource use issues and their on-site and offsite implications and impacts; attitudes and behaviour to natural resource management and environmental issues; nature and extent of behavioural change in resource use and management practices required across catchment stakeholders.

(ii) *economic context*: e.g. the nature and status of, and interdependencies within, the regional economy overall and on a sectoral basis; perceptions of future development and economic prospects; distribution of wealth and resources; economic vulnerability of the regional economy; financial viability of land managers.

(iii) *social/cultural context*: e.g. the catchment demography and related sustainability issues; cultural diversity and related resource use issues; the nature and commonality in community expectations (both within and outside the region) regarding the regional environment and socioeconomic situation, as well as planning processes; perceptions of equity and social justice; political and media support for catchment resource use issues and land use planning processes; social history and demographic change.

(iv) *policy/institutional context*: e.g. relevant policies and the organisational structures and processes for natural resource management across government, industry and community; resourcing and coordination characteristics of policies, plans and processes; stability and volatility of local and state political process.

(v) *scientific/technological context*:- e.g. the characteristics of the existing technology system; technical knowledge base and competencies to use advanced technologies across regional stakeholders; availability and feasibility of technical solutions; adequacy of scientific knowledge including appropriateness of scientific undertakings and its ability to assist decision-making.

The evaluative context will therefore impact on an evaluation and influence the interpretation of findings. A key issue is that ICM is only one of a number of processes influencing resource use management and planning in the Herbert River catchment and therefore any attribution of benefits need to be seen in this context. Table 3.2 provides a framework for considering the ICM contribution to a criteria (given that ICM may be only one of the contributors to change).

Abstract

Approaches to natural resource management based on the integration of community involvement, technical knowledge, and organisational structure and policy objectives are endorsed throughout Australia. The emerging paradigm of resource management supports a more flexible and adaptive approach to address the uncertainty, complexity and interconnectedness associated with natural resource and human management systems. The translation of this concept into practice however is proving difficult and proactive evaluation should help. But the evaluation of the effectiveness of integrated resource management (IRM) approaches both in Australia and internationally is relatively more neglected. This paper discusses issues of IRM evaluation and proposes a conceptual evaluation framework that identifies a range of technical, institutional, economic and social criteria that may influence the success of IRM in practice. This framework should facilitate the proper formulation of the natural resource management problem and its underlying characteristics.

Australian governments are investing considerable resources in integrated resource management (IRM) programs with high community expectations for the outcomes. The fundamental challenge of these programs is to improve the way our natural resources are used and managed with a long term perspective. However, the translation of the concept of an integrated approach to resource use and management into practice is proving difficult (Syme *et al.* 1994; AACM 1995). IRM is an evolving concept which lacks a well defined body of guiding principles capable of general application. The basic assumption that IRM approaches contribute effectively to the better management of our land and water resources has not been systematically or critically addressed.

Evaluations of the nature and impact of IRM programs are needed to: (a) evaluate public and private investment in IRM relative to alternative approaches; (b) identify the most critical social, economic, institutional and technical factors that influence IRM; and (c) develop appropriate performance criteria for assessing the potential impacts and influences of such approaches not only on the management of natural resource systems, but also on society as a whole. In this paper we examine the concept of IRM and review issues of evaluation of IRM in practice. A conceptual framework for the evaluation of IRM programs is developed that encompasses technical, economic, social and policy science perspectives.

The Evaluation Problem

Numerous studies focus on the biophysical and institutional aspects of natural resource management (eg. Chisholm and Dumsday 1987; McTainsh and Boughton 1993), or how integrated resource management should be conceptualised and structured (eg. Lang 1990; Mitchell and Hollick 1993; Syme *et al.* 1994; Margerum 1996). The evaluation of the effectiveness of integrated programs in resolving or ameliorating natural resource use and management problems, however, is one of the more neglected areas of IRM research.

Previous evaluations have generally been limited because they have been:

(i) fragmented and conducted from the viewpoint of a single disciplinary perspective or sectoral interest rather than that of the general community (Syme and Sadler 1994);
(ii) rarely applied systematically to the sociopolitical framework within which decisions are made (Syme and Sadler 1994);
(iii) hampered by lack of concrete measurable goals and identifiable outcome criteria (AACM 1995);
(iv) focussed on the assessment and monitoring of 'engineering-type' biophysical or economic performance criteria, such as impacts on water quality, or soil erosion and productivity (eg. Laut and Taplin 1989), rather than more holistic social and political criteria such as attitudinal change, equity and social justice (eg. Syme *et al.* 1994), or policy learning (eg. Davis and Weller 1993); and
(v) for practical reasons, broad one-off overviews that provide a snap-shot in time rather than a systematic longitudinal analysis.

Integrated Resource Management

The Emerging Paradigm

Demands for intergenerational equity and social justice are challenging the way we utilise and manage our natural resource systems. On-going resource degradation of our waterways, pastoral and agricultural lands, and concern for biological diversity is creating considerable public and community tension. It is widely advocated by both Commonwealth and most state governments in Australia that traditional approaches to resource use and economic growth need to be changed to ensure that development is sustainable and environmental qualities are maintained or enhanced.

Past policies and programs in Australia largely treated environmental management and conservation as a separate arena to mainstream political activities, such as economic management, infrastructure development, and social planning. Traditional approaches to resource management and planning have been identified as being responsible for *ad hoc* decision-making and piecemeal action aimed at treating symptoms of environmental problems, while systemic or cumulative effects and emergent properties are overlooked, long term changes masked, and social values and interests ignored (eg. Lang 1990; RAC 1993). However, the concept of ecologically sustainable development endorses the notion of the interrelatedness of environmental, economic, social and political aspects of resource use. In this context, the emerging paradigm of IRM supports the replacement of fragmented and frequently reactive sectoral or mono-disciplinary approaches with more flexible and integrated approaches that seek to reflect the complexity and interconnectedness of natural and human systems. Identifying the theory underlying any IRM program or policy highlights the assumptions, clarifies what evaluation measures are needed, and contributes to developing understanding of the causal linkages. Table 1 provides a comparison of the typical characteristics of the 'traditional' and emerging paradigms of IRM. These encompass elements relating to natural systems (eg. Gunderson *et al.* 1995; Funtowicz and Ravetz 1990), political systems (eg. Sabatier 1988; Boehmer-Christiansen 1994), social systems (eg. Crane 1988; Syme *et al.* 1994; Syme and Sadler 1994; Vanclay and Lawrence 1995), and technology (eg. Orlikowski 1992; Boehmer-Christiansen 1994; Holling 1995). The emerging paradigm identifies the fundamental basis for the resolution or amelioration of natural resource management problems as being the recognition of these four elements and their interdependencies. The characteristics of these elements reflect the complexities and breadth of the concept of IRM, as well as the difficulties of IRM evaluation in practice.

The Rationale for IRM

Advocates of IRM promote it as an approach to planning and management that places resource use problems and opportunities in a systemic or holistic framework with an aim to finding integrative solutions. Mitchell (1990) defines IRM as incorporating four components: (i) multiple purposes, multiple means, multiple participant strategies; (ii) blending of various resource sectors; (iii) using resource management as a mechanism for social and economic change; and (iv) striving for accommodation and compromise. Programs based on such approaches are designed with the intent of addressing resource use issues and their management in the broader context of their associated biophysical, economic, social and institutional attributes.

Table 1. Comparison of the typical characteristics of the traditional and the emerging paradigms of resource management.

Traditional Paradigm	Emerging Paradigm
Natural System: • Sustained yield: maximising production of a single resource and use for sustained economic development. • Ecosystem development characterised by ecological succession with fixed stable states, ie. predictable, causal linear dynamics. • Environmental concerns (eg. habitat protection, soil erosion) as constraints to output maximisation. • Conservation of individual resources (eg. soil) and preservation of natural resources in a reserve system. • Best management practices based on optimisation models. • Management focus on the scale of parcels of land. • Multiple use of a parcel of land in terms of productive values.	• Ecosystem management: maintenance of resource condition and long term sustainability of ecological relationships in complex evolving systems. • Ecosystem development characterised by long term change and chaos with a number of different pathways available, ie. unpredictable, discontinuous, nonlinear, self-organising and multivalued properties. • Environmental concerns (eg. biodiversity preservation, downstream effects) as the goals of resource management. • Holistic management of natural and human systems including off-reserve management and preservation of biodiversity. • Best management practices based on assessment of environmental, economic, and social trade-offs. • Management focus on the scale of landscapes and regions/catchments. • Multiple use of natural resources in terms of environmental, social and cultural values.
Political System: • Strategic analysis and planning; administrator as neutral expert. • Multiplicity of public agencies; sectoral division of responsibilities; fragmentation of initiatives. • Centralised procedural approach; sequential process of planning, implementation and regulatory control.	• Public participation and collaborative decision making; strategy development as an emergent process. • Institutions linked formally and informally; decentralised coordinated structures. • Learning organisations: on-going structural adaptations and change in institutions and organisations, and flexible adaptive policies.
Social System: • Rational behaviour, focussing on maintenance of profitability. • Dominant use of technical information in a rational decision making process. • Contextual neutrality; spatial and temporal distribution of resource commodities disassociated from its human and cultural context.	• Adaptive management, focussing on equity and social justice. • Conceptual use of information in decision-making processes dominated by political considerations. • Contextual relevance; landscape and resource management have a broad range of meanings across individuals and social groups linked to the cultural history and values of a place.
Technology: • Based on reductionist science, controlled and experimental research. • Disciplinary scientists as neutral expert. • Single scale focus, typically short term and local. • Technology an autonomous process, ie. a product of objective and rational knowledge. • Communication process focussed on teaching; linear model of technology transfer (expert to novice).	• Based on participative R&D process involving a multi-disciplinary team from biophysical, economic and social sciences in partnership with stakeholders. • Scientist becomes a participant in the process (rather than a "detached" expert) • Interdisciplinary focus, typically long term and cross scale. • Technology as the product of man, ie. a social construct that integrates/blends scientific and local knowledge. • Interaction process focussed on facilitating learning (individual, organisational, policy); adaptive and iterative.

Integrated approaches are described in the literature by a number of terms including integrated resource management (eg. Lang 1990; RAC 1993), integrated environmental management (eg.

Margerum and Born 1995), integrated catchment management (e.g. Mitchell and Hollick 1993; DPIQ 1993), watershed management (e.g. Mitchell 1990), environmental planning (eg. Armitage 1995), and bioregional planning (eg. Lambert and Elix 1996). Situations demanding integrated approaches have been defined as:

> *"…. where problems are highly complex, interests and objectives are numerous and in conflict, information and knowledge are quite incomplete, ends and means are ambiguous, control is fragmented and the external environment is in flux."* (Lang 1990, 3)

New strategic initiatives in a number of Australian states are attempting to integrate resource use management and planning (eg. Laut and Taplin 1989; Mitchell and Hollick 1993; Syme *et al.* 1994; AACM 1995). These initiatives inevitably focus on situations where there are competing and conflicting resource use issues and/or multiple institutional responsibilities. The guiding principles of integrated approaches to resource use and management have been stated as:

- Management of interrelated resources with regard to ecological processes and the maintenance of environmental quality;
- Involving community participation in natural resource management;
- Co-ordinating government, non-government and community natural resource management policies and activities (eg. RAC 1993).

The underlying philosophy of such programs is that there are no conceivably simple or short-term solutions, nor a single perspective that can provide an appropriate course of action to deal with complex resource use issues within a regional or catchment context. Current resource use and management problems are viewed as the result of the interaction between people and their environment, rather than simply a problem for the environment per se. They are also perceived to be beyond the scope of purely technological solutions or the resources and actions of governments alone. IRM programs are promoted therefore as long term processes of managing change in natural resource use through the continuing integration of community action and statutory, policy and institutional adjustments.

Claims made in the literature in support of the benefits of these programs include: the development of catchment management strategies with community-wide ownership (eg. Mitchell and Hollick 1993); improved awareness of catchment processes (e.g., AACM 1995); the resolution or amelioration of conflicts among catchment stakeholders (eg. Syme *et al.* 1994); the planning and implementation of resource use practices on a catchment wide basis that lead to sustainable use, management and conservation of natural resources (eg. DPIQ 1993); the development of new complementary institutional arrangements (e.g., Mitchell and Hollick 1993; Margerum 1996); and the establishment of an interactive participative process that links policy formulation and implementation so that lessons are learned and incorporated in the policy process (eg. Davis and Weller 1993).

Most of these perceived benefits relate to IRM processes rather than improvements in the health and integrity of natural resources. Moreover, while assumed, linkages clearly attributing these processes to improvements in natural resources are hard to identify or measure in practice. The level of complexity and nonlinearity of natural systems tends to reduce confidence in predictability. Separation in space and time of cause-and-effect relationships at the catchment level mean that closely defined relationships are very difficult to demonstrate (eg. Boehmer-Christiansen 1994; Funtowictz and Ravetz 1990).

Under the emerging paradigm, the broad and dispersed nature of many natural resource problems means that coordinated and community-based action for change is required to effect change. A major issue in achieving such change, however, is that although at the catchment scale, the practices of resource management may need to change, at the individual resource user level it may not be socially acceptable or economically viable to do so. A key aspect of this issue is that the focus on the improvement of resource management, rather than increased economic

performance, means costs are bourne by the individual resource user at least in the short term, while the benefits may accrue to society as a whole (Vanclay and Lawrence 1995). In sum, considerable challenges exist in the implementation of community-based programs that attempt to foster an integrated approach to natural resource use and management.

Integrated Resource Management in Practice in Australia

Like the emerging resource management paradigm, the implementation of IRM programs in Australia is in a formative and largely experimental stage. Much of the conceptual development and experience relates to catchment management programs which involve experimentation with both the approach undertaken, and the organisational structures established (e.g. Mitchell and Hollick 1993; Syme *et al.* 1994). Further, approaches vary across the different Australian states. For example in New South Wales, Total Catchment Management is a statutory program (Cunningham 1986), while in Queensland Integrated Catchment Management is a policy or planning process implemented through administrative and financial arrangements by the State Government (DPIQ 1991).

These multiple institutional processes and arrangements are evolving and generally in a state of flux within the confines of their sectoral responsibility. This situation mitigates against the facilitation of a change from a commodity focus to a more integrated or holistic approach to resource management. Moreover, IRM programs in general are poorly resourced; relying heavily on federal funding, lacking substantial local or state government support for implementation, and substantially limited by only short term financing arrangements and work plans. Commonly IRM approaches in Australia have focussed on technical solutions often with little regard to addressing the public and private costs and benefits of their implementation and their social impact. These factors create considerable uncertainty and challenges for community-based IRM programs.

To date, there has been little comprehensive evaluation of IRM in practice. Much of the focus of attention has been on the philosophy of IRM and its assumed product rather than IRM as a planning process (eg. Syme *et al.* 1994; AACM 1995). Significantly progress towards improvements in the natural resource base at a regional or catchment scale are yet to be systematically demonstrated.

Evaluating Resource Management Programs

General Paradigms for Program Evaluation

Patton defines evaluation research as:

> *"... the systematic collection of information about the activities, characteristics, and outcomes of programs for use by specific people to reduce uncertainties, improve effectiveness, and make decisions with regard to what those programs are doing and affecting."* (Patton 1986, 14)

The main focus of an evaluation may vary depending on the purpose of the evaluation and the stage of the program. The Department of Finance (1994), for example, recognises four types of evaluation:

(i) *appropriateness evaluations* which focus on the extent to which program objectives or desired outcomes align with government priorities and policy as well as client needs;
(ii) *cost effectiveness evaluations* which focus on the relationship between inputs expressed in dollar terms and outcomes, where the outcomes may not be readily expressed in dollar terms;
(iii) *effectiveness evaluations* which focus on the extent to which project outcomes are achieving program objectives,

(iv) *efficiency evaluations* which focus on the extent to which program inputs are minimised for a given level of program outputs, or to which outputs are maximised for a given level of inputs.

Figure 1 illustrates this framework and shows the links between the types of evaluation. Within this framework, many evaluations will encompass: the measurement of factors that affect the achievement of outcomes; the establishment of cause-effect interpretations as to whether the outcomes were caused by the program, or external factors; and the identification of any unanticipated outcomes which are contributing to the achievement of objectives or impacting negatively on clients (Department of Finance 1994). This implies that the evaluators can establish a causal connection between the changes brought about by the project, changes due to other factors, and thus the net effect of the program compared with a baseline of no-program.

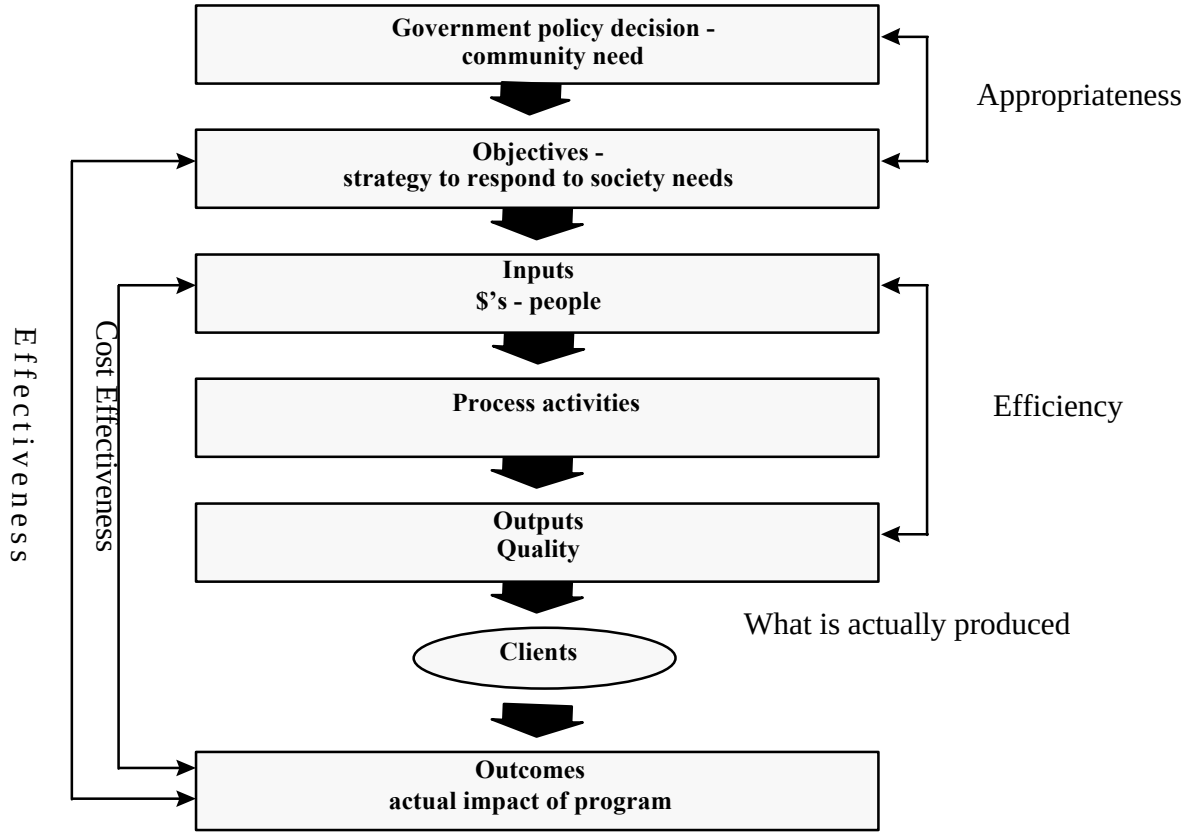

Figure 1. Levels of program evaluation. Adapted from ANAO and Department of Finance (1996).

Issues in Evaluating Natural Resources Management Programs

A review of the literature shows that of the relatively few attempts at evaluating natural resource management programs, most concentrate on the inputs alone (eg. ANAO 1997). While there may well be conceptual links between the inputs and goals achievement, measures of the inputs alone is a poor basis for designing program improvement. Several evaluations go beyond input measures to discuss the operation of management processes, although the measures in these studies are almost always limited to the opinions of the parties involved (AACM 1995). Some studies focus predominantly on the processes themselves on the grounds that related outcomes are improved community decision making processes themselves (eg. Syme and Sadler 1994;

Syme *et al.* 1994). The greatest difficulty for IRM program evaluation is that the critical outcomes are long term and can not be readily measured.

Most IRM programs are experimental. The literature is full of enthusiastic presentations as to why such programs will solve many problems - *ex ante*. The effects of resource management programs however are highly dependent on the specific social and economic context, and they may take a considerable time to become visible. To evaluate different models of natural resource management program implementation therefore requires, in particular, a focus on program processes and activities rather than the output of the program per se.

In a recent review of the literature on policy evaluation in natural resources, Wallace *et al.* (1995) identified three common problems facing implementing agencies of natural resource management policies: how to respond to a general call for increased public participation in policy making; how to evaluate programs in light of poorly defined and understood objectives; and how to monitor programs in light of new scientific understanding and changes in management philosophy and practice. In practice there is a general lack of use and development of substantive policy evaluation theory. Wallace *et al.* also claim that the traditional empirical model of evaluation, in which the referents for study are the formal programs and goals and objectives articulated in legislative acts or policy statements, is not a practical tool for most natural resource policies. Natural resources policy statements are often vague and unclear about their objectives and their intended policy effects and, hence, difficult to achieve or even define. Palfrey *et al.* (1992) propose an evaluation approach that ultimately refers effectiveness back to the 'guiding principles' in which the policy is embedded. Valid indicators of mental constructs such as justice, equity, equality and choice are however difficult to establish. Palfrey *et al.* point to the relevance and importance of 'processes' as indicators of both efficiency and effectiveness of policy implementation. 'Process' in this context refers not only to administrative, organisational and legislative mechanisms, but also the total network of operations involved in implementing and sustaining policy in action, including social interactions and participant perceptions of issues and how the program is progressing.

In an evaluation of public involvement in water resources planning, Syme and Sadler (1994) subscribed to the philosophy that evaluations of such exercises must be pragmatic and clearly linked to decision makers and their decision making context. They argue that decision making on natural resources management is improved "by processes that lead to informational exchange and joint evaluation of alternatives" (Syme and Sadler 1994, 525). In particular they advocate a partnership approach between the community and the agency to evaluation that incorporates evaluation on an on-going basis to provide timely direction to any public involvement program. In this sense program evaluation may be implemented as an ongoing collaborative learning process that will challenge institutions to adapt as much as the catchment community.

In recognition of these issues, frameworks for evaluating IRM programs need to take into account the fact that:

- IRM programs have social, economic, technical and institutional attributes;
- they are characterised by broad societal goals and task complexity;
- they generally lack clear goals and quantifiable and measurable outcomes;
- they are evolving processes in which the needs of the process and the perception of those needs amongst stakeholders in the community, government agencies and technical expertise are also changing;
- their influence or impacts are often incremental and accumulative, and generally accrue over a long timeframe; and
- they are inevitably undertaken in the context of changing political and institutional climate; that is, one that is in a state of flux.

Evaluation needs to be directed toward influencing what emerges in a positive and constructive way, rather than focussing only on *post hoc* evaluation related to mere achievement of initially proposed means of reaching objectives. The evaluation may be influential in modifying the objectives themselves. The importance of involving decision-makers and other stakeholders who represent a wide diversity of perspectives in such an evaluation process needs also to be recognised. The major benefits of stakeholder participation are seen as prevention or resolution of conflict and enhanced understanding of the program and evaluation findings (eg. Syme and Sadler 1994), including how the program works, a broader view of the key issues, and acceptance or ownership of the results. Moreover, as there are no universally accepted models for evaluation, the purpose of an evaluation should be clearly identified and agreed upon with all stakeholders in its planning.

An Integrated Framework for Evaluating IRM Programs

Because of the evolving and holistic nature of the concept of IRM, evaluations of IRM programs or processes require criteria from the biophysical, social, economic, and institutional/policy perspectives, and need to recognise the interrelationships between these evaluation criteria. This requires a multi-faceted evaluation methodology that provides a general analytical framework within which: (a) an evaluation can be planned to account for the broad range of issues encompassed by the integrated resource management concept as well as objectives of documented policies; and (b) the nature of IRM as an evolutionary process of managing change is recognised.

An Analytical Framework

Figure 2 presents a conceptual framework for evaluating IRM programs that identifies a range of technical, institutional, economic and social factors. Identification and understanding of the nature of these variables, their interrelationships, and their relative importance within a particular problem context needs to underpin the formulation of the IRM problem and the identification of its underlying characteristics by stakeholders. In this framework, the IRM problem definition and strategies for addressing them are an iterative process and evolve during implementation.

This evaluation framework also provides a structure for undertaking multidisciplinary research on the effectiveness of IRM programs. It adapts the Mazmanian-Sabatier framework of policy implementation model[1] (Mazmanian and Sabatier 1981; Sabatier 1986), but also includes socially significant evaluation indices[2] (eg. Crane 1988), and recognition of the principles of the PRIME procedural model (Syme *et al.* 1994). This latter model reminds us that evaluation needs to cope with multiple parallel tasks occurring at all times. Some of these tasks will be dealing with planning; some with research monitoring and evaluation. It also recognises that there should be appropriate areas of influence in the evaluation process by the community as well as agencies.

The evaluation framework provides a conceptual model for identifying the causal elements impacting on IRM programs and for establishing the hypotheses to be tested. In specific policies which have inadequate definitions, the hypotheses can be drawn from documentation and supplemented by the suggestions presented here for the framework. The four key elements of the evaluation framework are:

- Natural resource issue characterisation
- IRM program context
- Institutional structure
- Community processes.

For each of these elements, the framework identifies variables that may potentially influence the IRM program implementation process and its outcomes. These have been derived from policy documentation but more specifically from professional experience and analysis of IRM literature. The relevant variables for an evaluation will inevitably change depending on the social, economic

and political context as well as the stage of development of the IRM process. The proposed framework also incorporates an effective process of continuing feedback and improvement to the IRM implementation process as a whole. The stages in the evaluation process will therefore be iterative, interactive and inevitably influential.

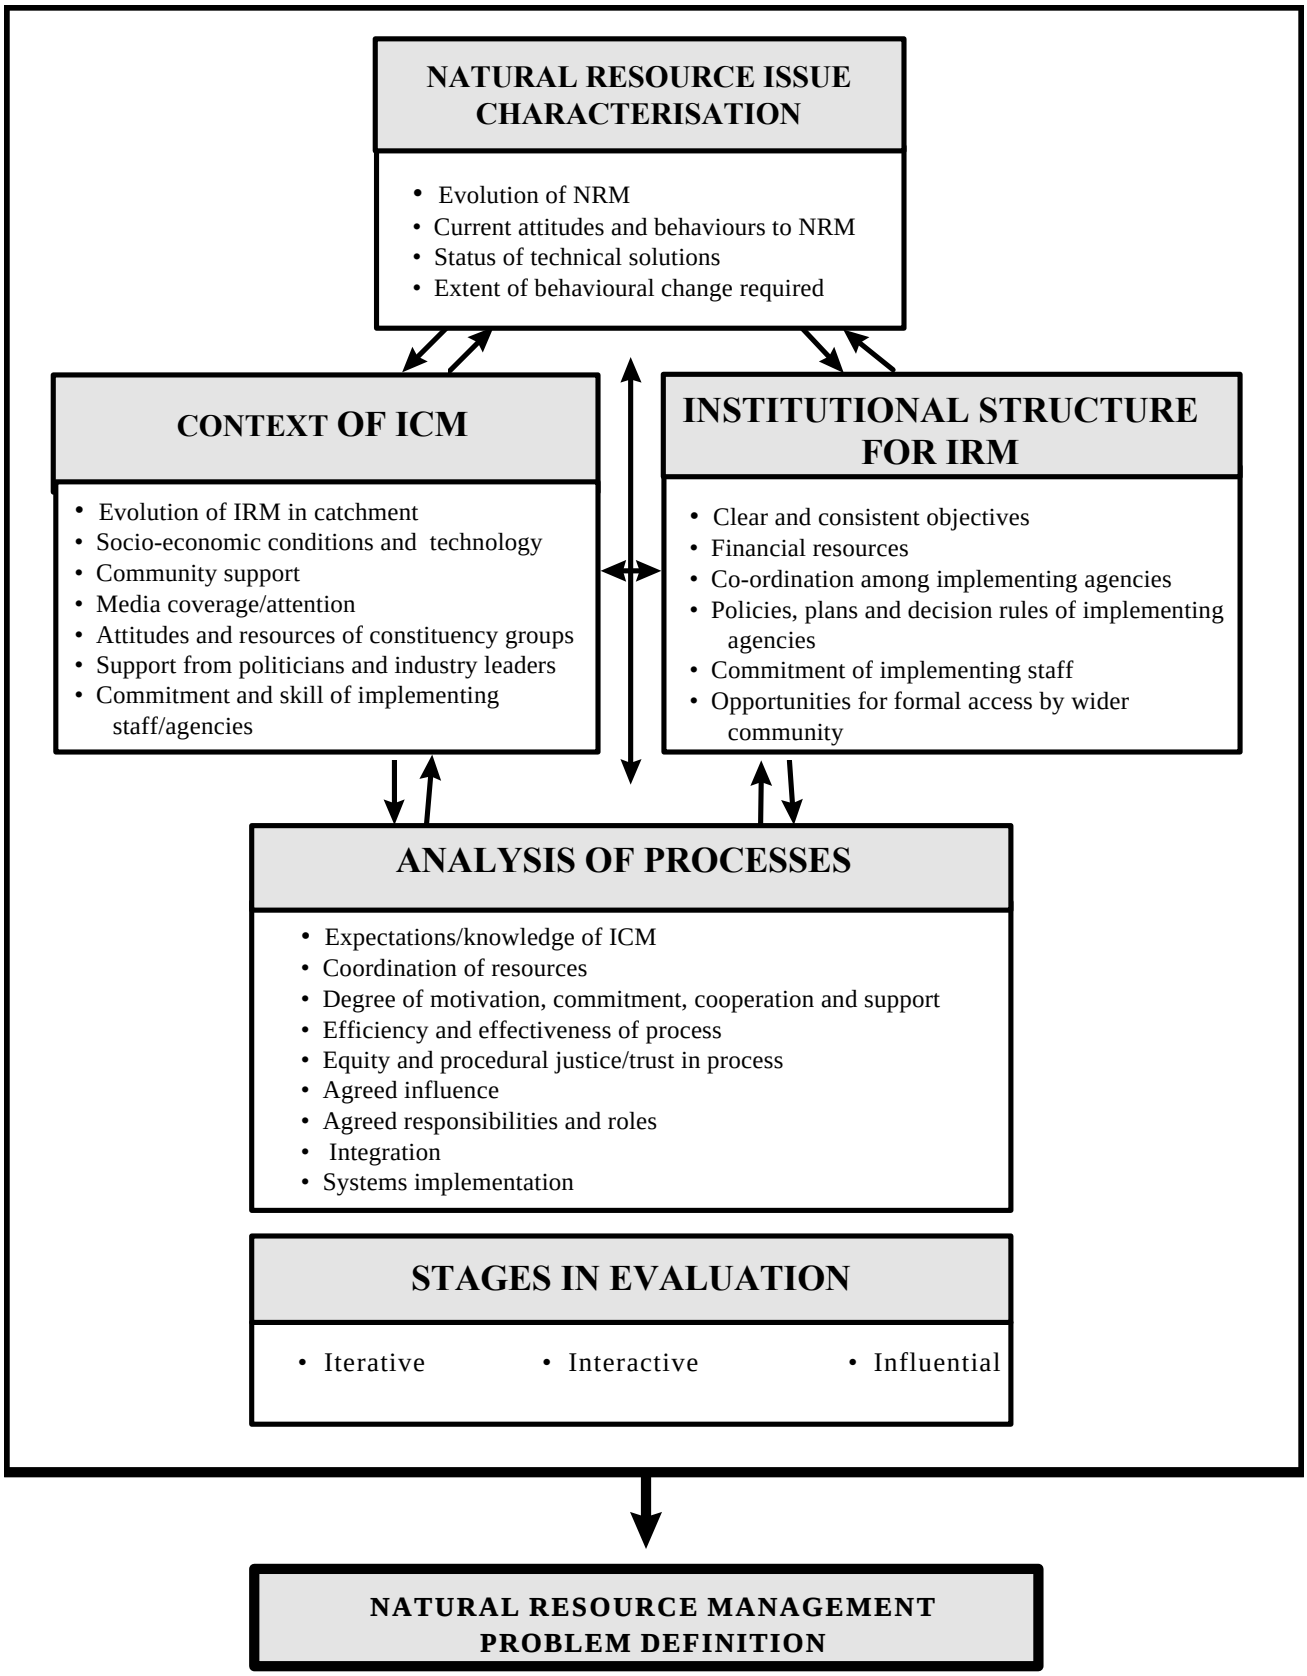

Figure 2. Conceptual framework for evaluating IRM programs.

Natural Resource Issue Characterisation

The first set of criteria aims to define and characterise natural resource issues and the context in which they came about. In particular it adapts and builds on the concept of the tractability of natural resource problems as identified in the Mazmanian-Sabatier framework (Mazmanian and Sabatier 1981; Sabatier 1986). The rational for this IRM component is that the natural resource, social and technological context of implementation will influence program performance and outcomes. The issue characterisation component of the framework therefore has four key criteria.

The evolution of natural resource use within the catchment: The importance of understanding an evaluation of a program or process within the historical natural resource, economic, institutional, social, and cultural context of resource use and management is well recognised.

Perspectives on natural resource use and management across stakeholder groups: The perspectives, expectations and behavioural responses on resource use and management may vary significantly across stakeholders and over time, and may be in conflict or contested by others. This means that the evaluation model must incorporate community as well as agency views.

Status of technical solutions: The technical knowledge base (ie. scientific, disciplinary and local expert) that can be brought to bear on the natural resource issues of concern and their community acceptability to guide substantive action is a key influence on the potential for achieving sustainability in practice.

Extent of behavioural change required: This criterion addresses natural resource issues in terms of the severity and extent of environmental threat, the number of persons responsible for its existence and management, the divergence in stakeholder opinions on the problem and its perceived solution, and how much the likely solutions are at variance from current practice.

IRM Program Context

The second set of criteria addresses to the specific circumstances and context in which the IRM program was initiated and has subsequently evolved. The following factors for evaluating the context of implementation of IRM may significantly influence the way IRM implementation proceeds, and determine the specific factors that are most likely to foster or hinder progress.

Evolution of IRM: The historical background to the initiation and development of an IRM program is an important contextual influence on its implementation.

Socio-economic conditions and technology: This criterion relates to the nature of, and variability in, socio-cultural and economic contexts within the catchment community and the capacity to change.

Community support: The community attitudes, perceptions, involvement and awareness of the IRM process can significantly influence the effectiveness of the IRM process.

Media coverage and attention: The nature and degree of media coverage on IRM and the environment in general may significantly influence stakeholder perspectives.

Attitudes and resources of constituency groups: This criterion addresses the nature of involvement of, and support provided by, community/interest groups and industry.

Support from politicians and industry leaders: Stakeholder perspectives and attitudes to natural resource issues can be significantly influenced by the opinions of, and support provided by, political and industry leaders.

Commitment and skills of implementing staff/agencies: The quality and capability of implementing staff and their supporting agencies is an important criterion.

Institutional Structure for IRM

The third set of criteria consider the organisational structures and processes for IRM. While the Mazmanian-Sabatier framework was created for evaluating statutory initiatives, the framework can be extended to a wider range of formal policies and programs as long as they are discrete and have explicit government proclamation. Proclamations state the policy decision being implemented and its objectives and program documents shape the implementation process by selecting the implementing agencies; by providing legal powers and financial resources to the agencies; and in diverse ways, influencing the commitment of implementing staff and the processes by which others may be involved. Closely following the Mazmanian-Sabatier framework, the following criteria for evaluating the institutional structure of IRM define the institutional conditions under which IRM programs are most likely to succeed.

Clear and consistent objectives: Objectives that are clearly worded and prioritised are essential to guide agency staff, others given key tasks (such as the catchment committees) and indeed to anyone potentially affected.

Finance: Although the relationship between ability to achieve program objectives and funding available finance is program dependent, at least some funding is necessary for program implementation.

Coordination: Coordination of the activities of agency programs and activities within and between levels of government and with community in general is a core requirement of IRM programs. Therefore one of the most important attributes of any program is the extent to which it can coordinate implementing agencies and activities of this diversity of interests.

Guidance to implementing agencies: The extent to which the program defines the processes, and as Mazmanian-Sabatier term, the "formal decision rules of the implementing agencies" will condition the progress of implementation. What are the implementers supposed to do - or is this undefined?

Staff commitment: Commitment of staff in the core implementing agency and those allied agencies that can substantially influence outcomes is essential to the success of programs.

Provisions for access by outsiders. The specification of an IRM program, its funding and staffing can influence the participation of external agencies, program target groups and the community. The key consideration is whether provisions have been made for adequate influence by community groups.

Analysis of Processes

The final set of influences, that is the community assessment component of the framework, aims to highlight factors that have the potential to influence the process of IRM implementation. For example, community awareness and attitudes towards land and water management and their links to existing levels of participation, intentions to participate and so on.

The rationale for this component of the evaluation framework is based on the basic premise that IRM - with its 'community-driven' emphasis - needs to be informed by the attitudes and actions of people living in the catchment or region of interest. Far from being passive recipients of natural resource management policy initiatives, different communities may show differing levels of involvement and commitment, and deal more effectively than others with any required change. For these reasons, 'recipes' for participation are untenable (Syme *et al.* 1994). Context is all important and, therefore, any method for evaluating processes should function in generic form, where proposed components are adapted to the situation at hand; that is, the particular catchment and program/policy being evaluated. The Processes component of the evaluation framework contains the following elements: expectations of the process by stakeholders, including the degree to which they are shared or separate; coordination of resources; degree of motivation, commitment, cooperation and support; efficiency and effectiveness of the process; equity and procedural justice / trust (in the process); agreed influence; agreed responsibilities and

roles; integration (that is degree of incorporation of processes in structure and context); and systems implementation.

Ideally the analysis of processes should cover all significant actors in the IRM process according to an overarching model such as PRIME (Syme *et al.* 1994). This model recognises that activities such as planning, research, implementation, monitoring and evaluation tend to occur simultaneously rather than in the rational order proposed by some natural resource programs. Therefore the evaluation process needs to deal with all activities simultaneously rather than sequentially. It provides a series of hypotheses for appropriate responsibilities and influence against which the evaluation can measure progress in a developmental context. Theoretically, this analysis can be done in a formative sense.

Implications for Integrated Resource Management

Approaches to natural resource management problems based on the integration of community involvement, technical knowledge, and organisational structure and policy objectives are endorsed throughout Australia. The emerging paradigm of resource management supports a more flexible and adaptive approach to address the uncertainty, complexity and interconnectedness associated with natural resource and human management systems. Operationalising these approaches to achieve sustainable development is proving to be a considerable challenge. There is not necessarily consensus on the emerging IRM paradigm as the solution to the problem. Evaluations of IRM programs can potentially contribute to a better understanding of the IRM process in terms of the technical and support needs, policy and institutional arrangements, and the community processes that need to be put in place.

The complexity associated with the evaluation of the effectiveness of IRM requires difficult trade-off decisions. Much of the difficulty arises because of the unique nature of natural resource programs in providing intangible services with broad social functions. In fact it is almost impossible to explicitly measure their fundamental impacts using traditional scientific methods of comparing the "with" and "without" scenarios. Evaluations are especially inhibited by: the separation in both space and time of cause and effect relationships in natural resource management; the fact that such programs are only 'one of many' influences on resource use and management such that attribution is a problem; and program objectives and goals that are often unrealistic or vague given the resources that have been committed to the program.

It should not be presumed however that IRM approaches are the best methods for achieving more sustainable use and management of our natural resources. Although conceptually appealing, they may not be the most effective or efficient approach. The fundamental questions evaluations need to address therefore include: Does integration work, ie. does it make a fundamental difference to the way resources are used and managed in the long term? What can realistically be expected of IRM approaches? If IRM approaches do work, what makes them work? What fosters or inhibits the IRM implementation process in terms of improving the severity or tractability of resource use problems? Or finally, how do they work best? That is, what are the necessary arrangements, procedures and processes that need to be put in place? This paper describes a logical framework that provides a tool for structuring a complex R&D approach to address these fundamental questions.

The evaluation framework is currently being tested in a five year longitudinal study being undertaken by a multi-disciplinary team of researchers in the context of a largely community-driven Integrated Catchment Management process in the Herbert River catchment of north Queensland. Researchers from different disciplinary backgrounds are addressing the four components of the framework simultaneously. The framework is being developed with the cooperation of the community of the catchment. The different perspectives are providing a more comprehensive understanding of IRM, as any one theoretical perspective will offer only a

partial view of such a complex process. Integrating the divergent views provides the opportunity to develop a new theoretical perspective that has a broader explanatory capacity than the initial disciplinary perspectives would provide in their own right. The challenge therefore is how to integrate the different disciplinary and community views on the evaluation of ICM, that is how to make an integrated evaluation. This is as difficult a process as it is for implementing IRM itself. Integration can be achieved if the different perspectives are seen as providing alternative 'worldviews' of IRM. We expect that the integration of the different community and disciplinary perspectives on the Herbert catchment case study may lead to modifications to the evaluation framework as it is presented here. Whatever evaluation model eventually emerges however will require testing for robustness or generality to ensure that more top down or legislatively-based IRM programs are also accommodated by the framework.

Notes

1. In seeking to explain variation in implementation success across programs and organisations, Mazmanian and Sabatier (1981) identified three sets of independent variables relating to: the tractability of the problem(s) being addressed by the statute; the ability of the statute to favourably structure the implementation process; and the net effect of a variety of non-statutory variables on the balance of support for the statutory objectives.

2. Crane (1988) identified a set of five assessment criteria for the evaluation of social policies which are equally relevant to natural resources program evaluation: inclusiveness; adequacy; equitableness; effectiveness/efficiency; and democratic involvement

Abstract

This paper provides a brief history of public policy and its administration in the primary industry sector in Australia. Major changes have occurred in the last decade, including the rise of Environmentally Sustainable Development as a focus for planning and implementation for Natural Resources Management. Increased community demand for input into policy and planning and decreased government resources devoted to policy implementation and institutional restructuring within government have been forces for change. These changes are demonstrated in the rise of the Landcare movement and community-oriented Integrated Catchment management programmes. Discussion pertaining to the successful implementation of these programmes identifies specific challenges concerning the effective vertical and horizontal integration of decision making among community, industry and government stakeholders. The tension between long term aspirations and short term decision making is explored. We suggest that a conceptual model for evaluation of policy implementation in this area is urgently needed and a tentative one is offered with suggestions about how to make it work. We conclude that, despite the problems associated with policy changes, the goal of environmental sustainability and changed government roles provide a major opportunity for the sugar industry. The concept of a 'green' sugar industry should provide a core platform for its operation in the next century.

Abstract

A brief analysis of the requirements in fostering mechanisms for the integration of recent and current research into decision-making is undertaken in this paper. This analysis is illustrated by some of the activities of the CSIRO Coastal Zone Program in north Queensland, particularly the development of a decision-support environment for addressing the off-site impacts of land use change and development of the Herbert Resource Information Centre. This collaborative and community-based resource is aimed at improving the basis of decision-making in natural resource and related management in the Herbert River Catchment.

Introduction

The 1992 Inter-governmental Agreement on the Environment commits all levels of government in Australia to achieving a balance between economic development and environmental integrity through the concept of Environmentally Sustainable Development. The impacts or potential impacts of increasingly intense natural resource exploitation in the coastal zone on the marine environment, the Great Barrier Reef being of particular note in north eastern Australia, are well recognised (Resource Assessment Commission, 1993). As a result, strategies are demanded that balance economic development in the coastal zone with downstream impacts, such as that on the marine environment (Brown, 1995).

Scientists traditionally respond to such challenges by advocating that further research is needed to fill gaps in our understanding. This reflects the pre-eminence of a belief system that asserts that there can be rational and objective management of natural resources (Lang, 1990; Funtowicz, and Ravetz, 1990 for a more general discussion). Indeed Boehmer-Christiansen (1994) asserts that "*The very success of physical and natural sciences … lies in the self-seeking belief which scientists (but few others) tend to share that there is a very direct link between more knowledge and appropriate action.*"

Continued research may be needed to enable more informed and appropriate management of natural resources at the terrestrial-marine interface in northern Australia. The rational scientific approach is increasingly being challenged by our greater understanding of the complexity and indeterminism of natural systems and by the apparent irrelevance of much research to decision-making (in as far as it often has minimal impact on practical resource management). Together these have eroded the belief that knowledge is all that is required. In order to more effectively integrate scientific understanding into the decision-making process, researchers are now seeking to understand the process itself.

In this paper, we propose that the adage that "further research is needed" provides scientists with little opportunity to have a positive impact on sustainable natural resource management. Only by being prepared to invest in understanding the context of decision-making and by finding novel ways of facilitating the uptake of past and future research by decision-makers can scientists hope to have a significant and consistent impact on practice. We explore this new role for R&D providers by reference to some current activities in integrated natural resource management at a catchment scale in the Herbert Catchment of North Queensland.

Limitations to the contribution of science to natural resource management

Research addressing natural resource management issues is based on an unwarranted confidence that it will lead to "objective and rational management of natural resources". This implies that there are demonstrably correct solutions to natural resource management problems; that is that we can achieve decisions based on unanswerable and irrefutable logic. This is naive, in that it does not recognise that natural resource management is *inherently* a political process in which different needs and interests are balanced. Where policy is presented as being based solely on scientific evidence, this is almost inevitably a politically expedient 'fig leaf' for more complex motivations and compromises (Boehmer-Christiansen, 1994). Effective natural resource management can occur without formal research but not without an effective political process.

Quite apart from the political nature of natural resource management, "objective and rational management" may often be unattainable. Science is itself a political process (though highly institutionalised), being based on attaining consensus amongst peers with the consensus achieved in ecology is generally more speculative than in physical sciences. Predicting processes at an ecosystem scale may simply be an intractable task since issues may be so complex and indeterminate that predictive understanding may be practically, or even theoretically, unattainable. Certainly, a strong case can be made that process-based understanding of ecosystem behaviour in response to stresses can often only be weakly predictive (Peters, 1991). Catchment scale resource management deals with complex ecological, social and economic interactions in a dynamic situation with long time-frames and often considerable separation between cause and effect and the potential for irreversible outcomes (e.g. Norton *et al.,* 1996). As a result, uncertainty and ignorance need to be managed and communicated so that they become recognised inputs to the decision-making process (Funtowicz and Ravetz, 1990; Costanza et al., 1992; Dovers, 1995).

In short, the traditional assumption that science can provide unambiguous answers becomes hard to defend when applied to natural resource management. Given the uncertain and complex nature of ecosystems, we have to accept that more scientific knowledge does not necessarily lead to better answers at a scale and within a timeframe appropriate for action.

Maximising the contribution of science to decision-making

While research rarely solves natural resource management problems, it clearly can contribute to their solution. We argue that, in order to optimise this contribution, researchers need to :

- understand the context of decision-making;
- understand and seek to facilitate the processes of analysis and synthesis for natural resource management; and
- seek to facilitate the integration of research outputs into these processes.

Understanding the decision-making context

The context of decision making encompasses legislative, economic, historical and social considerations. Knowledge and data are the fuel for the decision-making process in natural resource management, but the same fuel can be placed in different engines to quite different effect. A failure to appreciate context of application, the nature of the engine, is a recipe for irrelevant research.

Northern Australia has a history of limited planning and control. Government planning and management remains an anathema to many rural residents, particularly in the north. So, while effective natural resource management is agreed as being necessary, the process is politically unacceptable. At the same time, centralised government resources are being constantly reduced. In response to both these pressures, the State and Federal governments' preferred direction for natural resource management in northern Australia is towards negotiated and consensual management by multiple stakeholders and decision-makers (Brown, 1995). Initiatives such as Property Management Planning, LandCare and the Integrated Catchment Management (ICM) programme in Queensland are prominent examples of this ethos.

The participants in these initiatives have become major clients for research in rural north Queensland. However, in order to meet their needs, the processes themselves must be understood. What is required in, for example, understanding ICM as a decision-making context?

In October 1991, an Integrated Catchment Management Strategy for Queensland was released by the State Government. The Strategy is intended to provide a framework for fostering cooperation and coordination between landholders and other resource users, community groups and government agencies involved in the use and management of natural resources. It is

dependent on landholders, the community in general and government having a sound understanding of the interactions between natural resources and the need for a coordinated catchment-wide approach for addressing issues affecting these resources

To understand the implications of this initiative, we need to evaluate the process of implementation of ICM; to identify social, economic and institutional factors that facilitate or hinder this process, to evaluate the impacts in terms of attitude and behaviour and the tractability and severity of resource use conflicts and, thereby assess the specific technical and related information needs for effective ICM in a wet tropical environment. This demands consideration of the resource use and social history of a catchment, the legislative and institutional context of resource use, community and stakeholder attitudes and, of course, the nature, availability, distribution and use of current knowledge about relevant biophysical processes. A current multi-disciplinary project over five years is undertaking precisely this type of evaluation in the Herbert catchment of north Queensland.

Understanding and facilitating analysis and synthesis in natural resource management
If research providers can be criticised for failing to understand the context of application, they can also be criticised for failing to facilitate the uptake of existing knowledge. While there is much research relevant to catchment scale natural resource management in northern Australia that needs to be done, there is a lot that has been done already. This includes both formal research results and the vastly greater pool of experience of landholders, natural resource management professionals and the broader community. Much of this knowledge is, for one reason or another, inaccessible to those involved in the natural resource management decision-making process. Research providers should be able to re-package it to make it accessible, or provide the necessary tools to access and use it in its present form.

In 1995 a series of interviews were held with advisers from three state government agencies and industry working in the Herbert catchment of north Queensland. These interviews sought to characterise natural resource management tasks undertaken by these individuals at that time (see Walker and Johnson, 1996) and to obtain a broader perspective of the needs they had and constraints under which they operated in providing advice on natural resource management issues to decision makers such as local government. Some of the constraints and opportunities that they identified are described below under five headings that characterise steps in the process.

Step 1 - Problem formulation The activities of the advisers interviewed involved comparatively little routine work, but advisers were often faced with questions on quite new issues. As a result, one of the first problems faced by many advisers in addressing a new situation was - what is important here? What should I be considering? Addressing these questions demands a systems level view of biophysical issues, which is rarely effectively provided by research agencies. The challenge for research providers is how best to provide the information that advisers need to decide the issues that merit consideration in any particular context.

Step 2 - Task analysis Having decided on a range of issues that merit consideration, the adviser must decide how to address them. This requires an understanding of the level of accuracy and precision required, but also an understanding of the data resources and analytical tools available for use in analysis, and the limitations associated with these resources. Where does this information come from and who should provide it?

Step 3 - Data analysis Data analyses may take a number of forms. In many instances experience may be enough. In other instances accessing and interpreting data about a site may suffice. However, there will be instances where informed advice demands a more sophisticated analysis. Researchers can make a large contribution to the accessibility of data resources, both by expanding the natural resource data that is available and by developing means of allowing

potential users to find and interpret those data effectively. When advisers need to perform structured analyses, they are generally applying generic analytical tools that are research outputs to their particular instance. Researchers are accomplished at providing generic tools but less so when it comes to providing guidance in the application of those tools to site specific contexts. For example, any analytical tool will be based on a set of assumptions. These may be implicit or explicit but either way are often not effectively communicated to potential users.
Step 4 - Synthesis A response to a request for advice on a complex natural resource management issue will often require the synthesis of a range of analyses and arguments. A typical issue here was how best to integrate local knowledge and experience with more formal analyses of data, how to interpret the former in terms of the latter or *vice versa.* Research advances in systems perspectives on resource use are not easily accessible to practitioners.

Step 5 - Presentation The politics of natural resource management, particularly where contentious, put pressure on advisers for unambiguous answers. However, these will often not be available. Appropriate presentation of what is available and what it means is, therefore, very important (Funtowicz and Ravetz, 1990). Advice must be accessible and defendable. It must be presented at an appropriate levels of abstraction, for example predicting trends and presenting scenarios, rather than providing precise but quite possibly incorrect predictions. Uncertainties and assumptions must be clearly stated without undermining the advice. The data/knowledge must be plausible - particularly where using predictions as evidence.

Given the above requirements, the task of the professional natural resource manager is challenging. There are, however, many opportunities for research contributions. For example, the above analysis has underpinned the development of an advanced decision support environment for natural resource management called NRM Tools (Walker and Johnson, in press). The toolkit is designed to provide the flexibility of application demanded by users (Walker and Johnson, 1996) in combining and recombining analytical functionality to meet the demands of particular tasks. As such, NRM Tools is a powerful environment in which to package and deliver research outputs. NRM Tools provides a mechanism whereby decision makers can make use of quantitative models. It also provides means of delivering qualitative or semi-quantitative knowledge and guidelines produced by research by developing knowledge-based systems (most familiar in the form of expert systems) that can be integrated into decision-support tools. NRM Tools not only provides a means of making this analytical functionality more readily available to users, it also provides means of facilitating their use. In particular, modules are currently under development that *support* problem formulation ('I've been asked to comment on this change in resource management - what possible implications should I be considering?') and task analysis and tool construction ('I want to assess the implications of this land use change on water quality and flooding risks - what data and analytical tools do I have to help me do this?').

Facilitating the uptake of research outputs
Research initiatives such as the development of NRM Tools add value to biophysical research in making it available to managers. However, this is only true where the technologies upon which such outputs are based are themselves accessible. They may often not be. Here again, there are opportunities for researchers.

The Herbert Resource Information Centre (the HRIC) was established because many such decision makers in the Herbert River catchment did not have adequate access to basic information about the catchment. The HRIC is a community-based and collaborative joint-venture which integrates a large range of high quality data about the Herbert catchment into a GIS (Geographic Information System). The partners to the HRIC are the Hinchinbrook Shire Council, CSR (the sugar milling company in the catchment), the Herbert Productivity Board, the Queensland Department of Natural Resources and CSIRO. Two Centre staff manage the data

sets and undertake advanced analyses as required. Much routine analysis is undertaken directly by staff in the participating organisations.

As well as introducing GIS to the catchment, and thereby providing much more effective access to the range of data available about the catchment than was previously available, the HRIC provides both the technical requirements and ethos required for the use of NRM Tools by managers within the catchment. CSIRO's involvement in this project has, therefore, both been of benefit in establishing a resource that is useful in its own right and has fostered a context for uptake of research outputs, in this case NRM Tools.

The HRIC provides a context in which data, scientific knowledge and method can be better integrated into local political processes by local people. The collaborative nature of the centre can be expected to have an impact on the flow of information and the course of debate in the catchment.

Conclusions

The creation of new knowledge usually involves institutions that are different from those concerned with its application and dissemination. However, what is clearly increasingly required is that the former better understand the latter if they intend to justify their existence in terms of impact on natural resource management rather than advancement of knowledge *per se*. Boehmer-Christiansen (1994) identified seven ways that experts can further their own interests in policy development. The first three of these are : emphasise uncertainty and incompleteness of knowledge; emphasise complexity and difficulty; emphasise threats that can be tackled with more science and technology. We would suggest that the reality of natural resource management in the 1990s means that these strategies are a fast-track to irrelevance. We suggest it is far better to invest effort in exploring techniques by which scientific expertise can be transformed into information relevant to natural resource management.

Science is often more comfortable in providing advice on what ought to be done and why, rather than practical advice on how it might be achieved (Boehmer-Christiansen, 1994). Initiatives such as the NRM Tools and HRIC are designed to provide practitioners with access to scientific resources which they can then apply to the "how" problem. Our vision is one in which data, knowledge and scientific judgements of that data / knowledge can all be made available for integration into a negotiation process that attempts to deal with inherent uncertainty. Therefore, there is a considerable focus on communication of the principles, values and assumptions underlying analyses. Ideally initiatives such as NRM Tools and HRIC should ultimately lead to co-design of research in which researchers and local stakeholders interact to explore the extent to which applied science can make a contribution to effective and sustainable natural resource management.

Abstract
The operational reality behind the rhetoric of integrated natural resource management poses significant challenges for resource managers, resource use planners and research scientists. A variety of frameworks for integrated resource planning and use have been espoused. These tend to reflect the bias of the discipline or stakeholder group fostering the approach and may therefore be unpalatable to, and ignored by, other groups. In this paper, we are concerned with improved integration of research outcomes into decision making. Rather than propose a framework, we take a pragmatic view of the roles of managers, planners and scientists. In doing so, we draw principally on practical experience derived from a series of initiatives in a rural catchment in tropical Australia. On this basis, we argue for a particular and emerging role for a 'decision support systematist' in designing approaches to adaptive decision support that provide real opportunities for integrating research outcomes into decision-making.

Introduction

While the global imperative to achieve ecologically sustainable development has become something of a truism, the particular problems associated with operationalising this imperative are far from resolved. Management scale is one such challenge. Off-site impacts, cumulative impacts and other externalities have precipitated interest in seeking more effective natural resource use, management and planning at diverse geographic (enterprise, catchment, and regional) and temporal scales (or within what Gunderson *et al.,* 1995b:522-3, have called panarchies) such that the impacts of actions at any one level of operation in the hierarchy of spatial and temporal scales can be managed at other levels. Such initiatives pose substantial methodological and operational challenges, and provide a significant opportunity for research and development (R&D) initiatives.

The requirement for integration across multiple scales generates a "convergence zone" for a range of different resource management paradigms. Thus, catchment or regional-scale natural resource management is strongly influenced by experience in, and approaches to sustainable resource management at an enterprise scale (as in Farming Systems Research and Extension); approaches to resource use planning at a broader, traditionally agency-driven, scale (as in regional resource use planning); while an increasing emphasis on management of the environmental impacts of resource use exploitation has lead to growing interest in ecologically-based methods such as adaptive management. While valuable, these approaches modify theory and practice from disciplines with different objectives operating at different spatial scales. In effect, they attempt to fill a disciplinary void in approaches to integrated resource use and management through adaptation of precepts developed in quite different contexts. This convergence and adaptation is manifest in the pragmatic realities of initiatives seeking to foster improved integration of natural resource management activities at a catchment scale.

Notably, all three disciplines mentioned (FSR/E, regional resource use planning and adaptive management) have been strongly influenced in recent decades by the growing influence of more participatory approaches to management activities than traditionally applied. At the enterprise level, the shift from a linear 'science-push' technology transfer model for agricultural R&D to the FSR/E paradigm has been enormously influential (Chambers, 1992). Participative democracy has concomitantly emerged as an increasingly influential paradigm in the evolution of approaches to resource use planning in the post-war period. Traditionally, most decision-making in planning has been vested with regulatory authorities. However, in recent years policy in many countries has increasingly sought to involve the community in the decision-making process, on the premise that more robust and workable solutions will eventuate (Hyman & Stiflel, 1988). Similarly, adaptive management has progressed from an expert-based process relying primarily on extensive quantitative modelling to a more inclusive and participatory paradigm (Dovers & Mobbs, 1997). Assumptions about what is required to achieve sustainable resource use, particularly the role of technocrats, resource users and the broader community in resource use decision-making have been challenged accordingly.

Thus, the move towards community-driven natural resource management at a range of scales that integrates impacts at the enterprise (e.g. farm) level up to the regional has implications for roles and relationships between the diversity of stakeholders operating across these scales. In this paper, we explore these roles and responsibilities, with a particular emphasis on the integration of increments to understanding gained through research initiatives into the decision-making process. Our assessment is based on consideration of our experience in a set of research-based initiatives in a rural catchment in tropical Australia. Lessons from this experience lead us to propose that the requirements of integrated resource management and planning generate a critical role for natural resource professionals concerned with designing tools, methods and structures for integration. We propose the term 'decision support systematist' to describe this emerging role.

Context – The Herbert River Catchment

The Herbert River catchment drains an area of approximately 10 000 km^2 in Australia's sub-humid to humid tropical north east (lat. 15-19^0 S, long. 145-146^0 E) to the Coral Sea. Large areas of the catchment remain under natural vegetation (much managed for extensive cattle grazing), although approximately 35 to 40% of the coastal lowland area has been cleared for crop production or improved pastures. The catchment has a population of approximately 21 000 and is bounded by two World Heritage listed areas, the rainforests of the Wet Tropics on the steeper slopes of the central catchment and the Great Barrier Reef immediately adjacent to the catchment.

The area has experienced, and continues to experience, strong economic growth underpinned predominantly by its agricultural and tourist sectors. The sugar industry dominates the local economy with 70 000 ha of production and two sugar mills producing (Aus) $ 235 million worth of sugar in 1996/7. A plethora of government and statutory industry agencies claim, or are assigned, responsibility for different aspects of the management of the catchment and a number of agencies also contribute to management through the provision of research and development outputs and expertise.

The Herbert catchment, like many other parts of Australia's coastal zone, is a major focus of competition between alternative uses of resources with competition between agriculture, forestry, conservation, tourist and recreational uses, urban encroachment, public utilities and hobby farms. Growing competition has occurred in the context of increasing community expectation for the preservation of the natural environment, involvement in decision-making and effective conflict resolution.

The sugar industry has the potential for significant environmental impacts in the Herbert catchment (Johnson *et al.,* 1998). Soil erosion is recognised as a potential threat to long-term productivity, although the adoption of green cane harvesting-minimum tillage practices has been an important step in decreasing sediment supply to the coastal zone from sugar cane lands. Considerable areas of the riparian vegetation have been removed from the stream banks in sugar cane growing regions. Large areas of riverine rainforest with patches of eucalypts and the riverine rainforest have also been cleared. The wetlands, swamps, billabongs and waterholes of coastal areas are important wildlife habitat areas and form an integral part of a hydrological regime. Clearing for sugarcane has significantly reduced the area of this habitat. Potential exists for diffuse source pollution to generate water quality problems in both ground and surface waters. This has been perceived to be of particular concern given the adjacency of the Great Barrier Reef.

Growing concern about potential environmental impact is balanced by a recognition of the regional and national importance of an economically vibrant sugar industry. The economic terms-of-trade of the sugar industry and competing land uses are under pressure due to the

influence of increasing global competition, meaning that increased areas and yields are required in order to remain internationally competitive.

In order to achieve and maintain ecological and economic sustainability within the Herbert catchment, effective means of managing and reconciling industry imperatives at the farm and regional scales with the requirements of other users of the catchment (including conservation and environmental services) are required. In recognition of such issues, Governments have sought to implement integrated approaches to resource management to avoid the environmental and social damage sustained by conflicts in land use has gained prominence. In the Herbert, this has included for example, an Integrated Catchment Management program (Anon, 1991). In practice, the effectiveness of such initiatives is often constrained by a paucity of data at spatial and temporal scales relevant to decision-making, poor co-ordination or communication between participating stakeholders, limits to the data processing and analytical capabilities of participants in the decision-making process, and a poor understanding of key issues in sustainable resource use.

Case Study : Integrating R&D into decision-making in the Herbert River Catchment

In 1992, the CSIRO (Commonwealth Scientific and Industrial Research Organisation) initiated research in the Herbert catchment to assess the implications of land use change and land management strategies in the catchment with a particular emphasis on water quality. This initiative involved significant biophysical research (see e.g. Mitchell *et al.*, 1996) but also incorporated the development of a decision support system (DSS) to integrate the outputs of this research into decision making. In practice, what appeared to be a focussed and predominantly technical objective in the development of decision support (Walker & Johnson, 1996b) evolved into a much more substantial activity.

The research started from the premise that a technical decision support approach was warranted. However, the literature demonstrates that only a small proportion of decision support systems for resource management achieve operational uptake. The research group were, therefore, particularly concerned with balancing scientific with operational applicability. We therefore sought to:

- design tools, methods or structures for decision support that were adapted to the decision-making context;
- undertake capacity building to facilitate the application of new tools and ways of thinking to new problems in integrated resource management; and
- develop effective means of evaluating the impact of the process and product on decision-making.

These requirements were considered to be mutually dependent, thereby dictating the broad project lifecycle presented in Figure 1. In this section we recount this experience in integrating R&D into decision making before considering implications for scientists, planners and resource managers.

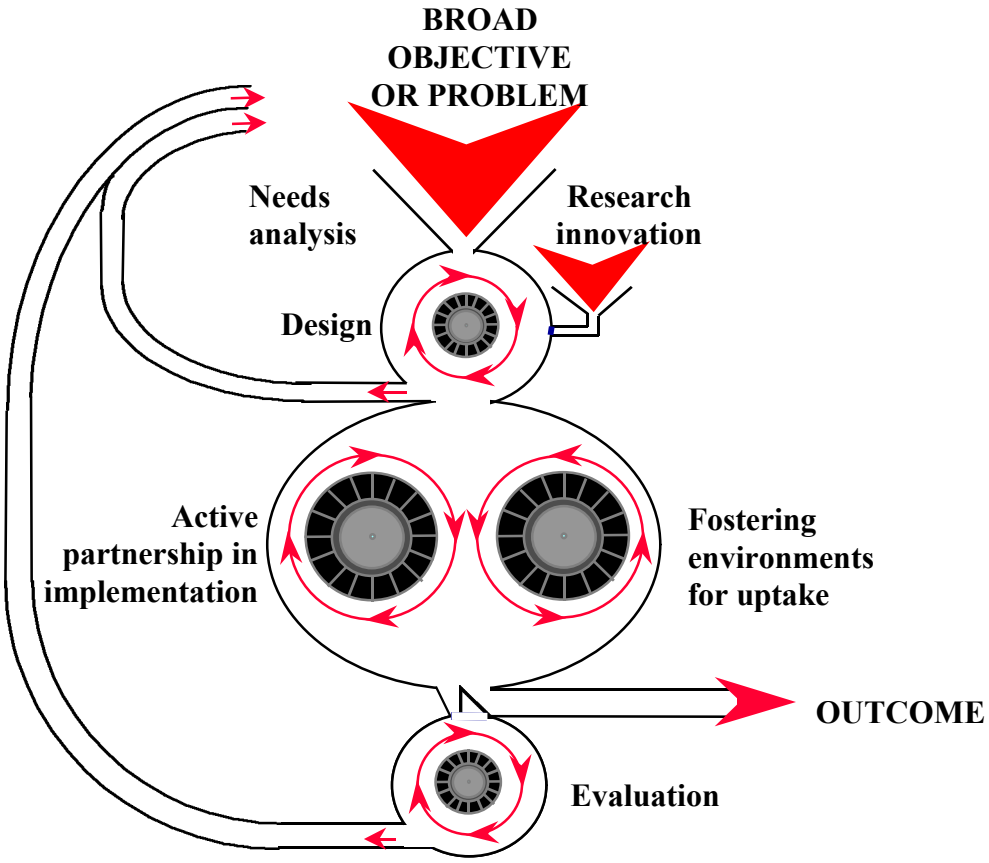

Figure 1 : A schematic presentation of the project lifecycle.

Designing appropriate interventions

The design of tools, methods or structures adapted to the decision-making context demanded the integration of a needs analysis process with technical and research innovation. For a project group with a research bias, the needs analysis process was a significant departure from standard practice.

Investigation of context as a basis for the design of R&D-based interventions is a well developed and widely applied process in many disciplines, including, for example, Rapid Rural Appraisal and the many associated methodologies that parallel, or have evolved from, RRA(Chambers, 1992). There was, however, a particular challenge to be faced in the establishment of interventions for natural resource management in the Herbert catchment. Such interventions were being developed for application in circumstances in which there was no tradition of substantive resource management at the scales (spatial and temporal) necessitated by the dictates of ecologically sustainable development. Therefore, the research group was faced with the challenge of investigating a decision-making context in which current structures and processes were acknowledged as inadequate and a substantial objective of the research process was their improvement.

This experience is by no means unique to our experience in the Herbert and may be a general feature of interventions for integrated resource management at a catchment scale. For example, in companion work to identify the opportunity for developing and delivering decision support systems in support of a regional resource planning project in the Central Highland of Queensland, Australia, Zhu and Dale (in review) had to apply a soft systems methodology (Checkland & Scholes, 1990). They did so in order to consider developing conceptual models of current practice, thereby providing a basis for designing desirable and feasible changes that might

be precipitated by the development and delivery of appropriate decision support systems (Zhu & Dale, in review).

Once the present context, the vision of the desired context and, thereby, potential R&D based interventions have been identified, it may often be possible to test the appropriateness and viability of proposed interventions through a formal, hypothesis-based analysis. The primary technical intervention that we developed for resource use planning in the Herbert catchment was called NRMtools. The broad design specifications of NRMtools, were formally tested before detailed design and prototyping was undertaken through interviews with a range of potential users to characterise current tasks, their context, constraints encountered and the viability of initiating a DSS –based solution (Walker & Johnson, 1996a).

This process substantially altered the course of the project. Thus, early scoping revealed that decision-making in the context of catchment management was characterised by the occurrence of many occasional or one-off tasks rather than routine, frequent and standardised processes. As a result, planning and action tended to involve the intuitive and highly flexible combination of available data and understanding, and use of techniques for synthesis and interpretation to meet a broad range of objectives. A decision support system focused solely on, for example, the impact of land use change on water quality, was seen to be of limited relevance in that it only provided a means of addressing one issue amongst many. Furthermore, a broad range of spatial and temporal scales was considered relevant and a complex and evolving legislative environment was described. As a consequence, while a potential role for decision support for helping to deal with this complexity was evident, it was not clear that a single system would meet a useful proportion of requirements. As a result, rather than a decision support system specifically and restrictively focussed on, for example, water quality issues, it was proposed that an attempt should be made to develop a broader and more flexible toolkit-based approach. This conceptual design (i.e. the research innovation) was formally tested through a further interview-based process (Walker and Johnson, 1996a).

Capacity building

It was apparent from the relationship established with potential users that the decision support tool under development for the Herbert potentially fulfilled a significant role in resource use planning in the catchment but that it was unlikely to be adopted given the existing capacity – in terms of data, information technology infrastructure, technical skills and decision-making structures – in the catchment. As well as developing the analytical tools, a concomitant investment in capacity building in the catchment was therefore required.

Johnson and Walker (1996) describe the approach used to facilitate the development and implementation of a collaborative Geographic Information Systems (GIS) facility involving industry, community, government and research agencies in the Herbert – the Herbert Resource Information Centre (HRIC). Geographic Information Systems have demonstrated capability to improve decision-making in resource management and underpin many of the decision support technologies for catchment scale management.

Development and implementation of the HRIC involved significant investment of time and resources on the part of stakeholders. Over a two year period, six stakeholders in the catchment (CSR Sugar Mills, Herbert Cane Protection and Productivity Board, Hinchinbrook Shire Council, Canegrowers Herbert River Executive, CSIRO and the Queensland Department of Natural Resources) developed a 10-year collaborative agreement to formally establish the HRIC. The agreement secured the financial and non-financial (in-kind) support of the stakeholders and bound them to support the HRIC's foundation philosophy of being a non-profit, community based collaborative GIS facility designed to support ecologically sustainable development in the Herbert catchment. The HRIC is staffed by 2 full time GIS specialists, whose role is to provide high level expertise and skills to facilitate the collection, storage, maintenance and analysis of natural resource data. Their role is also to ensure the products of these activities are delivered in

an efficient and timely manner to HRIC stakeholders. As such the HRIC offers a bureau service to its stakeholders, provides free GIS consultancy and project management skills and acts as a conduit for the transfer of relevant R&D products.

This initiative was a significant undertaking for a rural community. The CSIRO research team played a critical role in instigating and facilitating the initiative, including provision of technical inputs such needs and cost benefit analyses (Johnson and Walker, 1997). This role took us outside the normal activities of a scientific research group but was a critical contribution that could not have easily been made by the resource managers or planners working in the catchment.

Evaluation of process and product
The objectives of the HRIC can be summarised as:

- improved quality of data available for the Herbert catchment;
- improved access to data;
- better informed decisions in planning and implementing data collection and use projects;
- better informed decisions in natural resource management; and,
- improved collaboration.

The process of evaluating progress against these objectives fell beyond the remit and expertise of the resource managers and planners whose collaboration underpins the HRIC. As a consequence, the research team undertook a formal evaluation process which addressed the above objectives and also provided for the evaluation of less tangible aspects in relation to changed perceptions, attitudes, understanding and behaviour, particularly in relation to collaboration between groups, as a consequence of involvement in the HRIC.

The evaluation was conducted using qualitative research techniques. Individual, face-to-face interviews using a semi-structured interview schedule were conducted with key participants in the HRIC each year over three years. In the first round of interviews, anticipated impacts were elicited. In the second and third rounds, anticipated and actual impacts to date were elicited. At the end of the three-year period, the entire data set was entered into a qualitative data analysis package and tagged against key evaluative criteria providing a basis for a qualitative analysis. The evaluation is reported in full in Walker et al., 1998.

As well as providing a detailed assessment of progress as a management tool, the evaluation provided valuable insights into the applicability of this case study as a model for other catchments. While many regional planning activities promote a consultation process, few have been successful in devolving the decision-making capacity (as opposed to mandate alone) to the community. The HRIC is an example in which community groups have control and ownership of resource information. As such, the HRIC has generated significant interest and is widely viewed as a model for similar initiatives elsewhere. The local partners to the HRIC do not have the remit to evaluate the applicability of their experience to other areas and to extend the results. This role is increasingly falling back on the CSIRO research team (see Walker et al. 1998 for examples of such evaluation).

Lessons learnt : roles in integrated resource management

The preceding narrative describes our experience as a research team established to contribute to the resolution of catchment scale issues in integrated resource use through traditional science-based R&D. We have found that over a five year period that we have come to play quite a different role. In the remainder of this paper we examine this new role and discuss its implications for the conduct of R&D in integrated resource use and management.
We have already stated that integrated resource use and management represents a convergence zone for a range of disciplines. The convergence of practice and a range of theoretical

perspectives in integrated approaches to regional natural resource management provides opportunities for synergies (although in practice competition for 'territory' is often more evident). In particular, disciplinary diversity allows 'triangulation' of theory and methods to make effective use of complementarity between different disciplines – particularly in ameliorating the flaws of any one perspective or methodological approach (Yin, 1994). Nevertheless, the lack of a common and agreed theoretical basis suggests that integrated natural resource management is a domain more of praxis (integrating interpretation, empirical research, dialectic analysis and practical action – Lather 1986) than a disciplinary domain with a potential unitary theoretical basis. We argue, therefore, that the adaptive core of integrated resource management should remain as a shared objective and ethos (or paradigm in the strict sense) in which Yin's triangulation can occur, but should not be formalised. We propose that from a pragmatic and theoretical perspective, approaches to integrated resource use and management might best be considered from the perspective of tasks, roles and requirements. For the sake of discussion, we distinguish four broad categories of activity which equate broadly (but imperfectly) to four categories of 'actor' widely recognised as being involved in integrated resource management at a catchment scale. We will then present the case for a fifth role that we came to fill in our research in the Herbert. Our four categories are as follows.

- **Resource use** The activities of industry and community in interfacing with the resource base.
- **Resource management** We use the term Resource Management here to refer to the operational control of resource use activities as undertaken by managers within Government departments and resource managers within the private and community sector (including primary producers). Resource managers are, therefore, the clients for the integrated R&D products discussed here.
- **Planning** The planning function has traditionally been the domain of professional planners. However, the evolution of planning theory and practice has substantially broadened and redefined this role, such that the resource use planning undertaken by individuals with no formal planning background, who may not even recognise their activities as planning, is being increasingly recognised and fostered in policy. Thus individuals who would be described as activists or facilitators in a farming systems context are, at a catchment or landscape scale, performing a planning function.
- **Incrementing understanding of the systems being managed** Scientific rarely solves resource management problems, but can clearly contribute to their solution. As the domain of the professional scientist (including socio-economic as well as biophysical researchers), advancing understanding of the systems being managed is frequently the activity most removed from decision-making. However, participatory research method and a growing recognition of the role of local knowledge mean that an increasingly inclusive view of opportunities for incrementing knowledge is becoming recognised.

With the exception of the resource user, these categories may be viewed either as activities in integrated resource management or disciplines and professions that play a role in the process. This duality reflects the value and role of strong professional associations and the reality that professional monopolies on research, planning and resource management potentially inefficient and anti-democratic. Scientists, planners and resource managers are recognised occupations with professional and institutional structures that foster efficacy and rigour. While valuable, these structures provide challenges for integrated approaches. This is analogous to the conflict between participatory research and academic success (Cancian, 1993). Furthermore, it is axiomatic that increasingly participative approaches to resource use planning require community representatives to assume some research, planning and management roles.

Our needs analysis in the Herbert context clearly illustrated the general observation that, whether achieved through legislative control or self-regulation through participative policy, approaches to integrated resource use and management in an attempt to achieve ecologically sustainable development significantly complicate the activities of the resource user or manager.

Management for sustainability, both on-site and off-site, is inherently more complex than managing solely for maximum productivity or conservation. More facets of the resource base need to be monitored and managed, and a more holistic view of the range of potential impacts - particularly cumulative impacts - must be considered. In short, a complex system of interactions must be managed for multiple rather than single objectives.
In order to make defendable and effective decisions, resource managers and planners require:

- effective access to information pertinent to resource use and its impacts;
- the 'tools' to make effective use of that information;
- the capacity to make appropriate use of those information and tools;
- an appropriate decision-making environment (including legislative and institutional structures); and
- effective means of evaluating the outcomes of decisions made and planning activities and processes used.

The adoption of participatory approaches to resource management and the increasing complexity of the domain of resources being managed and the objectives associated with their management, extend the range of pertinent information, the range of tools required and the skills needed to use them. Much of this increase in complexity can be attributed to the expectation that resources can be managed effectively at multiple spatial and temporal scales. This places demands on managers, planners and scientists to take a highly integrated and comprehensive view. As discussed in the next section, they may struggle to fulfil these demands without the contributions of the decision support systematist.

Role and requirements : the natural manager

As decision-making becomes a more complex process addressing more complex issues such that a broader domain of information needs to be considered, managers are increasingly likely to lack the necessary expertise, and, therefore, capacity to make use of this expanded range of information and the tools to process it. Thus, in assessing options for expanding the area of cane production in the Herbert, the sugar industry which has traditionally have been able to assess land use suitability and economic viability on the basis of experience and local knowledge, is expected to investigate a much broader range of issues such as potential off-site impacts and cumulative degradation to the resource base at spatial and temporal scales beyond traditional expertise – necessitating the development of new skills to consider new information and apply new ways of thinking to consideration of that information. Given that sustainable resource management is the application of the outcomes of resource use planning processes, which are inherently political in that they balance the needs and interests of different stakeholders, the challenges associated with these changing requirements have significant implications for relationships between stakeholders. In consequence, these changes can be a significant source of stress for both individuals and communities.

This has important implications for the integration of R&D into decision-making for catchment or regional scale natural resource management. Our experience in the Herbert demonstrates that one of the constraints to moving towards ecologically sustainable development in the context of rural resource management is the capacity for resource users and managers to make the necessary shifts in their ways of operating. An external agency may be required to facilitate this transition as in our role in the Herbert. This includes :

- development of means of providing effective access to the broad range of technical data, local knowledge and process information that might be germane to decision-making;
- the development of operationally applicable tools for analysing (or 'ways of thinking about') the potential impacts of resource use in contexts in which testable predictions may be practically (or even theoretically) impossible; and
- a role in building the capacity to bring these into existing and evolving decision-making processes.

Role and contributions : the planner

A common assumption is that 'planners' belong to a discrete profession, and are most frequently employed within government agencies. Further, it is widely assumed that the enterprise of planning, despite recognition of inequities in planning process, is largely centrally driven in response to regional need. However, understanding of the planner and the planner's role is looking increasingly beyond state agencies to include both community and capital (after Alexander 1994) such that, "...planning is a general approach to decision making and is not tied to the activities of any profession or department of government." (Faludi, 1973:3).

It is useful to track the evolution of the planners role, at least in the body of theory, and of the planner themselves over the last half century. As with any of the 'professions', planning has undergone a substantial intellectual revision removing the modernist assumption of the technocratic planner maintaining critical distance, preparing blueprints for society to follow. Although this perspective remains, a necessary response to the challenges wrought by recognition of structural (power) and rational (knowledge) inequities in planning process has been the redefinition of the planner away from agency, programmatic characterisations toward multiple actor and role definitions. The planner is now *inter alia* technician, administrator, mobiliser, mediator, entrepreneur, advocate, adviser, interpreter, communicator, each emerging in response to the planning context. Each of these roles carries with it specific skills, with the agency planner in a regional context expected to fulfil each and frequently all. Far from remaining a specific disciplinary field, planning is therefore increasingly having to internalise inter-disciplinary perspectives and functions. The development of methodologies to accurately reflect community preference in the planning process, other than through a review of draft plans, is perhaps the most significant ongoing aspect of this transformation.

Where the resource user/manager/community representative is cast in the role of planner, the requirements are less clear. Nevertheless, both for agency-based and community-based planners (as in the Herbert) a key issue relates to access to appropriate tools (technical, information, language) to facilitate the planning process, and the integration of planning perspectives arising at multiple stakeholder scales. From the perspective of integrating R&D into decision making, the planner must play a key role in informing the research agendas and in linking the outputs into the broader set of activities that comprise the planning process. However, the range of demands already on the planners means that they are unlikely to have the capacity to integrate 'raw' research outputs into forms appropriate for inclusion in the planning process.

Role and contributions : the scientist

We argue that the research scientist is also not best placed to undertake this role of integration. Research addressing natural resource management issues is often based on an unwarranted confidence that it will lead to "objective and rational management of natural resources". This implies that there are demonstrably correct discrete solutions to natural resource management problems; that is that we can achieve management outcomes based on irrefutable logic. This reflects the pre-eminence of a belief system that asserts that there can be rational and objective management of natural resources (Lang, 1990; Funtowicz and Ravetz, 1990 for a more general discussion). This view probably persists more usefully in science than in planning or management. Indeed Boehmer-Christiansen (1994) asserts that "*The very success of physical and natural sciences … lies in the self-seeking belief which scientists (but few others) tend to share that there is a very direct link between more knowledge and appropriate action.*" The view of the role of science that Boehmer-Christiansen identifies is naive, in that effective natural resource management can occur without formal research but not without an effective political process.

Quite apart from the political nature of natural resource management, "objective and rational management" may often be unattainable. The scientific consensus achieved in ecology and

resource management is generally more speculative than in physical sciences. Predicting processes at an ecosystem scale may simply be an intractable task since issues may be so complex and indeterminate that predictive understanding may be practically, or even theoretically, unattainable (Oreskes *et al.*, 1994). Certainly, a strong case can be made that process-based understanding of ecosystem behaviour in response to stresses can often only be weakly predictive (Peters, 1991). Catchment scale resource management deals with complex ecological, social and economic interactions in a dynamic situation with long time-frames and often considerable separation between cause and effect and the potential for irreversible outcomes (e.g. Norton *et al.,* 1996). In short, the traditional assumption that science can provide unambiguous answers becomes hard to defend when applied to natural resource management. Given the uncertain and complex nature of ecosystems, we have to accept that more scientific knowledge does not necessarily lead to better answers at a scale and within a timeframe appropriate for action. As a result, uncertainty and ignorance need to be managed and communicated so that they become recognised inputs to the decision-making process (Funtowicz and Ravetz, 1990; Costanza et al., 1992; Dovers, 1995).

Nevertheless, the challenge to the rational scientific approach resulting from greater understanding of the complexity and indeterminism of natural systems and from the apparent irrelevance of much research to decision-making (in as far as it often has minimal impact on practical resource management) may have dangerous consequences. While research rarely solves natural resource management problems, it clearly can contribute to their solution. The adage that "further research is needed" may have provided scientists with little opportunity to have a positive impact on sustainable natural resource management in the past. However, undermining the scientific process by demanding that scientist become participatory, political or post-modern may seriously undermine the ability of the scientific establishment to make valuable contributions to resource management issues. So, while scientists must be prepared to invest in understanding the context of decision-making and its implications for R&D (see, e.g. Barnes et al., 1997 for an example based on our work in the Herbert) they are not necessarily productively placed as integrators and facilitators.

An emerging role: The development of adaptive mechanisms for decision support.

The key thesis in this paper is that the process of integration of R&D outputs and the development of adaptive mechanisms for decision support is an increasingly important activity in seeking inclusive, equitable and defendable decisions in resource allocation. In the previous section we have argued, on the basis of our experience in the Herbert, that this role is distinctly different to those of manager, planner or scientist and not one that sits appropriately within any of these categories. The objective is to design methods, tools and structures for the synthesis of information (including data and knowledge about systems function) into integrated resource management activities. In resource management for single objectives (whether of productivity or conservation) this would equate to technology transfer or extension. However, in the context of planning in complex environments with multiple competing objectives, this role becomes quite different. We propose that it involves the development of integrative tools or methods to support decision making but also a role in capacity building in the use of such tools or methods and the provision of evaluative processes for tracking their role and impact. Our experience in the Herbert, as reported here, illustrates each of these functions. For the purposes of discussion, we describe this as the domain of the 'decision support systematist'. This term is intended to reflect a decision-centred approach to decision support, which takes a much broader view of means-to-an-end but includes, *inter alia*, the development of effective means of integrating research output into decision-making process.

Discussion and Conclusions

Science is often more comfortable in providing advice on what ought to be done and why, rather than practical advice on how it might be achieved (Boehmer-Christiansen, 1994). Our work in the Herbert has led us to focus particularly on this latter challenge. The design of adaptive decision support mechanisms through initiatives such as the NRMtools and HRIC is intended to provide practitioners with access to scientific resources which they can then apply to the "how" problem. The challenge for the decision support systematist is to develop approaches by which data, knowledge and scientific judgements of that data / knowledge can all be made available for integration into a negotiation process that attempts to deal with inherent uncertainty. Therefore, there is a considerable focus on communication of the principles, values and assumptions underlying analyses.

Identification of this role does not imply adoption of any particular framework or approach to integrated resource management. A variety of frameworks, paradigms and methods for integrated resource planning and use have been espoused – including adaptive management (Gunderson et al 1995), communicative planning (Healy 1997) and community-based approaches such as Integrated Catchment Management (Anon, 1991). These frameworks tend to reflect the bias of the group fostering the approach. As a consequence, they may be unpalatable to, and therefore ignored by, other groups. So, while they seek to provide a rigorous framework, such approaches may, in fact, be brittle. Our intention in taking a role-based view of the process of improved natural resource use planning and management has been to attempt to avoid such problems.
We argue that the functional design (as opposed to the implementation) of decision support tools, the design and facilitation of capacity building exercises such as the HRIC and the design and implementation of evaluative strategies for assessing the impact of the process of such initiatives and their products represent an increasingly important role for natural resource planning professionals. Furthermore, while often and successfully performed in an *ad hoc* manner by scientists or planners, we believe that this is not a science or planning role.

We propose that the development of decision support mechanisms such as those outlined in this paper is an increasingly widespread activity. Recognition of these activities and the role of the decision support systematist will allow the comparative evaluation of methods and the establishment of best practice. It may also help to counteract the pressures on managers, planners and scientists to seek practical and theoretical approaches to comprehensiveness in all their activities and to thereby become equally and competitively involved in sloppy science, poorly executed planning processes and unprofessional resource management.

Abstract
Fostering effective use of GIS amongst a broad range of stakeholder groups and in the community as a whole requires investment in capacity building as well as in data integration and provision. Community-based collaborative joint ventures can achieve both these objectives. This paper reports the evaluation of one such initiative in tropical Australia and, on the basis of this experience, infers a set of issues that may determine the success or otherwise of similar ventures elsewhere.

Introduction

Sustainable resource use and participative democracy have emerged as increasingly influential paradigms in the evolution of approaches to resource use planning and management in the post-war period. Traditionally, most decision-making has been vested with regulatory authorities. In recent years significant changes have occurred to involve the community in the decision-making process (e.g. McKenna 1995). Assumptions about what is required to achieve sustainable resource use, particularly the role of technocrats, resource users and the broader community in resource use decision-making have been challenged accordingly. In the Australian context, a rhetorical move towards participatory resource planning has underpinned much policy (legislation and funding) in natural resource management and rural development for the past decade (Dale & Bellamy, 1998). This puts Australia at the forefront of international experience.
Experience suggests that in order to enable effective community participation in resource planning, four fundamental requirements must be met. Stakeholders must have :

- effective access to information pertinent to resource use planning;
- access to the analytical tools required to make effective use of that information:
- the capacity to make appropriate use of those analytical tools and data sets; and
- a legislative and institutional environment that fosters effective participation.

Community-based decision-making represents a change in the organisation and operation of information systems. A planning strategy is an aggregate of: (a) knowledge about the state-of-the-environment as a rolling audit of existing conditions and resource issues, (b) a management plan showing planned activities, (c) information services to analyse design constraints and options, and (d) evaluation to refine and modify the progress of activities. In the traditional agency-driven approach to resource use planning, the community is informed about the state-of-environment and the consequent plan. Increased community involvement may result in consultation or even negotiation about the interpretation of the former and the structure of the latter. However, delegation to the community means that they have to be responsible for these processes and have the capacity to undertake analysis and evaluation. So, the key distinction between an agency driven approach and a community driven approach is control of the information, evaluation and decision-making process. Empowerment of community based groups means they have involvement and ownership of both information and decision processes.

Appropriately structured community-based organisations can play a lead role in fulfilling these requirements. Historically, the local axis of industry representative bodies (such as the United Graziers' Association and Canegrowers) and other special interest lobby groups have played this role. More recently, advances in information technology have opened new opportunities for improving local capacity and participation in planning. As a result, a number of initiatives to create community resource information centres have arisen across Australia. Many of these initiatives are not specifically aligned with particular interest groups but aim to foster broader community sectors to participate in planning and decision-making. In this paper, we report on one such initiative and use consideration of this case study to identify key issues to be considered in establishing such ventures.

Case Study : The Herbert Resource Information Centre

The region

The Herbert River catchment drains an area of approximately 10 000 km^2 in Australia's sub-humid to humid tropical north east (lat. 15-19^0 S, long. 145-146^0 E) to the Coral Sea. Large areas of the catchment remain under natural vegetation (much managed for extensive cattle grazing), although approximately 35 to 40% of the coastal lowland area has been cleared for crop production or improved pastures. The catchment has a population of approximately 21 000 and is bounded by two World Heritage listed areas, the rainforests of the Wet Tropics on the steeper slopes of the central catchment and the Great Barrier Reef immediately adjacent to the catchment.

The area has experienced, and continues to experience, strong economic growth underpinned predominantly by its agricultural and tourist sectors. The sugar industry dominates the local economy with 70 000 ha of production and two sugar mills producing (Aus) $ 235 million worth of sugar in 1996/7. A plethora of government and statutory industry agencies claim, or are assigned, responsibility for different aspects of the management of the catchment and a number of agencies also contribute to management through the provision of research and development outputs and expertise.

The Herbert catchment, like many other parts of Australia's coastal zone, is a major focus of competition between alternative uses of resources with competition between agriculture, forestry, conservation, tourist and recreational uses, urban encroachment, public utilities and hobby farms. Growing competition has occurred in the context of increasing community expectation for the preservation of the natural environment, involvement in decision-making and effective conflict resolution.

The sugar industry has the potential for significant environmental impacts in the Herbert catchment (Johnson *et al,* 1997). Soil erosion is recognised as a potential threat to long-term productivity, although the adoption of green cane harvesting-minimum tillage practices has been an important step in decreasing sediment supply to the coastal zone from sugar cane lands. Considerable areas of the riparian vegetation have been removed from the stream banks in sugar cane growing regions. Large areas of riverine rainforest with patches of eucalypts and the riverine rainforest have also been cleared. The wetlands, swamps, billabongs and waterholes of coastal areas are important wildlife habitat areas and form an integral part of a hydrological regime. Clearing for sugarcane has significantly reduced the area of this habitat. Potential exists for diffuse source pollution to generate water quality problems in both ground and surface waters. This has been perceived to be of particular concern given the adjacency of the Great Barrier Reef.

Growing concern about potential environmental impact is balanced by a recognition of the regional and national importance of an economically vibrant sugar industry. The economic terms-of-trade of the sugar industry and competing land uses are under pressure due to the influence of increasing global competition, meaning that increased areas and yields are required in order to remain internationally competitive.

In order to achieve and maintain ecological and economic sustainability within the Herbert catchment, effective means of managing and reconciling industry imperatives at the farm and regional scales with the requirements of other users of the catchment (including conservation and environmental services) are required. In recognition of such issues, government agencies in most Australian states have sought to implement integrated approaches to resource management to

avoid the environmental and social damage sustained by conflicts in land use. Initiatives in the Herbert have included an ICM (Integrated Catchment Management) programme (Johnson *et al.*, 1996). In practice, the effectiveness of such initiatives is often constrained by a paucity of data at spatial and temporal scales relevant to decision-making, poor co-ordination or communication between participating stakeholders, limits to the data processing and analytical capabilities of participants in the decision-making process, and a poor understanding of key issues in sustainable resource use.

The establishment of the Herbert Resource Information Centre

In mid 1993, the Commonwealth Scientific and Industrial Research Organisation - CSIRO (one of the principle Federal scientific research agencies in Australia) initiated discussions with key stakeholders in the Herbert catchment to address the first of these constraints – inadequate data - by acquiring essential base data at a scale of 1:10 000. The costs of acquiring this data exceeded the individual financial capacity of any one of the interested stakeholders. In response, a joint venture (the Herbert Mapping Project or HMP) was developed between 11 agencies (industry, community, state, local and federal government) to fund the acquisition of digital orthophotography, cultural data (eg utilities, farm boundaries), natural features (eg streams, topography) and cadastral data for the lower catchment. The HMP was completed in July 1996.

As the HMP neared completion, it became evident to many stakeholders that the utility of the data collected could only be maximised through advanced analysis of the data in digital form. GIS provided the best means of satisfying their requirements for data analysis and presentation. A further collaborative joint venture, the Herbert Resource Information Centre (HRIC) was therefore proposed and a needs analysis and a cost-benefit analysis conducted.

The needs analysis involved the use of a four-part questionnaire to assess perceptions of the opportunities and constraints associated with GIS should it be adopted within the stakeholder groups. The results of the needs analysis clearly demonstrated that a collaborative GIS facility was commensurate with the organisational background, organisational requirements and operational characteristics of the potential participating organisations and provided the basis for designing a detailed business plan. This in turn provided the basis for a cost:benefit analysis which indicated an overall ratio of discounted benefits to discounted costs of 8.8:1. The results suggested that the collaborative GIS was both an attractive public and private investment. Full details of the needs analysis and cost:benefit analysis can be found in Johnson & Walker, 1997.

Having demonstrated the appropriateness and viability of a collaborative approach, six stakeholders in the catchment agreed to begin negotiations with a view to establishing a formal agreement. Four of these stakeholders (CSR Sugar Mills, Herbert Cane Protection and Productivity Board, Hinchinbrook Shire Council and Canegrowers Herbert River Executive) represent local industry and community while two (Queensland Department of Natural Resources and CSIRO) represent state and federal government respectively.

In August 1996, a 10 year collaborative agreement was signed by the six stakeholders to formally establish the HRIC. The agreement secures the financial and non-financial (in-kind) support of the stakeholders and binds them to support the HRIC's foundation philosophy of being a non-profit, community-based collaborative GIS facility designed to support both economic and ecologically sustainable development in the Herbert catchment.

The four local stakeholders provide a high level of representation of the community in the catchment. Given the highly democratic nature of local government in rural Australia, the involvement of Hinchinbrook Shire Council, as the local elected Government provides an

important avenue of representation to all ratepayers in the catchment. Furthermore, the sugar industry representatives in the HRIC represent a significant sector of the community. Of a population of 21 000, 18 000 of whom live in the lower floodplain, there are some 840 canegrowing families and a total of 7 000 employed in the sugar industry. The Canegrowers Herbert River Executive is the local branch of the representative body for cane producers in Queensland and plays a key role in industry planning and representation and is funded by grower levy. The milling sector (CSR Sugar Mills) are the biggest employer in the catchment and play a central role in many of the resource use planning and management issues addressed in the catchment. The Herbert Cane Protection and Productivity Board is a local organisation funded equally by levies from cane farmers in the catchment and the milling sector to provide a range of technical services back to the growers. These four local stakeholders provide all the funding for the HRIC. The State and Federal government representation provides in-kind support in the form of data and some technical skills.

The structure of the HRIC is intended to result in a genuinely community-based GIS initiative. Thus, the HRIC's mission statement is "*To manage the acquisition and dissemination of geographic information within a collaborative framework, to the advantage of all interests in the Herbert River Catchment*". A strong schools program and documented use of the HRIC's services by a range of community organisations and clubs as well as local Aboriginal groups bears witness to this community orientation. In this sense, the HRIC builds on a strong history in rural Australia of active community and representative groups playing a key role in local politics and governance.

The HRIC is staffed by 2 full time GIS specialists, whose role is to provide expertise and skills to facilitate the collection, storage, maintenance and analysis of natural resource data and to ensure the products of these activities are delivered to HRIC stakeholders. As such, the HRIC offers a bureau service to its stakeholders, providing GIS consultancy and project management skills and acting as a conduit for the transfer of relevant R&D products. Furthermore, HRIC staff undertake a core function in assisting relevant stakeholders to implement GIS as part of their business operations. An additional function is to promote an environment for the facilitation of improved communication and collaboration between the HRIC stakeholders.

Within each of the stakeholder organisations, GIS groups were formed to facilitate the planning and implementation of GIS within their host organisation (although the state and federal government stakeholders already had significant GIS capability at the time of HRIC formation). Capacity building had begun, without being recognised as such, within the mapping project in so far as participation in the mapping project lead to an understanding of the need for GIS through user identification of a need and technical input providing options. Capacity building within the Mapping Project, the HRIC and stakeholder organisations has therefore enabled rapid adoption of GIS, a technology unknown to many of the participants three years ago.

Evaluation

Objectives

It was evident to the Mapping Project participants that contiguous with realising the Project's primary objective, production a high quality base data set for catchment management, participation had made a significant impact on the way that participants went about their business in relation to resource management in the catchment. Participants felt they had gained a sophisticated view of the nature of spatial data, its uncertainties, limitations and potential range of application. Furthermore, collaboration seemed to have fostered a new spirit of understanding and co-operation between agencies. It was anticipated that the HRIC would likewise have significant impacts. In order to be able to demonstrate these impacts rigorously (rather than

relying on anecdotal evidence) and derive lessons from the HRIC in establishing best practice for community-based resource centres, a three-year evaluation programme was established.
The objectives of the HRIC can be summarised as:

- improved quality of data available for the Herbert catchment;
- improved access to data;
- better informed decisions in planning & implementing data collection & use projects;
- better informed decisions in natural resource management; and,
- improved collaboration.

These objectives were explicitly addressed in the evaluation but there was also provision for the evaluation of less tangible aspects in relation to changed perceptions, attitudes, understanding & behaviour, particularly in relation to collaboration between groups, as a consequence of involvement in the HRIC.

Methods

The HRIC evaluation was conducted using qualitative research techniques (see Denzin and Lincoln (eds), 1994 and Patton, 1987). Individual, face-to-face interviews using a semi-structured interview schedule were conducted with key participants in the HRIC each year over three years. Nineteen people were interviewed in February 1996 (6 months before completion of the joint venture agreement and employment of HRIC staff), follow-up interviews were conducted in February 1997 (19 interviewees) and March 1998 (17 interviewees). Each interview took approximately 90 - 120 minutes and was tape-recorded. There was some change in key participants such that a total of 41 individuals were interviewed over the three years with a core group of 7 individuals being interviewed at each of the three times. The issues addressed in the survey are summarised in Box 1. In the first round of interviews, anticipated impacts were elicited. In the second and third rounds, anticipated and actual impacts to date were elicited.

Box 1 : A summary of issues covered by the evaluation

Operational Impacts

- Intentions in using new data sets that became available, implications for existing data, constraints to use.
- Impacts of involvement in the HRIC on data availability, data collection, data storage, data access, complexity of decision-making, efficiency of decision-making, quality of decisions made, presentation of decisions.
- Impact of the HRIC on the resolution of resource management issues within the catchment.
- Impacts of participation in the HRIC on the types of activities agency involved in.

Evaluation of Process

- Importance of HMP in triggering HRIC.
- Constraints to use of HRIC.
- Impact on other agencies.
- Use of the HRIC by non-partners & impacts on those users
- Interaction with other organisations: changes to general levels frequency of interaction; understanding of the objectives of each agency; understanding of the constraints under which each agency operates; understanding of the data needs of each agency, willingness to work with the other agencies, nature and process of interactions, confidence in other groups.
- Evaluation of the dynamics of the process (key participants; positives, negatives).

Changes in Understanding

- Awareness of the quality and availability of data.
- Credibility of data resources.
- Understanding of the limitations associated with spatial data.
- Understanding of data resources used by other groups in the project.
- Understanding of the data needs of other groups.
- Most important things learnt from involvement in HRIC.
- Understanding of the tractability of resource management issues
- Understanding of the quality and limitations of data; awareness of the availability of data

After each set of interviews, interviewee responses were transcribed and collated. At the end of the three year period, the entire data set was entered into the NUD*IST qualitative data analysis package (QSR, 1997) and tagged against key evaluative criteria providing a basis for the qualitative analysis reported here.

Outcomes

After the two and half years of formal operation of the HRIC covered by this evaluation, the HRIC and the partners to the HRIC have collected, collated and synthesised a high quality spatial database for the catchment. The resources in the HRIC had been widely used by individual partners for routine activities in planning infrastructure developments, assessing the resource bases and integrating monitoring activities. Direct (private) benefits had accrued to each of the joint venture partners. In some cases these benefits were already substantial while in others, substantial benefits were anticipated in the near future.

The extent and speed of operational impact across the range of activities in partner organisations is illustrated in Figures 1a and 1b. As well as providing detailed descriptions, interviewees were asked to rank both predicted and actual impacts against the range of criteria discussed above, both for their own organisation (1a) and for all the others (1b). It is interesting to note that predictions tended to be higher for others than for self-assessment. This may reflect the inevitable concerns about equity in a collaborative venture but may also reflect a more accurate understanding of the informants' own agency than of others – leading to assessments that are more informed and better reflect reality. The graphs do not provide any evidence for any period of disillusionment so often associated with ventures based on a new technology. It is likely, however, that the annual time step of the evaluation has simply failed to capture short term crises of confidence that were reported anecdotally by the partners. Furthermore, it is possible that the capacity building outcomes of the HMP equipped participants with more realistic expectations of timelines and outcomes possible in such a project. Predicted impacts were generally stable or climbing over the three years. Equally, impacts perceived to have occurred were high and climbing up towards anticipated levels of impact – demonstrating that the venture had started to meet expectations very rapidly.

Figure 1a. Self Assessed Impact
0 = no impact, 3 = very significant impact

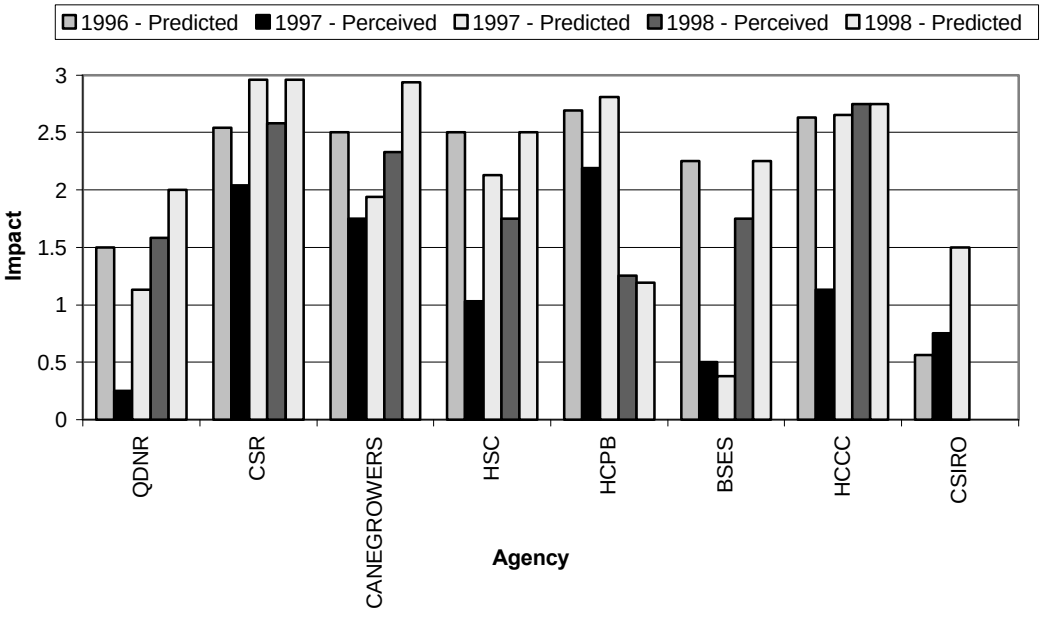

Figure 1 b. Predictions by all partners
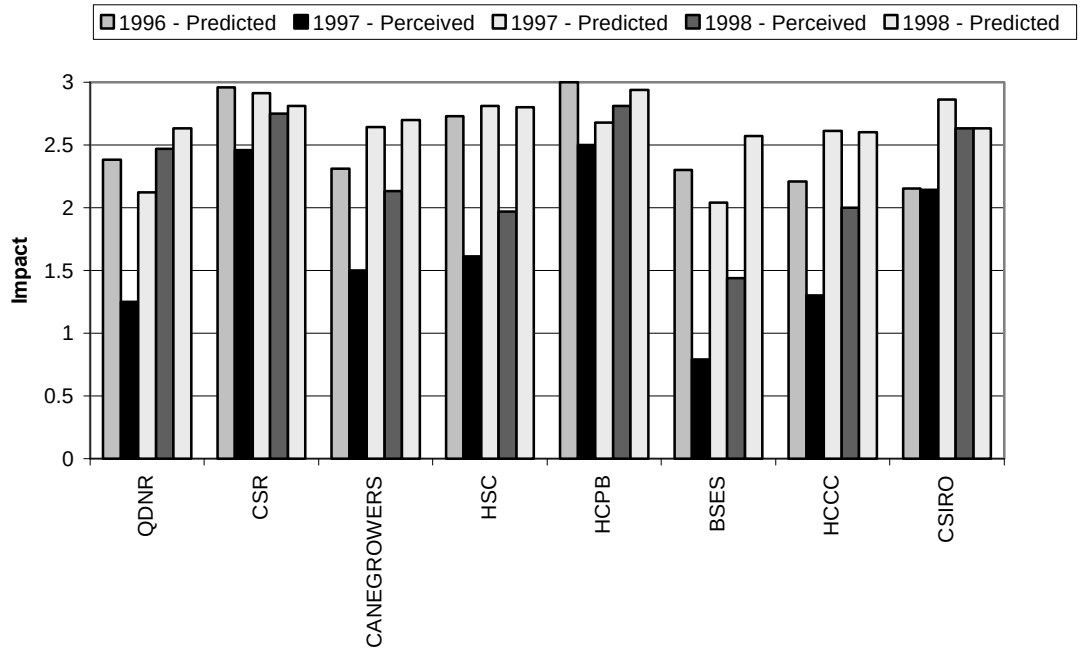
0 = no impact, 3 = very significant impact



Specific outcomes against the HRIC objectives were as follows.

Improved quality of data available for the Herbert catchment and improved access to that data.

"Totally replaced and enhanced previous data."
"A very significant impact on data access…Not only have we been accessing data, but government agencies as well."[1]

Data access improved dramatically with participants becoming more aware of the range of data available and having access to all but that which was 'commercial-in-confidence'. There were still significant differences in perception between individuals of the general quality of data available in the Herbert, particularly between active users and less active users. Nevertheless, many participants had come to better understand the limitations of key data sets, including, for example, an increased understanding of the implications of scale on use, as well as limitations of the data. Paradoxically (or at least unexpectedly), this had made them more confident in use of that data (although it may be that this rise in confidence is confounded by improved access to better data sets). This understanding of the data in combination with a knowledge that all parties were operating with common data resulted in higher levels of confidence in using the data.

Better informed decisions in planning and implementing data collection and use

"Changed from pen/paper in drawers and files to digital form…that sort of software gets better/easier to use…Main constraint is going to be money."
"The staff expertise really came through in the technical advice on how to go about our project."

While processes for data collection were only moderately impacted for most parties, compatibility with other data had become a significant criteria such that data storage and management collectively and individually had been significantly impacted. Furthermore, for some activities, radical changes in data collection (e.g. from field survey to ortho-photo and satellite imagery) had

[1] These and the following quotes are directly taken from interview material

been instigated. In general, while the interviewees saw compatible data collection and storage as important, and indeed the project would fail if it did not occur, other factors were seen as more important. Common 'ownership' of the HRIC generated agreed, common and trusted data sets. In this context, issues of absolute data accuracy might, perhaps, be less significant than the opportunity to discuss differences in interpretation of the meaning of those data sets.

Better informed decisions in resource management

"Efficiency and quality of decisions gets better…(also) presentation of decisions."
"Quality of decisions is high. Without HRIC could not make decisions for (sugar) crushing agreement effectively because we did not know the exact area under cane."

Formal spatial analyses were being used in planning decisions, often with a substantial cost saving and resulted in decisions perceived to be as good as, and frequently better than, would have been achieved with previous processes. GIS-based products were increasingly being used in negotiations regarding resource-use. However, improved consideration of complex resource management issues that cut across sectors and stakeholders resulting in more efficient and better quality decisions were still anticipated but not yet achieved. There was, however, a general perception that achieving this objective was a question of time rather than a function of more fundamental constraints, although it had become increasing apparent to participants that data itself does not make decisions.

Improved collaboration

"HRIC has made me more aware of the …way people think and other people do business…drawn into a lot of projects."
"Everyone's willingness to share…it has changed attitude…not 'what's mine is mine' but what's ours is ours'…to get a large public company and a shire council to work together is incredible…"

In terms of motivation for involvement and strategic direction, many initially saw the HRIC as a data source and a means of cost sharing in data collection. However, a shifting emphasis towards a role in skills development, skills sharing and project brokering was unanimously supported. The HRIC was increasingly seen as a significant force for changing planning processes rather than a technical service. Certainly, the key assumption that collaborative joint venture was an appropriate mechanism for fostering broader uptake of GIS technologies in the catchment was perceived to have stood the test of time. An initial mixture of optimism and uncertainty was replaced over the three-year period by a very positive view of the HRIC and a sense of real pride in what had been achieved. For the people interviewed, involvement in the HRIC has meant additional work, meetings and a requirement to quickly develop new skills in emerging fields. In some cases it has also meant developing working relationships where none would have existed previously. However, all participants saw this as a positive experience both for themselves and their community.

Equally significantly, the collaborative nature of the initiative had important impacts. Willingness to work together increased amongst the partners to the Centre and external use of the HRIC by businesses and the broader community began to occur (although issues of user payment for HRIC services and third party data remained a complex challenge). Improved collaboration between agencies was not reported for all the combinations of partners however, in no case were relationships reported as having become worse. Some concern was expressed, however, about groups that did not become formally involved in the Centre becoming somewhat marginalised in key developments in the area.

Contributions to success

The evaluation presented here demonstrates that from the participants' perspective, the first three years of the HRIC have been a success. The interview material demonstrates that the participants in the HRIC believed that certain key features of the catchment and the agencies involved were important in the success of the establishment of the HRIC.

Skilled professional staff

Although the capacity of hardware and software was a necessary base from which to operate the centre, the interviewees tended to attribute a significant proportion of the success of the HRIC to the qualities and skills of the staff employed by the Centre. The importance of the Centre staff was recognised from the outset – the Board making a conscious decision to provide attractive terms and conditions in order to recruit staff with the mixture of negotiation / facilitation, management and technical skills required. The change in Centre Manager at the end of the second year of operation had consequences that provided further evidence of just how critical these appointments were. While only two staff are employed by the Centre, one of their key roles has been to build capacity in the partner agencies through the provision of training courses and high level support for staff in those organisations. As a consequence, some 40 people have received formal GIS training over the course of three years with several of those now spending a significant proportion of their time on GIS-based work within their organisations. This has meant that the Centre staff have played an increasingly strategic role in support of a growing range of individuals, thereby avoiding overload in the face of burgeoning use of GIS within the catchment. The qualities and skills of the staff have certainly facilitated the success of the HRIC. Nevertheless, while it is reasonable to argue that the Centre staff might, had they been less competent, have caused the failure of the Centre, it does not follow that their skills in themselves totally explain the HRIC's success.

Common goals

The overwhelming dominance of the sugar industry in the catchment meant that, while not always in agreement, key players had very significant interests in common – none of the partners are, for example, competitors in terms of resource use.

Existing infrastructure

Similarly, the fact that GIS infrastructure and investment within the catchment (as opposed to the Government agencies involved) was negligible meant that there were no vested interests within agencies to overcome in designing and implementing a collaborative venture.

Location

The 'neutrality' of the Centre was also important in avoiding conflicts of interest. The Centre and its staff are not viewed as being overly aligned to any one of the partners in the venture (although an early arrangement whereby the Centre was located within the offices of one of the agencies was viewed as a problem from this perspective and was changed at the earliest possible convenience).

Credibility

Having established a structure that avoided potential barriers to effective collaboration, the success of the Centre depended on establishing credibility as rapidly as possible in order to

maintain and enhance commitment to the joint venture agreement and associated financial contributions. Early projects that clearly demonstrated benefits to partners were therefore very important early in the Centre's operations. Outcomes of broader collaborative or public benefit were not required immediately, however, there was significant pressure for benefits to accrue to individual partners early in the process to maintain commitment.

An evolutionary history

The evolution of the HRIC from the Herbert Mapping Project was very significant. The completion of the HMP meant that the HRIC started with a high quality base to which the data provided by partners could be rectified relatively rapidly such that it wasn't necessary to spend a substantial period at the outset collecting data. More importantly, many of the participants in the first round of interviews stressed that involvement in the HMP had provided them with experience and understanding that was invaluable in the early stages of the HRIC in that it provided them with practical experience in a successful joint venture and demonstrated that they could work together effectively for mutually beneficial outcomes. Even so, a highly evolutionary approach to establishing the Centre (and a great deal of good will) was required at the outset. Interestingly the importance of this evolutionary approach was not widely acknowledged amongst participants in the third round of interviews. Many informants felt that in establishing the HRIC again, they would seek to employ staff, generate a strategic plan and so on at the very outset. Consideration of the interview material from the first two years suggests that this would not have been realistic.
Despite overall success, some significant threats had been encountered, as follows.

Issues of intellectual property

In so far as significant problems and threats to the HRIC had been encountered, many related to issues of tightening data access policy, both amongst partners and external (particularly within Government agencies) and related issues of Intellectual Property and liability. These remain a significant challenge.

'Head office'

Another significant set of threats that had to be carefully managed by the participants was the need to ' sell' the initiative within their own organisations. While individuals and local offices were enthusiastic and committed participants, it was necessary for all those agencies to sell continued involvement and financial contribution very carefully to other parts of their organisations in order to be able to protect their continued involvement from cuts associated with general 'resource squeeze' in their parent agencies.

Over-commitment

As awareness of what the Centre could offer spread, demand for the HRIC's services grew rapidly. As a result, prioritisation of tasks and effective restriction of access to services was necessary to avoid serious over-commitment and the danger of failing to meet critical objectives.

Towards best practice

We are not aware of equivalent data sets to the evaluation reported here for other initiatives in Australia. Nevertheless, the evaluation of the HRIC presented in the previous section provides

an appropriate means of considering key issues that may need to be addressed in the establishment of information centres.

- The HRIC provides access to integrated data sets but also plays a project brokering and capacity building role. How does the impact of this dual approach compare with initiatives solely targeted at information provision?
- The HRIC has a tight regional focus covering a rural catchment centred on a single population centre and dominated by a single industry. What implications might a wider geographical area of mandate or more complex community structure have?
- The relative socio-economic homogeneity of the catchment means that the individual goals of the partner organisation to the HRIC and the common goals of the HRIC are highly compatible – there are no dominant resource use conflicts between partners. Would the Centre have succeeded in a more complex environment with more substantive conflicts?
- The HRIC evolved from the Herbert Mapping Project, an initiative with a very specific and tangible technical objective. In the early rounds of evaluation this evolutionary approach was seen as critical to success. Could a similar centre have been established without this initial focussed output?
- Although initially facilitated by State and Federal Government, the HRIC has a high (and growing) level of local ownership. Furthermore, the initiative was seen as being 'neutral' rather than the associated with any particular local agency. All stakeholders agreed that this was key to the success of the venture - that the HRIC was seen as an independent broker of information for the explicit reason that all parties had a stake. What implications does this have for future initiatives that are locally initiated by one party (eg. Local Government)?
- How important are private benefits in enabling a contribution to the public good? Individual partners in the HRIC have tangible and specific business oriented objectives for being involved, for which they can see an early return on investment that in its own right justifies their involvement. As a consequence, they felt able to be thoroughly committed to the notion that the HRIC provides a greater public code, educational & capacity building role. Does this mean that initiatives more specifically targeted at these public rather than private benefits are less likely to succeed?

Conclusions

While many regional planning activities promote a consultation process, few have been successful in mitigating the decision-making process completely to community stakeholder groups. The Herbert Resource Information Centre, is an example in which community groups have control and ownership of resource information and related decision-making. This initiative is an exceptional example of community based decision-making, an exemplifies an emerging trend for self determination and community empowerment in undertaking the planning process. The most distinctive features of the HRIC are its capacity building function for stakeholders and the enthusiasm and willingness to learn on the part of the participants. Both are derived from a healthy balance between individual (agency) interests and community spirit. Commitment to joint projects was directly related to a sense of ownership and involvement in the decision-making process. It is reasonable to assume that this level of interest maybe more difficult to instigate and sustain in more complex regional communities. The HRIC model will not be applicable across all circumstances – the level of community involvement that can be attained is likely to remain across a spectrum of possibilities from community consultation to community initiated ventures.

Acknowledgements

The authors would like to thank the members of the HRIC Board, the HRIC staff and the HRIC users who took part in the interviews reported here both for their time in participating in this evaluation and for the opportunity to have collaborated with them over the last three years in establishing the HRIC.

Abstract
This paper discusses local understanding about catchment processes and its potential contribution to the progress of Integrated Catchment Management (ICM) and reports on some trial exercises undertaken in the Herbert River Catchment. The paper contrasts two approaches to local understanding: 'technical knowledge' and 'landscape literacy'. This is followed by a discussion of what would be involved in development of a method for identifying and evaluating differences in local knowledge and the role of these differences in an ICM context. The first section of the paper considers some of the conceptual pre-requisites to how local knowledge can be incorporated into ICM. The final section considers some of the pragmatic issues which were encountered in some trials conducted in association with this paper.

Introduction

The origins of this paper stem from an evaluation process of a research program on Integrated Catchment Management (ICM) in the Herbert Catchment of north Queensland. Throughout the evaluation process, interviews and workshops with farmer groups demonstrated that farmers and researchers have significantly different understandings of the landscape they interact with. Whilst researchers were comfortable with the notion of a catchment and the processes which occur within it, the evaluation demonstrated that the concept was not natural for farmers, who were focussed at a farm scale. This raised the issue of considering the role of different approaches to knowledge, and their relevance to ICM. To investigate these issues, a series of interviews and workshops were designed with farmers and resource professionals on the subjects such as sediment entering the water ways and land clearing for cane farm expansion.

This discussion paper considers the outcomes of these interviews and workshops, and the reasons for incorporating local knowledge into ICM generally. It considers two main approaches to investigating local knowledge. The first of these is consideration of Indigenous Technical Knowledge – which has involved the study of specific knowledge that local peoples have developed about the resources they use. This knowledge is based on intimate interaction with a resource on a small scale. Unlike science, the knowledge does not necessarily attempt to explain broad phenomena with common principles. The individual ways that farmers and other resource users have interacted with the natural world can offer insights that the broad application of scientific principles and experiments may overlook. The second approach to local understanding discussed in this paper considers the ability of land users to read the health and status of the environment they interact with. This approach has been termed 'landscape literacy' or 'land literacy'. Given it's broad approach and consideration of the cultural and historical factors shaping the way humans interact with the environment, it has much potential in the evaluation of ICM.

Conceptualising local understanding

The nature of local knowledge
Local knowledge has been viewed and defined in a number of contrasting and, perhaps for different purposes, equally valid ways. Local agroecological knowledge is often a contemporary and dynamic explanation of how the world works with potentially universal application. It can be primarily derived from observation and experimentation by farmers, or it can be a system of unique and idiosyncratic elements of traditional knowledge that are culturally bound, predominantly heuristic and passed on through generations.

Indigenous knowledge and scientific knowledge.
For the purposes of better understanding indigenous knowledge, a useful comparison can be made with scientific knowledge. Whereas scientific knowledge aims to discover universally applicable phenomena such as gravity and temperature, the scale and focus of indigenous knowledge local. It is concerned with explaining local circumstances, and as such indigenous

knowledge has only limited experimentation. By contrast, scientific knowledge relies on almost infinite replication through experiments to prove the universal consistency of phenomena. Unlike the formal modes of distributing scientific knowledge -journals, seminars and scholastic instruction, indigenous knowledge is distributed through informal mechanisms such as the knowledge a parent passes to a child. There is no significant difference in terms of accessing scientific and indigenous knowledge. Both tend to be reasonably open unless providing access to the knowledge is going to disadvantage those who hold it. A final difference is that supernatural explanations may be present in indigenous knowledge, whereas they are absent in scientific knowledge.

Knowledge as Understanding that can be Articulated

This approach requires some important definitions. Data are a recorded set of observations (which may be quantitative or qualitative). Knowledge is the outcome, independently of the interpreter, of the interpretation of data. Understanding is the outcome, specific to the interpreter, of the interpretation of data or knowledge: the comprehension that the interpreter achieves. So, the interpretation of observation may advance an individual's understanding. Some part of this advance can be articulated and communicated as knowledge. The distinction between what can and cannot be articulated is of importance in taking a practical view of local knowledge and its contribution to R&E. Furthermore, it is compatible with the knowledge engineering paradigm that underpins many powerful theoretical, methodological and implementational advances in cognitive science and artificial intelligence.

Knowledge is thus seen as a central aspect of culture, derived from education and experience, that may be used, in conjunction with consideration of a value system and competing priorities and possibilities, to make decisions and, therefore, lead to actions (such as farming practice). Actions may also be intuitive, short circuiting the consideration of knowledge in their genesis. What is perceived about the natural world, however, is influenced by what can be observed, and, the way in which perceptions are transformed into knowledge is influenced by the mode of learning, which may differ from one society to another. It is clear then, that the way in which knowledge is acquired and transformed into decisions, depends on the cultural context but knowledge is distinguishable from other aspects of a person's, or a community's, culture. This definition of knowledge as being something that can be separated from the person who knows it, essentially a position that conforms to a Popperian philosophy of science (Popper, 1972), is quite different to the more widespread sociological definition used within the recent farming systems literature which views the two as inseparable. So, for example, Scoones and Thompson (1994) challenge 'the assumption of a positivist view of investigation that sees knowledge as a tangible stock or store to be tapped' and see 'the process of knowing' as 'engaged, value-bonded and context determined' they argue that the 'human mind is not simply a mirror that accurately reflects a reality' but that 'interpretation, translation and representation are social acts that cannot be assumed to be neutral and objective'. Taking this perspective further, Röling (1996) states that "Reality is not assumed to exist independently of the human observer or to project itself on the mind through the senses…". Blaike et al.(1997) put these theoretical considerations into context by stating "These processes [of advancing ideas], and hence knowledge, are inextricably linked to the social, environmental and institutional contexts within which they are found. For example, a partly deforested hillside in the tropics may be viewed very differently by a local subsistence farmer ..., a cattle rancher, and an NR scientist...". In addressing perceptions of landscape, Colquhoun (1997) takes the view that knowledge includes "intangible deep feeling of what meets us in a landscape". These definitions make local knowledge essentially indistinguishable from local people conflating knowledge, values, perceptions and even emotions.

Local Knowledge, Indigenous Knowledge and Technical Knowledge

The terms 'local knowledge' and 'indigenous knowledge' have often been used interchangeably. However, here local knowledge denotes locally derived understanding which is based more on

experience and real world observation than indigenous knowledge, which may reflect cultural beliefs and values to a greater extent. This distinction has important practical implications. So, investigation of indigenous knowledge (principally the realm of anthropological and ethnographic research, which are particularly concerned with mapping and explaining cultural differences), has tended to focus on knowledge that is idiosyncratic and culturally bound, often being traditional and handed down orally. Such investigation has practical as well as academic application – of 242 published papers retrieved from a search of CAB Abstracts for 1996/7, 85 are concerned with medicinal aspects of rare ethno-botanical knowledge or the ethics associated with the search for such knowledge. Some indigenous knowledge, and hence research into it, has profound implications for resource management and development. Historically, for example, it has been suggested that the cultural beliefs held by Mayan Indians that people were literally made of maize (thus making it a sacred plant) precluded commercial exploitation of this crop by indigenous people, whereas Hispanic settlers were not so restricted (Asturias, 1949). Such cultural beliefs can be pervasive, the sacred nature of maize in the previous example was bound up with notions of soil fertility and its decline through continuous cropping. Sallas (1994), working today in the Peruvian Andes, reports similar culturally derived constraints to the adoption of modern potato varieties, that although higher yielding than local varieties, are less resistant to some pests and diseases and require inputs of chemicals for yields to be achieved. The modern potato varieties and the chemicals applied to them are considered by older people in the community to 'bring more diseases' and to be 'poisonous' both to 'mother earth' and to the people who eat the potatoes.

Indigenous Technical Knowledge (ITK)

Sinclair and Walker (1999) contend that many management actions undertaken by farmers have an explanatory basis, although such explanations may differ from a scientific rationale and may require careful interaction with farmers to elicit. Unfortunately, farmers' explanations for agroecological phenomena, have not received adequate attention, and in the present enthusiasm for moving from considering what people do, as in studies of ITK - or farmer's performance, to the cultural context in which knowledge is generated - or the process of knowledge generation and development (Scoones and Thompson, 1994), there is a risk that the gains from explicit representation of farmer's explanatory understanding will continue to be overlooked. The key issue here, once again, boils down to whether it is valid to abstract farmers' knowledge about ecology from the broader set of considerations that govern agricultural practice and whether this can be done without overly distorting it. A major confusion has arisen here between the limitations of using external scientific ('etic') explanations of local practice and seeking the farmer's own ('emic') explanation. So, for example, Richards (1989) in an influential article, explains how complex intercropping layouts in a field, that scientists may interpret as a carefully planned arrangement based on consideration of inter-specific competition and weed and pest control may, in fact, represent a set of contingent responses by the farmer to various events throughout the season so that what is observed at the end of the season is the result of a completed performance (influenced by a range of unfolding ecological and socio-economic factors), rather than the result of a specific plan in the mind of the farmer at the beginning of the season. However, while it is clear in this case that the farmer may not have planned the design from the outset, and that what transpired over the season and why can only be interpreted by considering the sequence of events that actually occurred in time (which may be impractical if the dialogue begins at the end of the season), knowledge of plant ecology on the part of the farmer is not precluded, it has not, in fact, been adequately sought.

Sinclair and Walker (1999) argue that a major justification for abstracting farmers' ecological knowledge from other social and cultural aspects determining agricultural practice, is that it can be postulated that core knowledge about natural processes is likely to have some applicability across contexts, rather than being entirely unique to the situation and society in which it was derived. This is a somewhat contentious view that flies in the face of postmodernist approaches to anthropology Tyler (1987). There is, however, some compelling evidence to support this

likelihood. Firstly, Berlin's seminal work on ethnobiological classification (Berlin 1992) reveals widespread regularity in the way in which people classify and name plants and animals in quite different non-literate societies. Thus, he asserts that when people function as ethnobiologists they 'discern' rather than 'construct' order from their observation of a biological reality, in which groups of plants and animals appear as a series of discontinuities, whose structure and content are seen by all human beings in essentially the same way. He contrasts this with other areas of human experience which are culturally constructed and to which anthropologists have devoted much study, such as social organisation, ritual, religious beliefs and notions of beauty, for which no such universal regularity may be expected.

An ability to read the landscape

The body of theory on indigenous knowledge tends to concern information about some means of achieving an objective. However, the use of this 'technical knowledge' as a basis for evaluating understanding is fraught with difficulty. Technical knowledge may be purely empirical or based on some explanatory or mechanistic understanding. This is significant because the origins of technical knowledge may dictate the extent to which it can be extrapolated to providing solutions to different but related problems. Empirical technical knowledge may be brittle while that derived from some sounder model of system functioning may be more robust. This means that while investigation of the current state of technical knowledge may provide a basis for planning R,D&E priorities, it does not provide a very effective means of monitoring change in local understanding. Even characterising the current state of technical knowledge for research planning purposes is problematic. For example, when is technical knowledge inadequate? When resource managers can not solve a problem? What about instances where they can not see a problem? Furthermore, taking a problem-oriented perspective makes it difficult to distinguish the biophysical, social, institutional, legislative influences on and components of solutions.

An integrated approach : 'landscape literacy'

In recognition of the constraints associated with a problem-oriented perspective, some researchers working in the field of local knowledge have instead focused on, for example, the indigenous ecological knowledge that appears to underlie management practice and technical knowledge. The term that we use here to describe this hypothesised deeper, mechanistic understanding is 'landscape literacy'. This approach refers to the ability to 'read' the health and status of individual's surrounding environment (Campbell 1996).

Landscape literacy, sometimes termed 'land literacy', has been investigated in Australia in association with the National Landcare Program (NLP). The NLP has triggered a series of 'watch' and 'care' type programs which have been popular with state and federal resource management agencies and resource users alike (Campbell 1996). Examples of these include 'Saltwatch', 'Rivercare' and 'Coastcare' and they involve community monitoring of biophysical phenomena. The 'land literacy' approach has included some original approaches, such as farm fly overs to observe land management issues from the air Campbell (1996).

This involved taking farmers for a flight over their farms to demonstrate visually the position of the land in the context of a catchment. This enabled farmers to see catchment scale biophysical phenomenon such as erosion unfolding through their farms. It also enabled farmers to better see how run-off can be an issue at a farm level. Whilst such initiatives can illustrate the difference between the scale at with which the farmer is familiar and that at which biophysical processes operate, it doesn't represent a 'meeting of minds' as such, because the onus is on the farmer alone to change his or her thinking.

According to Campbell (1996) the most significant aspect of the 'land literacy' approach is the speed and effectiveness with which they transmit local environmental knowledge and share techniques to encourage people to 'read' the health of their landscape. Yet the programs he describes have had difficulty proving themselves significant data gathering through rigorous

processes. Yet even if the technical credentials of land literacy programs are confirmed, there remain further problems with this approach. For example, whilst community based monitoring 'watch' and 'care' programs foster an increased understanding of biophysical processes amongst the rural community, they only represent a 'meeting of minds' if resource users share their version of catchment processes. Structured ways of incorporating their knowledge therefore need to go beyond the level of recording biophysical data into a centralised database.

A further problem with landscape literacy is that it is more a concept than a measurable attribute. Direct measurement of the current state of landscape literacy is probably therefore exceedingly difficult. However, detection of significant changes in landscape literacy through a structured program is achievable and likely to be more relevant. One such measure could be the assessment of changes in the quality of 'problem formulation' by the community or groups within the community in response to natural resource management challenges. Given that the assessment of integrated approaches such as ICM is more concerned with detecting broad changes in thinking and behaviour, landscape literacy provides a powerful means of evaluating ICM. The study of landscape literacy is also more relevant to the analysis of broad orientations to landscape and the delineation of different groups within a catchment based upon their perceptions of their surrounds. Moreover, it provides a useful framework for considering the differences in perception between resource researchers and resources users.

Why might the assessment of local understanding be relevant to an ICM strategy?
We argue that there are three broad categories of reasons for considering assessment of local knowledge as a contribution to the ICM process.

1. ICM promotes a holistic or systems perspective on resource management issues. This must include consideration of the differing perceptions and understanding of resource management issues across different stakeholder groups.
2. Investigation of local knowledge provides a means of targeting and evaluating implementational, research and extension priorities. This can be achieved by helping to identifying constraints on action (understanding, processes, institutional structures…), by helping to educate the resource management professionals involved in the ICM process on issues from the local perspective and helping to identify key gaps in understanding as identified locally.
3. Evaluating the impact of an ICM process. Given that ICM is a participatory process that places considerable emphasis on capacity building, an ability to characterise changes in local knowledge provides a powerful tool in the assessment of the impact of an ICM initiative.

Systems thinking and participation
One of the fundamental goals of Integrated Catchment Management (ICM) is to address problems experienced by resource users in an holistic manner. However, this is complicated by the fact that diverse members of a management regime –such as a catchment- do not view and understand their world in exactly the same way. Furthermore, it would be a mistake to assume that stakeholders and resource users conceive or understand the catchment in the same way as resource professionals and researchers. This is simply because different people develop their knowledge of a resource or environment in their own individual way, and this is shaped by cultural and historical processes. Unless this is acknowledged and accommodated, integrated approaches to resource management such as ICM may be constrained by misunderstanding. It follows, therefore, that, systems approaches may seem as foreign to resource users as conventional research and development strategies. This is because systems approaches, like reductionist science, are an abstraction applied to simplify reality sufficiently to improve understanding. To achieve this, they are based on assumptions and objectives - different assumptions and objectives allowing different understandings. The research question for this paper concerns where a given management approach -in this case a systems understanding of a catchment- is inconsistent with how the human agents within the system (eg. farmers, resource users) conceptualise it. Where a model of system function which is based entirely on an external

perspective (whether integrated or not) is used to underpin research development and extension programs, the relevance of this research (and hence support for it) may be compromised.

Local knowledge as a means of targeting and evaluating research and extension
Assessment of local understanding in relation to catchment management could contribute to an ICM programme by providing a basis for targeting research and extension activities and providing a basis for evaluating the impact of an ICM process.

Targeting research and extension activities.
One of the essential questions facing research , development and extension providers intending to facilitate participatory initiatives such as Integrated Catchment Management is the extent to which natural resource management at a catchment scale is constrained by an inadequate technical understanding of bio-physical processes (ie. a problem that can be tackled through analytical research) and the extent to which it is constrained by inadequate process. If bio-physical understanding is demonstrably inadequate then further bio-physical research is merited. If bio-physical understanding is adequate but process inhibits appropriate response to the implications of that knowledge, then biophysical research is of lower priority. If some mixture of ignorance and inadequate process applies, the implications for R,D&E are concomitantly more complex. The use of local knowledge has the potential to assist targeting research priorities by analysing local observations of biophysical phenomena. Furthermore, if external research staff consider these observations, then the research program may not only be better targeted, but more accepted by local communities.

Educating Professionals
In many circumstances research and extension staff have only a limited appreciation of local knowledge and, in some cases, of local practice. This clearly constrains their ability to understand the nature of the problems facing farmers, the constraints they are under and the opportunities for improvement. It also affects their ability to communicate with farmers, affecting both their ability to obtain information from farmers about their system during diagnosis and then their ability to disseminate information and other products of research to farmers in the extension phase. Farmers' knowledge may also be more developed in some aspects, particularly those that are locally important, than that of researchers and the scientific literature. There are some stark examples of where ignorance of farmer knowledge and practice has led to inappropriate research and extension efforts and how systematic documentation of such local knowledge has led to researchers changing their behaviour (Sinclair and Walker 1999).

Local Perception Of Inadequacy Of Knowledge
In certain circumstances farmers may be aware of aspects of their knowledge systems which are less well developed than they would like, which then constrains their ability to manage their farming practice. This represents articulation of research requirements by farmers (Sinclair and Walker 1999).

Evaluating the impact of an ICM process
One of the main objectives of ICM as a policy initiative is to foster an ability at a local level (including both the community and local state government representatives) to conceptualise and agree on natural resource management problems as and when they arrive and, thereby, agree on and implement solutions in an integrated and holistic manner. There are various ways in which changes to this capacity might be measured, including case study consideration of 'on the ground' activities. While important, this measures some synthesis of change in local understanding and motivation with institutional, financial and other circumstantial factors. Direct consideration of changes in local understanding of catchment issues and processes helps to deconvolve these factors and, therefore, provides one line of enquiry in evaluating improvement or otherwise in the capacity of the community within the catchment to achieve the sustainable and balanced use of natural resources. In summary, an increasing understanding

of the state of the environment and impacts on the environment can be an important indicator of the efficacy of the ICM process.

Approaches to investigating local knowledge

In the previous sections we have discussed the nature of local knowledge and explored the potential relevance of the investigation of local knowledge to ICM processes. Any practical application of approaches to investigating local knowledge in order to inform and evaluate program initiation would need to be based on some approach to knowledge elicitation and analysis. For example, assessment of the impact of an ICM process through consideration of impact on the 'landscape literacy' of resource users and managers in a catchment might document changes over time in the characterisation of the bio-physical aspects of a key set of natural resource management problems (both causes and consequences) and proposed solutions to these problems. Analysis might consider the extent to which consensus as to the nature of pertinent problems and potential solutions has evolved and evaluate the extent to which changes in perception are supported by data and, thereby, assess the contribution of ICM to any such changes. These objectives would need to be underpinned by a series of workshops and interviews with a range of different community groups within the catchment. In this section we explore some of the tasks that might be tackled ad some approaches to those tasks.

Key research tasks

For defined groups within the catchment a study would need document the following on an annual basis.

1. Characterisation of each issue
   For example,
   How is the issue conceptualised / perceived (causes, implications etc.)?
   How much consensus is there in characterisation of the problems?
   Can differences be delineated into broad groups of approach?

2. Completeness of understanding for each issue
   For example,
   Has the perceived problem / issue been demonstrated to be a real problem / issue?
   If not, why not?
   In particular, what further information is required if the problem is to be adequately understood?

3. Availability of potential solutions for each issue
   For example,
   What are the perceived solutions to the problems?
   What is the nature of the proposed solutions (including type eg. technical intervention, institutional change, fiscal change, economic change, social change..) ?
   What consensus is there on potential solutions?
   What further information is needed in order to further develop and evaluate potential solutions to a point where application is appropriate?

4. Analysis of change over time.
   For example,
   Are stakeholders becoming aware of differences in approach amongst other groups?
   Are the differences in local understanding becoming more or less pronounced throughout the ICM process?

To investigate the some of these issues, a series of trials were conducted with resource users and professionals in the Herbert River catchment. These trials were useful in revealing some of the pragmatic and operational issues involved in the elicitation of local knowledge. Two main

approaches were trialed: work with individuals and work with small groups. The trials involved a combination of structured interviews, semi-structured interviews and scenario based discussions. A summary of these trials is discussed below.

Trial 1: knowledge elicitation, representation and analysis: interviews with individuals

A trial of methods was designed to explore a range of approaches to eliciting technical knowledge relating to catchment management (with an initial focus on characterisation of the physical nature of issues / problems) in order to scope out some of the operational issues that would be involved in the design of a large scale research project. The trials contributed to a broader evaluation exercise for the ICM research program in the catchment. The overall evaluation exercise addressed issues such as water quality; water quantity (availability); drainage; flood protection; riparian zone management; habitat management and protection; soil erosion and sedimentation; and pest management, and the local knowledge trials reflected these broad categories. Given the 'integrated' nature of ICM individual issues were not treated in isolation. For the individual interviews, three techniques to knowledge elicitation, representation and analysis were investigated. Two farmers, two researchers and one drainage engineer were interviewed. Each completed all three parts of the trial in a single interview of between one and one and a half hours.

1. Questionnaire survey.
A number of statements of problems, causes and consequences within the catchment were derived from the overall ICM evaluation program. Informants were asked to react to these statements by using a 5 point scale. Analysis of responses to the questionnaire survey enabled some quantitative measure of consensus of understanding on the physical nature of issues in the catchment across and within groups concerned with catchment management. The questionnaire survey was well received by all informants and seemingly both straight forward and of interest to them. The results are presented in Appendix 1. These results are of interest but fail to capture much of the detailed understanding displayed by the different informants. The results of the questionnaire apparently identify a considerable diversity of views across informants without obvious patterns in terms of informant type. However, this masks an impressive convergence of opinion between informants that was clear during the interviews. Although significant effort was put into the structure and content of the questions, it is clear that at the very least much more sophisticated questions are required. However, on the basis of these trials it is unlikely that this type of questionnaire survey alone will adequately reveal the structure of perception.

2. Semi-structured discussion
This part of the interview focussed on soil erosion in the Herbert and what happens to soil from paddocks in both the upper and lower catchments once it is washed off the paddock and into the stream system.
The following were focussed on in particular:
i) The factors that determine whether significant soil erosion will occur as a result of rainfall.
ii) Factors determining how much sediment enters the river system
iii) The fate eroded soil once it enters the stream system
The semi-structured interviews investigated the potential for explanatory knowledge to be used to help create a formalised knowledge base, with a view towards developing consensus models of the behaviour of the physical system. It was also considered a potential way to capture a range of inconsistent perceptions across the informants. By contrast with the questionnaire, most informants found the semi-structured interview seeking explanatory knowledge uncomfortable. Although this did produce some interesting results, notably in the different approaches to explanation taken by the different informants, it was not found to be a very successful means of eliciting knowledge. Although the semi-structured interviews were not very successful, the knowledge elicited, as well as much of the subsidiary information collected while completing the

questionnaire were highly amenable to representation within the formal grammar and knowledge base structure used.

The questions for the semi-structured interviews are reproduced as Appendix 2. An excerpt of these interviews is reproduced in Box 3.

Box 3
The following excerpt provides an example of local knowledge being used to explain the relationship between rain impact, ground cover and sediment flow: In this example, the informant can see some benefits from ground cover being used to reduce sediment entering the waterflow, however, he has difficulty seeing on-farm benefits from stream side vegetation:
INTERVIEWER : In terms of ground cover side of things, why does that minimise soil erosion?
INFORMANT: It minimises and might even reduce rain drop impact. It also slows down the speed at which the water flows over the land and therefore removes most of its erosive energy and also the energy that it has available to carry sediment as it moves.
INTERVIEWER : Those are the two main impacts?
INFORMANT: Yes I think so.
INTERVIEWER : And vegetation along the stream banks is important?
INFORMANT: Yes but all that does is to cause energy reduction at the top of the stream bank rather than over the whole paddock behind it and as I said before, in my opinion, having that sort of track is probably beneficial to the waterway but its not necessarily beneficial from the point of view of conserving the soil resource because you could envisage the situation where you allow the stuff to build up until you had a great big build up of sediment behind whatever track you had and what are you going to do with it then? You could dig it up with a spade and spread it back on the paddock but it would just get washed up again, so I tend to think the use of vetava [grass], whilst its not a bad idea, its bit of a band-aid measure. You're better of stopping the stuff from being removed from its point of generation to start from.

3. A scenario-based approach

This exercise was based on three fictitious plans for cane expansion in a fictitious catchment. Information was provided in the form of a map and three scenarios presented in relation to that map. Informants were asked which they would favour and, more importantly, their justifications for favouring that plan. The scenario-based exercise was recorded and the taped interaction was used to explore, for each informant, a representation of the argument and evidence that they used to present and justify their selection. Two means of doing this were explored : descriptive analysis and use of a formal grammar designed to capture the structure of an argument.
The scenario-based exercise proved more difficult for the informants than was expected. However, it was extremely successful in that it captured a considerable amount of information about the interpretation and application of knowledge as well as the knowledge itself. Despite general consensus on physical issues of concern in cane expansion, each of the three scenarios (which have different potential environmental impacts and implications for productivity) was selected by at least one informant. This range of responses can be attributed to different values, different views of what the future holds and different interpretations of the implications of common understanding. These factors are obviously at the heart of ICM.
The text of the scenario exercise is reproduced as Appendix 3. An excerpt from the scenario based approach is represented in Box 4.

Box 4
Excerpt from scenario based approach to eliciting local knowledge.
INTERVIEWER : I want your ideas on how you go about considering which option would be most appropriate
INFORMANT: I feel that I wouldn't want to be draining this area here through that eastern block, I feel it needs something like that would have to be done
INTERVIEWER : Why would you not want to do this?
INFORMANT: I think it would be too much downstream effect not only on landholders but also on this whole wetland area
INTERVIEWER : What would that be?
INFORMANT: You going to be putting water from one catchment area into another catchment area which already is a huge catchment area to start with and your sending it the longest way to get to the coast.
INTERVIEWER : It would be an increase in water coming through that grazing land and into the wetland?
INFORMANT: That's right I would say that if a study was done into what the drainage capacity of this area would be, it wouldn't be able to handle that also, because you've got all these streams running into it also. The other thing is that you have a lot of problems with drainage schemes. I don't think enough consideration is taken into the fact that not only the water from the farms ends up in that drainage scheme but the land around it the surrounding country side tends to go into that area, we've seen this happen in the Herbert before where drainage schemes haven't been planned properly

Trial 2 : Making comparisons across groups: workshops with multiple participants

Following the first series of trials, the use of small groups was investigated as a means of eliciting local knowledge. It was decided that a number of different (but preferably related) scenario selection exercises would provide a useful trial, considering different management options in a fictitious catchment. Maps of the topography and hydrology of the hypothetical catchment, current land use and tenure, soils and land use suitability for sugar cane were prepared to support the exercise, and a scenario description was also prepared (see Appendix 4). Two groups of 8 farmers each were approached, each representing having different demographic characteristics and different levels of experience in sugar farming. The first consisted of farmers over 50 with more than 20 years cane farming experience. The second consisted of farmers under 40, all of whom were at least second generation cane farmers. All of the first group attended the workshop. Some members of the second group accepted the invitation but did not in the end attend.

Both workshops resulted in considerable and heated discussion, thereby providing a considerable insight into farmers' perceptions of catchment scale issues. While the scenario provided a useful point of departure and reference for this discussion, it proved hard to keep the discussion focussed on the scenario, such that it proved impossible to get a clear justification for the group for selection of a particular scenario. It is anticipated that altering the scenario rules and moving towards a scenario selection and vote at the end of this workshop would mitigate this problem. On the basis of the trial only, it was difficult to clearly delineate differences between groups of farmers. Nonetheless, some interesting insights from this introductory study are worth noting, an example of which is reproduced in Box 5.

Box 5

The group workshops indicated that there were different perspectives amongst farmers. However, based on the scale of the study it was difficult to delineate significant broad trends in perception. The same applied to the farmer's ability to 'read the landscape' or 'land literacy'. Some comments gave isolated examples reflecting farmer's land literacy. Though insufficient to draw significant conclusions on the basis of this land literacy, it revealed that it could be elicited reasonably well with minor changes to the workshop process.

As part of the group based workshops, farmers were asked about expansion into wetland's areas. For this group of farmers most agreed that wetlands were best left untouched because they thought that wetlands helped to absorb nutrient runoff from farms and provided wildlife habitat. These farmers tended to think beyond their own farm into the surrounding area (workshop comments in different font).

"Should there be expansion into the wetlands area?"

"Wetlands shouldn't be touched - not allowed to. "

"I don't believe they should be drained - they are important wildlife habitats and they help to preserve aquifers. "

Other farmers were more focussed on their own farm operations. If wetlands should be expanded into or not was a case of whether wetlands were suitable for cane growing:

"When a wetland is next to a creek it is impossible to keep it drained."

"Forget about trying to drain mangroves - no other land use is worthwhile."

"It depends on what you call a "wetland". If you conserve everything; you can't grow cane. On the other hand, you could knock it all over and have nothing but cane. Up till now the policy has largely been; knock it down and grow cane."

Other farmers looked at the question from a dual perspective:

Box 5 continued.

"Some of the wetlands should be kept but not all of it - some would be OK to develop."

This group of farmers were mostly agreed in their approach to clearing remaining patches of rainforest. The economic argument was the strongest:

"What about the remaining patches of rainforest - are they worth keeping?"

"Many of the trees in these areas are not original vegetation - in fact they are more recently grown - 80 years or less."

"There is pressure to clear for economic reasons. The government or the community needs to be prepared to buy back the land at the market value."

"The landowner will always go the way of economics."

"If the community wants to preserve the forest then it should be prepared to buy it. The farmer had to buy it first."

The discussion continued on the basis that clearing is acceptable and it shifted to consider how close clearing should get to streams.

Catchment Coordinator: "The Water Resources Act (1993) protects the top of the banks but the River Trust does have the power to enforce wider restrictions."

"The River Trust and the BSES need to accept responsibility to assess clearing to river banks in order to determine how much protection is required. This should be tied up with legislation."

"This would be hard to police."

"Could there not be registered easements between all properties which would be tied up by law."

Other Issues for Consideration

The workshops attempted to use hypothetical situations to trial elicitation of local knowledge. It became apparent that the use of hypothetical scenarios were problematic. What emerged was that farmers were much more confident with knowledge which applied specifically to their farm. This reveals something about the nature of local knowledge. An advantage is that it provides experience and perspectives that may be overlooked by scientific method, however applying outside of the farm requires ingenuity and initiative. An example of this issue is presented in Box 6.

Box 6
Identifying problems from first hand experience
It became evident that farmers were having difficulties making predictions about the hypothetical catchment because their understanding was so intrinsically tied to their own individual circumstances. Whilst asked to consider some potential scenarios, farmers spoke almost entirely of their first hand experience:
'Around my house, floods have dropped sediment – as much as 4 inches.'
'My local creek is now always dirty – never clear'
The workshop highlighted some important characteristics of local knowledge. Unlike scientific method, the predictive capacity of local knowledge is low. The advantage of local knowledge is that it can provide an impressive level of detail and insight by drawing on personal experiences, and inform an agenda for systematic research.

The validity of an investigation of local knowledge

The interviews and workshops with farmer groups in the Herbert Catchment described in the previous section were undertaken as methodological trials and were not intended to produce particular insight into local knowledge and ICM in the Herbert. Nevertheless, assessment of the material elicited illustrates that while farmers knew precisely what the word 'catchment' meant, they did not naturally view the landscape that they live and work in as being part of a catchment and, therefore, did not see the catchment as a natural unit of management. By contrast, for natural resource professionals who were the authors and champions of ICM, a model of the landscape as a set of catchments that provided natural units for rational management was both intuitive and powerful. The limitations of this simple but external model of the landscape makes the expected 'meeting of minds' between the two groups more demanding than would otherwise have been anticipated.

This simple example illustrates the basis for a view that while local knowledge is a critical component of initiatives such as ICM, this does not provide a justification for its explicit and professional investigation. As the pendulum swings away from an interventionist external paradigm for development to an increasingly participatory one, it is being argued that development professionals should leave the systems thinking to the target communities – if provided with the range of technological solutions available, local communities can undertake their own systems synthesis to generate solutions (Blaike et al., 1997). It would appear to follow from this that farmers do their own analyses, research and information exchange and there is no need for a systems perspective on the part of development professionals. It is increasingly fashionable to put this view forward in terms of contrasting hard and soft systems approaches (Scoones and Thompson, 1994) with the implication that since rural development is inherently a process played out by various people making decisions (referred to as actors), that only soft systems methods (Checkland and Scholes, 1990), that concentrate on the social organisation of knowledge (Engel, 1995) are appropriate. In this frame of analysis, attempting to obtain a systematic understanding of what local people know about the ecology of their environment and farming practices is criticised as being inherently extractive, because it is assumed that it must entail the imposition of an external rationality (Scoones and Thompson, 1994). This view questions the validity of systematic study of local knowledge by development professionals as a part of the development process but, notwithstanding its current popularity, unnecessarily polarises the debate on relevant methodology for working with rural people and their knowledge, and raises concerns, which on further examination, are invalid.

In reality, hard and soft systems methods are not mutually exclusive but, in fact, play different roles and are appropriate for different purposes and hence for application at different hierarchical levels. The 'hardness' of a system is determined by how well defined, stable and quantitative the system mechanism and purposes are. It is, therefore, useful to conceive of resource management activities as consisting of harder ecological systems at the organism, field, farm and catchment levels that are managed by people within household and other social

structures, thereby creating increasingly soft systems as more of the social structure is included. Farmers, therefore, albeit within a complex soft systems framework, are managing the ecology of their farming practices, which can be tractably understood, at least to some extent, using a blend of hard and soft systems methods. Thus, partial views of the relatively 'hard' ecology of a farming system are a useful and valid tool, providing their partial nature is fully understood, in as much as what farmers actually do in their farming practice is determined by other social and cultural factors, as well as their knowledge of agroecology. Indeed, a systematic appreciation of farmers ecological knowledge can sometimes help to distinguish the action of socio-economic determinants.

Although it is a danger that has often been apparent when researchers have analysed local knowledge, seeking to obtain a systematic view of local knowledge does not necessarily imply the imposition of an external rationality. It is possible to seek local explanations and to represent them. The western scientific tradition does not have an exclusive claim to systematic understanding of ecological processes and it would be patronising to posit that farmers do not have locally derived understanding that may be systematic. There is, in fact, increasing evidence from various agrarian societies, from studies using a variety of different methods, that farmers often possess a sophisticated, locally derived and general understanding of agroecology comparable with, although different from, scientific formulations (Berlin 1992; Fairhead and Leach 1994; Richards 1994; Thapa, Sinclair, and Walker 1995). It is important then not to confuse the development and use of formal methods with the imposition of a particular rationality. Quite different explanations for particular ecological phenomena or the efficacy of farming practices can be codified using formal notation. Indeed, dealing with local knowledge explicitly, may assist in revealing where external interpretation occurs, as well as common ground between different knowledge systems. The use of formal methods to represent local knowledge (a process of abstraction rather than extraction) can, therefore, be seen as according rural people's knowledge a status on a par with scientific knowledge rather than as an 'extractive' process that somehow diminishes or distorts it. However, empowerment of local people in a participatory development process does not necessarily preclude the need for strategic research and extension by development professionals. In fact, the existence of sophisticated ecological knowledge amongst farmers, based on their own observation and experimentation, improves the prospects for research to be done by supporting institutions that address fundamental questions that farmers have difficulty tackling because of resource constraints or limitations in their ability to make observations. While in many situations it is unlikely that professional researchers can improve on farmer's adaptive research, they may well be in a position to contribute by doing strategic research and extending information about ecological mechanisms that farmers find difficult to observe. To design such strategic research and extension activity on the basis of what farmers require and to be able to communicate effectively about agroecology, development professionals need to be aware of what farmers already know (Sinclair and Walker, 1999). It is for these reasons that a more suitable reaction to the failings of a systems approach based on external perspectives, is to seek an internal (local) construction of a model of the system that development professionals can access and use. Furthermore, this approach is both compatible with, and complementary to, participatory approaches to research and extension.

In summary, it is reasonable to propose that initiatives that are aimed at impacting on management (implying that people change their behaviour) are likely to be much more efficient where premised on the conception of the system used in management than on some external conception or none at all. This does not mean that the models of system functioning held by farmers are more correct than the models that might be generated by external professionals. However, the farmer's model of the system is an important consideration for ICM and a representation of a local community's view of the systems and practices under development will seriously enhance research, development and extension.
The discussion of local knowledge presented in this paper provides some useful insights into the complex set of issues involved in elicitating, recording and analysing local understanding of

catchment processes. Conceptually, there are some clear advantages of incorporating local knowledge into ICM processes, notably in terms of targeting and evaluating research. A review of literature revealed that educating natural resource professionals about farmer knowledge and practice has the potential to change their perception of what is important, the terminology they use and the type of research they do. It may reveal important understandings of the catchment which scientific inquiry has overlooked.

Where attitudes and behaviour are unsustainable, it is important to understand why these attitudes and behaviours exist, and what sort of perception of the land they reflect. The literature review and the trials confirmed that local knowledge has the potential to play a significant role in addressing these issues. It can assist research and external managers to understand the ways catchment groups perceive their environment, and what the implications of these perspectives are. Local knowledge is also a key consideration for improving rates of adoption in research, development and extension programs. Through the analysis of local knowledge, ICM programs can be developed in such a way that public participation is meaningful to both researchers and resources users alike.

Appendix 1 : questionnaire survey

Codes for informants in questionnaire results :
1 - Farmer
2 - Farmer
3 - Researcher
4 - Researcher
5 - Drainage engineer

Response codes:
SA - strongly agree
A - agree
NS - not sure
D - disagree
SD - strongly disagree

Water quality (pollutants)

	SA	A	NS	D	SD
The problem					
Water quality within the rivers, streams, estuaries and ground water in the Herbert is declining.		3	4	125	
Nutrient loads within the rivers, streams, estuaries and ground water in the Herbert are unacceptably high.				123 45	
Pesticide residues within the rivers, streams, estuaries and ground water in the Herbert are unacceptably high.			34	125	
Causes					
Urban areas are a significant source of pollutants in the Herbert catchment.		134	25		
Agricultural production is a significant source of pollutants in the Herbert catchment		34		125	
Mining is a significant source of pollutants in the Herbert catchment		124 5		3	
Aquaculture is a significant source of pollutants in the Herbert catchment			5	123 4	
Consequences					
Pollutants in the streams, rivers and estuaries of the Herbert catchment are causing significant damage to freshwater and coastal ecosystems			34	125	
Pollutants in the streams, rivers and estuaries of the Herbert catchment are causing algal blooms				123 4	5

Ranking

Rank the following sources of pollutants in terms of importance at the mouth of the Herbert River (1=greatest, 4=least).

Urban sources
Agricultural production
Mining
Aquaculture

How confident are you about this ranking?

Water quality (sediments).

	SA	A	NS	D	SD
The problem					
Soil erosion and sediment loads in the Herbert River are significantly higher than they would have been under natural conditions.		345		12	
Soil erosion and sediment loads in the upper catchment are significantly higher than they would have been under natural conditions.		123 45			
Soil erosion and sediment loads in the lower catchment are significantly higher than they would have been under natural conditions.		4		123 5	
Causes					
Removal of native vegetation in the lower catchment is a primary cause of increased sediment load		245		13	
Removal of native vegetation in the upper catchment is a primary cause of increased sediment load		123 45			
River bank collapse due to inadequate riparian zones is a primary cause of increased sediment load		145	3	2	

Erosion rates have not increased but more sediments are reaching the river system as a result of removal of substantial areas of riparian vegetation on tributaries of the Herbert river		12	35	4	
Stock concentration along water courses in upper catchment is a primary cause of increased sediment load		135	24		
Road construction and similar work is a primary cause of increased sediment load	4	135		2	
Old mining areas are a primary source of increased sediment load	1	235	4		
Impacts					
Increased sediment loads are causing accelerated sedimentation / aggradation of the river system		1345		2	
Increased sediment loads are reducing the efficiency of natural and man-made drainage systems		12345			
Sedimentation of stream beds is causing an increased number of overbank flood events		15	34	2	
The Hinchinbrook Channel and Missionary Bay are experiencing increases in sedimentation	4	135	2		

Ranking

Rank the following causes for increased sediment accession into the drainage system in terms of importance (1=greatest, 7=least).

Inadequate vegetation cover (upper catchment)
Inadequate vegetation cover (lower catchment)
River bank collapse
Stock concentration along water courses
Removal of riparian zones as sediment traps
Road construction
Erosion from mining areas

How confident are you about this ranking?

Surface water quantity - wet season

The problem	SA	A	NS	D	SD
The way in which water moves through the catchment has changed as a result of man's activities	2345	1			
Rainfall runoff from inland areas of the catchment is significantly faster than it would have been under natural conditions.		12345			
Coastal areas of the catchment are more often inundated with water and that water stays around for longer than it used to.		1235	4		
Causes					
Clearing of native vegetation for conversion to pastures increases runoff rates		12345			
Clearing of native vegetation for cane production increases runoff rates	35	124			
Clearing of native vegetation for forestry increases runoff rates		1	5	234	
Converting pasture to cane land increases runoff rates		1345		2	
The introduction of levees and other control features and unintentional interventions (eg. raised banks for the railway) have significantly altered water flows	235	4		1	
Drainage schemes in areas of expansion are having a serious impact down stream by increasing the rate of runoff	5	1234			
Laser levelling is having a serious impact down stream by increasing the rate of runoff		45	3	1	2
Increased flooding risks can primarily be attributed to siltation of the river beds.		235		14	
Consequences					
The design capacities of drainage schemes in the coastal areas of the catchment have been exceeded		1235	4		

Paddocks in the lower catchment are under water more often and for longer		123 5	4		
This leads to a decline in cane yield		123 45			
Increased flooding is causing significant land degradation			5	123 4	
Increased flooding is causing habitat destruction		4		123 5	

Surface water quantity - dry season

The problem	SA	A	NS	D	SD
Base flows in some areas in the river and stream systems are significantly reduced from their natural levels		134	2	5	
Causes					
Increased runoff rates during the wet season mean that less water is stored in the catchment through into the dry season		124		35	
Extraction of water for irrigation from the river during the wet season means that less water is stored in the catchment through into the dry season		4		123 5	
Consequences					
Some wetland areas are becoming drier as a result of inadequate recharge during drier periods		12	4	35	
Reduced base flows in the dry season are causing increased habitat destruction		3	14	25	
Reduced base flows are having an ecological impact - for example on fish breeding		13	4	25	
Changes in the timing of water flow may cause acid sulphate soil problems to occur in the Herbert		35	2	14	

Ground water

The problem	SA	A	NS	D	SD
Ground water resources in some areas within the Herbert catchment are becoming depleted		3	4	125	
Causes					
Excessive pumping of ground water in some areas for irrigation is having an impact on ground water levels.		34		125	
Alteration of drainage characteristics of catchment is leading to more runoff and less deep penetration to recharge ground water		234		15	
Consequences					
Reduction in ground water means that the baseflow in streams in the dry season has dropped		234		15	
Reduction in ground water means that the baseflow in the main river in the dry season has dropped		34		125	

Appendix 2 : Semi structured interview questions

1. Presentation of the issue

I'd like to talk in more detail about one particular issue - soil erosion in the Herbert and what happens to soil from paddocks in both the upper and lower catchments once it is washed off the paddock and into the stream system.

There seems to be considerable disagreement about how widespread this type of erosion is in the catchment and what its consequences are.

In particular :

i) What are the factors that determine whether significant soil erosion will occur as a result of rainfall? Why?
ii) What factors determine how much sediment enters the river system? Why?
iii) What happens to eroded soil once it enters the stream system?

Appendix 3 : Scenario selection by individuals

(supported by use of an A0 sized map showing a fictitious catchment in north Queensland in some detail)

Having looked at your opinions on the issues and the basis for some of these I'd like to briefly look at the implications they have for decision making.

I would like to present three plans for cane expansion in a fictitious catchment and ask you which you would favour and, more importantly, your justifications for favouring that plan.

Details
A mill (in the town) shown requires an increased throughput to remain economically viable.

Two areas for expansion have been identified - Eastern Block and Western Block.

Expansion has been agreed for one of the two sites - the question is which?

The Eastern Block would require drainage of the small wetland area.

The Western Block could be converted without drainage.

However, extensive drainage taking water from this area completely would increase land use suitability from 3 to 2 for most of the area.

Scenarios
Scenario 1 : Convert Eastern Block.
Scenario 2 : Convert Western Block without drainage scheme
Scenario 3 : Convert Western Block with a drainage scheme.

Appendix 4 : Group-based scenario discussion

Cane Expansion in the Milltown Catchment

The Milltown catchment is somewhere in north Queensland. Cane has been grown in the area for many years, however the management of the catchment's sugar mill (situated in Milltown) feels that it has to increase production in order to remain nationally and internationally competitive. Two areas have been identified as being suitable for expansion - The Common on the eastern side of the catchment, formerly Crown Reserve land but now under leasehold to Milltown Council, and The Station, part of a freehold grazing property on the western side of the catchment.

Conversion of The Common would require some drainage works. Conversion of The Station could be done without a drainage scheme. However, a major drainage scheme has been proposed which would increase the land use suitability for cane of most of The Station from 3 to 2. This would involve a major drain running up through the lowland rainforest area to the south of Milltown and then across the southern edge of the town to the sea.

The Milltown catchment is typical of many in north Queensland. Flooding and drainage, water supply for irrigation in the dry season, water quality, acid sulphate soils, soil erosion and the sedimentation of river systems are all actual or potential problems. Habitat management and protection are also significant issues with rapidly declining lowland rainforest and wetland areas. Two high-profile and endangered animal species are found in the catchment.

We would like you as a group to discuss the ways to try to meet the sugar mill's needs for increased through-put and the industry's desire to produce more cane in the Milltown Catchment. In making your recommendation (as a group) think as broadly as possible about options for the catchment. Whatever you recommend, we are particularly interested in the reasons for your recommendation and the issues that you feel needed to be considered in reaching your conclusion.
