ACKNOWLEDGEMENTS

The authors wish to acknowledge the financial support of the Land and Water Resources Research and Development Corporation over a five year period, which made this research possible.

The authors wish to express their extreme gratitude to all those people with have an interest or who are actively involved in the implementation of Integrated Catchment Management in Queensland and who gave time from their busy schedules to complete interviews or questionnaire survey forms that were fundamental to the success of many project activities. Of special note are the following people and agencies who willingly co-operated and provided valuable assistance to this five-year research project:

- The members of the Herbert River Catchment Coordinating Committee who actively participated and contributed their valuable time, views and knowledge.
- Dave Horsley, CSR Herbert River Mills, who was an invaluable source of information on natural resource management and related activities in the Herbert River catchment, provided substantial advice to the researchers and contributed actively to many of the research activities of this project.
- The Herbert River Catchment Coordinators, Rob Hunt and subsequently Andrew Petroeschevsky, who provided valuable comment and information as well as facilitating interactions with HRCCC members.
- Ray Quabba, Chair of the HRCCC, who gave his time, knowledge, invaluable assistance and encouragement to the researchers over the life of the project.
- Philip Rowland, Mike Merrin and Don Begbie, Department of Natural Resources, Queensland who have actively supported the project since its commencement and provided valuable assistance and access to information to the researchers involved.
- Luis Laredo, CSIRO Tropical Agriculture, Brisbane, who has provided valuable general computing assistance to the researchers involved and contributed actively to database development and management for some key research activities.
- Kathy Mitchell and Leesa Austin, CSIRO Tropical Agriculture Brisbane, for invaluable assistance in the preparation of this publication.
- Jan Green, CSIRO Tropical Agriculture Brisbane, who has provided valuable assistance to the preparation and design of this publication.

Abstract: The emerging focus on ecologically sustainable development (ESD) has caused a paradigm shift in the theory underpinning natural resource management. Increasingly, this shift is reflected in policy. The adoption of the new paradigm for natural resource and environmental policy and research demands a new approach to evaluation. This paper develops a systems framework for the evaluation of natural resource management programmes based on a consideration of the changing nature of approaches to natural resource management programs and observation of and experience in the practical assessment of on-the-ground projects. The framework provides the basis for an integrated evaluation of the different perspectives (i.e. social, economic, environmental, institutional and technological) on the natural resource management and planning process. It recognizes the multiple levels and nested nature of natural resource management policy and research, namely: problem characterisation, policy formulation and intent, program logic, and on-ground implementation. Having developed and presented this framework on the basis of practical experience, we demonstrate its utility through application to six contrasting case studies and discuss the implications.

1. INTRODUCTION

Recent theoretical developments in the natural, social, policy, information and management sciences reveal parallel development of a new paradigm of progress toward sustainable development that emphasise continuous change, adaptation and learning (e.g. Funtowicz and Ravetz 1990, Orlikowski 1992, Boehmer-Christiansen 1994, Gunderson *et al.* 1995, Chambers 1997, Ison *et al.* 1997, Wallace *et al.* 1996, Dovers and Mobbs 1997). Although there is limited consensus on exactly what sustainable development means, it has become the widely accepted term that describes "the goal of achieving a high, equitable and sustainable quality of life by integrating into a single conceptual framework the social, economic and environmental activities, outcomes and impacts of human society" (Eckersley 1998, p.6). Continuous change is perceived to be inherent in social, political, economic, technological and environmental systems. Realities are multiple, in constant flux, sometimes in conflict, difficult to measure and demand judgement. Change is increasingly recognised as being non-linear and dynamic, and to be more interconnected and instantly communicated than ever before. For change to be acceptable and beneficial, it must be socially, economically, institutionally and environmentally sustainable. Coping with and managing accelerated change requires a systemic approach characterised by pluralism, adaptation and learning that is incumbent upon personal responsibility and opportunity at the local level.

Increasingly, this shift in theory is reflected in policy. A range of new natural resource and environmental policy models and other sustainability initiatives are emerging worldwide (e.g. Gunderson *et al.* 1995; Wallace *et al.* 1996; Gardner and Stern 1996; Bellamy *et al.* 1999). In general these policy models are framed at the macro level (eg. national, state, regional, catchment) with the intent of facilitating the emergence of adaptive processes and progress towards sustainable development at the micro or local level (eg. sub-catchment, municipal/local government area or farm enterprise). The predominant rhetoric of these approaches is grounded in the underlying assumptions of the new paradigm of change, adaptation and learning and includes:

- Systemic approaches
- Long term perspectives and multiple scales of relevance
- 'Wicked' problems
- Inherent ignorance
- Relevance of the human and cultural context of implementation
- Pluralism in individual, community and professional values, agendas and behaviours
- Responsibility and accountability (eg. duty of care) at both individual and institutional levels.

In practice, implementation of natural resource management policy models is proving challenging to the individuals, the institutions and the communities concerned (eg. Dorcey 1991; Gunderson *et al.* 1995; Syme *et al.* 1994; Gardner and Stern 1996, Bellamy *et al.* 1999)).

As a consequence, actual impact has often fallen short of expectation. Chambers (1997) remarks that "myths have led to massive misallocation of funds and human resources, to misguided programmes, to missed opportunities and among professionals to deception, cynicism and loss of commitment" (p.100). We argue that such difficulties can be attributed in part to the inadequacy in evaluation of the efficacy of policies, planning and research on natural resource management initiatives that can contribute to on-going improvement in their development and implementation.

2. EVALUATION IN NATURAL RESOURCE MANAGEMENT

Program evaluation and policy analysis are recognised as critical elements of successful policy development and implementation (Dovers 1996). With increasing demands for both adaptive approaches and better scrutiny of the use of public funds, and greater accountability for environmental protection and equity in natural resource use, the focus of policy analysis and program evaluation and implementation has shifted. The new focus is on improving transparency and accountability including how effectively and equitably resources are used, making explicit the purpose of the policy or program, monitoring the process of implementation and assessing value and general performance. In Australia, monitoring and evaluation has become a high priority for funding bodies in order to address the need for responsible accountability in the investment of taxpayers funds for on-ground works projects (e.g. ANAO 1997) and on research (e.g. LWRRDC 1997). However, performance monitoring, evaluation and review in natural resource management policy have been widely neglected, with a substantial gap emerging between theory and practice (Wallace *et al.* 1995; Curtis *et al.* 1998; Bellamy *et al.* 1999).

2.1 The Practice

Within the context of integrated resource management policy implementation, Bellamy *et al.* (1999) have challenged the efficacy of conventional models of evaluation. Evaluation of natural resource management and planning has generally been:

- fragmented in terms of reconciling the different domain perspectives in evaluation (Bellamy *et al.* 1999);
- insensitive to the socio-economic, policy/institutional, and environmental context within which performance is assessed (Syme and Sadler 1994; Bellamy *et al.* 1999);
- hampered by an inherent lack of assessable goals and outcome measures (Wallace *et al.* 1995; ANAO 1997); and
- broad one-off overviews conducted as a cross-sectoral snap-shot in time rather than a systematic longitudinal study (Bellamy *et al.* 1999).

Although approaches to natural resource management based on the integration of community involvement, technical knowledge, and organisational structure and policy objectives are endorsed both in Australia and overseas, there are no generally accepted models of evaluation of such initiatives. Existing frameworks may provide a checklist of multiple-disciplinary criteria relating to the environmental, social, economic and institutional perspectives but not an integrated evaluation (Bellamy *et al.* 1999). Significantly, no clear evaluative framework has emerged to guide continuous improvements in the way natural resource management policy initiatives and research contribute to on-going improvements in the sustainability of resource use and social well-being of the communities concerned. In effect, an over-arching systemic framework to guide the evaluation of NRM policy initiatives is lacking.

2.2 Theory Development

Theory development for the evaluation of complex and integrated approaches to natural resource use management and planning, in general, is poorly constructed. Ison *et al.* (1997) argue that the emerging systems perspectives of complexity science, 'chaos' and self-organising theories and complex adaptive systems can "bridge the natural, socio-economic and management sciences by serving either as explanations of phenomena or as metaphors which can guide thinking and action" (p.261). General systems theory has the potential to provide evaluation with a powerful conceptual tool for analysing complex uncertain impact chains. We argue that natural resource management initiatives need to be evaluated as a system that links the objectives and instrumental rationale of the policy, program or product to actual performance on the ground. An effective framework for evaluating the success of natural resource management and planning approaches needs to be based on pragmatic considerations and draw on evaluation principles and methods from a broad spectrum of other disciplines (e.g. evaluation research, social psychology, impact assessment, ecology, economics, organisational science, management science, and technology assessment) to characterise, monitor and evaluate the process and its outcomes. Synthesis of these multiple perspectives to define the construct space for evaluation of these phenomena requires the development of an integrated or systems approach (Bellamy *et al.* 1999).

2.3 Bridging the Gap

Developing an improved framework and methodologies for analysing situations, incorporating institutional concerns and, in turn, informing the process requires a systemic and integrated approach that needs to:

(a) evaluate public and private investment in integrated approaches to natural resource management;
(b) identify critical social, economic, institutional, environmental and technological factors that influence the success of natural resource management initiatives;
(c) develop appropriate performance criteria for assessing the potential impacts of an approach not only on the management of natural resource systems, but also on institutional arrangements and society as a whole; and
(d) identify what the outcomes and expectations of an integrated resource management initiative might be;
(e) establish guidelines and techniques for self-evaluation of progress towards the achievement of agreed objectives and planned outcomes, including consideration of equity and social justice issues.

It is critical that policy makers, researchers, project managers and so on are able to implement effective evaluation of their programs and activities. However, these people inevitably have limited time and skills to apply to the evaluation process, at the very least because it is incumbent on them to undertake evaluation efficiently so that the evaluation process does not in itself adversely affect achievement of operational objectives. Our practical experience suggests, however, that both community-based resource management groups and resource management agencies are very amenable to the suggestion that a significant investment might usefully be made on evaluation. In the remainder of the paper we consider, on the basis of our broad case study experience, some of the operational challenges that these objectives pose. These in turn provide a basis for presenting an integrative systems-based framework to structure the evaluation of natural resource management initiatives. Finally we demonstrate the application of the systems-based framework through six case studies and discuss the implications.

3. EVALUATION CHALLENGES

3.1 Implementational Issues in Evaluation

Our experience in evaluation of a range of different natural resource management policy initiatives, including policy issues and evaluation (eg. Syme *et al.* 1994, Syme and Sadler 1994; McDonald and Bellamy 1997, Bellamy and Johnson 1999; Bellamy *et al.* 1999; Hooper *et al.* 1999), methods and tools for management and planning (e.g. Bellamy *et al.* 1996; Walker and Johnson, 1996; Johnson and Walker, 1997; Bellamy and MacLeod 1999) and natural resource management research and development (e.g. Bellamy and MacLeod 1998; Walker *et al.* 1997; Bellamy and Dale 1998) demonstrates that there are a number of common factors that make the natural resource management evaluation process implementationally demanding and potentially costly. These difficulties are particularly pertinent to evaluation of sustainability initiatives with broad societal purposes. The key challenges on the basis of our experience are breadth of evaluation, multi-dimensionality of impacts, intangible objectives and outcomes, additionality, short term versus long term impacts, evolution or drift in objectives, multiple perspectives on criteria for success, transaction costs and intrusiveness.

Breadth of evaluation. Evaluation of impact against a single criterion or overly limited set of criteria may miss important benefits and lead to significant costs remaining unrecognised. There is a need for a multi-disciplinary approach that provides for an integrated evaluation of multiple perspectives and worldviews on natural resources initiatives.

Multi-dimensionality of impacts. The impact or influence of a sustainability initiative is potentially multidimensional. It may encompass, for example:

- Individual and organisational learning effects (e.g. new collaborations, partnerships or strategic alliances, networking);
- Behavioural changes (e.g. new skills, new planning processes, sharing of information);
- Impacts on norms/standards (e.g. new ways of technical assessment, accessibility of information);
- Social effects (e.g. system and networking externalities); and
- Contributions to knowledge bases, scientific progress, and human and social development.

Intangible objectives and outcomes. Many policy programs and planning processes have vague and even unrealistic aims and objectives. In addition, many of the important measures of progress or success are intangible and difficult to measure and are innate to the elusive nature of sustainability concept. These factors make the identification of appropriate criteria for evaluation difficult.

Relationships between initiatives/Additionality There is considerable ambiguity associated with cause-and-effect relationships in natural resource management problems. These problems involve dynamic, complex, multi-dimensional processes that are affected by a number of factors. There are many influences on resource use and management such that it is not generally possible to provide definitive answers with regard to causality, that is to identify uniquely the difference that particular policies or programs can make to what would have happened without their implementation. However, as Patton (1989) observes, it is possible to arrive at some "reasonable estimation of the likelihood that particular activities have had particular effects" (p. 376).

Short term needs versus long-term impacts. Impacts or outcomes of a sustainability policy or research initiative may take a considerable time to be realised and only become visible beyond the lifetime of any evaluation. Although the outputs or products may be easier to

measure and track than the ultimate outcomes of an initiative, they do not generally provide a good rigorous measure of achievement of stated goals and objectives.

Evolution or drift in objectives. There are difficulties related to the dynamic nature of the context of implementation of natural resource management initiatives and the potential for changing 'fit' of objectives with instrumental assumptions and context. For example, a sustainability initiative may, at inception have a clear relationship between issue, intent, assumptions, criteria and context. At a somewhat later date the issue and intent may have evolved markedly either in conjunction with or independently of changes in context. However, instrumental assumptions and evaluative criteria may not have co-evolved, leading to a complex distortion that needs to be dealt with in the evaluation process.

Multiple perspectives on criteria for success. In the case of policies promoting sustainability by multiple stakeholder participation the 'views' of the purposes of the program and the criteria of success of the different stakeholders may be quite diverse. Establishment of an evaluation framework which includes the perception of each stakeholder according to their function within the overall system, can be problematic. Depending on one's role there may be subtle or distinctly different priorities for outcome and criteria for measuring whether the outcomes have been achieved. These differences may be necessary for the healthy functioning of the system as a whole.

Transaction costs. Because of the complexity of holistic natural resource policies there is a tension as to how "internal" or "external' the evaluation should be. This can only be solved on a case by case study. The decision on the balance of the evaluation becomes increasingly complex with increasingly multi-faceted environments and complex communities and economies. Outsiders may know too little about how the system operates to be efficient and effective evaluators. "Insiders" may be blinkered by their past history. The transaction costs in limiting both impediments and achieving a balance can be large.

Intrusiveness. There is a fundamental requirement that the evaluation process should be as non-intrusive as possible on effective implementation of the project, policy, or research initiative. As Heisenberg's uncertainty principle has shown, the act of observation itself can interfere with the very system one is observing.

3.2 Evaluation Principles for NRM Policy Implementation

These common implementational issues do not provide a justification for seeking a common framework for evaluation in natural resource management. However, they highlight some clear commonalties in relation to the evaluation process. As such, evaluation in natural resource management, therefore, needs to:

(a) address a system that links objective to consequence;
(b) be conducted in terms of the fundamental assumptions and instrumental hypotheses that underpin core policy, program or research objectives;
(c) be grounded in the natural resource, policy/institutional, economic, socio-cultural and technological contexts of implementation in practice;
(d) be based on the establishment of practical, valid and equitable evaluation criteria by which change can be monitored and assessed;
(e) involve methodological pluralism (including both quantitative and qualitative methods) to ensure rigour and comprehensiveness in assessment; and
(f) provide for the integration of the different disciplinary perspectives on evaluation (i.e. social, economic, environmental, policy and technological perspectives).

Furthermore, evaluation has not only to allow for the assessment of *impact (*i.e. environmental, economic, social, institutional, and technological) but importantly it also had to be implemented as a *process tool* (Bellamy and MacLeod 1999) that:

- supports purposeful and informative stakeholder participation;
- creates improved opportunities for the incorporation of on-going learning processes at individual, organisational and policy levels;
- facilitates negotiation and mediation processes; and
- supports the move towards the amelioration of, or improvement in, the tractability of problems.

In summary, evaluation of natural resource management and planning initiatives needs to be directed towards assessing both impact (social, economic, institutional, environmental, and technological), and influencing what emerges in an on-going positive and constructive way. This can be facilitated through a participatory approach that improves understanding of processes and causal linkages, fosters learning (by stakeholders and researchers), and facilitates negotiation and mediation. Evaluation therefore should be interactive, iterative, and influential (Bellamy *et al.* 1999). As the evaluation process itself inevitably will be influential, evaluation needs to be implemented as an ongoing collaborative learning process involving all stakeholders.

4. DEVELOPMENT OF A SYSTEMS-BASED FRAMEWORK

The challenges outlined in the previous section provide a set of requirements of any framework for guiding the evaluation of natural resource management initiatives. Figure 1 illustrates a framework derived from these key principles. This framework recognises the multiple levels and nested nature of natural resource management policy, namely: issue characterisation, policy formulation and intent, program logic, and on-ground implementation. It links both the intent and rationale of the natural resource management policy, process or tool to its implementation and performance 'on the ground'. It also provides the basis for synthesising the multiple perspectives on the evaluation of the phenomenon of interest. The fundamental elements of this framework are defined in Table 1 and discussed in the following sections of this report.

Table 1: Definition of elements of a natural resource management initiative.

Element	Definition
Context	The social, economic, environmental, institutional and technological factors that influence the framing or characterisation of the problem, rationality underlying the policy response, the implementation process and on-ground performance.
Issue characterisation	The nature of the issue or problem underlying the initiative being evaluated (e.g. program or policy, activity, process, method/tool, body of knowledge), and the context in which the issue or problem developed.
Intent/Objective	The objectives or intent of (a) the initiative being evaluated, its expected outcomes and key stakeholders, and (b) the evaluation itself.
Instrumental assumptions	Statement of the theoretical assumptions and instrumental hypotheses or rationality underpinning the implementation of the initiative.
Evaluation criteria	Environmental, economic, social, policy/institutional and technological measures or indicators that reflect on performance in achieving key objectives and outcomes. In turn, performance is influenced by contextual factors (e.g. environmental, economic, social, institutional, technological) that constrain or otherwise influence the implementation of the initiative.
Process of implementation	The activities, strategies or operations by which the initiative is implemented or delivered and which produce the outputs and, in turn, outcomes of the initiative.
Evaluation Methods	The quantitative and qualitative performance assessment methods for (a) the evaluation of performance measures/criteria and (b) the interpretation or analysis of findings.
Products	The outputs or deliverables produced by an initiative over which it has control.
Outcomes	The impacts that are achieved, both anticipated and unanticipated, by the initiative

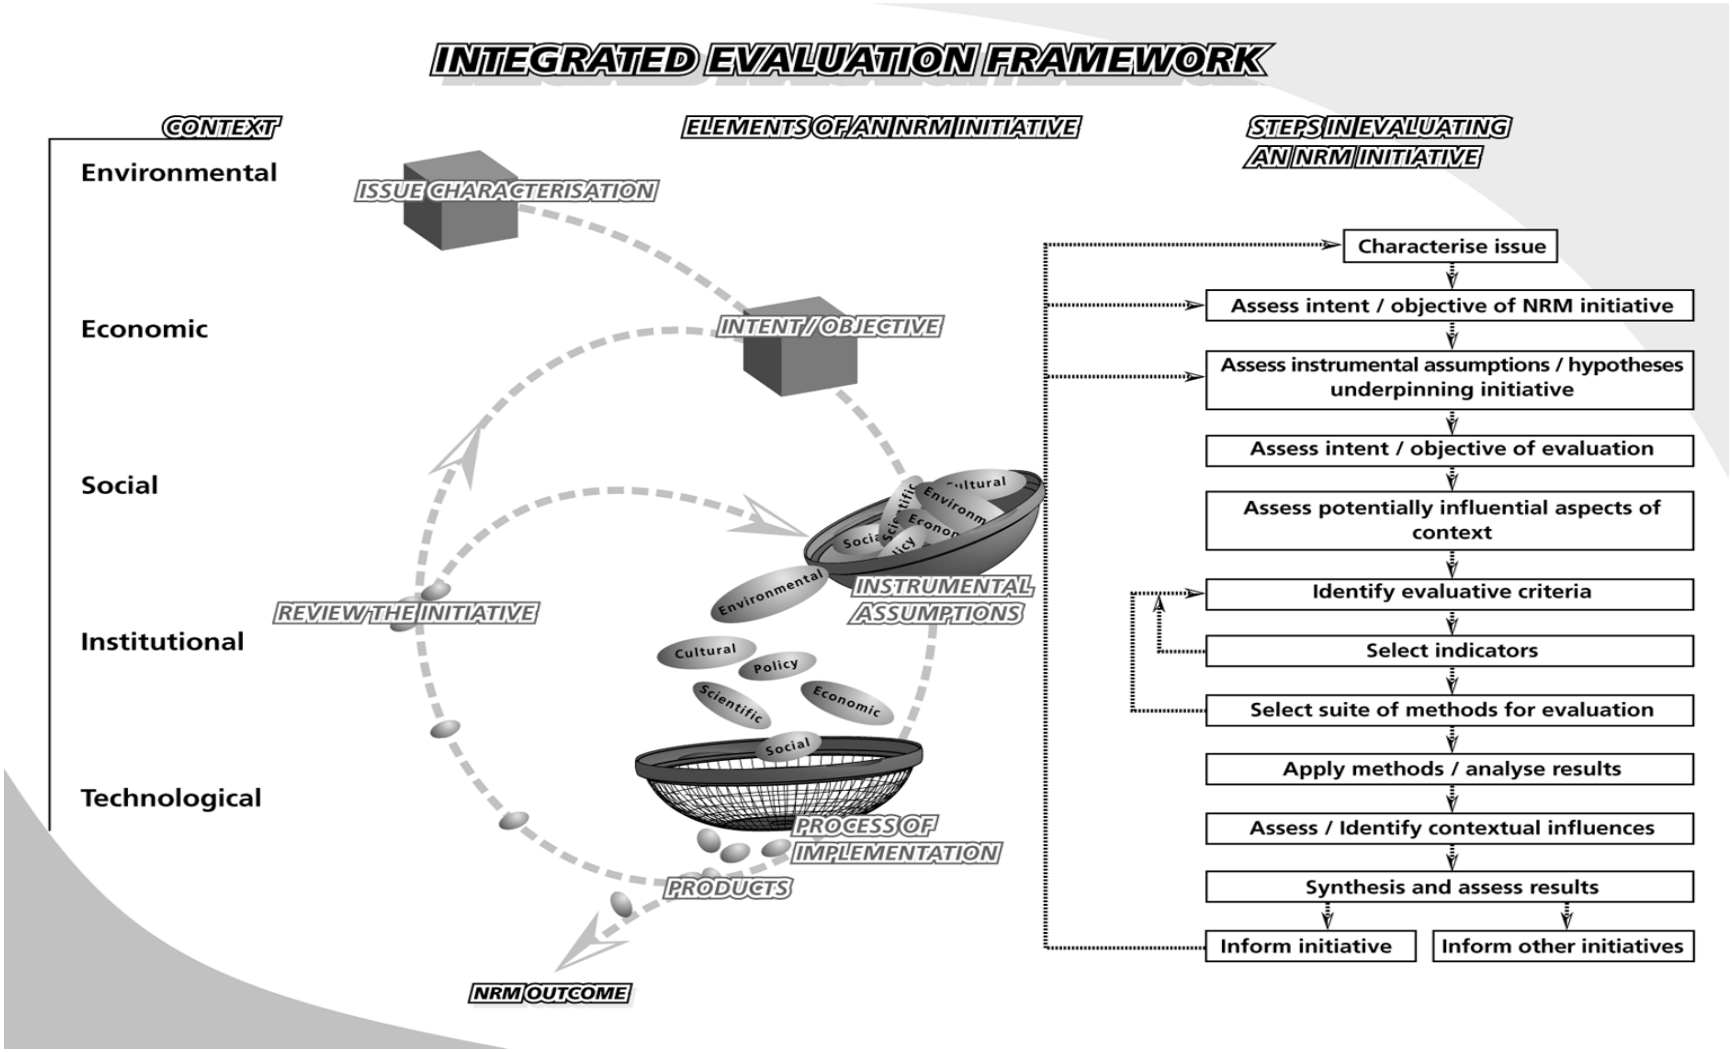

Figure 1. Integrated framework for the evaluation of natural resource management policy initiatives.

4.1 Context

The implementation of policy or program initiatives for natural resource management is context sensitive. That is, a wide range of socio-cultural, economic, environmental, institutional and technological factors at a range of administrative levels or geographical scales (eg. state, regional, catchment, local) will influence *all* aspects of the implementation of a natural resource management initiative from the initial framing of the issue or problem itself and the conceptualisation of the policy response through to the implementation process and finally to on-ground performance.

Importantly, within a particular community established social networks and interactions, societal values, legal policy frameworks and historical influences have shaped human association with the natural resource environment and will continue to influence that association and the pattern of behaviour in the future. As a consequence the impact of a particular initiative on the community of interest concerned, and ultimately the sustainability of the natural resources, may vary considerably for different situational contexts. Therefore, characterising the environmental, social, economic, institutional and technological influences that affect the achievement of key objectives and outcomes of the initiative being evaluated is fundamental to an understanding of its performance. The evaluative context will also impact on an evaluation and influence its analysis and interpretation.

4.2 Issue Characterisation.

The nature of the issue or problem underpinning a policy, program or other natural resource management initiative requires careful definition. A poorly defined problem leads to a poorly formulated policy, program or research activity. It is necessary to clearly characterise both the general background to the phenomenon or issue being evaluated and the context in which the issue evolved. This provides the basis for matching progress in the policy response or research initiative to the impact on the tractability of the sustainability problem. In practice, the issue characterisation required to underpin evaluation of the initiative may lead to reconsideration of the issue and, thereby, the initiative.

4.3 Intent/Objectives

The objectives and intent of the phenomenon being evaluated (e.g. policy, program, activity, process, method, tool, and body of knowledge) and the expected outcomes need to be clearly identified so that they can be linked to the on-ground impacts of implementation. The stakeholders are likely to include a range of government agencies, industry and community interests that may evolve over time as the issue or problem is better defined.

Clear identification of the purpose of an evaluation is also fundamental to planning an effective evaluation. The agreed limits and boundary conditions of the evaluation, and the nature of the involvement of participants and/or collaborators in the evaluation, should be negotiated and clearly defined to develop common expectations and ownership of the evaluation findings and to focus the performance assessment on the critical evaluative criteria for measuring change. Although not necessarily mutually exclusive, five broad purposes for evaluation and a range of potential outcomes are identified in Table 2.

Table 2. Purposes of an evaluation and possible outcomes.

Evaluation Purpose
Improving Research or Program Management • Develop a common understanding of objectives and expected outcomes • Provide a basis for informed decision-making on program/research direction, resource allocation and attainable levels of performance. • Identify and focus attention on factors influencing the initiative's outputs and outcomes • Identify gaps in performance and insights on how they might be addressed • Facilitate a robust and integrated approach to program planning and implementation.
Improving Transparency and Accountability • Evaluate costs and benefits of an investment of public or private resources • Improving efficiency and effectiveness of a program or process • Early identification of unanticipated outcomes
Reducing Risk and Uncertainty • Identify impacts of a project, program or process • Identify information pathways and processes and their role • Develop understanding of causal relationships • Identify equity and social justice issues
Fostering Learning • Influence decision-making and policy development • Support on going information exchange, feedback and learning • Improve awareness of equity and social justice problems as they arise
Improving Process • Facilitate continuous participation • Support the public consultation process • Build stakeholder capacity • Develop ownership of project outcomes • Provide information and a structural framework to underpin negotiations • Provide a platform for cultural change.

4.4 Instrumental Assumptions

Theories represent the most systematic way of building synthesising and integrating diverse knowledge. Theory describes the phenomenon of interest by identifying: (i) the boundary that defines the domain of interest, (ii) key constructs or "entities of interest" in that domain, (iii) the values or states these constructs or entities can take, and (iv) the relationship among the key constructs or entities (Eierman *et al.* 1995). Theory can be used in evaluation, for example, to propose and test links among key factors indicating the direction and degree of influence they have on natural resource management implementation and impact. An atheoretical research or evaluation approach may collect interesting facts but there is a danger that no unifying theme or predictable patterns or relationships emerge. Defining the construct space of a phenomenon provides the basis for establishing validity and ultimately sound measures that can be applied to a variety of contexts.

Whether explicitly identified or, more often, implicit, a policy or research initiative will have some basis in theory. Each theory base brings with it different methodologies, assumptions and value systems. In evaluation, identifying the theory underpinning the implementation of the phenomenon of interest therefore will highlight the underlying assumptions and instrumental hypotheses, clarify what evaluation measures are needed, and contribute to an understanding of causal linkages (Bellamy *et al.* 1999). Significantly, it is necessary to make explicit and transparent the rationale of the phenomenon being evaluated, that is the hidden or implicitly held assumptions, behaviours and motivations reflected in identified goals of that phenomenon and which influence decision-making and policy implementation processes and ultimately the outcomes. Such underlying assumptions or instrumental hypotheses may relate to: program or policy logic; stakeholder involvement; collaboration; implementation process; policy and institutional arrangements; technical information and support; communication and interaction process; policy impacts; or program products and outcomes. Some examples are provided in Table 3.

Table 3. Types of assumptions or hypotheses underling the rationale for a policy or program.

Element	Assumptions or Instrumental Hypotheses may relate to:
Program or policy logic	• The appropriateness of the underlying theory base. • Adequacy of inferences of causal theory for achieving objectives and desired outcomes/changes.
Stakeholder/ participant involvement	• Expectations of the benefits and costs of participation (e.g the role and influence of participatory processes; development of understanding or learnings; acceptance and ownership of results). • The need for inclusiveness or the extent to which the program, project or activity as implemented takes into account all relevant stakeholder groups who have a stake in the research, project or policy process. • Cooperation amongst participants. • Effectiveness of a partnership approach (e.g. synergies developed, value of informational exchange and joint evaluation of alternatives, prevention and resolution of conflict). • Adequacy of the provisions/arrangements for access by stakeholders and the general public.
Policy and institutional arrangements	• Adequacy of government policy (eg. Landcare and ICM.), statutory and regulatory controls: (e.g. water allocation, land management and control, local government planning schemes) and industry or voluntary standards (tree clearing, pest management, etc.) in accomplishing their goals/intent. • Effectiveness of guiding principles underlying a policy. • Clarity, understanding of, and consistency in, policy objectives and outcomes. • Existence or effectiveness of a complementary implementation process to a strategy or plan. • Coordination across levels of decision-making, including all three tiers of government. • Resourcing, commitment and skill of those responsible for implementation. • Support of stakeholders and politicians for policy or arrangements. • Alignment of objectives with government priorities and policy objectives.
Process	• Perceptions of appropriate role, responsibilities and influence. • Representativeness of participants and capacity to maintain a mandate • Emergence of collaborative learning processes. • Democratic involvement (i.e. the degree to which persons directly influenced, or the general public are empowered to contribute to the planning, implementation, improvement, or termination of the project, program or policy). • Expectations on fairness and equity of processes. • Perceptions of change in socio-economic conditions, and community attitudes and behaviour as outcomes. • Need for community or regional processes to be put in place. • Acceptance and success of expected outcomes of a negotiatory approach. • Stakeholder needs and expectations of the process. • Understanding of objectives, process and outcomes of object of evaluation, or an evaluation itself. • Acceptability of solutions identified. • Responsiveness of policy formulation and institutional learning processes. • Support that technical information and modelling tools and mechanisms can provide. • Nature and rate of adoption/uptake of research findings or product. • Adequacy and sufficiency of technical knowledge base or understanding to guide substantive action. • Importance of context (social, economic, institutional, technological) on implementation, performance and use.
IT system/tool development	• Feasibility, adequacy, and equitableness of data sharing in practice. • Accessibility of technology to stakeholders. • Design needs and their effectiveness or impacts. • Impact and effectiveness of system development and implementation processes. • Role of information and technology in planning. • Role of and need for information and knowledge. • Acceptance and degree of use of technology as outcomes. • Importance of context on use and influence.
Communication	• Adequacy and effectiveness of feedback mechanisms in policy and planning approaches • Equity in, and accessibility of, information technology and other communication mechanisms. • Adequacy and effectiveness of network of social interactions (at individual and organisational levels) and their linkages to decision-making processes. • Acceptability and ownership of results.
Impact	• Cost-effectiveness and efficiency of one approach relative to other possible alternative approaches in achieving the goals of the object of interest. • Equitableness (e.g. the extent to which the distribution of benefits and risks associated with the impact of the object of interest on the different groups of people affected by it are fair and just). • Effectiveness of project, activity or methodological approach in achieving stated or agreed objectives.
Project products and outcomes	• Expectations of the program or project by researchers, R&D providers, or stakeholders. • Adequacy of expected outcomes (the degree to which the policy, program or project or accomplishes its goals, eg. reduction in adverse impact or tractability of the problem). • Alignment of outcomes with government priorities and policy as well as funders, stakeholder or client needs.

4.5 Evaluative Criteria

The fundamental basis for evaluation is the establishment of practical criteria by which change can be monitored and assessed in order to evaluate what influence or impact the policy initiative of interest is having on the problem or issue it was set up to tackle. Criteria also provide the basis for testing underlying assumptions and instrumental hypotheses relating to the natural resource management policy initiative.

Evaluative criteria should reflect the achievement of key objectives of the initiative. Criteria can be measured by one or more indicators, which may be defined as:

> *a statistic or parameter that if tracked over time provides information on changes in the condition of the phenomenon, which has significance beyond the properties of the statistic itself* (Eckersley 1998, p.11).

Brown (1998) defines a good indicator for measuring progress toward environmental sustainability as "sensitive to matters of time and social priorities, of place and scale, and in a framework that links social, economic and environmental data" (p.272). Importantly, indicators should be emergent from a deeper understanding of complex system function (Eckersley 1998).

Scope of criteria

Because of the evolving and holistic nature of the concept of sustainability, Bellamy *et al.* (1999) have proposed that the selection of evaluation criteria for natural resource management initiatives should be informed by the context of implementation. Evaluative criteria therefore may be:

(i) *Environmental*: for example, the evolution of resource use and management systems in the region, the major resource use issues and their on-site and offsite implications and impacts, attitudes and behaviour to natural resource management and environmental issues, and the nature and extent of behavioural change in resource use and management practices required across catchment stakeholders.

(ii) *Economic*: for example, the nature and status of, and interdependencies within, the regional economy overall and on a sectoral basis, perceptions of future development and economic prospects, the distribution of wealth and resources within the community, the economic vulnerability of the regional economy, and economic viability of land managers.

(iii) *Social/cultural:* for example, the regional demography and related sustainability issues, cultural diversity and related resource use issues, the nature and commonality in community expectations (both within and outside the region) regarding the catchment's environment and socioeconomic situation, as well as the catchment management and land use planning process, perceptions of equity and social justice, political and media support for catchment issues and NRM processes, and social history and demographic change.

(iv) *Policy/institutional:* for example, relevant policies and the organisational structures and processes for natural resource management across government, industry and community, the resourcing and coordination characteristics of policies, plans and processes, and the stability and volatility of local and state political process.

(v) *Scientific/technological:* for example, the characteristics of the existing technology system; technical knowledge base and competencies to use advanced technologies across stakeholders, the availability and feasibility of technical solutions, and the adequacy of scientific knowledge including appropriateness of scientific understanding and its ability to assist decision-making.

The relative importance of the influence of each of these elements will vary depending on the particular objectives of the initiative, the objective of the evaluation itself and the characteristics of the context of implementation. Importantly, each criterion will measure only a portion of the total construct space of the context of implementation.

Bellamy *et al.* (1999) identified a set of factors influencing community-based natural resource management initiatives based on an integration of three models from the social and institutional sciences:

- Mazmanian-Sabatier policy implementation model (Mazmanian and Sabatier 1981; Sabatier 1986) which identified variables relating to: the tractability of the problem(s) being addressed by the statute; the ability of the statute to favourably structure the implementation process; and the net effect of a variety of non-statutory variables on the balance of support for the statutory objectives.
- Crane's (1988) socially significant evaluation indices, that is inclusiveness, adequacy, equitableness, effectiveness/efficiency, and democratic involvement; and
- Syme *et al.*'s (1994) PRIME procedural model which emphasises that evaluation needs to cope with multiple parallel tasks occurring at all times. Some of these tasks will be dealing with planning; some with research monitoring and evaluation. It also recognises that there should be appropriate areas of influence in the evaluation process by the community as well as the implementing agencies.

The set of factors identified is presented in Table 4. In effect, it provides a series of variables to consider in developing hypotheses for appropriate responsibilities and influence against which the evaluation can identify criteria to measure progress in a developmental context. For natural resource management initiatives, these hypotheses may relate, for example, to:

- state or tractability of natural resource management issues (social, economic, environmental, institutional; technological);
- stakeholder perspectives and behaviours on natural resource issues;
- knowledge base on natural resource issues and their management,
- institutional arrangements and policy frameworks;
- stakeholder coordination and communication processes;
- stakeholder capacity to adapt and to undertake natural resource management and planning; and
- equity and fairness of resource use outcomes.

Such hypotheses provide a basis for identifying criteria for use in evaluation of a natural resource management policy initiative. The hypotheses that are relevant to a particular situation will inevitably change in response to the social, economic and political context as well as the stage of development of the natural resource management initiative.

Iterative development process

Potentially there is scope for a whole suite of measures that will reflect the influences and impacts of the natural resource management initiative. For practical and efficiency reasons, each evaluation will need to focus on a selected number of critical evaluation criteria and indicators that are relatively readily measurable over time, yet rigorous and effective in reflecting change in an evaluative criteria. Therefore, the identification of evaluation criteria and their related indicators for a particular natural resource management initiative necessarily involves an iterative process of development to continually refine the criteria to a critical but manageable set. This process of refinement needs to take into account:

(i) the objectives or intent of the phenomenon of interest (ie. the natural resource management initiative);
(ii) the objectives or intent of the evaluation itself; and

(iii) the feasibility and practicality of methods given the resources available and the constraints of the context of implementation.

Inevitably criteria need to be reviewed and revised in light of experience and in order to capture emerging issues that need to be evaluated.

Table 4. Variables influencing natural resource management initiatives (after Bellamy *et al.* 1999).

1. Natural resource issue characterisation, eg.:
   - Historical context and evolution of resource use
   - Diversity of stakeholder perspectives on natural resource use and management
   - Status of the technical knowledge base to guide substantive action
   - Extent of problem recognition and acceptance of change required by different stakeholders

2. Context of implementation of natural resource management initiative, eg.:
   - Evolution of on-ground policy or program implementation
   - Socio-economic conditions and trends of context of implementation
   - Media coverage and attention
   - Attitudes and resources of local constituency groups
   - Support from politicians and industry leaders
   - Commitment and skills of implementing staff/agencies

3. Institutional structures for natural resource management, eg.:
   - Clarity and consistency of objectives of NRM initiative
   - Financial resources
   - Coordination among implementing agencies
   - Policies, plans and decision rules of implementing agencies
   - Commitment of implementing staff
   - Opportunities for formal access by wider community

4. Analysis of community processes, eg.:
   - Expectations/knowledge of process by stakeholders, including the degree to which they are shared or separate
   - Coordination of resources
   - Degree of motivation, commitment, cooperation and support
   - Efficiency and effectiveness of process
   - Equity and procedural justice/trust in process
   - Agreed influence
   - Agreed responsibilities and roles
   - Integration (that is degree of incorporation of processes in structure and context)
   - Systems implementation

4.6 Evaluative Methods

Methodological pluralism

No single evaluation method will be comprehensively applicable. As Patton (1987) notes "evaluation has moved into a period of methodological diversity with a focus on methodological appropriateness". As a consequence, the framework for evaluation presented in this report is designed to be independent of the methods for evaluation applied. Methodological pluralism can contribute to rigour in evaluation research (e.g. Patton 1987; Chambers 1997). Multiple methods will be needed at different stages of the project, for different project components, and for different implementational contexts. These may include both quantitative and qualitative methods. Moreover, many will be concurrent, involving multiple parallel tasks.

The purpose and design of an evaluation will determine, and be influenced by, the timing of evaluation. There are three well-recognised stages of evaluation: *ex-ante* evaluation undertaken before implementation; *progress* evaluation during implementation; and *ex-post* evaluation after completion of a project or program. Across all of these stages, the Department of Finance (1994) proposes four fundamental criteria to guide the design of an

evaluation: usefulness and relevance to the evaluation purpose, feasibility and cost-effectiveness, equity and social justice, and technical validity. As there is no recognised best or generic evaluation methodology, a balance is required amongst these various considerations when designing an evaluation.

Managing Bias
The conventional scientific paradigm conceives a research process that yields an objective, rational, political neutral body of knowledge that informs decision-making processes (e.g. Ozawa 1996). However, a multitude of discretionary judgments is made during the course of an evaluation. The formulation of the problem, the analytical models used, the methodological approach adopted, the information selected as relevant, the data collection techniques, the scope and construction of questions addressed, and so on will reflect the world views (e.g. the values, priorities, experience and organisational culture) of those who participate in the design, development, implementation and interpretation of the evaluation. For example, Wong (1997) has shown embedded bias to be an inescapable feature of the design and development of information technology innovations for integrated environmental management.

Some form of bias is inevitable in evaluation. In the context of natural resource management initiatives, there is a strong case for methodological pluralism. There is not likely to be one best, let alone all encompassing, perspective for understanding and evaluating complex problems. Multiple methods and triangulation of observation can contribute to methodological rigour in evaluation (Patton 1987). In particular diversity in methods allows 'triangulation' of theory and methods to make effective use of their complementarities, particularly in ameliorating in any one perspective or approach (Yin 1994). Values and instrumental assumptions need to be made explicit in theoretical frameworks, principles of inquiry and evaluative methods adopted.

Design Criteria
In designing a pluralistic approach to evaluation of the performance and impact of an natural resource management initiative, a number of criteria need to be considered including:

1. *Scope of assessment* (eg. scale or level of impact, as ell as impact of overall approach or focussed evaluations of specific components).
2. *Form of evaluation* (eg. self-evaluation or external assessment).
3. *Mode(s) of analysis* (eg. longitudinal study, cross-sectorial study, focussed/case study, needs analysis, on-going monitoring).
4. *Unit(s) of analysis* (eg. individual, group, organisational, regional resources, regional economy, regional community, state policy development).
5. *Information required and types of comparisons* to be made (eg. description, judgments, interpretation, qualitative assessments, quantitative assessments).
6. *Method(s) for inferring process of change* (eg. methods for representing raw data to identify process patterns, comparison of change in performance criteria).

Evaluations need to be clear about "matching research methods to the nuances of particular evaluation questions, the idiosyncrasies of specific program situations, and information needs of identifiable stakeholders" (Patton 1987, p.169). Therefore, the choice of methods needs to be appropriate and sensitive to the realities of the specific context of natural resource management policy or program implementation.

4.7 Process of Implementation

The influence of the actual process of implementation on performance of the natural resource management initiative needs to be recognised and accounted for in analysing the

findings. The evolution of the process of implementation may vary from one situational context to another for a host of local community (ie. catchment, region) contextual factors as identified in Section 4.1 above. Monitoring of the evolution of the process of implementation for the initiative and the 'local' social, economic, environmental, institutional and technological context is an essential element of evaluating an natural resource management policy initiative.

4.8 Products and Outcomes

The products of an natural resource management initiative are the tangible outputs of that initiative over which it has some degree of control, such as the establishment of a multi-stakeholder coordinating committee or the development of a catchment management plan. In contrast, the outcomes of an initiative relate to the anticipated and unanticipated impacts of those products and the implementation process for the initiative, such as improved adoption on-farm of sustainable practices or improved water quality.

4.9 Implementing an Evaluation

Evaluation needs to be directed toward influencing what emerges in a positive and constructive way, rather than focussing only on *post hoc* evaluation related to mere achievement of initially proposed means of reaching objectives. Importantly, the evaluation may be influential in modifying the objectives themselves. The evaluation therefore needs to incorporate an effective process of continuing feedback and improvement to the natural resource management implementation process as a whole. The different stages in the evaluation process will therefore be iterative, interactive and inevitably influential. However it has some distinctly recognisable steps as identified in Figure 1.

5. APPLICATION OF THE FRAMEWORK

The framework presented above has been derived from our collective professional experience, the analysis of relevant literature and more specifically through a long term R&D initiative to evaluate an Integrated Catchment Management process in the Herbert River catchment in wet tropical north Queensland (Bellamy *et al.* 1999). In this section, we now 'validate' the framework for a range of different natural resource management initiatives and contexts to explore its applicability and evaluability for natural resource management in general.

5.1 NRM Case Studies

Case studies can shed light on the conceptual problems involved in the practice of evaluation in natural resource management. Moreover, it can be argued that the strong trend towards participatory and integrative initiatives in resource management in policy design and implementation, research and development and on-the-ground resource management initiatives means that these traditionally discrete spheres of activity in resource management are developing many commonalities – thus justifying a common or generic approach to evaluation as presented above. We examine this proposition through its application to six case studies concerned with natural resource management initiatives including policy processes, research projects, technology development and increments to knowledge base, that is:

1. Implementation of ICM in Queensland (McDonald *et al.* 1999; Bellamy *et al.* 1999)
2. R&D on Regional Resource Use Planning in the Queensland Central Highlands (Bellamy and Dale 1998)

3. Development of Landassess DSS for sustainable grazing management (Bellamy *et al.* 1996; Bellamy and MacLeod 1999)
4. Herbert Resources Information Centre (Walker *et al* 1999)
5. Integrating R&D in catchment management planning (Sarah Ewing, University of Melbourne, *pers. comm*).
6. Assessing information needs for ICM (Walker and Bellamy 1999).

These six broad ranging NRM case studies relate to experience in research and development activities in Australia and were selected to illustrate a range of:

- *scales of application* (national/state policy, regional, catchment, local community, individual/farm enterprise);
- *type of product* (improved process, a tool or method or increments to knowledge);
- *level of intervention* (research, information & extension, planning, implementation & negotiation) and
- *stage of evaluation* (ie. ex-ante, progress, ex-poste).

The case studies are compared in terms of these factors in Figures 3 and Table 5 and using the framework as a reporting structure they are presented in Boxes 1 to 6 below.

5.2 Role and Effectiveness of Framework

The six case studies provide an assessment of the use of the integrated evaluation framework developed in this report for three different situations:

1. Establishment of comprehensive evaluation criteria and methods for on-going evaluations of natural resource management policy initiatives (ie. Case studies 1 and 2).
2. Clarification, structuring and comprehensive presentation of previous evaluations of tools for natural resource management (ie. Case studies 3 and 4).
3. Development of descriptive criteria for R&D on research integration and information issues in catchment management planning (ie. Case studies 5 and 6).

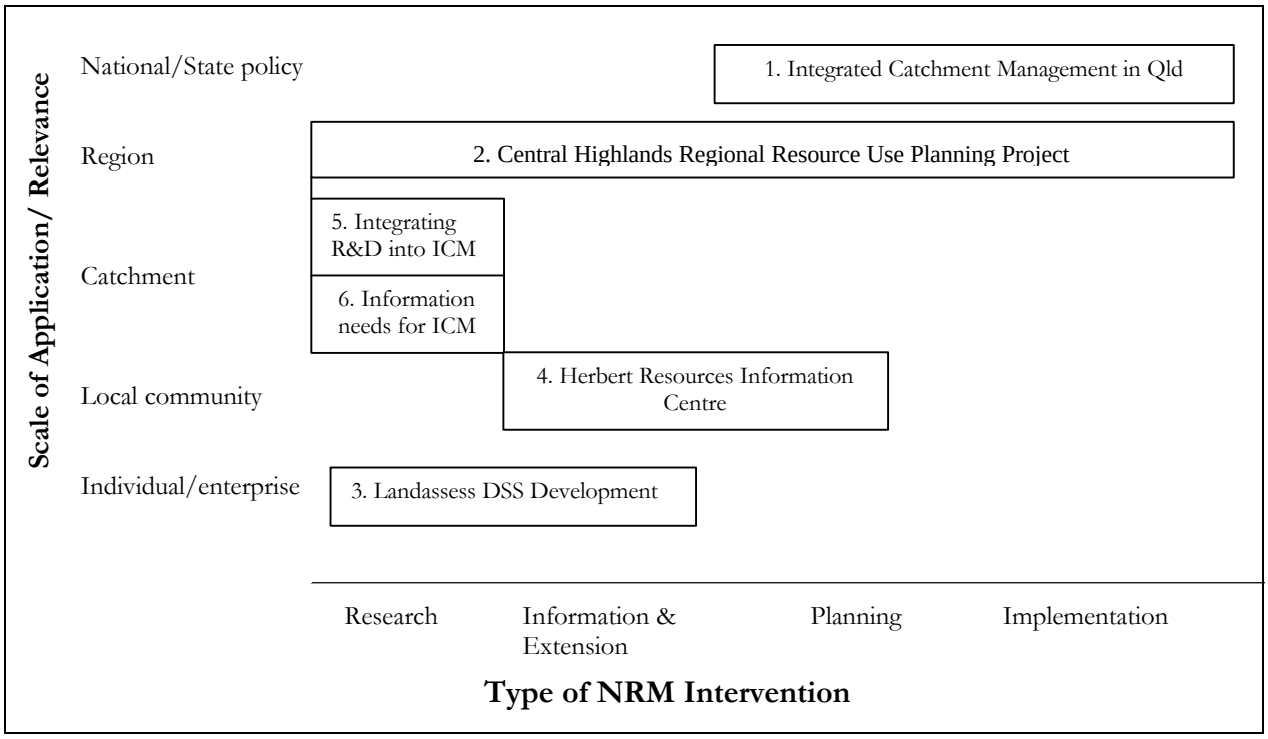

Figure 3. Comparison of Case Studies

Table 5. Case studies for the evaluation framework

Case Study	Scale of Application	Type of NRM Intervention	Principal Product	Evaluation stage
1. Implementation of ICM in Queensland	State policy	Planning; Implementation	Improved process	Progress
2. R&D on Regional Resource Use Planning in the Queensland Central Highlands	Region	Research; Information & extension; Implementation, Planning	Improved process	Progress
3. Development of Landassess DSS for sustainable grazing management	Property/ paddock	Research; Information & extension	Tool/method	Progress and Ex poste
4. Herbert Resources Information Centre	Local community	Information & extension; Planning	Tool/method	Progress
5. Integrating R&D in catchment management planning	Catchment	Research	Increment to Knowledge	Ex poste
6. Assessing information needs for ICM	Catchment	Research	Increment to Knowledge	Ex poste

Based on our collective experience in applying the framework in these case studies, it was found to have a number of strengths:

- *Multiple perspectives:* the framework forces a broad perspective through facilitating the consideration of a wide range of hypotheses or underlying assumptions and therefore evaluation criteria (eg. environmental, social, economic, institutional and technological). Specifically, the logic of the framework was not confined to traditional program evaluation methods.
- *Integration of perspectives on the evaluation:* the framework provided the basis for integration of the multiple perspectives on the evaluation of each initiative, particularly when used in a formative evaluation context (eg. Case studies 1 and 2).
- *Problem bounding*: the framework forced a 'bounding' of the problem or issue of interest through forcing a focus on the specific elements of relevance to the assumptions underlying an initiative and importantly the purpose of the evaluation.
- *Structuring logic:* the framework provides a logical structure and set of steps for undertaking an evaluation.
- *Reporting structure:* the framework provided an effective structure for rapidly reporting on an evaluation (eg. Case studies 3 and 4).
- *Descriptive assessment*: the framework was found to facilitate the development of descriptors for critical or comparative assessment of natural resource management initiatives rather than being confined to only evaluations of performance of initiatives (eg. Case studies 5 and 6).

However, there were a number of important challenges posed in applying the framework:

- *Manageable array of criteria*: a significant challenge was how to deal with the potentially unbounded scope of possible evaluation criteria in light of the practical realities of available resources and the need for 'sensitive' evaluation that moves the process forward rather than undermines it.
- *Motivation:* the framework challenged the user to carefully consider the purpose of the evaluation, that is what is motivating the evaluation and in this sense it was considered that the evaluation process could be seen as threatening.
- *Capacity to address:* in fostering a focus on the big picture, the framework encourages the development of a whole suite of indicators or evaluative measures. However, it is not

usually possible to address all the elements of the big picture such that the extent that the evaluation can address each criterion may vary greatly.

- *Demanding iterative process*: in recognition of the dynamic nature of the implementational context of natural resource management policy initiatives, evaluation objectives and related criteria need to be reviewed and refined regularly to ensure continuing relevance and this can be very demanding.

In summary, the framework proved effective in all case studies, that is across a range of contexts of use and for different scales of application and levels of intervention. However, there were some important issues relating to the scope and complexity of the task at hand that need to be considered in the evaluation of complex issues relating to natural resource management policy.

BOX 1. Case Study: Integrated Catchment Management (ICM) in Queensland

ELEMENT	DESCRIPTION
Issue Characterisation	• Resource degradation of waterways, pastoral and agricultural lands, concern for biological diversity • Fragmented centralised governance approaches need to be replaced by more adaptive and integrated approaches at a catchment scale involving partnerships between government, industry and communities • There is considerable public and private investment in integrated approaches with high community expectations but the translation of the concept into practice is experimental and evolutionary. • Evaluation is necessary to determine whether strategies are achieving desired resource management outcomes • Evaluation is fundamental to identifying impact, supporting an adaptive integrated approach that is flexible to meet the challenges of change, and informing on-going learning at individual, community, institutional and policy levels.
Intent/Objective	The stated intent of the Integrated Catchment Management (ICM) policy initiative in Queensland is a coordinated approach to integrate the management of land, water and related biological resources in order to achieve their sustainable and balanced use by: a. generating a better understanding of ecosystem interactions at a catchment scale by the community and Government and moving towards common or agreed goals through development of a catchment management strategy; b. facilitating coordination and cooperation within and between Government agencies and the community to enable the prioritisation of actions, and joint or independent action to seek solutions to problems. Evaluation of ICM in practice is needed to guide continuous improvements in the way the policy initiative contributes to on-going change.
Instrumental Assumptions	• Land and water resources are basic and interactive components of natural ecosystems and therefore management of land and water resources should be based on geographic units which account for the interactions between these resources. • Management of land and water resources must be coordinated. • Land and water resource management decisions must be based on the best available information • Sound land and water management is best achieved through the informed action of the individual users and managers of these resources • For change in resource use to be acceptable and beneficial it must be socially, economically, institutionally and environmentally sustainable. Therefore, a balance between economic development and conservation of land and water resources must be maintained.
Context of Implementation	*Policy/Institutional*: • ICM is a community-based policy initiative with no legislative base implemented through admin. and fin. arrangements of State Government. • Evolving political and legislative context. *Environmental:* • Competing and conflicting resource use issues with increasing demands and values being placed on resources for a range of uses. *Economic:* • ICM program poorly resourced, relying heavily on federal funding with short term financing arrangements and work plans. • Focus of policy on technical solutions with a failure to clearly address the public and private costs and benefits and their social/ cultural implications. *Social/cultural:* • Requires voluntary coordinated local community-based support and action in the context of no previous experience in these issues at community level. • Costs largely borne by individual resource users in the short term, while many benefits accrue to society as a whole.

BOX 1. Case Study: Integrated Catchment Management (ICM) in Queensland (cont.)

EVALUATION CRITERIA	EVALUATION MEASURE/INDICATORS	METHODS FOR ASSESSMENT
Resource Use Context	Tractability of resource use issues and tensions in the catchment: a. External environment vigilance in community b. Characteristics of catchment resource use c. Community attitudes and behaviour	Longitudinal study involving: • Participant observation at State level policy and program meetings • Questionnaire surveys of Chairs and Coordinators of all Catchment Committees • Literature survey including minutes of all State level ICM coordinators meetings, policy releases, reviews • Analysis of financial and other reports • Media monitoring and content analysis
Institutional Structure	• Adequacy of policy frameworks and institutional arrangements to address issues at a catchment scale • Community capacity to plan and implement catchment management strategy	
Community Process	Adequacy and equity of community processes: a. mechanisms for communication and interaction on catchment issues b. Equity of opportunity for involvement c. Level of strategic alliances/partnerships developed to exploit future synergy	
Technology Context	Adequacy of available technology: a. Capability to identify and address catchment resource use issues b. Technical support for effective implementation of on-ground activities.	
KEY FINDINGS	• There are clear enough technical solutions to many of the natural resources management problems in Queensland. The biggest obstacle to ICM is the process within the community and within government to redress and prevent resource management problems - political and social processes to apply technological solutions. Not surprisingly, this change of philosophy is accompanied by uncertainty and resistance especially when the way forward is not signposted. As yet there is no well tested solution to this problem as a guide to action • The difficulty of promoting a program with relatively few immediate benefits but often with immediate cost implications for land holders. Those catchments with more apparent and visible resource issues will have a better chance of focussing community attention. • While considerable progress has been achieved in some catchments and in some regions, the depth, coverage, and effectiveness of the Queensland integrated resource management system is very patchy. • Catchment Coordinating Committees (CCCs) conduct a wide range of activities reflecting largely the age and maturity of the CCCs. A progression of activities can be recognised from organisational activities - public awareness and involvement - issues generation - catchment planning - technical studies. Most respondents believed that support from the general public was low due largely to the public's low level of awareness about natural resource management issues. • Dept. of Natural resources (DNR) is the lead agency for ICM which was perceived to be a successful partnership between DNR and the rural land owner interests and not much more than that. There was a widely held view that local governments, both politically and at officer level have not been involved effectively in the ICM process although this is evolving. • There was a disturbing low level of satisfaction amongst the respondents at the state level (especially the Coordinators). CCCs have to contend with low awareness in the general public about resources management issues and a general resistance to external intervention. A surprising, consistent and very significant result from the survey was respondents universal view that there is too much government regulation. • There is a clear absence of a "whole of government" approach, commitment or involvement in ICM. State politicians seemed to ignore ICM and there was ineffective, even counter productive involvement of some state agencies. • Financial resources for a program with such ambitious goals has been erratic and low. A key source of funds has been the NLP, without which ICM would struggle to survive. CCCs are required to find funding on their own initiative rather than use established revenue sources as do most public programs. At present they have no revenue raising capacities and there is a lack of confidence in government funding for implementation, which is of particular concern given that once CCCs have been established and created strategies, their requirement for funds for on-ground works will increase their financial requirements. Planning is inexpensive relative to action.	

BOX 2. Case Study: R&D on Regional Resource Use Planning in the Central Highlands of Queensland

ELEMENT	DESCRIPTION
Issue Characterisation	Many natural resource use and management problems cannot be effectively addressed by individual action at the local or farm level but require regionally-based solutions through the agreed actions of a number of actors. Regional planning approaches in the past have tended to take a sectoral or a single issue focus, such as economic development, social planning and nature conservation management. A new emerging paradigm of a regionally-driven, integrated and ecosystem management approach to resource use planning is now being advocated. This new approach aims to achieve more sustainable and equitable resource use and management outcomes at a regional level. The effectiveness of such approaches at meeting these objectives has not been systematically addressed. Their impact is likely to be multi-dimensional; involving social, economic, institutional, environmental, and technological elements. However the implementation of such sustainability initiatives is experimental and there have been few evaluations of their long term impact. Where evaluations have been undertaken, regional economic development and growth management has often overshadowed the importance of environmental considerations.
Intent/Objective	The project is being undertaken as an active partnership with a range of government, industry and community groups with a stake in the region. It aims to define and assess the nature of existing regional resource use planning in the Central Highlands, and to evaluate the effectiveness of a regionally-driven and negotiated planning systems approach to achieve more sustainable and equitable resource use outcomes. In essence, the project is designed to: (a) strengthen human resource and institutional capacities to undertake regional resource use planning in the Queensland Central Highlands region, and (b) generate research results and new innovations that have the potential to support a shift towards more sustainable and equitable resource use within rangelands.
Instrumental Assumptions	The instrumental hypothesis of this R&D is that improving the *overall system* of resource use planning in the region will increase the level of positive interaction among regional stakeholder groups over time, and lead to better informed and more negotiated solutions to natural resource problems. The fundamental assumptions of this approach relate to: • the representativeness of regional stakeholder groups and peak bodies; • the degree to which individuals, groups and the general public are empowered to be involved in regional resource planning; • the role and value of a participatory approach to the R&D; • the role and value of capacity building; • the importance and value of learning processes; • perceptions of roles, responsibilities and influence of regional stakeholders; • perceptions of community/regional processes that need to be put in place; • technical information and modelling tools that can guide substantive action; • adequacy of a negotiatory approach; • importance of context (social, economic, environmental, institutional, technological); and • stakeholder perceptions and understanding of the project's objectives, processes and outcomes.
Context of Implementation	Natural resource use issue/problem: Diversity of significant issues and problems rather than a single chronic problem (eg. of magnitude of salinity) to focus regional community attention Institutional: Multitude of poorly coordinated agencies/organisations responsible for natural resource management with few formal or effective linkages as well as a multiplicity of relevant policy frameworks which are invariably sectorally or single-issue based. Economic: region emerging from a long-term 'drought' with economic hardship and industry downturn in major rural industries and mining sectors. A growing area with opportunities for development. Social: Diverse cultures within the community with very different perspectives and value-systems on natural resource management. Cultural: indigenous land rights an emerging issue. Growing community interest in cultural heritage. Technology: Communication technology constrained in many areas such that opportunities for use not equally distributed/accessible through the community. Capacity to change constrained by these factors as well as social and economic contextual factors.

BOX 2. Case Study: R&D on Regional Resource Use Planning in the Central Highlands of Queensland (Cont.)

EVALUATION CRITERIA	EVALUATION MEASURE/INDICATORS	METHODS FOR ASSESSMENT
1. Progress towards regional sustainability of resource use	*Resource use context:* • Reduction in the severity of impact or improvement in the tractability of regional resource use issues and tensions. • Contribution to improvement in regional sustainability indicators *Equity of resource use:* • Enhanced perceptions of fairness in the overall regional resource use planning system and related decision-making processes. *Regional Processes:* • Improved mechanisms for communication or interaction on regional issues. • Improved recognition of importance of a regional perspective in planning.	• Bench-marking of attitudes, perspectives and behaviour through semi-structured interviews with key stakeholders and individual RSG workshops. • Self-evaluation by individual Regional Stakeholder Groups of their planning processes using questionnaires. • On-going monitoring and document analysis of the research process and stakeholder interactions. • Monitoring of key regional indicators through State-of-the-Region reporting. • Organisational mapping • Interactive annual forums involving representatives of all stakeholders. • Meta-analysis of other activity specific evaluations
2. Improvement in the degree of involvement and participant capacity to undertake regional resource use planning.	*Technical Capacity:* • Improvement in technical capacity to undertake planning initiatives *Planning Systems:* • Improvement in planning structures and processes within individual stakeholder groups. *Institutional Arrangements:* • Improvement in broader institutional structures at the regional level to undertake regional planning. *Research Capacity* • Influence/impact on peer researchers and regional planning practitioners of Regional Stakeholder Groups within and outside the region.	
3. Role and effectiveness of additional information and IT development for regional resource use planning	*Knowledge base* • Improvement in the body of knowledge to support regional resource use planning *Analytical Capability* • Improvement in regional analytical capacity to formulate and evaluate regional options, their likely implications and current trends for planning and negotiation.	
4. Effectiveness of the collaborative and participatory approaches to the R&D and regional planning processes;	*Participation:* • Improvement in and satisfaction with stakeholder involvement in regional decision making *Collaboration:* • Improvement in stakeholder capacity to collaborate and opportunities for future collaboration	
KEY FINDINGS	R&D In-progress.	

BOX 3. Case Study: Development of Landassess DSS for sustainable grazing management

ELEMENT	DESCRIPTION
Issue Characterisation	• Increasing public concern for resource conservation and environmental quality of our pastoral lands. • Land degradation occurred over a long timeframe of use but a lack of methods for (a) identification of early warning of sustainability problems, or (b) the assessment of potential effects of management options and implications for future use. • Perceived need for government agencies and industry to determine the current state of lands, monitor change and foster a 'voluntary' approach to sustainable land use. • The role and effectiveness of computer-based agricultural IT innovations are being strongly questioned by R&D and industry organisations.
Intent/Objective	• Develop methods for a computer based decision support system to assess the current state of a grazing management unit (eg. paddock) and to assist pastoral resource managers to formulate and evaluate alternative strategies for the sustainable use of the management unit. • Better define the role of IT innovations in sustainable resource management. • Develop methods to evaluate the effectiveness of science-based IT innovations for achieving a move toward sustainable resource use outcomes.
Instrumental Assumptions	• Considerable public and private investment is being made in multiple objective IT innovations to address complex decision-making on natural resource use and management. The expectation being that the technology will increase the effectiveness of decisions and the efficiency of the decision process for individuals and organisations involved with its use. Research supporting such outcomes is generally lacking. • The perceived need for integration of the multiple levels and concerns regarding natural system functionality and grazing impact requires an interdisciplinary approach at scales relevant to grazing management decision-making (ie. paddock, property). • Evaluations of IT effectiveness generally approached as an applied problem (eg. user acceptance, level of usage of product, task efficiency, user/ organisational relevance, system functionality and ease of use) and has not recognised IT innovations as social constructs. In particular, the relationship between the collaborative processes involved with most IT development and complex evolving natural and human systems has generally been ignored. • Need to deal with the dynamic and varied situational context of key stakeholders and to manage end user expectations of R&D over a relatively long development timeframes.
Context of Implementation	Policy/Institutional : • New legislation required land managers to demonstrate sustainable use of pastoral lands. • Fragmentation of land management responsibilities for across three agencies with very different 'cultures'. Environmental: • Land degradation continuing to occur through impact of grazing of beef cattle. • Large heterogeneous grazing management units • New management practices changing spatial and temporal distribution of grazing impact. Economic: • Industry export-oriented, with fluctuating prices, low input and low return operations. Social/cultural: • Divergence of views on what sustainable use means within and between government, industry and the community. • Past focus of industry and government on development (ie. improving animal production, infrastructure) rather than land resource management. Technological: • No system of appraisal of sustainability of pastoral activities exists. • Poor integration, access to, and sharing of existing data and knowledge.

BOX 3. Case Study: Development of Landassess DSS for sustainable grazing management (Cont.)

EVALUATION CRITERIA	EVALUATION MEASURE/INDICATORS	METHODS FOR ASSESSMENT
1. Progress toward sustainable grazing resource use:	• Contribution to improved interaction and communication on sustainable use of pastoral lands between government agencies. • Contribution to improved understanding of sustainable use in grazing systems to support advisory and extension activities.	• The evaluation involved a collaborative between a scientific research agency and three government agencies responsible for pastoral land management, and grazing industry representatives. The evaluation methods included the assessment of needs, the evaluation of process, and stakeholder reflections on potential impact through: a. process evaluation through documentation of the dynamics of the IT development process and its organisational context; b. formative evaluation in order to improve the DSS system development process • An ex poste strategic constituency assessment of key stakeholder group expectations of the effectiveness of the DSS innovation as a product based on stakeholder workshops. • An ex poste strategic constituency assessment of the overall effectiveness of the participative system development process based on face to face interviews using a scenario approach..
2. Stakeholder capacity building	• Improved access, sharing and meaningful use of data/ knowledge on sustainable grazing practices. • Improvement in analytical capacity to assess current state of the land resource and to formulate and evaluate management options. • Endurance of collaborative R&D alliance.	
Effectiveness of IT development process	• Stakeholder satisfaction with level of involvement and influence in IT development process. • Stakeholder views of costs/benefits of collaboration. • Stakeholder satisfaction with relevance, functionality and ease of use of IT product.	
KEY FINDINGS	*R&D on Sustainability:* • IT innovations are characterised by: a. multiple stakeholders and multiple and evolving objectives. b. focus on broad societal purposes, c. a broad outcomes and impacts (eg. learning processes and stakeholder behaviour modifications). • Learning processes occur through participatory process of IT development, and the interactive use of an IT tool. • DSS have the potential to foster an adaptive and flexible approach to resource management decision-making at policy, advisory and enterprise levels. *IT Evaluation:* • An iterative, participative and pluralistic approach is needed to evaluate IT development in terms of both a process tool and product success, i.e., one that encompasses: a. intangible outcomes (eg. stakeholder learning processes and behavioural change, improved stakeholder relationships and interaction processes, broader societal benefits), and b. tangible outputs (e.g. technical quality, institutional efficiency, usage). • Impacts will accrue over a long time frame and are often not visible to beyond the life of the IT development process.	

BOX 4. Case Study: Herbert Resource Information Centre

ELEMENT	DESCRIPTION
Issue Characterisation	Building Stakeholder Capacity Traditionally, most decision-making in planning natural resource use options has been vested with regulatory authorities. In recent years significant changes have occurred to involve the community in the decision-making process. Initiatives are needed to ensure that communities have access to the information needed to underpin this decision-making and to develop the capacity of stakeholders to use that information. Evaluation Such initiatives will impact on the decision making process. What impacts occur?
Intent/Objective	Herbert Resource Information Centre *(HRIC)* To build capacity for stakeholder participation in resource use planning by providing four fundamental requirements for effective participation: • effective access to information pertinent to resource use planning; • access to the analytical tools required to make effective use of that information: • the capacity to make appropriate use of those analytical tools and data sets; and • an organisational structure that fosters effective collaboration. Evaluation To assess the impact of one such initiative
Instrumental Assumptions	The HRIC structure and functions can deliver the following : • improved quality of data available for the Herbert catchment; • improved access to data; • better informed decisions in planning & implementing data collection & use projects; • better informed decisions in natural resource management; and, • improved collaboration.
Context of Implementation	*Technological:* • Use of spatial data in decision-making is map-based • Limited existing GIS capacity used solely for map production • No network facilities for data-sharing • Existing data dispersed within and between agencies • No rigorous data/meta data management • High quality base data available from Herbert Mapping Project *Institutional* • Limited use of spatial data within stakeholder groups • Very limited sharing of spatial data across groups • Limited computing ability in stakeholder agencies • Almost no GIS skills • Staff willing and able to take on new skills

BOX 4. Case Study: Herbert Resource Information Centre (Cont.)

EVALUATION CRITERIA	EVALUATION MEASURE/INDICATORS	METHODS FOR ASSESSMENT
Operational Impacts	• Intentions in using new data sets that became available, implications for existing data, constraints to use. • Impacts of involvement in the HRIC on data availability, data collection, data storage, data access, complexity of decision-making, efficiency of decision-making, quality of decisions made, presentation of decisions. • Impact of the HRIC on the resolution of resource management issues within the catchment. • Impacts of participation in the HRIC on the types of activities agency involved in	Qualitative research techniques. Individual, face-to-face interviews using a semi-structured interview schedule with key participants in the HRIC each year over three years : 19 in February 1996 (6 months before completion of the joint venture agreement and employment of HRIC staff), 19 in February 1997; 17 in March 1998 (17 interviewees). With some change in key participants a total of 41 individuals were interviewed over the three years with a core group of 7 individuals being interviewed at each of the three times.
Evaluation of Process	• Importance of Herbert Mapping Project in triggering HRIC. • Constraints to use of HRIC. • Impact on other agencies. • Use of the HRIC by non-partners & impacts on those users • Interaction with other organisations: changes to general levels frequency of interaction; understanding of the objectives of each agency; understanding of the constraints under which each agency operates; understanding of the data needs of each agency, willingness to work with the other agencies, nature and process of interactions, confidence in other groups. • Evaluation of the dynamics of the process (key participants; positives, negatives).	
Changes in Understanding	• Awareness of the quality and availability of data. • Credibility of data resources. • Understanding of the limitations associated with spatial data. • Understanding of data resources used by other groups in the project. • Understanding of the data needs of other groups. • Most important things learnt from involvement in HRIC. • Understanding of the tractability of resource management issues • Understanding of the quality and limitations of data; awareness of the availability of data,.	
KEY FINDINGS	*Improved quality of data available for the Herbert catchment and improved access to that data:* Data access improved dramatically with participants becoming more aware of the range of data available and having access to all but that which was 'commercial-in-confidence'. *Better informed decisions in planning and implementing data collection and use:* While processes for data collection were only moderately impacted for most parties, compatibility with other data had become a significant criteria such that data storage and management collectively and individually had been significantly impacted. *Better informed decisions in resource management:* Formal spatial analyses were being used in planning decisions, often with a substantial cost saving and resulted in decisions perceived to be as good as, and frequently better than, would have been achieved with previous processes. *Improved collaboration:* Willingness to work together increased amongst the partners to the Centre and external use of the HRIC by businesses and the broader community began to occur. *Contributions to success: The* key contributions to the success of the Centre were identified as : skilled professional staff, common goals, lack of pre-existing (and therefore potentially competitive) infrastructure, neutrality of location, credibility, and an evolutionary history. *Threats::* Issues of intellectual property, 'head office' pressures within partners to the initiative, and over-commitment	

BOX 5. Case Study: Integrating R&D in Catchment Management Planning (Sarah Ewing, University of Melbourne, Pers. Comm)

ELEMENT	DESCRIPTION
Issue Characterisation	There is much R&D going on in relation to catchment management but this effort is lost if research results are not taken up and implemented by land, water and vegetation managers. The catchment planning process is one which has the potential to embrace R&D outcomes but the question remains how that R&D might best be made available to the planning process. As a first step, it would be helpful to know how R&D has been made available to planners thus far, particularly where explicit attempts have been made to facilitate technical and/or research input.
Intent/Objective	A major element of Australia's approach to ICM is the development and implementation of catchment-based land and water management plans that are driven by local communities. Indeed, regional ICM strategies form the basis of partnership agreements between federal, state and local governments and the community. Typically, catchment plans seek to document the key land and water management issues in the catchment; to develop integrated strategies for their remediation; to identify roles and responsibilities for action; to allocate priorities to the recommended actions; and to raise community awareness of catchment issues. The objective of this research is to document the range of approaches (or models) used by catchment planners in Australia to access technical information in support of the planning task. Specifically, the project is seeking to provide examples of face-to-face information exchange through fora such as workshops, technical advisory groups, workshops and expert panels.
Instrumental Assumptions	That: • In the course of an ICM planning process, knowledge gaps will be identified • An important objective of an ICM plan is to ensure that it is built upon the best available advice and information • The strategic use of R&D outcomes will help ensure that the plan is built on best available information • R&D can help address gaps in understanding • R&D is useful/applicable for a range of institutional contexts and planning needs

BOX 5. Case Study: Integrating R&D in Catchment Management Planning (Cont.)

EVALUATION CRITERIA	EVALUATION MEASURE/INDICATORS	METHODS FOR ASSESSMENT
Characteristics of approach to the integration of R&D through face-to-face information exchange	• Type of approach • Rationale for the approach (ie on what basis the approach was chosen) • Role/model of community participation/engagement employed • Stage(s) in planning task for which model used (eg. identification of need for planning, documenting key issues, developing strategies for remediation, identifying roles and responsibilities, allocating priorities, raising awareness, informing on-ground action, monitoring, plan review) • Purpose(s)/stages for which R&D useful within model (see previous) • Other information sources used (eg. local knowledge, database) • Outcomes of approach • Perceived strengths of approach • Perceived weaknesses of approach	• Review of literature to identify and review documented approaches • Case study • Survey/interviews • Content analysis
Characteristics of context of application of approach/model	• Requirements/imperatives for catchment planning • Political/legislative context in which the model/approach has been (or is being) used in catchment management planning. • Geographical context (urban, peri-urban, rural) • Environmental context of catchment (eg. key issues being addressed) • Resourcing context (eg. funding, level of agency support, staffing) • Sources and accessibility of relevant data • Scale of planning (eg. local, catchment, region, national) • Role of local community in planning • Timeframe for planning • Prior experience of constituents with planning processes.	
KEY FINDINGS	R&D in Progress	

BOX 6. Case Study: Information Needs for Integrated Catchment Management

ELEMENT	DESCRIPTION
Issue Characterisation	Significant investments are being made throughout Australia in approaches to natural resource management based on the integration of community involvement, technical knowledge, and organisational structure and policy objectives. A fundamental principle invariably underpinning these approaches is that land and water resource management decisions must be based on the best available information. However there is a lack of guiding principles or recommendations on information needs and provision for those responsible for planning and implementing these approaches to support an effective process.
Intent/Objective	The research objective is to explore key issues and considerations for planning information needs and provision for community-based approaches to integrated resource management through case study investigation of Integrated Catchment Management (ICM) in Queensland, and the Herbert River ICM process in particular. The evaluation objective is to develop a framework to guide the assessment of information needs for ICM based on the experience in the Herbert River catchment ICM process.
Instrumental Assumptions	• The sustained and balanced use of land, water and related biological resources can be achieved through the integrated catchment management approaches. • A successful ICM initiative requires four fundamental tasks to be undertaken: ↳ the development of a catchment strategy; ↳ raising community awareness of catchment scale issues and solutions; ↳ the precipitation of action to bring about solutions; and ↳ an effective ICM implementation program. • Decisions relating to these planning tasks must be based on the best available information. • Information on land and water resources, particularly on the interactions between these resources, is often deficient or not readily accessible. While additional information is often desired, management decisions will need to be made using available data to avoid unacceptable delays.

BOX 6. Case Study: Information Needs for Integrated Catchment Management (Cont,)

EVALUATION CRITERIA	DESCRIPTIVE MEASURES/DESCRIPTORS	METHODS FOR ASSESSMENT
Information needs for developing a catchment management strategy	• Categories of information required to underpin the development of an ICM strategy document • Requirements for collating, storing and accessing the information that underpins strategy development • Role local experience plays in developing a catchment strategy • Contribution R&D plays	• On-going monitoring and analysis of documentation relating to the Herbert River ICM process. • Face-to-face interviews of key participants using a semi-structured questionnaire. • Meta-analysis of other specific evaluations.
Information needs for raising awareness of issues	• Specific information needs for raising community and agency/organisational awareness on land & water management issues • Requirements for the integration of information to raise awareness of issues amongst community and agencies • Role of local experience, information & networks play in raised awareness • Role R&D plays	
Information needs for precipitating / catalysing action	• Information needs associated with enabling action aimed at the resolution of specific resource management issues • Requirements for the collection, storage, access and sharing of information to facilitate action by participants in the ICM process seeking to resolve resource management problems • Role local experience and information plays in precipitating action to resolve problems • Role R&D plays	
Information needs for implementing an effective ICM program	• Specific information needs faced by a CCC in establishing and implementing an effective ICM program • Role local experience plays in the effective management of the ICM process • Role R&D plays and how incorporated into the initiative	
Characterisation of Context	• Availability of previous integrative technical reports • Organisational infrastructure in stakeholder groups for information management and analysis • Experience and skills of stakeholder groups, particularly HRCCC members	
KEY FINDINGS	R&D in Progress	

6. CONCLUSION

While natural resource management and environmental planning are increasingly being promoted globally as mechanisms to resolve intractable resource use problems and conflicts, there still remains no common theoretical base upon which such approaches are developed and implemented. Consequently, a clear evaluative framework has failed to emerge to guide continuous improvements in the way that such initiatives actually contribute toward achieving sustainable and equitable resource use and management. This report has sought to place natural resource management policy implementation and related research in a clear theoretical context as a first step to establishing an integrated framework for evaluating such initiatives.

Natural resource management policy and planning initiatives need to be evaluated as a system that links the initiative's objectives and rationale to performance 'on the ground'. The evaluation strategy presented here provides a basis for an integrated evaluation of the different perspectives (i.e. social, economic, environmental, policy and institutional) on the performance of the policy, program or research processes, a framework for guiding its implementation and a rigorous basis for synthesising findings. The strategy recognises evaluation as a means of not only assessing impact but also as a critical process tool for improving program and research management, providing a basis for assessing accountability, fostering learning, improving the body of knowledge, and improving the implementation of natural resource management policy.

The framework established has sought to overcome significant challenges to evaluation in complex natural resource and human systems. We have used the findings of a number of case studies of sustainability initiatives in Australia (i.e. policy programs, research processes and knowledge development) to develop a systems-based analytical framework for evaluation in these contexts. It needs to be stressed, however, that this is a framework only. Key measures and criteria developed within this framework need to be developed to meet the specific needs of particular application contexts, as well as being negotiated with those actors involved in the policy and planning process.

Unless there are structured and coordinated attempts to adopt improved evaluative frameworks appropriate to the theoretical context within which natural resource management and planning occurs, we do not believe that there can be significant and continuous improvements in the way that policy initiatives can contribute to sustainable and equitable resource use outcomes at the local, regional, national and global levels. As a consequence, integrated approaches to natural resource management may be discarded before a fair and comprehensive assessment of their potential role and impact is determined. This would be counter to the general theoretical developments in systems theory, ecology and the participative and adaptive management philosophies that currently drive natural resource management policy reform.

Importantly, the challenge to create policy processes, institutional arrangements and natural resource management practices which enable the choice of methods, tools and mechanisms most suited to moving communities towards achieving sustainable and equitable outcomes of resource use and management needs rigorous evaluation incorporated as part of the change process. Evaluation is fundamental to identifying change, supporting an adaptive approach that is flexible enough to meet the challenge of this change, and enabling learning at individual, community, institutional and policy levels.

7. ACKNOWLEDGEMENTS

We would like to acknowledge the financial support of the Land and Water Resources Research and Development Corporation and the co-operation of the Herbert River Catchment Coordinating Committee in undertaking this research.

1 INTRODUCTION

Program evaluation and policy analysis are recognised as critical elements of successful policy development and implementation. With increasing demands for better scrutiny of the use of public funds, and greater accountability for environmental protection and equity in resource use, the focus of policy, program and research evaluation and implementation has shifted.

Recent thinking on ecological sustainable development (ESD) emphasises continuous change, adaptation and learning. This emerging focus has caused a shift in the theory underpinning Natural Resource Management (NRM). Increasingly, this shift in theory is reflected in policy. The adoption of new policy models for natural resource and environmental management demands a new approach to evaluation.

The booklet provides the basis for an integrated evaluation of the different perspectives (i.e. social, economic, environmental, institutional and technological) on the effectiveness of NRM **policy initiatives**.

WHAT IS A POLICY INITIATIVE?

- A ***process*** (e.g. an Integrated Catchment Management (ICM) program implementation);
- A ***product*** (e.g. Decision Support System (DSS) to support a process);
- An ***increment to a body of knowledge*** to help NRM understanding (e.g. a research activity).

The framework for the booklet is a compilation of information developed as part of a project investigating factors that influence the success of community based approaches to Integrated Catchment Management in the Herbert River Catchment [1].

This evaluation guide complements SHEF (Self Help Evaluation Framework for Integrated Catchment Management), which was designed to provide ICM evaluation questions for catchment group members, individual landholders, interested community members and committees as a method of self-assessment (Self Help Evaluation Framework for Integrated Catchment Management, CSIRO, LWWRDC) for **informing action**.

[1] LWRRDC R&D Project CTC7 – Evaluation of Integrated Catchment Management in a Wet Tropical Environment.

WHAT IS THE PURPOSE OF THIS FRAMEWORK?

Increasingly, governments and community are placing a high priority on performance monitoring, evaluation and review of NRM policy initiatives.

This framework is an evaluation tool to help facilitate improved development and management of policy initiatives in Natural Resource Management. In particular, it aims to guide continuous improvements in the way policy development contributes to the sustainability of resource use and the general well-being of the communities concerned.

Where SHEF is concerned with informing action, this framework deals with **informing policy**.

WHO WILL BENEFIT FROM USING THIS BOOKLET?

- Policy makers;
- Program managers;
- Catchment and regional coordinators; and
- Community facilitators.

WHY IS EVALUATION OF NRM POLICY IMPORTANT?

The challenge to create policy processes, institutional arrangements and NRM practices that can contribute towards achieving sustainable and equitable resource use outcomes requires rigorous evaluation as part of the change process.

Evaluation is fundamental to:

- identifying change;
- supporting an adaptive approach that is flexible enough to meet the challenge of this change; and
- enabling learning at individual, community, institutional and policy levels.

Although approaches to NRM, based on the integration of community involvement, technical knowledge, organisational structure and policy objectives, are endorsed in both Australia and overseas, there are no generally accepted models of evaluation of such initiatives.

Existing frameworks may provide a *checklist* of multi-disciplinary criteria but not an **integrated evaluation**.

Significantly, no clear evaluative framework has emerged to guide continuous development in the way NRM policy initiatives contribute to on-going improvements in resource use sustainability and social well-being of the communities concerned.

In effect, an over-arching **systemic framework to guide the evaluation of NRM** policy initiatives is lacking.

HOW CAN EVALUATION IMPROVE NRM?

- Assess **public and private investment** in integrated approaches to NRM.
- **Identify** the most critical social, economic, institutional, environmental and technological **factors that influence** NRM approaches.
- **Identify** what the **outcomes and expectations** of an NRM initiative might realistically be.
- **Develop appropriate performance criteria** for assessing the potential impacts and influences on the management of resources, on institutional arrangements and on society as a whole.
- **Establish guidelines and techniques** for identifying progress towards agreed objectives and outcomes, including consideration of equity and social justice issues.

THE FORMAT

This evaluation guide deals with the rationale behind NRM evaluation together with the steps required:

- WHY A SYSTEMS APPROACH TO EVALUATION?
- WHY IS CONTEXT IMPORTANT?
- AN INTEGRATED APPROACH: ESTABLISHING CRITERIA AND IDENTIFYING METHODS:
  - Issue characterisation
  - Intent/objective
  - Instrumental assumptions
  - Evaluative criteria
  - Evaluation methods
  - Process of implementation
- REASONS FOR EVALUATION AND EXPECTED BENEFITS

2 WHY A SYSTEMS APPROACH?

A systems approach integrates knowledge from several fields of study to design projects that generate knowledge and understanding of the issue at hand (Fig. 1).

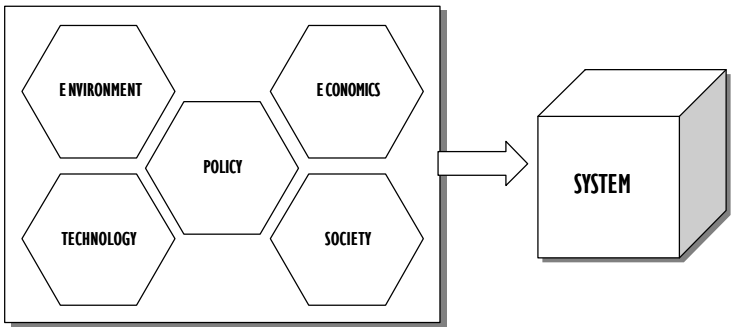

Figure 1.
In the context of NRM evaluation, the fields of study would include environmental, social, economic and political sciences.

Sustainable development is widely accepted as being the intent of achieving an equitable and sustainable quality of life by integrating social, economic and environmental activities, along with outcomes and impacts of human society into a single conceptual framework.

Continuous change is inherent in most systems. For change to be acceptable and beneficial, it must be socially, economically, institutionally and environmentally sustainable.

Coping with and managing accelerated change requires a **systemic** approach characterised by adaptation and learning that is incumbent upon personal responsibility and opportunity at the local level.

NRM initiatives need to be evaluated as such a system, linking the objectives and instrumental rationale of the policy, program or product to on-ground performance.

An effective framework for evaluating NRM and planning approaches needs to be based on practical considerations. Another important requirement is to draw on a broad spectrum of other disciplines to characterise, monitor and evaluate the process and its outcomes. These disciplines include evaluation research, social psychology, impact assessment, ecology, economics, organisational science, management science, and technology assessment. An **integrated systems approach** is needed to synthesise these multiple perspectives.

3 WHY IS CONTEXT IMPORTANT?

The implementation of policy and program initiatives for natural resource management is context sensitive and a wide range of factors make a difference to their implementation and impact. The context of implementation is multi-dimensional. Environmental, economic, social, policy/institutional and technological elements at various administrative levels or geographical scales (eg. state, regional, catchment, local) influence *all* aspects of implementation. This context evolves over time and influences the progress and impact of a policy initiative. The areas influenced include the initial framing of the issue or problem itself and the conceptualisation of the policy response through to the implementation process and finally to the on-ground performance.

Characterising the contextual elements that affect the achievement of key objectives and outcomes of the implementation processes of the initiative being evaluated is fundamental to an understanding of its performance. The influence of context on performance of the initiative and the evaluation itself needs to be recognised and accounted for in analysing the findings.

Importantly, within a particular community, established social networks and interactions, societal values, legal policy frameworks and historical influences have shaped human association with the natural resource environment and will continue to influence the association and pattern of behaviour in the future. As a consequence, the impact of a particular initiative on the community concerned and ultimately the sustainability of the natural resources concerned may vary considerably for different situational contexts.

CONTEXTUAL FACTORS

Each regional context will have its own particular social, economic, environmental, institutional and cultural backgrounds. An important part of evaluation is to define the context in which that evaluation takes place. The contextual factors will differ in different regions.

The evolution of natural resource use within a region:

The importance of understanding an evaluation of a program or process within the historical natural resource, economic, institutional, social and cultural context of resource use and management is well recognised. The historical background to the initiation and development of an NRM program determines the context of that program and thus its implementation.

Perspectives on NRM and use across stakeholder groups:

The perspectives, expectations and behavioural responses on resource use and management may vary significantly across stakeholders and over time, and may be in conflict or contested by others. This means that the evaluation model must incorporate both community and agency views.

Community attitudes, perceptions, involvement, and awareness of the NRM process can significantly influence the effectiveness of the process.

Stakeholder perspectives and attitudes to natural resource issues can be significantly influenced by the opinions of, and support provided by, political and industry leaders.

The quality and capability commitment of implementing staff and their supporting agencies are very important.

The nature and degree of media coverage on NRM issues and the presentation of NRM may significantly influence stakeholder perspectives.

Status of technical solutions:

The technical knowledge base (i.e. scientific, disciplinary and local expert) that can be brought to bear on the natural resource issues of concern and on the community acceptability to guide substantive action is a key influence on the potential for achieving sustainability in practice.

Extent of behavioural change required:

Depending on the particular NRM issue, the number of resource users and managers responsible for its existence or required to take action to ameliorate or resolve the problem may be numerous and widespread, or small in number and localised. Therefore important considerations are:

- the severity and extent of environmental threat;
- the number of persons responsible for its existence and management;
- the divergence in stakeholder opinions on the problem and its perceived solution; and
- how much the likely solutions are at variance with common practice.

Table 1. Examples of context of implementation from three case studies.

i. ICM IN QUEENSLAND

Policy/Institutional:
- ICM is a community-based policy initiative with no legislative base implemented though administrative and financial arrangements of State Government.
- Evolving political and legislative context.

Environmental:
- Competing and conflicting resource use issues with increasing demands and values being placed on resources for a range of uses.

Economic:
- ICM program poorly resourced, relying heavily on federal funding with short term financing arrangements and work plans.
- Focus of policy on technical solutions with a failure to clearly address the public and private costs and benefits and their social/ cultural implications.

Social/cultural:
- Requires voluntary coordinated local community-based support and action in the context of no previous experience in these issues at community level.
- Costs largely borne by individual resource users in the short term, while many benefits accrue to society as a whole.

ii. REGIONAL RESOURCE USE PLANNING IN THE CENTRAL HIGHLANDS OF QUEENSLAND

Natural resource use issue/problem:
- Diversity of significant issues and problems rather than a single chronic problem (eg. of magnitude of salinity) to focus regional community attention

Institutional:
- Multitude of poorly coordinated agencies/organisations responsible for natural resource management with few formal or effective linkages as well as a multiplicity of relevant policy frameworks which are invariably sectoral or single-issue based.

Economic:
- Region emerging from a long-term 'drought' with economic hardship and industry downturn in major rural industries and mining sectors. A growing area with opportunities for development.

Social:
- Diverse cultures within the community with very different perspectives and value-systems on natural resource management.

Cultural:
- Indigenous land rights an emerging issue. Growing community interest in cultural heritage.

Technology:
- Communication technology constrained in many areas such that opportunities for use not equally distributed/accessible through the community. Capacity to change constrained by these factors as well as social and economic contextual factors.

iii. LANDASSESS DSS FOR SUSTAINABLE GRAZING MANAGEMENT

Policy/Institutional:
- New legislation required land managers to demonstrate sustainable use of pastoral lands.
- Fragmentation of land management responsibilities for across three agencies with very different 'cultures'.

Environmental:
- Land degradation continuing to occur through impact of grazing of beef cattle.
- Large heterogeneous grazing management units
- New management practices changing spatial and temporal distribution of grazing impact.

Economic:
- Industry export-oriented, with fluctuating prices, low input and low return operations.

Social/cultural:
- Divergence of views on what sustainable use means within and between government, industry and the community.
- Past focus of industry and government on development (ie. improving animal production, infrastructure) rather than land resource management.

Technological:
- No system of appraisal of sustainability of pastoral activities exists.
- Poor integration, access to, and sharing of existing data and knowledge.

4 AN INTEGRATED SYSTEMS APPROACH: ESTABLISHING CRITERIA & IDENTIFYING METHODS

In the past, evaluation of NRM policy processes has generally been:

- fragmented in reconciling perspectives from different fields of knowledge;
- largely insensitive to the socio-economic, policy/institutional, environmental and technological contexts;
- hampered by a lack of assessable goals and outcome measures; and
- broad one-off overviews conducted as a cross-sectional snapshot rather than a systematic longitudinal study.

The **integrated approach** to evaluation recognises many levels in NRM policy and research:

- problem characterisation;
- policy formulation and intent;
- program logic; and
- on-ground implementation.

Furthermore, evaluation must allow for assessment of *impact* (i.e. environmental, economic, social, institutional and technological) and be implemented as a *process tool* that:

- Supports purposeful and informative stakeholder participation;
- Creates improved opportunities for the incorporation of on-going learning processes at individual, organisational and policy levels;
- Facilitates negotiation and mediation processes; and
- Supports the move towards the amelioration of, or improvement in, the tractability of problems.

Evaluation in NRM needs to be addressed as a system that:

- Links objective to consequence;
- Considers the fundamental assumptions and instrumental hypotheses that underpin core policy, program or research objectives;
- Is grounded in natural resource, policy/institutional, economic, socio-cultural and technological contexts;
- Establishes practical, valid and equitable evaluation criteria by which change can be monitored and assessed;
- Involves methodological pluralism (including both quantitative and qualitative methods) to ensure rigour and comprehensiveness in assessment; and
- Integrates different disciplinary perspectives (i.e. social, economic, environmental, policy and technological perspectives)
- **= *AN INTEGRATED SYSTEMS APPROACH***

Evaluation of NRM initiatives should be interactive, iterative and meaningful and be directed towards influencing what emerges in an on-going positive and constructive way. As the evaluation process itself will inevitably be influential, it also needs to be implemented as a collaborative learning process involving all stakeholders.

The framework presented here demonstrates the need for considering the various elements of evaluation within a regional context (Table 2). The elements of the implementation of the policy initiative and the necessary iterative process within the evaluation are seen in Figure 2.

Table 2. Definition of elements of the evaluation framework.

ELEMENT	DEFINITION
Context	The social, economic, environmental, institutional and technological factors that influence the framing or characterisation of the problem, rationality underlying the policy response, the implementation process and on-ground performance.
Issue characterisation	The nature of the issue or problem underlying the initiative being evaluated (e.g. program or policy, activity, process, method/tool, body of knowledge), and the context in which the issue or problem developed.
Intent/Objective	The objectives or intent of (a) the initiative being evaluated, its expected outcomes and key stakeholders, and (b) the evaluation itself.
Instrumental assumptions	Statement of the theoretical assumptions and instrumental hypotheses or rationality underpinning the implementation of the initiative.
Evaluation criteria	Environmental, economic, social, policy/institutional and technological measures or indicators that reflect on performance in achieving key objectives and outcomes. In turn, performance is influenced by contextual factors (e.g. environmental, economic, social, institutional, technological) that constrain or otherwise influence the implementation of the initiative.
Evaluation Methods	The quantitative and qualitative performance assessment methods for (a) the evaluation of performance measures/criteria and (b) the interpretation or analysis of findings.
Process of implementation	The activities, strategies or operations by which the initiative is implemented or delivered and which produce the outputs and, in turn, outcomes of the initiative.
Products	The outputs or deliverables produced by an initiative over which it has control.
Outcomes	The impacts that are achieved, both anticipated and unanticipated, by the initiative

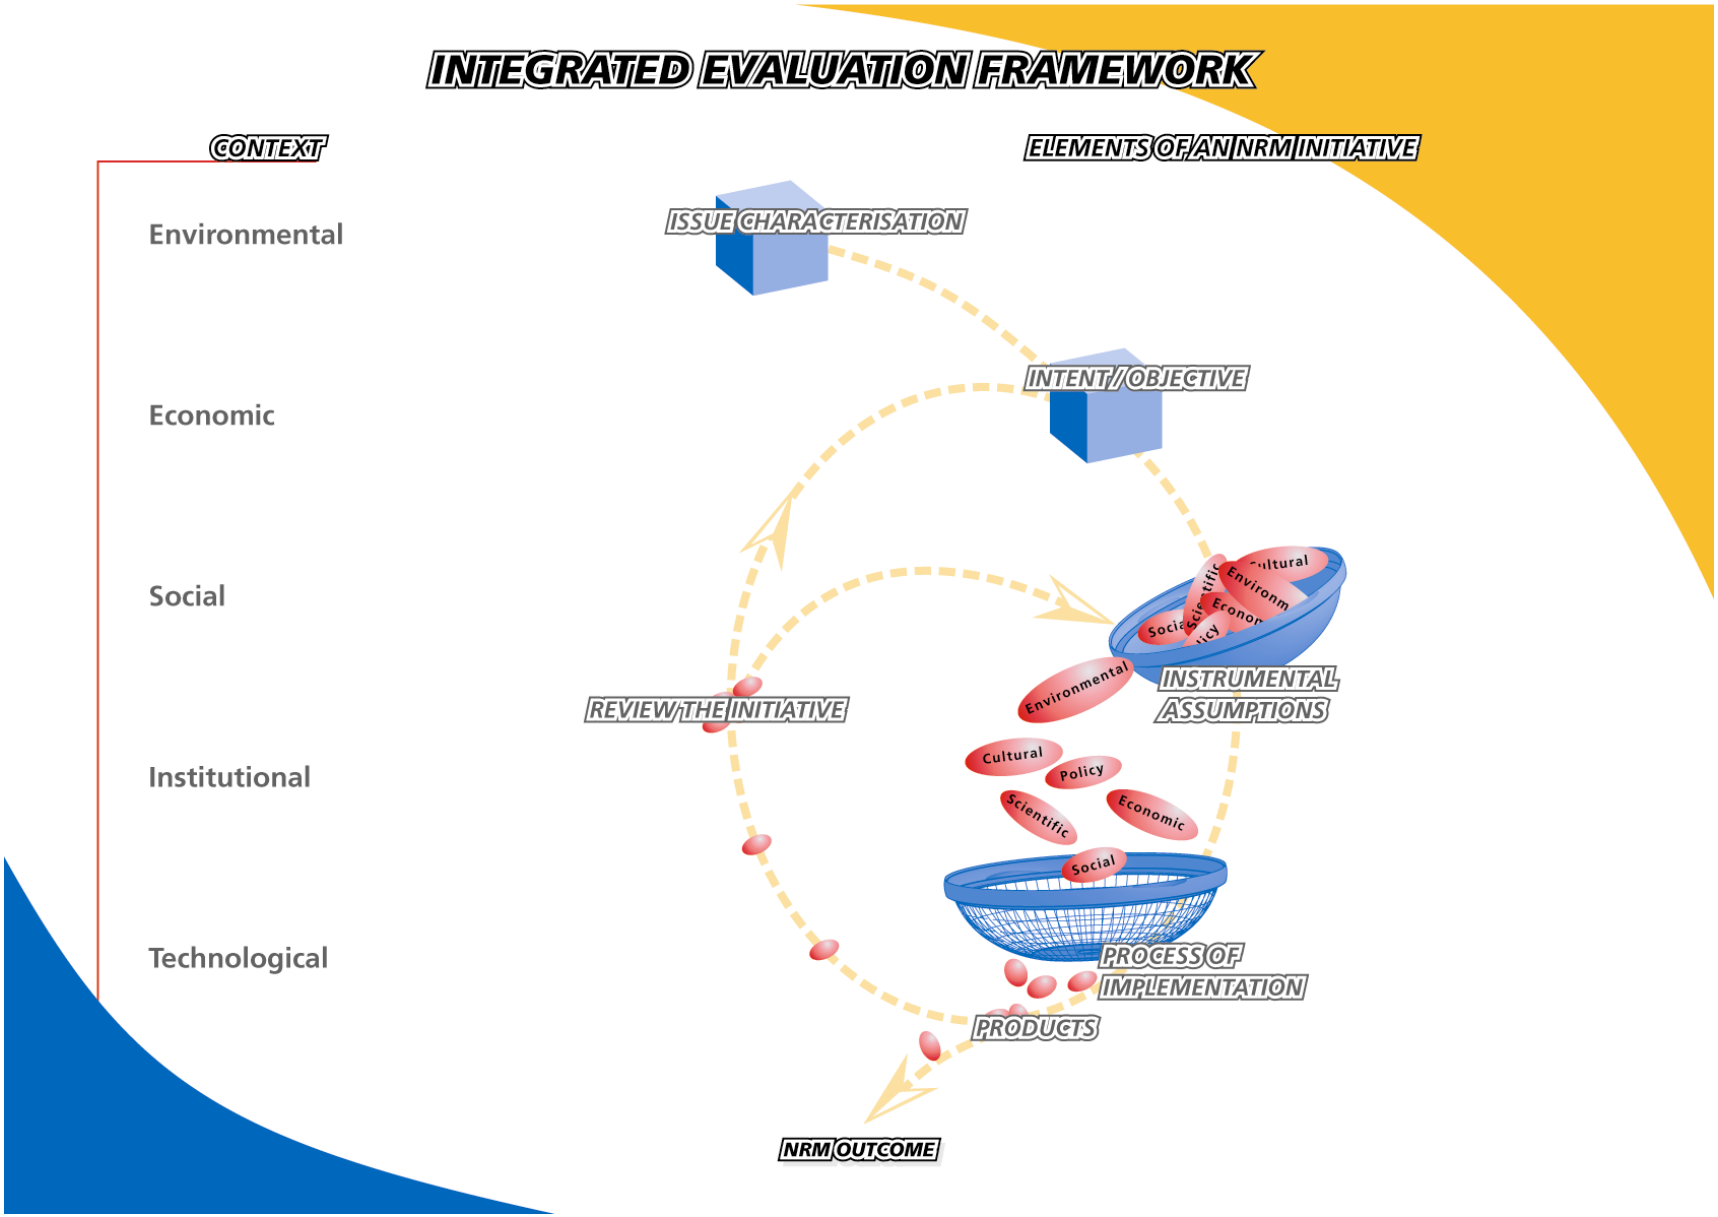

Figure 2 Integrated NRM evaluation framework, using a systemic approach encompasses scientific, economic, policy, social and environmental issues.

ISSUE CHARACTERISATION

The nature of the issue or problem underpinning a policy, program or other NRM initiative requires careful definition.

A poorly defined problem leads to a poorly formulated policy or program. Both the general background to the initiative or issue being evaluated and the context in which the issue evolved must be clearly characterised.

This provides the basis for matching progress in the policy response or program initiative to the impact on the tractability (i.e. manageability) of the sustainability problem.

In practice (Table 3), the issue characterisation required to underpin evaluation may lead to reconsideration of the issue and, thereby, the initiative.

Table 3. Examples of Issue Characterisation from case studies.

i. ICM in Queensland

- Resource degradation of waterways, pastoral and agricultural lands, concern for biological diversity
- Fragmented centralised governance approaches need to be replaced by more adaptive and integrated approaches at a catchment scale involving partnerships between government, industry and communities
- There is considerable public and private investment in integrated approaches with high community expectations but the translation of the concept into practice is experimental and evolutionary.
- Evaluation is necessary to determine whether strategies are achieving desired resource management outcomes
- Evaluation is fundamental to identifying impact, supporting an adaptive integrated approach that is flexible to meet the challenges of change, and informing on-going learning at individual, community, institutional and policy levels.

ii. Regional Resource Use Planning in the Central Highlands of Queensland

- Many natural resource use and management problems cannot be effectively addressed by individual action at the local or farm level but require regionally-based solutions through the agreed actions of a number of actors.
- Regional planning approaches in the past have tended to take a sectoral or a single issue focus, such as economic development, social planning and nature conservation management.
- A new emerging paradigm of a regionally-driven, integrated and ecosystem management approach to resource use planning is now being advocated. This new approach aims to achieve more sustainable and equitable resource use and management outcomes at a regional level.
- The effectiveness of such approaches at meeting these objectives has not been systematically addressed.
- Their impact is likely to be multi-dimensional; involving social, economic, institutional, environmental, and technological elements.
- However the implementation of such sustainability initiatives is experimental and there have been few evaluations of their long term impact.
- Where evaluations have been undertaken, regional economic development and growth management has often overshadowed the importance of environmental considerations.

iii. Landassess Decision Support System (DSS) for sustainable grazing management

- Increasing public concern for resource conservation and environmental quality of our pastoral lands.
- Land degradation occurred over a long timeframe of use but a lack of methods for (a) identification of early warning of sustainability problems, or (b) the assessment of potential effects of management options and implications for future use.
- Perceived need for government agencies and industry to determine the current state of lands, monitor change and foster a 'voluntary' approach to sustainable land use.
- The role and effectiveness of computer-based agricultural IT innovations are being strongly questioned by R&D and industry organisations.

INTENT/OBJECTIVE

Evaluations need to be clear about matching research methods to the nuances of particular evaluation questions, the idiosyncrasies of specific program situations, and information needs of identifiable stakeholder clients (Table 4).

Firstly, the **objectives and intent of the initiative** being evaluated and the expected outcomes need to be clearly identified so that they can be linked to the on-ground impacts of implementation. The stakeholders are likely to include a range of government agencies, industry and community interests that may evolve over time as the issue or problem is better defined.

Clear identification of the purpose of an evaluation is also fundamental to planning an effective evaluation. The agreed limits and boundary conditions of the evaluation, and the nature of the involvement of participants and/or collaborators in the evaluation, should be negotiated and clearly defined to develop common expectations and ownership of the evaluation findings and to focus the performance assessment on the critical evaluative criteria for measuring change.

Table 4. Examples of Intent/Objective from case studies.

i. ICM in Queensland

The stated intent of the Integrated Catchment Management (ICM) policy initiative in Queensland is a coordinated approach to integrate the management of land, water and related biological resources in order to achieve their sustainable and balanced use by:

- generating a better understanding of ecosystem interactions at a catchment scale by the community and Government and moving towards common or agreed goals through development of a catchment management strategy;
- facilitating coordination and cooperation within and between Government agencies and the community to enable the prioritisation of actions, and joint or independent action to seek solutions to problems.

Evaluation of ICM in practice is needed to guide continuous improvements in the way the policy initiative contributes to on-going change.

ii. Regional Resource Use Planning in the Central Highlands of Queensland

The project is being undertaken as an active partnership with a range of government, industry and community groups with a stake in the region. It aims to define and assess the nature of existing regional resource use planning in the Central Highlands, and to evaluate the effectiveness of a regionally-driven and negotiated planning systems approach to achieve more sustainable and equitable resource use outcomes. In essence, the project is designed to:

- strengthen human resource and institutional capacities to undertake regional resource use planning in the Queensland Central Highlands region, and
- generate research results and new innovations that have the potential to support a shift towards more sustainable and equitable resource use within rangelands.

iii. Landassess DSS for sustainable grazing management

- Develop methods for a computer based decision support system to assess the current state of a grazing management unit (eg. paddock) and to assist pastoral resource managers to formulate and evaluate alternative strategies for the sustainable use of the management unit.
- Better define the role of IT innovations in sustainable resource management.
- Develop methods to evaluate the effectiveness of science-based IT innovations for achieving a move toward sustainable resource use outcomes.

INSTRUMENTAL ASSUMPTIONS

Theories represent the most systematic way of building, synthesising and integrating diverse knowledge. They identify:

- the boundary that defines the area of interest;
- key constructs of that area;
- the values these constructs can take; and
- the relationship among the key constructs.

Theory can be used in evaluation to propose and test links among key factors indicating the direction and degree of influence they have on NRM implementation and impact.

An atheoretical research or evaluation approach may collect interesting facts but the danger is that no unifying theme or patterns or relationships may emerge. Defining the construct space of an initiative provides the basis for establishing validity and, ultimately, sound measures that can be applied to a variety of contexts.

Whether explicitly or, more often implicitly, identified, a policy or research initiative will have some basis in theory. Each theory base brings with it different methodologies, assumptions and value systems.

In evaluation, identifying the theory underpinning the implementation of the initiative, therefore, will highlight:

- the underlying assumptions and instrumental hypotheses;
- clarify what evaluation measures are needed; and
- contribute to an understanding of causal linkages.

Significantly, the rationale of the initiative being evaluated must be made explicit. Such underlying assumptions or instrumental hypotheses may relate to:

- state or tractability of NRM issues (social, economic, environmental, institutional; technological);
- stakeholder perspectives and behaviours on natural resource issues;
- knowledge base on natural resource issues and their management,
- institutional arrangements and policy frameworks;
- stakeholder coordination and communication processes;
- stakeholder capacity to adapt and to undertake NRM and planning; and
- equity and fairness of resource use outcomes.
-

The **systems approach** presented here provides a framework for identifying a series of hypotheses for appropriate responsibilities and influence against which the evaluation can identify criteria to measure progress in a developmental context (Table 5).

Table 5. Examples of Instrumental Assumptions from case studies.

i. ICM in Queensland

- Land and water resources are basic and interactive components of natural ecosystems and therefore management of land and water resources should be based on geographic units which account for the interactions between these resources.
- Management of land and water resources must be coordinated.
- Land and water resource management decisions must be based on the best available information
- Sound land and water management is best achieved through the informed action of the individual users and managers of these resources
- For change in resource use to be acceptable and beneficial it must be socially, economically, institutionally and environmentally sustainable. Therefore, a balance between economic development and conservation of land and water resources must be maintained.

ii. Regional Resource Use Planning in the Central Highlands of Queensland

The instrumental hypothesis of this R&D is that improving the *overall system* of resource use planning in the region will increase the level of positive interaction among regional stakeholder groups over time, and lead to better informed and more negotiated solutions to natural resource problems. The fundamental assumptions of this approach relate to:

- the representativeness of regional stakeholder groups and peak bodies;
- the degree to which individuals, groups and the general public are empowered to be involved in regional resource planning;
- the role and value of a participatory approach to the R&D;
- the role and value of capacity building;
- the importance and value of learning processes;
- perceptions of roles, responsibilities and influence of regional stakeholders;
- perceptions of community/regional processes that need to be put in place;
- technical information and modelling tools that can guide substantive action;
- adequacy of a negotiatory approach;
- importance of context (social, economic, environmental, institutional, technological); and
- stakeholder perceptions and understanding of the project's objectives, processes and outcomes.

iii. Landassess DSS for sustainable grazing management

- Considerable public and private investment is being made in multiple objective IT innovations to address complex decision-making on natural resource use and management. The expectation being that the technology will increase the effectiveness of decisions and the efficiency of the decision process for individuals and organisations involved with its use. Research supporting such outcomes is generally lacking.
- The perceived need for integration of the multiple levels and concerns regarding natural system functionality and grazing impact requires an interdisciplinary approach at scales relevant to grazing management decision-making (ie. paddock, property).
- Evaluations of IT effectiveness generally approached as an applied problem (eg. user acceptance, level of usage of product, task efficiency, user/ organisational relevance, system functionality and ease of use) and has not recognised IT innovations as social constructs. In particular, the relationship between the collaborative processes involved with most IT development and complex evolving natural and human systems has generally been ignored.
- Need to deal with the dynamic and varied situational context of key stakeholders and to manage end user expectations of R&D over a relatively long development timeframes.

EVALUATIVE CRITERIA

The fundamental basis for evaluation is the establishment of practical criteria by which change can be monitored and assessed in order to evaluate progress and impact.

Criteria also provide the basis for testing underlying assumptions and instrumental hypotheses relating to the NRM initiative.

Evaluative criteria should reflect the achievement of key objectives of the initiative.

DEFINITIONS:

Criteria can be measured by one or more indicators, which may be defined as:

> *a parameter tracked over time that provides information on changes in the condition of the phenomenon, which has significance beyond the properties of the parameter itself* (Eckersley 1998, p.11).

A good **indicator** for measuring progress toward environmental sustainability is:

> *sensitive to temporal and social priorities, to place and scale, and in a framework that links social, economic and environmental data* (Brown 1998, p. 272).

Importantly, indicators should result from a deep understanding of **complex system function**.

SCOPE OF CRITERIA

Because of the evolving and holistic nature of the concept of sustainability, evaluation of NRM initiatives requires criteria from the biophysical, social, economic, policy, and institutional perspectives.

Some examples of evaluative criteria, therefore, may be:

Environmental:

- the evolution of resource use and management systems in the region;
- the major resource use issues and their on-site and off-site implications and impacts;
- attitudes and behaviour to NRM and environmental issues; and
- the nature and extent of behavioural change in resource use and management practices required across stakeholders.

Economic:

- the nature and status of, and inter-dependencies within, the overall regional economy;
- perceptions of future development and economic prospects;
- the distribution of wealth and resources within the community;
- the economic vulnerability of the regional economy;
- economic viability of land managers; and
- financial resourcing of policy initiatives.

Social/cultural:

- social history and regional demographic change;
- cultural diversity and related resource use issues;
- the nature of, and commonality in, community expectations (within and outside the region) regarding the environment and socio-economic situation, and resource management and planning processes;
- perceptions of equity and social justice trust in process; and
- political and media support for NRM processes.

Policy/institutional:

- adequacy and consistency of relevant policies and the organisational structures and processes for NRM across government, industry and community;
- the resourcing and coordination characteristics of policies, plans and processes;
- the stability and volatility of local and state political process;
- opportunities for access to policy processes by the wider community; and
- perceptions of responsibilities and roles.

Scientific/technological:

- the characteristics of the existing technology system;
- technical knowledge base and competencies to use advanced technologies across stakeholders;
- the availability and feasibility of technical solutions; and
- the adequacy of scientific knowledge including appropriateness of scientific understanding and its ability to assist decision-making.

The relative importance of the influence of each of these elements will vary depending on the particular objectives of the initiative and the objective of the evaluation itself. Importantly, each criterion will measure only a portion of the total context of implementation. Examples of Evaluative Criteria from three case studies are shown in Table 6.

Table 6. Examples of Evaluative Criteria from case studies

i. ICM IN QUEENSLAND

Resource Use Context

⇒ Tractability of resource use issues and tensions in the catchment:
- External environment vigilance in community
- Characteristics of catchment resource use
- Community attitudes and behaviour

Institutional Structure

⇒ Adequacy of policy frameworks and institutional arrangements to address issues at a catchment scale

⇒ Community capacity to plan and implement catchment management strategy

Community Process

⇒ Adequacy and equity of community processes:
- Mechanisms for communication and interaction on catchment issues
- Equity of opportunity for involvement
- Level of strategic alliances/partnerships developed to exploit future synergy

Technology Context

⇒ Adequacy of available technology:
- Capability to identify and address catchment resource use issues
- Technical support for effective implementation of on-ground activities.

ii. REGIONAL RESOURCE USE PLANNING IN THE CENTRAL HIGHLANDS OF QUEENSLAND

Progress towards regional sustainability of resource use

⇒ Resource use context::
- Reduction in the severity of impact or improvement in the tractability of regional resource use issues and tensions.
- Contribution to improvement in regional sustainability indicators

⇒ Equity of resource use:
- Enhanced perceptions of fairness in the overall regional resource use planning system and related decision-making processes.

⇒ Regional processes:
- Improved mechanisms for communication or interaction on regional issues.
- Improved recognition of importance of a regional perspective in planning.

Improvement in the degree of involvement and participant capacity to undertake regional resource use planning.

⇒ Technical capacity:
- Improvement in technical capacity to undertake planning initiatives

⇒ Planning systems:
- Improvement in planning structures and processes within individual stakeholder groups.

⇒ Institutional arrangements*:*
- Improvement in broader institutional structures at the regional level to undertake regional planning.

⇒ Research capacity:
- Influence/impact on peer researchers and regional planning practitioners of Regional Stakeholder Groups within and outside the region.

Role and effectiveness of additional information and IT development for regional resource use planning

⇒ Knowledge base:
- Improvement in the body of knowledge to support regional resource use planning

⇒ Analytical capability:
- Improvement in regional analytical capacity to formulate and evaluate regional options, their likely implications and current trends for planning and negotiation.

Effectiveness of the collaborative and participatory approaches to the R&D and regional planning processes;

⇒ Participation:
- Improvement in and satisfaction with stakeholder involvement in regional decision making

⇒ Collaboration:
- Improvement in stakeholder capacity to collaborate and opportunities for future collaboration

Table 6 (continued). Examples of Evaluative Criteria from case studies

iii. LANDASSESS DSS FOR SUSTAINABLE GRAZING MANAGEMENT

Progress toward sustainable grazing resource use:

⇒ Contribution to improved interaction and communication on sustainable use of pastoral lands between government agencies.

⇒ Contribution to improved understanding of sustainable use in grazing systems to support advisory and extension activities.

Stakeholder capacity building:

⇒ Improved access, sharing and meaningful use of data/ knowledge on sustainable grazing practices.

⇒ Improvement in analytical capacity to assess current state of the land resource and to formulate and evaluate management options.

⇒ Endurance of collaborative R&D alliance

Effectiveness of IT development process:

⇒ Stakeholder satisfaction with level of involvement and influence in IT development process.

⇒ Stakeholder views of costs/benefits of collaboration.

⇒ Stakeholder satisfaction with relevance, functionality and ease of use of IT product.

ITERATIVE DEVELOPMENT PROCESS

A whole suite of measures has the potential to reflect the influences and impacts of the NRM initiative. For practical and efficiency reasons, each evaluation will need to focus on a selected number of critical evaluation criteria and indicators that are relatively readily measurable over time, yet rigorous and effective in reflecting change.

It is important to note that the identification of evaluation criteria and their related indicators for a particular NRM initiative necessarily involves an iterative process of development to continually refine the criteria to a critical but manageable set.

This process of refinement needs to take into account:

- the objectives or intent of the phenomenon of interest (ie. the NRM initiative);
- the objectives or intent of the evaluation itself;
- the feasibility and practicality of methods given the resources available; and
- the constraints of the context of implementation.

Inevitably, criteria need to be reviewed and revised in light of experience in order to capture emerging issues that need to be evaluated.

EVALUATION METHODS

The purpose and design of an evaluation will determine, and be influenced by, timing. Three well-recognised stages of evaluation are:

- *ex-ante* evaluation undertaken before implementation;
- progress evaluation during implementation; and
- *ex-post* evaluation after completion of a project or program.

Across all of these stages, four fundamental criteria guide the design of an evaluation:

- usefulness and relevance to the evaluation purpose;
- feasibility and cost-effectiveness;
- equity and social justice; and
- technical validity.

As there is no recognised *best* or *generic* evaluation methodology, a balance is required among the various considerations when designing an evaluation.

MANAGING BIAS

The conventional scientific model sees an objective, rational, political and neutral body of knowledge that informs decision-making processes. However, a multitude of discretionary judgments is made during the course of an evaluation. The formulation of the problem, the analytical models, the methodological approach, the relevant information, the data collection techniques, the scope and construction of questions, and so on reflect the views of those who participate in the design, development, implementation and interpretation of the evaluation.

Some form of bias is inevitable in evaluation. In the context of NRM initiatives, there is a strong case for **methodological pluralism**. There is not likely to be one best, let alone all encompassing, perspective for understanding and evaluating complex problems. Diversity in methods allows 'triangulation' of theory and methods to make effective use of their complementarities, particularly in ameliorating any one perspective or approach. Values and instrumental assumptions need to be made explicit in theoretical frameworks, principles of inquiry and evaluative methods.

No single evaluation method will be totally applicable. Evaluation has moved into a period of methodological diversity with a focus on methodological appropriateness. As a consequence, the framework for evaluation presented here is designed to be independent of the methods applied for evaluation.

Methodological pluralism can contribute to rigour in evaluation. Multiple methods are needed at different stages of the project, for different project components, and for different planning contexts. These may include both

quantitative and qualitative methods. Moreover, many will be concurrent, involving multiple parallel tasks.

DESIGN CRITERIA

In designing a pluralistic approach to evaluation of the performance and impact of an NRM initiative, criteria that need to be considered include:

- ***Scope of assessment*** (eg. scale or level of impact, as well as impact of overall approach or focussed evaluations of specific components).
- ***Form of evaluation*** (eg. self-evaluation or external assessment).
- ***Mode(s) of analysis*** (eg. longitudinal study, cross-sectorial study, focussed/case study, needs analysis, on-going monitoring).
- ***Unit(s) of analysis*** (eg. individual, group, organisational, regional resources, regional economy, regional community, state policy development).
- ***Information required and types of comparisons*** to be made (eg. description, judgments, interpretation, qualitative assessments, quantitative assessments).
- ***Method(s) for inferring process of change*** (eg. methods for representing raw data to identify process patterns, comparison of change in performance criteria).

Finally, the choice of methods needs to be **appropriate and sensitive to the realities of the specific context** of NRM policy or program implementation.

PROCESS OF IMPLEMENTATION

Activities associated with a policy initiative (such as planning, research, implementation, monitoring and evaluation) usually occur simultaneously rather than sequentially. The evaluation process, therefore, needs to deal with all activities simultaneously rather than sequentially.

The evolution of the process of implementation of a policy initiative will vary from one particular region to another for a host of local contextual factors. The influence of this process on the on-ground success of the NRM initiative needs to be recognised and accounted for in analysing the findings.

PRODUCTS AND OUTCOMES

The products of an natural resource management initiative are the tangible outputs of that initiative over which it has some degree of control, such as the establishment of a multi-stakeholder coordinating committee or a catchment management plan. In contrast, the outcomes of an initiative relate to the anticipated and unanticipated impacts of those products and the implementation

process for the initiative, such as improved adoption on-farm of sustainable practices or improved water quality.

This impact or influence is potentially multi-dimensional. It may encompass, for example:

- Individual and organisational learning effects (e.g. new collaborations, partnerships or strategic alliances, networking);
- Behavioural changes (e.g. new skills, new planning processes, sharing of information);
- Impacts on norms/standards (e.g. new ways of technical assessment, accessibility of information);
- Social effects (e.g. system and networking externalities); and
- Contributions to knowledge bases, scientific progress, and human and social development.

IMPLEMENTING AN EVALUATION

The necessary steps to implement evaluation of the policy initiative are seen in Figure 3.

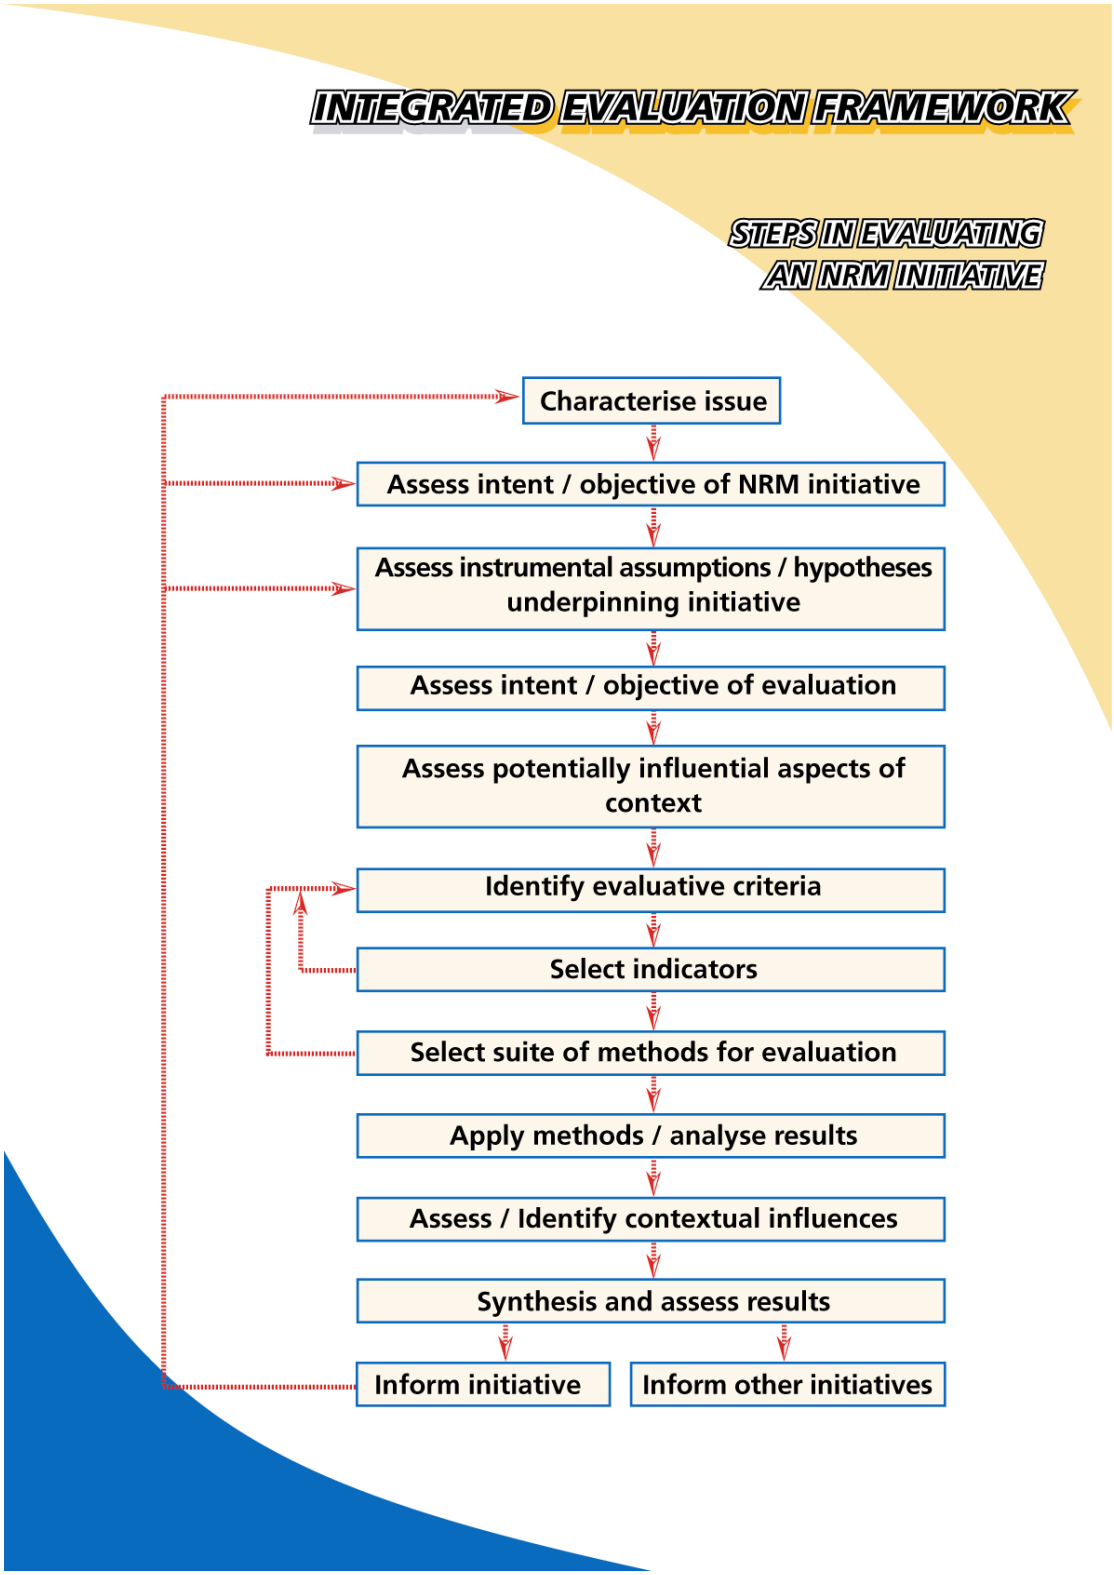

Figure 3. Steps in implementing and NRM evaluation process.

5 REASONS FOR EVALUATION AND EXPECTED BENEFITS

Evaluation needs to be directed toward influencing what emerges in a positive and constructive way, rather than focussing only on *post hoc* evaluation, which is related to achievement of initially proposed means of reaching objectives.

Importantly, the evaluation may be influential in modifying the objectives themselves. The evaluation therefore needs to incorporate an effective process of continuing feedback and improvement to the NRM implementation process as a whole. The different stages in the evaluation process will therefore be iterative, interactive and inevitably influential (Figures 2 & 3).

While natural resource management and environmental planning are increasingly being promoted globally as mechanisms to resolve intractable resource use problems and conflicts, there still remains no common theoretical base upon which such approaches are developed and implemented. Consequently, a clear evaluative framework has failed to emerge to guide continuous improvements in the way that such initiatives actually contribute toward achieving sustainable and equitable resource use and management. This guide has sought to place NRM evaluation in a clear context as a first step to establishing an integrated framework for evaluating such initiatives.

Natural resource management policy and planning initiatives need to be evaluated as a system that links the initiative's objectives and rationale to performance 'on the ground'. The evaluation strategy presented here provides:

- a basis for an integrated evaluation of the different perspectives (i.e. social, economic, environmental, policy and institutional) on the performance of the policy, program or research processes;
- a framework for guiding its implementation; and
- a rigorous basis for synthesising findings.

The strategy recognises evaluation as a means of not only assessing impact but also as a critical process tool (Table 7) for:

- improving program and research management;
- providing a basis for assessing accountability;
- fostering learning;
- improving the body of knowledge; and
- improving the implementation of natural resource management policy.

The framework established has sought to overcome significant challenges to evaluation in complex natural resource and human systems. We have used the

findings of a number of case studies of sustainability initiatives in Australia (i.e. policy programs, research processes and knowledge development) to develop a systems-based analytical framework for evaluation in these contexts.

It needs to be stressed, however, that this is a framework only. Key measures and criteria developed within this framework need to be developed to meet the specific needs of particular application contexts, as well as being negotiated with those actors involved in the policy and planning process.

Unless there are structured and coordinated attempts to adopt improved evaluative frameworks appropriate to the theoretical context within which natural resource management and planning occurs, we do not believe there can be significant and continuous improvements in the way policy initiatives can contribute to sustainable and equitable resource use outcomes at the local, regional, national and global levels.

As a consequence, integrated approaches to natural resource management may be discarded before a fair and comprehensive assessment of their potential role and impact is determined. This would be counter to the general theoretical developments in systems theory, ecology and the participatory and adaptive management philosophies that currently drive natural resource management policy reform.

Importantly, the challenge to create policy processes, institutional arrangements and natural resource management practices, which enable the choice of methods, tools and mechanisms most suited to moving communities towards achieving sustainable and equitable outcomes of resource use and management, needs rigorous evaluation incorporated as part of the change process.

Table 7. Benefits of NRM evaluation.

Improve program management

- Develop a common understanding of objectives and expected outcomes.
- Provide a basis for informed decision making on program/research direction, resource allocation and attainable levels of performance.
- Identify and focus attention on factors influencing program outputs and outcomes.
- Identify gaps in performance and insights on how they might be addressed.
- Facilitate a robust and integrated approach to program planning and implementation.

Improve transparency and accountability

- Evaluate costs and benefits of an investment of public or private resources.
- Improve efficiency and effectiveness of a program or process.
- Identify unanticipated outcomes early.
- Identify equity and social justice issues.

Reduce risk and uncertainty

- Identify impacts of a project, program or process.
- Identify information pathways and processes and their roles.
- Develop understanding of causal relationships.

Foster learning

- Influence decision-making policy development.
- Support an ongoing information exchange, feedback and learning.
- Improve awareness of equity and social justice programs as they arise.
- Identify impacts of a project, program or process.
- Identify information pathways and processes and their roles.

Improve process

- Facilitate continuous participation.
- Support the public consultation process.
- Build stakeholder capacity.
- Develop ownership of project outcomes.
- Provide information and structural framework to underpin negotiations.
- Provide a platform for cultural change.

1. INTRODUCTION

1.1 The LWRRDC CTC7 R&D Project

In 1994, the Land and Water Resources Research and Development Corporation (LWRRDC) funded research staff of the CSIRO Tropical Agriculture (in Brisbane and Townsville), CSIRO Land and Water (in Perth), and the University of Queensland Department of Geographical Sciences and Planning (in Brisbane) to undertake research on Integrated Catchment Management (ICM) processes[1]. This longitudinal study over five years focuses on the community-driven ICM program in Queensland using the Herbert River Catchment process as a case study. The objectives of the investigation are to.

1. Monitor and document the process of implementation of ICM in the Herbert River catchment and identify the social, economic and institutional factors that facilitate or hinder this process.
2. Evaluate key impacts of the implementation of the ICM process in terms of attitude and behaviour changes in the community and changes in the severity or tractability of the resource use conflicts for the catchment.
3. Assess the specific technical and related information needs that are relevant to an effective ICM implementation process in a wet tropical environment.
4. Develop a framework and related methods for evaluating the process of ICM implementation that will facilitate the development of more effective catchment management programs in Australia.

The project acknowledges that ICM requires systematic evaluation (Bellamy *et al.* 1999). For example, ICM as a process needs to take many and often conflicting considerations into account, and it operates in a complex environment where uncertainty is more often the rule than the exception. Indicators of progress are not easily defined and, to date, this area of investigation has largely been neglected (Bellamy *et al.* 1999). As such, practice is well ahead of theory as community-based catchment management programs are in place before any sound proposition of how they work best has been formulated (Mobbs and Dovers 1999). The complexities of catchment management are such that longitudinal studies of processes are extremely valuable, if not essential, if the issues of catchment management are to be better understood and appropriate lessons learned.

In responding to these challenges, the LWRRDC CTC7 R&D Project adopted an interdisciplinary approach and drew on areas of expertise in natural resource science, social science, land use planning, resource economics, policy science, evaluation research and information technology to address the following key questions relating to the integrated catchment management program implementation in the Herbert River catchment:

- Does it work? What can realistically be expected? What difference does it make to the way resources are managed?
- What makes it work? What fosters or hinders the ICM implementation processes? Are these technical, economic, institutional or social?
- How does it work best? What are the necessary arrangements, procedures and processes that need to be put in place?

1.2 ICM Policy in Queensland

The Queensland State Government released an ICM Strategy for Queensland outlining the broad policy and structural arrangements in October 1991 (DPIQ 1991). It provided a framework for encouraging cooperation and coordination between landholders and other resource users, community groups and government agencies from all levels involved in the use and management of natural resources. The Queensland Department of Natural Resources (DNR) is currently the lead government agency for implementing the Strategy. Other state government agencies, including the Department of Primary Industries (DPI), Environmental Protection Authority (EPA) and the Department of Communication, Information and Local Government and Planning (DCILGP), also play a role in promoting and supporting the ICM policy initiative.

The key elements of this ICM policy initiative promoted in Queensland are:

- *Voluntary program*. Participation in ICM is voluntary for both community and government.
- *Community based*, meaning that all structures have a majority of community members. Formation of catchment coordinating committees (CCCs) is dependent on interest from the community and other sectors.
- *Partnership* between the levels of government, industry and the community. All sectors and key stakeholders are to be involved. As the CCCs do not have statutory "teeth", implementation of strategies relies on negotiated and voluntary action by responsible agencies and individuals.
- Processes used by the committees in coordinating and integrating management of the catchment are *participative and consultative*.
- ICM is about taking a *strategic and planned* approach to tackling important issues (Rowland and Begbie 1997).

Central to the implementation of ICM in Queensland is the establishment of Catchment Coordinating Committees (CCC). The Queensland Integrated Catchment management Strategy (QDPI 1991) identifies that:

> Catchment Coordinating Committees are established to address complex catchment management issues that involve many community groups and government agencies. Catchment Coordinating Committees comprise representatives of the major sectors of the community and government that are involved in, or influenced by the management of land and water resources in the catchment. Their major roles are to provide a forum for community input and discussion, to prioritise the issues and to develop and promote the adoption of catchment management strategies.

At the catchment level land use and resource management is influenced, managed and controlled by a complex domain of government and industry-based natural resource management programs. Of these, the most important are related to state and federal government land administration, river management, nature conservation (including World Heritage Areas and National Parks), and local government infrastructure and town planning (McDonald and Bellamy 1997; Vella 1999) and industry arrangements (such as the sugar land allocation process (Shrubsole and Johnson 1999). The ICM policy initiative is only one of a number of processes and policy initiatives all designed to influence the way natural resources are used and managed.

To-date implementation of the ICM Strategy in Queensland has occurred in 36 catchments covering nearly 80% of the area of the state. The impact of the impact of land and water use on freshwater and marine ecosystems, water quality, soil erosion and sedimentation of watercourses, salinity induced through clearing of vegetation, loss of habitat on land in rivers and streams, the spread of weeds by water and competition for land and water resources are

the important issues requiring a new approach under ICM. A plethora of groups and organisations in government, industry and the community are stakeholders, making an integrated approach through coordinated action even more challenging. McDonald *et al.* (1999) provides an anthology of ICM in Queensland that traces its development from the launch of the ICM Strategy in 1991.

The Herbert River Catchment was one of the earliest priority catchments to be endorsed by the Queensland State Government in 1993.

1.3 The Herbert River Catchment

1.3.1 Resource Use Context

The Herbert River Catchment drains an area of approximately 10,000 km^2 with its major river outlet flowing into the extensive mangrove areas of the Hinchinbrook channel. It is the largest of the river systems located in Australia's sub-humid to humid tropical north east (Figure 1). The catchment has a dominantly summer rainfall with approximately 75% on average falling between December and March. The lower catchment encompasses the shire of Hinchinbrook and the upper catchment area the shire of Herberton.

At the commencement of European settlement in the late 1800s, the Herbert catchment was heavily timbered with extensive freshwater wetlands in the coastal lowlands. The catchment has since undergone significant modifications. Although large areas of the catchment still remain under natural vegetation, about 40% of the coastal lowlands in the lower catchment have been cleared for crop production or improved pastures. Agricultural and pastoral activities are the largest users of land (in area) in the catchment. The sugar industry located in the lower catchment is dominant both socially and economically. Other important industries are forestry and small crops such as pineapples, melons and pumpkins but given its proximity to the wet tropical coast including the Great Barrier Reef Marine Park fishing and recreational activities are also important contributors. The middle and upper catchment have significant areas of rainforest in protected areas and State Forest Reserves. The upper catchment is, however, dominated by natural pastures for beef cattle production. Small areas of the catchment are utilised for mining and industrial activities, or alienated for urban development.

The population in 1996 was approximately 18000 people (1996 National Census), of which 75% live in the lower catchment. The contrast in the physical and socio-economic contexts of the upper and lower parts of the catchment is very strong, with little interaction between authorities or community members largely due to logistical and accessibility constraints imposed by the rugged topography of the middle catchment. Since the early 1980s, the catchment has experienced strong economic growth, underpinned predominantly by its agricultural and tourist sectors. The performance of these sectors in the future is dependent to a large extent on the ecologically sustainable development of the natural resource base.

Sugarcane production which is confined to the lower Herbert coastal plain is expanding its area under production at about 7% per annum. Currently approximately 75,000 ha of land is cultivated to supply the two mills in the region (Victoria and Macknade). Only about 5,500 ha of this area is licensed to be irrigated from surface supplies. The rapid expansion of sugarcane in recent years has largely occurred on the more marginal lands for production, that is on poorly drained coastal wetlands, and previous grazing lands.

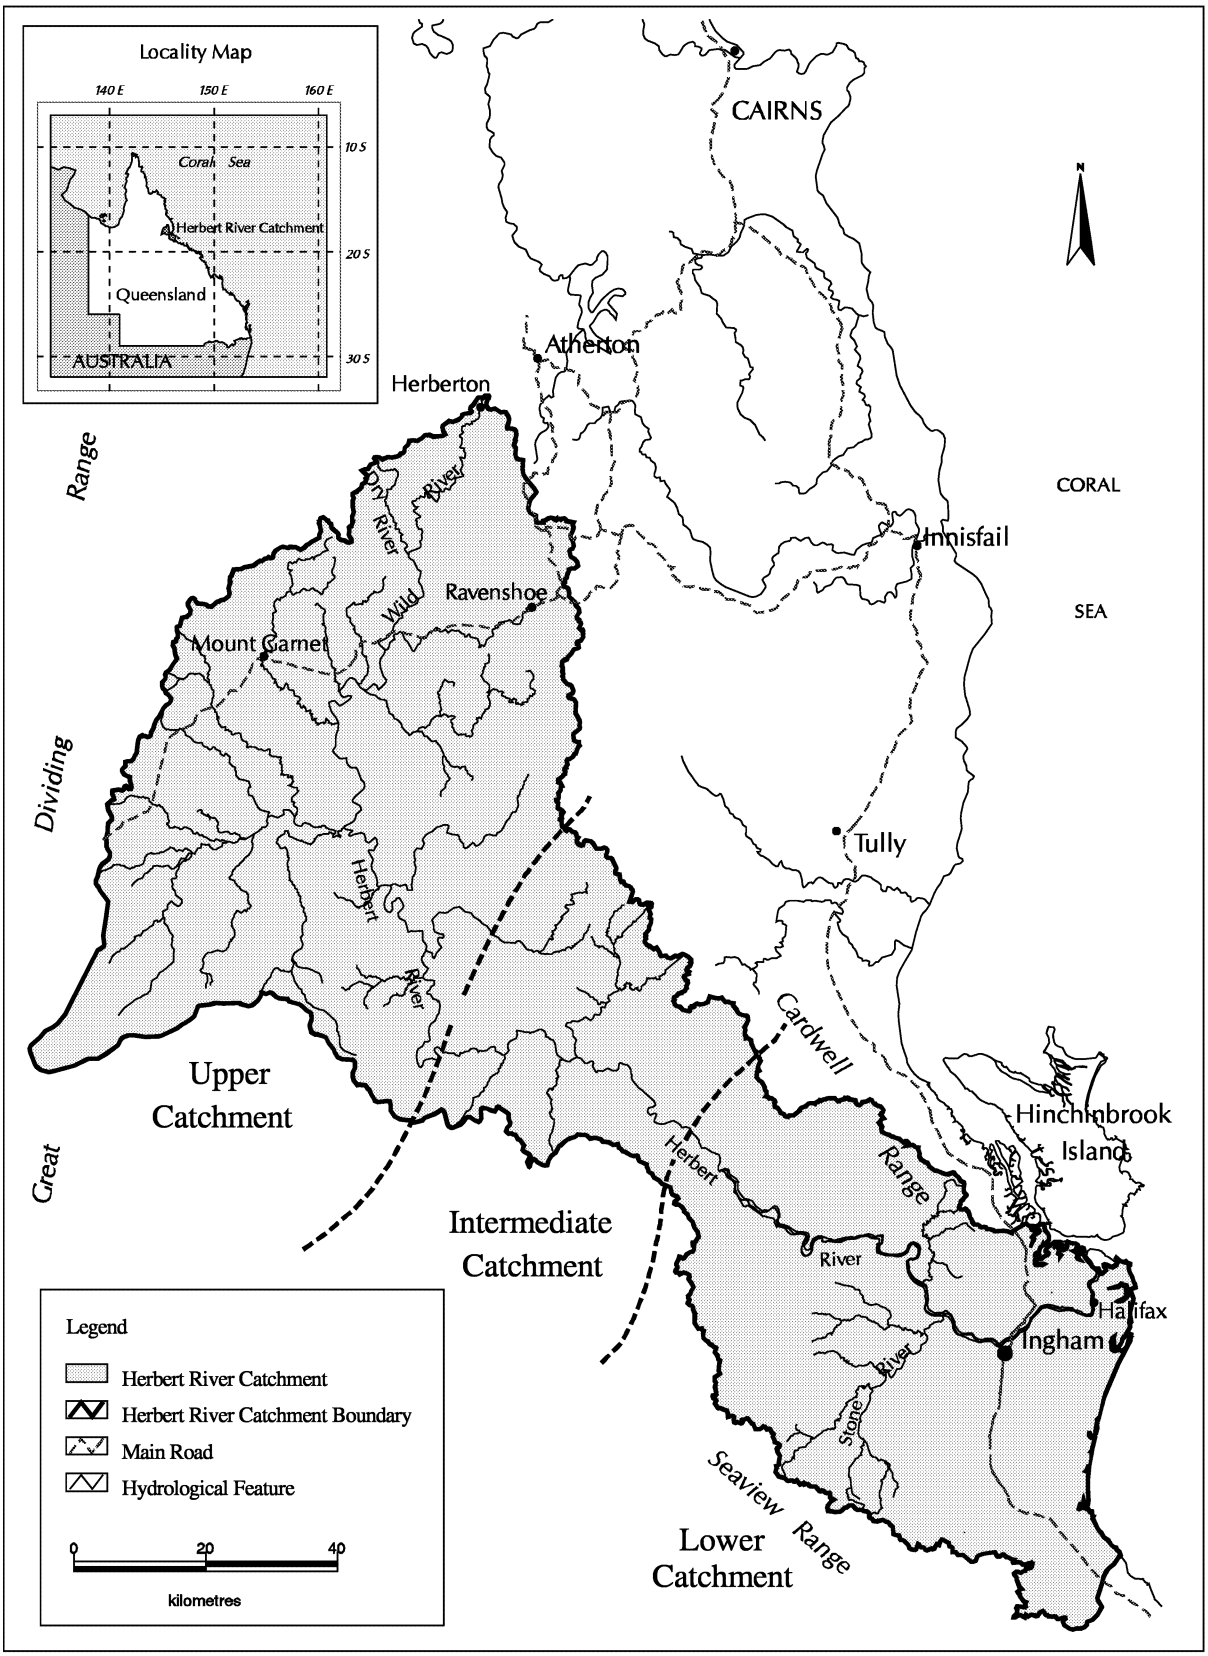

Figure 1. Herbert River Catchment.

Considerable areas of riparian vegetation have been removed from the stream banks (Johnson *et al.* 1998b). The wetlands, swamps, billabongs and waterholes of coastal areas play an important role in floodplain ecology (eg. providing wildlife habitats) and as an integral part of the surface and ground water hydrological regimes of floodplains (eg. providing important hyrological functions). Clearing for sugarcane has significantly reduced the area of this habitat type in the Herbert River floodplain. Johnson *et al.* (1997) have shown a 60% decrease in the area of *Melaleuca* dominated vegetation patterns and a 50% decrease in riparian rainforest patterns since European settlement. Significantly, current natural resource use in the catchment is having an impact on terrestrial and riverine systems and on the adjacent marine environment. Significant issues are diffuse source pollution of waterways, heavy metal contamination, and soil erosion and sedimentation (Johnson 1995).

As previously noted, the economy of the lower catchment is heavily dependent on the sugar industry and the economy of the upper catchment is dependent on the cattle industry. The economic impact of these industries on the regional economy of North Queensland shows that, together, these industries make a significant contribution (both direct and flow-on effects) to gross output and employment in the region. Specifically, in 1995 the contribution to regional output and employment of sugar production in the Herbert River District and the Cattle industry in the upper catchment have been estimated as (Robinson *et al.* 1999):

- *Output*: the sugar industry of the lower Herbert River catchment contributed to over $354m of output in the regional economy, including $206m of output from sugar production and a further $148m in flow-on impacts from other industries in the region. The cattle industry in the upper Herbert River catchment contributed $16m in output to the regional economy, including $13m in output from Cattle production and a further $3m in flow-on impacts.
- *Regional employment*: the sugar industry of the lower Herbert River catchment provided employment for over 3,300 people in the Northern statistical division in 1995. Over 1,300 of these people are estimated to be employed directly in the production of sugar with a further 1,936 people employed in industries supporting the sugar industry. The cattle industry in the upper Herbert River catchment is estimated to provide employment for 170 people, which includes 120 people employed directly in cattle production and a further 49 in support industries.

This information suggests that the economic sustainability of these industries, particularly the sugar industry, is important to the regional economy. However, the financial viability of cane farmers in the future is not optimistic. Although the real prices of agriculture have increased steadily over the past 25 years, the rate of increase has not been as rapid as the increase in costs of inputs to production. Deterioration in cane growers terms of trade coupled with financial inability to implement sustainable management practices represents a significant threat to sustainable development of the Herbert River catchment.

1.3.2 Previous Land and Water Management Studies

ICM is the most recent attempt to address the resource management challenges of the Herbert River catchment. Concern over flooding has been a community issue in the lower catchment since the 1880s. However flood mitigation works and the development of uncoordinated drainage systems have been the cause of considerable community conflict. Since the 1970s, there have been five major studies commissioned by the Herbert River Improvement Trust (HRIT) and the Hinchinbrook Shire Council in collaboration with state government agencies that have examined water management related issues with respect to flooding management, rural drainage planning, and stream management planning (Gutteridge Haskins and Davey 1976, 1977; Gutteridge Haskins and Davey 1977, 1980;

Cameron McNamara 1980; Cameron McNamara 1984; Ian Drummond and Associates 1993).

A major flood caused a very significant reduction in sugar cane yield in 1991 and fuelled continuing concerns for flooding and drainage. Mining dams, some of which were abandoned in the late 1890s, were also perceived to pose a hazard to downstream residents. These and other resource use issues led to community conflict that impeded economic and social development for the Herbert River catchment community and prompted the call for an ICM process for the catchment in 1992.

2. CONCEPTUAL APPROACH TO THE RESEARCH

2.1 Conceptual Framework for NRM Research

Program evaluation and policy analysis are recognised as critical elements of successful policy development and implementation. However, although approaches to NRM based on the integration of community involvement, technical knowledge, organisational structure and policy objectives are endorsed in both Australia and overseas, there are no generally accepted models of evaluation of such initiatives. In particular, evaluation of NRM policy processes has generally been:

- fragmented in reconciling perspectives from different fields of knowledge;
- largely insensitive to the socio-economic, policy/institutional, environmental and technological contexts;
- hampered by a lack of assessable goals and outcome measures; and
- broad one-off overviews conducted as a cross-sectional snapshot rather than a systematic longitudinal study.

Conventional cost benefit analysis, cost-effectiveness and other policy analysis methods do not apply well in this context (ANAO 1997). In a review of the literature on policy evaluation in natural resources, Wallace *et al.* (1995) identified three common problems facing implementing agencies of natural resource management policies:

- how to respond to a general call for increased public participation in policy making;
- how to evaluate programs in light of poorly defined and understood objectives; and
- how to monitor programs in light of new scientific understanding and changes in management philosophy and practice.

In practice there is a general lack of use and development of substantive policy evaluation theory. Wallace *et al.* also claim that using the traditional empirical model of evaluation, in which the referents for study are the formal programs and goals and objectives articulated in legislative acts or policy statements, is not practical for most natural resource policies. Natural resources policy statements are often vague and unclear about their objectives and their intended policy effects and, hence, difficult to achieve or even define. Palfrey *et al.* (1992) propose an evaluation approach that ultimately refers effectiveness back to the 'guiding principles' in which the policy is embedded. Valid indicators of mental constructs such as justice, equity, equality and choice are however difficult to establish. Palfrey *et al.* point to the relevance and importance of 'processes' as indicators of both efficiency and effectiveness of policy implementation. 'Process' in this context refers not only to administrative, organisational and legislative mechanisms, but also the total network of operations involved in implementing and sustaining policy in action, including social interactions and participant perceptions of issues and how the program is progressing.

To this end, we argue that the challenge to create policy processes, institutional arrangements and NRM practices that can contribute towards achieving sustainable and equitable resource use outcomes requires rigorous evaluation as part of the change process (Bellamy *et al.* 1999). Evaluation is fundamental to**:**

- identifying change;
- supporting an adaptive approach that is flexible enough to meet the challenge of this change; and
- enabling learning at individual, community, institutional and policy levels.

Coping with and managing accelerated change requires a systemic approach characterised by adaptation and learning that is incumbent upon personal responsibility and opportunity at the local level. NRM initiatives need to be evaluated as such a system that:

- links objective to consequence;
- considers the fundamental assumptions and instrumental hypotheses that underpin core policy, program or research objectives;
- is grounded in natural resource, policy/institutional, economic, socio-cultural and technological contexts;
- establishes practical, valid and equitable evaluation criteria by which change can be monitored and assessed;
- involves methodological pluralism (including both quantitative and qualitative methods) to ensure rigour and comprehensiveness in assessment; and
- integrates different disciplinary perspectives (i.e. social, economic, environmental, policy and technological perspectives).

Significantly, at the commencement of the CTC7 R&D project, no clear evaluative framework had emerged to guide continuous development in the way NRM policy initiatives contribute to on-going improvements in resource use sustainability and social well-being of the communities concerned. In effect, an over-arching systemic framework to guide the evaluation of NRM policy initiatives is lacking.

2.2 An Integrated Systems Approach

In response to these issues, in the first year of the project the CTC7 research team members developed a conceptual framework for evaluating integrated resource management programs that identifies a range of environmental, policy/institutional, economic, social and technological factors). This framework adapts the Mazmanian-Sabatier framework (Mazmanian and Sabatier 1981; Sabatier 1986) that identified a variety of legal, political and 'tractability' factors that impact on the different stages of policy implementation. The framework also includes socially significant evaluation indices such as inclusiveness, adequacy, equitableness, effectiveness, efficiency, and democratic involvement (eg. Crane 1988), and recognition of the principles of the PRIME procedural model (Syme *et al.* 1994). This latter model recognises that evaluation needs to cope with multiple parallel tasks occurring at all times. Some of these tasks will be dealing with planning; some with research monitoring and evaluation. The PRIME model also recognises that there should be appropriate areas of influence in the evaluation process by the community as well as agencies.

The framework is presented in Table 1 and it identifies the four fundamental elements of the framework developed for evaluating ICM in the Herbert River catchment (Bellamy *et al.* 1999a) as:

(i) Characterisation of the natural resource issue
(ii) Implementation context for the ICM policy initiative
(iii) Policy frameworks and institutional arrangements for ICM
(iv) Community processes for ICM.

Based on an assessment of the underlying assumptions and instrumental hypotheses underpinning the objectives of the ICM policy initiative in Queensland and with consideration of the variability in the multi-dimensional contexts of most catchment situations, the team members developed a set of variables for each of these four elements that can potentially influence the ICM process and its outcomes. The steps in the process undertaken in this exercise to develop criteria and identify investigative methods for evaluating ICM in the Herbert River Catchment is illustrated in Figure 2 and described in more detail in Bellamy *et al.* 1999b; 1999c).

Table 1. Variables influencing natural resource management initiatives (after Bellamy *et al.* 1999a).

1. Natural resource issue characterisation in the catchment:
   - Historical context and evolution of resource use and management
   - Stakeholder perspectives on natural resource use and management
   - Status of the technical knowledge base to guide substantive action
   - Extent of problem recognition and acceptance of change required by different stakeholders

2. Implementational context for the ICM initiative:
   - Evolution of on-ground policy or program implementation
   - Socio-economic conditions and technology
   - Media coverage and attention
   - Attitudes and resources of local constituency groups
   - Support from politicians and industry leaders

3. Policy frameworks and institutional arrangements for ICM:
   - Clarity and consistency of objectives of NRM initiative
   - Financial resources
   - Coordination among implementing agencies
   - Policies, plans and decision rules of implementing agencies
   - Commitment and skills of implementing staff
   - Opportunities for formal access by wider community

4. Community processes for ICM:
   - Expectations/knowledge of process by stakeholders, including the degree to which they are shared or separate
   - Coordination of resources
   - Degree of motivation, commitment, cooperation and support
   - Efficiency and effectiveness of process
   - Equity and procedural justice/trust in process
   - Agreed influence
   - Agreed responsibilities and roles
   - Integration (that is degree of incorporation of processes in structure and context)

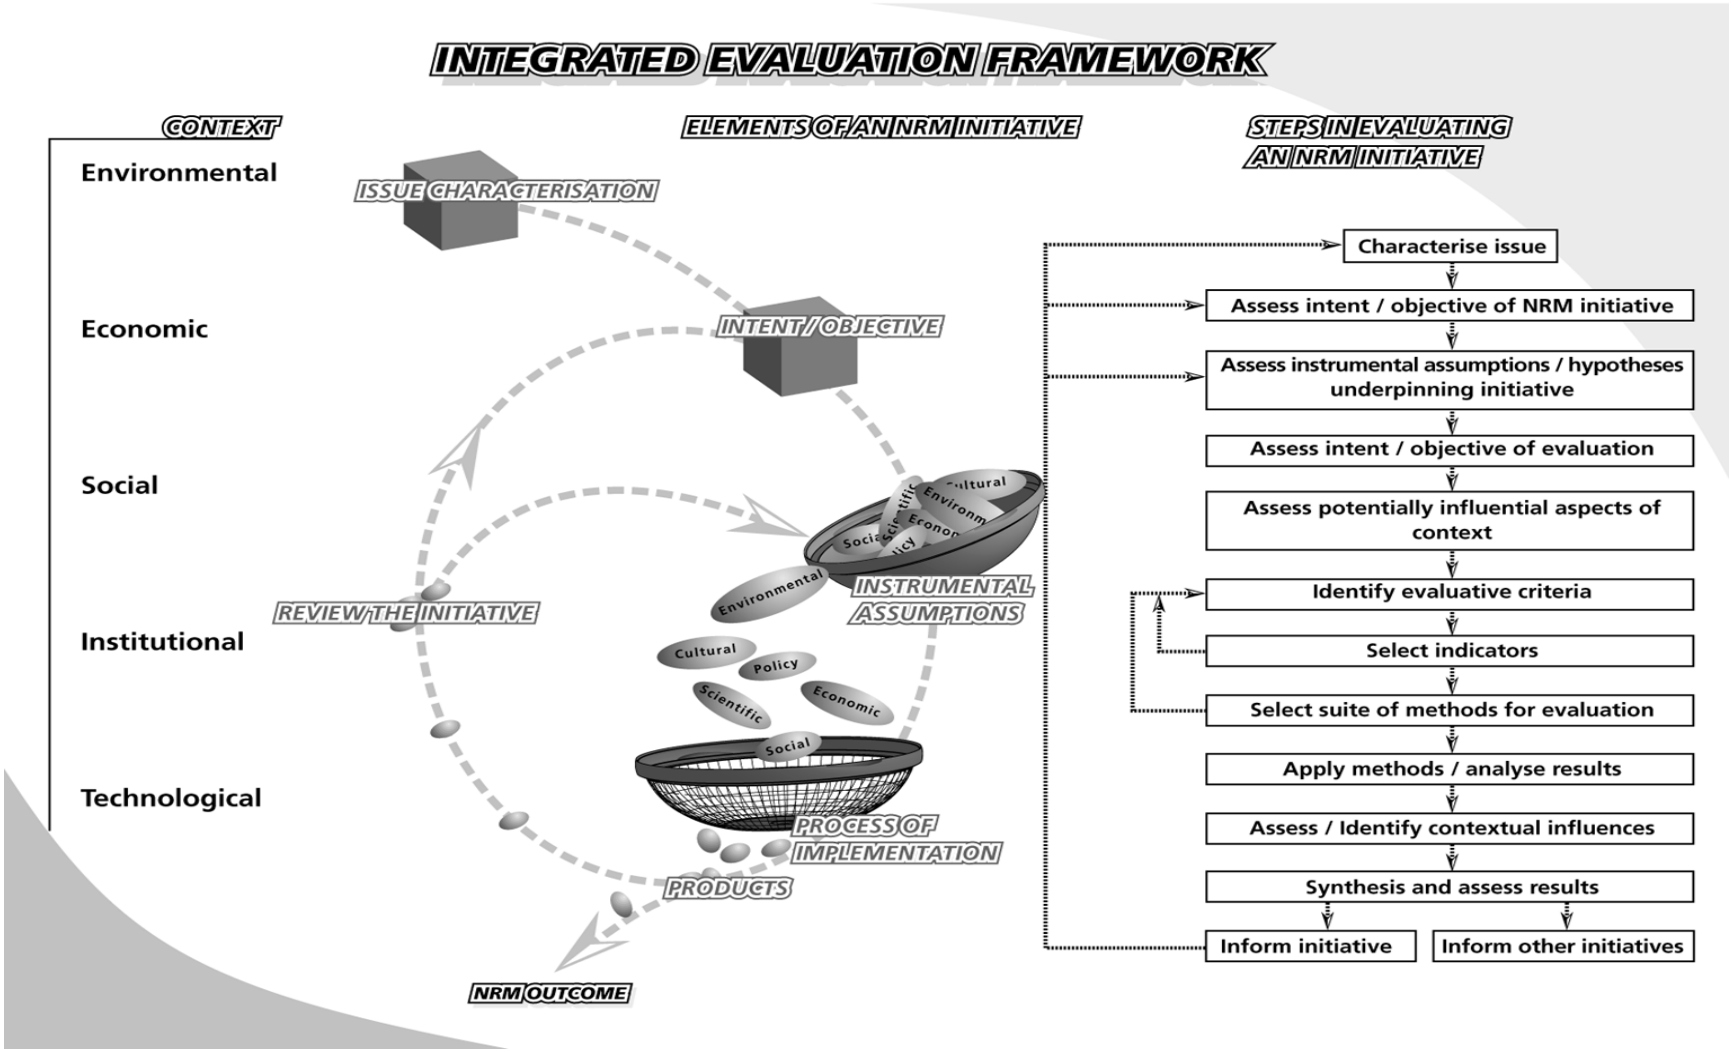

Figure 2. Integrated Evaluation Framework for NRM Policy Initiatives (see Bellamy et al. 1999b; 1999c).

3. METHODS FOR MONITORING & EVALUATING AN ICM POLICY INITIATIVE

3.1 Overview of Methodology

The CTC7 Project's approach to R&D on the integration of natural resource management and policy in the Herbert River catchment through a community-based ICM initiative had two basic characteristics:

(a) *interdisciplinary research* to integrate disciplines and balance economic, social, institutional and environmental considerations; and
(b) *methodological pluralism* involving matching quantitative and qualitative forms of analysis to ensure research rigour.

An interdisciplinary research approach is defined as:

> …. the use of an integrating theory or framework to link two or more disciplines, such that experts in each field work together to address a problem, or such that a single researcher draws on the different disciplines to address a problem. (Mobbs and Dovers 1999, p.3)

The conceptual framework presented in Figure 1 was developed by the research team members in the first year of the project to provide the theoretical underpinning and integrating framework for the research. It provided the basis for:

- the development of *evaluation criteria* for monitoring change and assessing progress and influence;
- structuring the implementation of disciplinary-based *research activities*;
- guiding the selection of investigative methods; and
- the *synthesis of findings* to provide an integrated evaluation.

3.2 A framework of Evaluation Criteria

The framework of evaluation criteria used in this study is identified in Table 2 and the process for their development and the related investigative methods is illustrated in Figure 2 and described in more detail in Bellamy *et al.* 1999b and c). Methodological pluralism through the use of a diversity of qualitative and quantitative techniques contributes to rigour in evaluation (Patton 198?). This diversity in methods allowed for 'triangulation' of theory and methods that make effective use of their complementarities in the analysis of findings.

3.3 Research Activity Summaries

Based on the framework of evaluative criteria, eleven separate and disciplinary-based research activities were established as the core investigative units for this interdisciplinary research project. These research activities are listed in Table 3. A full summary of each research activity that identifies its objectives, relationship to the evaluation framework, description of methods, key findings, recommendations and further reading is provided in Appendix 1 to this report.

Table 2. A framework of evaluation criteria and methods for ICM in the Herbert River catchment.

Evaluation Criteria/Measures	Methods (RA = Research Activity – see Appendix 1)
Characterisation of NRM Issues in the Catchment ➢ Extent and severity of resource use problems and progress of management responses ➢ Diversity of stakeholder knowledge, attitudes and values on natural resource use and management ➢ Scientific understanding, feasibility and acceptability of technical solutions to natural resource problems ➢ Extent of behavioural change required and by whom	• Spatial and temporal analysis of change in land cover and land use since European settlement using airphoto interpretation and GIS techniques and ABS and local mill data **(RA1)** • Integration of existing natural resource information (map and textual) from local state and federal agencies in a Herbert River Catchment Atlas **(RA 1)** • Spatial and temporal analysis of nutrient and pesticide usage in the lower Herbert catchment through analysis of sugar industry records, chemical company sales records and producer interviews **(RA 1)** • Bench-marking attitudes, values and behaviour through two surveys of Herbert community residents in 1995 and 1998 **(RA 6)** • Assessment of the local understanding on catchment processes and its potential contribution to progress in ICM through trial stakeholder interviews and workshops **(RA 2)** • Mapping of change in the system of organisational structures and linkages on NRM in the Herbert catchment from 1993 to 1998 through interviews of key informants and review of documentation **(RA 4)** • Spatial and temporal analysis of the sugarcane assignment process from 1993-1996 in the Herbert through review of official records, semi-structured interviews of key informants, GIS techniques and geo-statistical analysis **(RA 5)**
Implementation Context for the ICM Policy Initiative in the Herbert River Catchment ➢ Local rationale and motivation for the commencement and on-going development of the Herbert River ICM initiative ➢ Socio-economic conditions and use of technology ➢ Community attitudes and support for ICM ➢ Attitudes and resources of local constituency groups ➢ Support from politicians ➢ Media coverage and attention to NRM issues and ICM	• On-going monitoring and analysis of documentation on the ICM process including consultancy reports, HRCCC meeting minutes, stakeholder organisation annual reports **(RA 4)** • Analysis of ABS Census data for 1991 and 1996 for the catchment **(RA 4, RA 9)** • Bench-marking attitudes, values and behaviour through two mail-out surveys of Herbert community residents in 1995 and 1998 **(RA6)** • Bench-marking attitudes, values and behaviour through semi-structured interviews of HRCCC members in 1995, 1997 and 1998 **(RA 4)** • Catchment stakeholder workshop to benchmark attitudes and values on natural resource issues and ICM in 1995 **(RA 4)** • Interactive annual forums with HRCCC members as a group **(RA 4)** • Content analysis of a local tabloid newspaper to assess change in presentation of NRM issues and ICM since initial inception of ICM in 1990 **(RA 8)** • Input-output economic analysis of the Herbert catchment regional economy in 1996 **(RA 9)**

Evaluation Criteria/Measures	Methods (RA = Research Activity – see Appendix 1)
Adequacy of Policy Frameworks and Institutional Arrangements for ICM at state and local catchment levels ➢ Clarity and consistency of roles and objectives of ICM and other responsible agencies/groups for NRM ➢ Adequacy of financial resources for ICM ➢ Coordination among ICM and other responsible agencies/groups for NRM ➢ Adequacy and effectiveness of policies, plans and decision rules of ICM and other responsible agencies/groups for NRM ➢ Commitment and skill of staff in ICM and other responsible agencies/groups for NRM ➢ Opportunities for formal access by wider community	• On-going monitoring of the evolving legislative and administrative arrangements for ICM and NRM at the local, state and Commonwealth level though annual open-ended interviews with government officials/key informants/participants and compilation and review of documentary sources (**RA 3)** • On-going monitoring and analysis of documentation on the ICM process and arrangements in the Herbert including consultancy reports, HRCCC meeting minutes, agency annual reports. (**RA 4)** • Catchment stakeholder workshop to benchmark attitudes and values on institutional arrangements and ICM in 1995 **(RA 4)** • Bench-marking attitudes, values and behaviour through mail-out surveys of Catchment Coordinators and Chairs across Queensland in 1995 and 1997 **(RA 3)** • Interactive annual forums with HRCCC members as a group **(RA 4)** • Bench-marking attitudes, values and behaviour through semi-structured interviews of HRCCC members in 1995, 1997 and 1998 **(RA 4)** • Review of ICM and Local Government Planning schemes based on review of legislation, consultancy reports and documentation on institutional and administrative arrangements as well as semi-structured interviews with key informants in the Herbert River catchment (**RA 4)** • Mapping of change in the system of organisational structures and linkages on NRM in the Herbert catchment from 1993 to 1998 through semi-structured interviews of key informants and review of documentation (**RA 4)** • Valuation of the establishment and operational costs of the HRCCC based on a review of official records and semi-structured interviews of key informants **(RA 9)**

Evaluation Criteria/Measures	Methods (RA = Research Activity – see Appendix 1)
Adequacy and Equity of the Herbert River ICM Processes ➢ Knowledge and expectations of the process by stakeholders ➢ Degree of coordination of resources to address catchment issues ➢ Degree of motivation, commitment , cooperation and support for the process ➢ Efficiency and effectiveness of process ➢ Equity and procedural justice and perceptions of trust in process ➢ Influence of ICM on planning activities in the catchment ➢ Agreed responsibilities and roles ➢ Integration (of processes in structure and context)	• Catchment stakeholder workshop to benchmark perspectives on community-based policy initiatives and ICM in 1995 **(RA 4)** • Bench-marking attitudes, values and behaviour through two mail-out surveys of Herbert community residents in 1995 and 1998 **(RA6)** • Bench-marking attitudes, values and behaviour through semi-structured interviews of HRCCC members in 1995, 1997 and 1998 **(RA 4)** • Bench-marking attitudes and values through mail-out surveys of Catchment Coordinators and Chairs across Queensland in 1995 and 1997 **(RA 3)** • On-going monitoring of the evolving legislative and administrative arrangements for ICM and NRM at the local, state and Commonwealth level though annual open-ended interviews with government officials/key informants/participants and compiling documentary sources (**RA 3)** • Review of ICM and Local Government Planning schemes based on review of legislation, consultancy reports and documentation on institutional and administrative arrangements as well as semi-structured interviews with key informants in the Herbert River catchment (**RA 4)** • Content analysis of a local tabloid newspaper to assess change in presentation of NRM issues and ICM from 1990 to 1998 **(RA 8)** • Spatial and temporal analysis of the sugarcane assignment process from 1993-1996 in the Herbert through review of official records, semi-structured interviews of key informants, GIS techniques and geo-statistical analysis **(RA 5)** • Telephone interview questionnaire of 60 stakeholders to assess the degree of communication among stakeholders and effectiveness of organisational communication networks of ICM in the Herbert **(RA 7)** • Cost-benefit Analysis of the activities of the Herbert River Catchment Coordinating Committee **(RA 9)** • Mapping of the change in the system of organisational structures and linkages on NRM in the Herbert catchment from 1993 to 1998 through semi-structured interviews of key informants and review of documentation (**RA 4)**

4. ICM IN THE HERBERT RIVER CATCHMENT

4.1 Inception of ICM in the Herbert River Catchment

ICM in the Herbert River catchment is a voluntary process initiated by key actors in the local community from the sugar industry and local government with the convening of Catchment Management Steering Committee in July 1992. The impetus for principal stakeholders in the catchment to lobby the then Minister for Primary Industries for support and endorsement of an ICM process in the Herbert River catchment was threefold:

a. Broad community-based concern over the ineffectiveness of fragmented government decision making on river management issues (in particular flooding and drainage), and the failure of past studies to move beyond the development of plans and lead to action on the ground to resolve these issues;
b. The perceived need within the catchment for more active and meaningful community involvement in decision making on these issues, that is beyond a basic consultative approach; and
c. The personal and political agendas of influential actors in the lower Herbert catchment, who were in part motivated by a desire for 'a piece of the action' (i.e. ICM in Queensland), including potential funding opportunities for 'pet projects' of interest to specific stakeholders (such as on-ground drainage works in sugarcane producing areas).

In February 1993 the Herbert River Catchment ICM Steering Committee sent letters of invitation to 14 organisations to nominate representatives for the HRCCC. The key issues that were identified in this invitation as needing to be addressed in the Herbert catchment were:

1. *Land Management* (erosion control, drainage coordination, land use practices, interface of drainage with coastal outlets);
2. *River management* (stream bank erosion/slippage, habitat protection, coordination of levee bank structures, bed rejuvenation, flood management planning);
3. *Community awareness* (education regarding catchment management, environmentally friendly sustainable agriculture and its linkages with the well being of the total community);
4. *Coordination of agencies and resources* (RIT, Drainage Boards, CSIRO CZP, SRDC, DEH, DPI); and
5. *Land use planning* (formulating advice regarding Crown land allocation and use, liaison with industry, local authorities and Govt. agencies regarding land sue and infrastructure planning).

The Herbert River Catchment Coordinating Committee (HRCCC) was officially launched by the Minister in March 1993. A Catchment Coordinator was appointed in April 1994 by the HRCCC in collaboration with the Queensland Government lead agency for ICM (currently DNR) to formally facilitate the process.

Community views on natural resource issues in the Herbert catchment

In the 1970s and 1980s, there were a number of major studies commissioned by local government and statutory river management authorities in the Herbert catchment in collaboration with the State government. These were largely engineering studies that examined water management issues in the lower catchment relating to flooding, rural drainage planning, and stream management. Table 4 compares the issues identified in these studies with two subsequent workshops; the first being a meeting of community stakeholders held in 1992 that was the catalyst for the establishment of ICM in the Herbert, and the second a workshop held in late 1995 as part of this case study research to evaluate the Herbert ICM process.

Table 4. Comparison of Issue Characterisation in the Herbert River catchment prior to 1995.

	Herbert Technical Studies 1976, 1980, 1984	Community Workshop August 1992	ICM Evaluation Project Stakeholder Workshop June 1995
Key Issues Identified	Lower Herbert Catchment focus: • flood mitigation • stream and river bank erosion • uncoordinated drainage on river floodplain	• flooding • sedimentation • bank erosion • major river course changes • rural drainage • tourism and recreation • biological issues (including wildlife habitats) • water quality and quantity	• lack of long term planning of water management and land development • lack of coordinated drainage strategies • conflict over flood protection works • riparian zone management • habitat management and protection • increased erosion and sedimentation in river • pest management planning • long term sustainability of agriculture • land development/conservation conflicts
Perceived Key Impacts	• economic consequences (e.g. major crop losses) • infrastructure and property damage	• loss of valued land • loss of production • infrastructure/asset damage • access difficulties • loss of recreational and tourism opportunities	• loss of crop production and profitability • land degradation • river aggradation • reduced stream capacity • stream bank destabilisation • habitat destruction/modification • water quality and quantity problems • localised flooding • conservation impacts • social conflicts • alienation of land for other uses
Key Mechanisms Identified for Addressing Issues	• a range of largely engineering-based studies to investigate stream processes/river morphology for flood management and rural drainage coordination • flood mitigation works (e.g. levees, floodgates, overflow channels, rock works) • removal of river vegetation	• a range of infrastructure and related works programs (eg. removal of river sediment, bank stabilisation; rationalisation of levee system; increased capacity of flood gates; stream bank revegetation) • review/reform of institutional structures and arrangements for river management • ICM implementation to support a coordinated approach to decision-making and to facilitate community participation • community education and PR plan	• create a common understanding of ICM • foster and maintain a long term commitment to an ICM process which is seen as a "way of doing business" for government and the community • local government as action agency - use planning and development controls • state government to foster cooperation • use controls on leasehold land • industry codes of practice

A comparison of these suggests that (a) the 'solutions' established by the earlier engineering studies and methods used to arrive at those solutions were not in line with community expectations, and (b) community perspectives on issues across catchment interests have evolved over time to encompass a broader range of natural resource management issues including riparian zone management, habitat management and protection, impacts of agricultural activities on tourism and recreation, and calls for greater community involvement in decision-making. Most significantly at the 1995 workshop (Bellamy *et al.*1995) several stakeholder groups identified the lack of long term planning of water management and rural land development activities as a major issue needing to be addressed for the first time.

Perceived impacts of natural resource management issues have broadened from an initial focus on productivity and infrastructure impacts to encompass loss of alternative use opportunities and environmental and ecological factors. Perceptions of the key mechanisms for resolution have also shifted from an initial focus on "engineering based" approaches to include policy incentives and legislative controls or individual action. The key mechanisms for a more integrated planning approach to resource management and land development were seen as an effective ICM process with the support of state government to foster cooperation, the development of industry codes of practice, and the use local government planning and development controls.

This was the local background to the commencement of the ICM process in the Herbert River catchment.

4.2 External Context, Funding and Organisational Arrangements

As only one small catchment in Queensland, the progress of community based ICM in the Herbert is greatly affected by the State's ICM program in particular, but also the complex set of resource management and resource allocation programs that impinge on development, decisions and finances in the area. Successes and failures, factors that constrain and assist the ICM program can only be judged against this baseline.

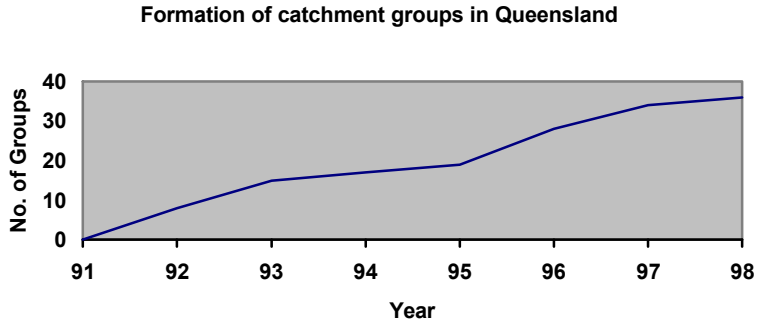
In Australia, land use planning and natural resources management are State Government functions, undertaken by a range of conventional and essentially single-purpose agencies. All of the Australian States have adopted programs of integrated catchment management under a variety of names and using a variety of policy and legislative frameworks. In some states ICM is called Total Catchment Management (TCM) or Integrated Catchment Management. At present the application of ICM varies widely throughout Australia, with some states such as NSW having established legislation, whilst others such as WA and Qld have no generic legislative powers. In effect there have been six experiments running in parallel but as yet no dominant model has emerged. Clearly, events in the Herbert may have been different if it had been located, for example, in Victoria.

The initial stage of the ICM program focused on five Pilot Study Areas: Johnstone River, Lockyer Valley, Pioneer River, Mitchell River and the Mary River. Catchment coordinating committees were established for each study area, comprising representatives from key interests groups from government, industry and the community. The committees role is to hold forums on catchment issues for community comments, identify and prioritise issues of concern in the catchment and develop and promote the implementation of catchment management strategies.

Critical to the survival and success of any program is the level of commitment through funding and staffing. ICM at the State level has survived using a mixture of state program and core funds and, most importantly through the National Landcare Program and its

successor, the Natural Heritage Trust. It is difficult to define accurately just what resources have been available for the ICM program and the Catchment Committees. Most significantly, the host Department, DPI then DNR (from 1995), provide in-kind support centrally and in the regions in the form of staff time and operational expenses. No one has estimated this accurately. Because catchment related research, planning and implementation support are closely interconnected with many programs. Disentangling specific ICM related expenditures (eg river improvement, water allocation) is difficult and conceptually dangerous. Most of the funding has been directed towards the appointment of catchment coordinators and to awareness raising and planing activities. Implementation of ICM priority projects and changes to resource allocation process require the cooperation of government agencies with finance and responsibilities in areas such as river improvement, land use planning, conservation and water allocation. The role of ICM committees in Queensland is to influence these activities not to take them over.

The ICM program in Queensland has been experimental, evolutionary and incremental. The early pilot studies informed the expansion and maturing process to the point that over 35 catchments are now formally included in the program as illustrated in the diagram below.



The ICM program has been surprisingly robust – its philosophy and implementation have remained relatively constant since 1991. Notable changes to the policy and institutional context include:

- Catchment Coordinating Committees are formally endorsed by the (now) Landcare and Catchment Management Council. Until 'committees' gain this recognition they are termed 'groups'. This developmental process has depended on improved understanding of community-based processes and the diffusion of ideas and experiences across the State
- The adoption of a strategic approach post-1993 was encouraged by strong incentives – no strategy, no funding. In general there has been acceptance of the need for strategies to guide catchment action and to focus the ICM process
- More recently strategic approaches have been adopted at the regional level in the form of regional NRM strategies.
- The NHT has played a significant role in funding ICM projects and process since 1995.

4.3 The Herbert River Catchment Coordinating Committee

4.3.1 Membership

The membership of the HRCCC is based on a representational structure. The steering committee set up in July 1992 identified key stakeholder organisations in the Herbert with a responsibility or interest in natural resource management in the catchment and in February 1993 invited them to nominate representatives for the HRCCC. Since then the HRCCC has reviewed membership and opportunistically invited additional stakeholder groups to participate in ICM through membership on the HRCCC as they saw fit. The number of

members on the HRCCC therefore has fluctuated since it was formally established in March 1993. The sector groups represented on the ICM Steering Committee in 1992 and on the HRCCC in 1993, 1995, 1997, 1998 are compared in Table 5.

Table 5. HRCCC membership 1992-1998.

a. Facilitation from Water Resources Commission and Catchment Coordinator for Johnstone River ICM (part time)
b. Facilitation from Herbert Catchment Coordinator (full-time)

Current representation on the HRCCC is diverse involving local industry (sugar, cattle, fishing, horticulture), local government and other statutory bodies, conservation and community interests. In 1998, nine of the current members (50%) had been involved with the HRCCC since its inception in March 1993. For example, one of the local government representatives on the HRCCC is also a sugarcane farmer and a beef cattle producer. Most of the members are active community members with multiple sectoral interests or 'hats'. Eleven of the seventeen HRCCC members are either sugarcane farmers or employed within the sugar industry reflecting the economic, social and cultural importance of the sugar industry in the lower Herbert catchment community. Until the beginning of 1999, the HRCCC has no state government departmental representation. However, the process is consultative with government and a Catchment Coordinator informally facilitates this.

The diverse membership reflects the influential groups, power structures, and community interest in the Herbert River catchment. For example, although the ICM initiative originated from community action in the lower catchment, the HRCCC from its inception recognised the need and actively sought the involvement of representatives from the upper catchment. In support of this involvement, the HRCCC negotiated funding for on-ground works to address problems and concerns relating to derelict tin mining dams in the upper catchment which were becoming a potentially divisive issue between the upper and lower catchment communities (i.e. poor domestic water quality and reduced river capacity due to increased sedimentation in the lower catchment caused by abandoned mine waste and tailing dams in the upper catchment).

Catchment Coordinator

The Catchment Coordinator's position is funded through the federal government's National Landcare Program and based in the Department of Natural Resources, the lead government agency for ICM in Queensland. In addition, local stakeholder groups including Local Government and sugar industry bodies have provided in-kind support in terms of office accommodation, administrative support and their HRCCC member's time. State and federal government grants that are awarded through a competitive bidding process also financially support most HRCCC activities.

On appointment in April 1994, the Catchment Coordinator adopted a strongly proactive role within the HRCCC in setting the initial agenda. This served to establish a legitimate role for the Coordinator within the committee and also for him to gain personal credibility with the 'established' community leaders of the HRCCC membership. Over time the Coordinator has moved to play a more facilitatory role within the HRCCC, particularly with the appointment in 1996 of a new Chairman. The new Chair has taken a more influential and proactive approach in setting the agenda, negotiating the functional role of the HRCCC, and in attempting to raise the profile of ICM within the Herbert community.

The Upper Herbert River Catchment Group

A Sub-Committee of the HRCCC was formally formed for the upper catchment in December 1998 to discuss and raise issues of particular relevance to the upper catchment. This sub-committee, the Upper Herbert River Catchment Group, arose because community members in the upper catchment felt that they were not equally represented on the HRCCC. The HRCCC membership has been overwhelmingly dominated by members from the lower catchment and has inevitably tended to have a focus on issues affecting the lower floodplain. In addition, there were logistical issues relating to the long distance between the upper and lower catchments (ie. a 4-5 hour drive). The new sub-Committee has 16 members selected to represent a broad range of catchment stakeholders from the community, industry and government as identified in Table 6.

In early 1999, the new Upper Herbert River Catchment Group identified and prioritised the key issues for the upper catchment as detailed in Table 7. Although there are some commonalities with those issues identified by the formal HRCCC, the focus of the issues identified by the upper catchment sub-committee is quite different in that they are largely concerned with specific land and water management issues rather than including broader planning and public good issues.

Table 6. Upper Herbert River Catchment Group representation.

Sector	**Stakeholder Group**
Industry Organisations	Mining industry Cattle industry/AG FORCE (2) Dairy industry Timber industry Red Bend Irrigators
Community Organisations	Herberton community Innot Springs community Ravenshoe community and tourism Coolgarra mining area Mt. Garnet Landcare Conservation (2)
Government	Herberton Shire Council Queensland National Parks and Wildlife Service Environmental Protection Agency

Table 7. Key issues in priority order for the Upper catchment.

1.	Weeds in general (ie. noxious weeds, ponded pastures, stream blockers)
2.	Erosion (ie. cost effective measures)
3.	Water conservation (ie. crop water requirements, changed water requirements (eg. for dairy, cane), best practices water harvesting, storage)
4.	Water quality (ie. turbidity, chemical, sediment)
5.	Land clearing (ie. best practice in native forest, management (fire, grazing, timber), potential cropping areas)
6.	Soil fertility (ie. potential for cropping – forage and fruit, salinity, manganese, nitrification)
7.	Wetland/wildlife preservation (ie. birds/maintenance of habitat (natural, artificial), feral animals)
8.	Land subdivision (ie. more and larger approvals, water quality implications, licensing, multiplier effects of dams)
9.	Creek and river restoration (ie. repair and cleaning)

4.3.2 Role of the HRCCC.

Since its formation the HRCCC has provided a forum for discussion and a marshalling of agency and community interests in a way that did not happen before the introduction of the institutional framework provided by ICM. In particular, the HRCCC has provided the functional roles of fostering coordination and cooperation across natural resource management interests in the catchment and of information provider and distributor on catchment resource issues.

The HRCCC's perception of its role has evolved from one of delivering natural resource outcomes and solving natural resource management issues on the ground to a more strategic role (McDonald and Bellamy 1997). The emerging attitude amongst HRCCC members to their role involves establishing a decision-making culture relating to natural resource use and agricultural development based on ICM principles as 'a way of doing business', and providing a strategic direction on resource management for the catchment through influencing catchment decision-making and planning processes. Notably, the HRCCC is facilitating a move within the catchment community from a prime focus of concern on disaster management (i.e. issues of river management including flood mitigation and drainage) to one that embraces the broader concept of natural resource management and community responsibility for the environment.

Specifically in 1998 HRCCC members identified ICM's role in terms of the activities of high to very high importance to ICM in the Herbert as (in order of relative importance):

- Encouraging Local Government to take an active role in environmental management issues
- Encouraging joint projects between community, industry and state and local government
- Providing a continuing source of advice to local government on catchment issues
- Encouraging discussion between community interest groups on environmental issues
- Raising the level of local awareness and knowledge of environmental issues on the catchment
- Encouraging coordination of state government programs
- Encouraging research
- Developing solutions for, and better understanding of, environmental problems in the Herbert catchment.

However the HRCCC considered roles of moderate to high importance were:

- Undertaking specific on-ground projects with other bodies.

A set of objectives were identified for the ICM initiative in the Herbert Catchment by the HRCCC in its draft Catchment Management Strategy for the first time (HRCCC 1996, p.i):

- Co-ordinate government agencies and the community to pursue common goals
- Seek community involvement in catchment management
- Reflect the requirements of the wider community within the Catchment
- Identify and rectify natural resource degradation
- Promote ways to prevent and reduce natural resource degradation
- Promote the wise use of all natural resources within the Catchment
- Identify key indicators of biodiversity and monitor as a measure of catchment health
- Encourage the retention of significant natural habitats within the Catchment.

These objectives are caste in general terms that encompass both ICM's role as a coordinator for natural resource management and planning processes between the catchment community, industry and government agencies as well as its role as a monitor of catchment health.

Beyond influencing perspectives on natural resource management and establishing a strategic direction for the future, the real challenge for the HRCCC and the Herbert community in general is to achieve its vision for the catchment as identified in the Catchment Management Strategy. Importantly, the potential lies for this approach, particularly through its key linkages and involvement of Local Government bodies to significantly influence future decision-making culture on agricultural development and resource use planning in the catchment. Early evidence of this is the incorporation of ICM principles into the new Hinchinbrook Shire Planning Scheme (McDonald and Bellamy 1997; Vella 1999).

4.3.3 HRCCC Priorities in NRM

The most important resource management issues in the catchment identified by HRCCC members since the inception of ICM are compared in Table 8. In general, member's perspectives on natural resource management issues had broadened and become more strategic in scope since 1995.

Table 8. Comparison of Perceived Key Resource Management Issues by the HRCCC 1993-1998.

March 1993	November 1995	November 1997	November 1998
Rural drainage	Rural drainage	Rural drainage	Drainage coordination/ management on floodplains
River improvement	Stream bed and bank erosion	River management	Waterways management and flooding
Rehabilitation of mining dams in upper catchment (water quality)	Urban flooding	Water quality	Water quality
Land management database	Allocation of sugar caneland	Caneland expansion	Land clearing/ sugar industry expansion
	Land clearing	Riparian management	Riparian vegetation management
		Wetland degradation	Wetland degradation/ management
Sugar industry infrastructure		Pest and weed management	Weed management
		Coordinated extension approach	Land use planning, catchment management
		Catchment planning	Grazing land degradation/erosion
			Water quantity/availability (upper)

Rural drainage, flooding, river management and sugar industry expansion and related land clearing have remained key issues for the HRCCC members across all surveys. However since 1997 additional issues identified were water quality (particularly relating to fish kills,

and stream sedimentation), riparian vegetation and wetlands management, pest and weed management, land use planning and a coordinated approach to catchment management. While in 1998, with closer linkages to the upper catchment community seeming to develop, two further issues largely important to the upper catchment were also identified as grazing land degradation/erosion and water availability issues.

4.4 HRCCC Activities and Achievements in NRM

4.4.1 Catchment Management Strategy

In May 1997, the HRCCC released a Herbert River Catchment Management Strategy for public comment (HRCCC 1996). This strategy is intended to provide a strategic framework for the future management of the Herbert River catchment's natural resources. It is issues-based and it identifies a broad range of priority management and planning issues, which are summarised in Table 9. Specifically, the strategy discusses key management and planning issues, identifies what needs to be done, who should take responsibility for undertaking the work and how the issue is to be addressed. An example of a strategy and the stakeholders to be involved is provided in Table 10. The strategy's issue focus is consistent with Laut and Taplin's (1989) view that an emerging trend for catchment management would be to concentrate on *issues* rather than on establishing a holistic strategic management approach in the catchment. Importantly, it clearly identifies the need for a coordinated effort amongst stakeholders in order to address these issues and move the community towards achieving sustainable development.

The strategy reflects the rhetoric of the Queensland ICM policy initiative in that it presents ICM in the Herbert as a partnership approach among local communities, local government, state government agencies, and industry bodies aimed at solving the priority resource use problems in the catchment. However, at this early stage in the implementation of ICM in the Herbert River catchment, members do not perceive the strategy guiding catchment stakeholders to implement substantive action to resolve catchment resource management issues. Rather HRCCC members perceive the strategy more as a vision for the future and a means at this point in time of securing eligibility for funding for projects and a Catchment Coordinator from federal and state government sources. Once State Government endorsement is obtained, members expect that it will provide the basis for gaining commitment of responsible State Government agencies to undertake projects in the Herbert catchment to address these issues. Importantly, the development of the Catchment Management Strategy is perceived by members to have been of value because of a number of qualities and outcomes of the development process that include:

1. *inclusive and transparent* to all members involved; bringing all viewpoints across organisations on issues together and out into the open.
2. *establishing a clear direction* for the HRCCC; helping to focus the HRCCC as an organisation and providing an overall vision for the catchment and a guide for action in the future.
3. *raising awareness* of catchment issues; especially improving Committee member's awareness of issues as well as other stakeholder's viewpoints on those issues.
4. *highlighting areas of common ground*; by identifying areas of agreement across diverse sector groups on some catchment issues, it provided a basis for the Committee to move ahead and develop better natural resource management and planning projects.

Table 9. Issues and key strategies identified in the Herbert River Catchment strategy (HRCCC 1996).

Key Issues	Recommended Strategies
Land Management (LM) • Inappropriate land use allocation and its impact on resources and natural systems • Impacts of land management on productivity • Impacts on other values of land and adjacent land and water resources	LM1 Coordinate land use planning to achieve balanced use of land, water and related natural resources LM2 Encourage best management practices in all rural industries LM3 Implement arrangements to reduce adverse impacts of agricultural drainage on natural systems and existing developments LM4 Reduce adverse impacts of non-agricultural land uses.
Water Management (WM) • Full and over-allocation of existing resources • Increasing demands on finite surface and groundwater supplies • Limited monitoring of water quantity and quality • Threats to quality of surface and groundwater supplies	WM1 Assess available resources and develop appropriate allocation policies in consultation with stakeholders WM2 Promote efficient use of water resources within the Catchment WM3 Promote the coordinated planning and implementation of water management schemes in the catchment WM4 Reduce contaminant inputs to surface and groundwater systems from point and diffuse sources WM5 Establish and promote water monitoring priorities and standards for the catchment.
Stream Management (SM) • Lack of awareness of stream values shown in development actions • Stream bank erosion and stream migration • Sedimentation • Impact of uncoordinated levee banks and flood mitigation schemes • Impacts of degradation of riparian zones • Instream habitat degradation such as weed invasion and loss of water holes	SM1 Continue implementation of a strategic approach to stream management SM2 Facilitate appropriate protection and management of riparian zones throughout the catchment SM3 Ensure development and engineering works associated with streams take account of all stream functions and issues SM4 Identify and protect sensitive areas, to retain the function and health of our stream systems SM5 Develop fisheries and habitat management plan for the stream systems of the catchment, involving stakeholder groups and the broad community SM6 Provide community awareness, support and involvement in stream management
Habitat Management (HM) • Threats to significant terrestrial and aquatic habitats and species • Loss of wetland and instream habitat quality and subsequent impacts on fish stocks • Fragmentation of remaining habitats through loss of connectivity (ie. corridors)	HM1 Promote the values of habitat retention and restoration to the broader community through awareness, technical support and incentives HM2 Maximise the habitat values of existing protected areas HM3 Ensure the retention of significant habitat values outside protected area reserves HM4 Protect and rehabilitate wetland habitats on the Floodplain HM5 Re-establish and manage riparian vegetation on watercourses throughout the catchment and ensure retention of existing riparian vegetation.

The first draft of the Herbert River Catchment Management Strategy took three years for the HRCCC to prepare, and was an important process in revealing the diversity and often conflicting perspectives across stakeholder groups represented on the committee. It was prepared by HRCCC members through a series of working groups and internal workshopping and released initially for public comment in June 1997. This received only interim endorsement from DNR. A revision of the strategy was made in 1998 and full endorsement of the strategy is currently being negotiated with the relevant State government agencies. Planned improvements to the strategy will address their concerns relating to better recognition of indigenous land issues and an apparent over emphasise on state government activities and responsibilities in addressing some catchment issues, that is the need for better recognition of local community responsibilities and action

Table 10. Example of the format for a strategy as identified in the Herbert River Catchment Management Strategy (HRCCC 1996).

What is to be done?	Who can do it?#	Priority*
Strategy HM1 : Promote the values of habitat retention and restoration to the broader community through awareness, technical support and incentives		
a) Provide technical support in the areas of: • land development planning • habitat retention • habitat management	DEH, DPI, DNR	1 1
b) Encourage all levels of Government to provide for habitat management through realistic incentives and/or sufficient funding.	CCC, LG	
c) Develop and promote awareness programs to highlight the values of habitat retention and implement through farm planning	DEH, CCC, DPI, DNR	2

Immediate, commences within 6 months 2. Short-term, commences within 12 months 3. Mid-term, commences within 2 years 4. Long term, commence within 3-5 years	

4.4.2 Achievements of ICM in the Herbert Catchment

The key achievements of ICM in the Herbert in its first five years of activity may be summarised as:

(i) Initiating a range of focussed or single-issue land management projects to establish credibility and raise awareness of ICM process and natural resource management in general with the Herbert community (rather than focussing on issues of strategic importance to catchment management).

(ii) Achieving recognition as a legitimate community referral agency for the state and local government authorities on proposed developmental and infrastructure projects and other natural resource issues in the catchment.

(iii) Providing an effective community forum for discussing and progressing catchment issues, including revealing the range of different stakeholder perspectives on these issues as well as highlighting potential areas of community conflict.

(iv) Development of a Herbert River Catchment Management Plan that provides the essential elements of a 'sustainable' vision for the catchment.

(v) Establishing a coordinative role within the Herbert River community as principal broker negotiating funding for industry and community groups to undertake natural resource management projects and activities in the catchment.
(vi) Information provider and disseminator through HRCCC meetings providing a 'community forum', initiating focussed activities that locally have a relatively high profile, as well as through the existing communication networks of HRCCC member organisations.
(vii) Influencing development proposals and planning processes in the catchment to incorporate ICM principles.

Progress on the Herbert ICM process has been incremental and evolutionary. The specific development in these major achievements identified by HRCCC members in the 1995, 1997 and 1998 are summarised in Table 11. The achievements recognised have broadened since 1997 to encompass community impact (e.g. awareness raising) and an HRCCC role as a recognised and influential body on natural resource management issues in the catchment.

Table 11. Members opinions of HRCCC achievements.

1995 Achievements	1997 Achievements	1998 Achievements
• Establishing a group that is bringing key catchment group representatives together to talk and share ideas. • Preparation of an initial draft catchment strategy. • Assisting community groups and agencies to undertake projects (e.g. tin mining sites in upper catchment).	• HRCCC meetings providing a forum that brings people together in the catchment with very different views. • The preparation and launching for public review of the Draft Herbert River Catchment Strategy. • Getting funding and undertaking a range of projects. • Raising awareness of catchment problems amongst HRCCC members and within the community • Taking on a coordinative and integrative role on natural resource issues in region • Recognition as a source of advice on natural resource issues in the catchment.	• Providing a forum that brings very different people in the catchment together to exchange ideas and providing a catalyst for change • Supporting and brokering funding for a wide range of projects on natural resource management (including the development of a catchment management strategy) • Raising community awareness of catchment NRM issues • As an influential group on NRM in the catchment

4.4.3 Significant Projects

From 1995 to 1998, there was a significant increase in the number and variety of project that the HRCCC became engaged in as shown in Table 12. They broadened from tin mines and tailing dam inventory in the upper catchment in 1995 to include in 1997 and 1998 a joint project with Herbert River Improvement Trust (HRIT) at Long Pocket on bank stabilisation, the owl nesting box program, a Catchment Atlas, several restoration and revegetation projects, riparian vegetation mapping study, weed control, riparian "community" forum, acid sulphate soils awareness, and a cooperative project to link ICM and local government planning.

Table 12. Comparison of key projects undertaken by the HRCCC, 1995-1998.

November 1995	November 1997	December 1998
• Funding for tin mine and tailing dams inventory.	• Project with HRIT at Long Pocket wash away. • Several Owl nesting box program • Joint restoration and revegetation projects (e.g. Wharps area, riparian area management, artificial wetland development, tree planting). • Riparian vegetation mapping study • Riparian "community" forum. • Acid sulphate soils awareness.	• Mine tailing dam survey (upper) • Joint project with HRIT at Long Pocket on riverbank rehabilitation • Owl nesting boxes • Getting community involved in Landcare projects (eg. Wharps Estate, creek restoration, tree planting, Waterwatch) • Riparian vegetation mapping • Acid sulfate soils awareness • Herbert River Catchment Management Strategy • Catchment Atlas • Support for Herbert Mapping Project which led to the establishment of the Herbert Resources Information Centre (HRIC) • Weed control/clearing of waterways • ICM/Local Government wetlands study

These projects have been undertaken by the HRCCC to meet its stated objectives and they have been funded from both the public purse as well as from the catchment community. Evaluations have been undertaken of a number of activities relating to specific issues identified in the Herbert Catchment Management Strategy. These are the preservation of natural habitats, management of vegetation in riparian areas, management of floodplain drainage, management of wetlands, management of acid sulfate soils, strategic river bank protection, and stabilisation of mining dams in the upper catchment. If the activities undertaken did result in changed resource management practices, the estimated costs and benefits incurred are summarised in Table 13. They are also described in more detail in Activity Summary 9 of Appendix 1 of this report.

Overall, the activities undertaken by the HRCCC have the potential to significantly improve or preserve the condition of natural resources in the catchment.

Table 13. Summary of potential costs and benefits of HRCCC activities (from Robinson *et al.* 1999*)*.

Issue	HRCCC Activity	Potential Costs of Activity	Potential Benefits
Management of vegetation in riparian areas	• Mapping of riparian vegetation • Raising community awareness of restoration and retention of riparian vegetation • Organising a Community Riparian Forum with guest speakers	*Individual landowners:* • Cost of revegetation/restoration of riparian areas varies with width required along watercourse and extent of revegetation (eg. 40m buffer corridor costs $120K/km) • Opportunity cost of land which varies with cane assignment/farm size (eg. a 4ha riparian area, with 40% normally under cane would incur a net income loss of $4,000 per annum. This would represent 4% per annum of the net income for a farm with 100ha assignment but 10% per annum net income loss for a farm with 40ha assignment)	*Individual landowners:* • Reduced rat damage to cane crop (eg. value of protection of 8ha area of riparian vegetation is $23K per annum) • Avoided cost of baiting control (where applicable) • Reduced damage to cane resulting from aquatic weed inundation • Improved drainage • Stabilisation of river bank leading to reduced risk of cane loss due to stream bank collapse and scouring *Catchment Community:* • Improved water quality downstream • Improved habitat for fish and crustacea leading to reduced fish kills • Improved natural habitat and source of nutrients for riverine plants and wildlife • Aesthetic benefits (eg. Native wildlife habitat)
Preservation of natural habitats	• Owl box program in support of an integrated approach to pest management	*Individual landowners* • Cost of building owl nesting box and hunting perches ($80/box) *Catchment Community:* • Cost of hire of cherry picker of $1500	*Individual landowners* • Reduced rat damage to cane (see above) *Catchment Community:* • Adoption of ecologically sensitive pest control • Aesthetic benefits
Management of drainage	• Lobbying for technical drainage expert extension officer • Fostering of Landcare group to resolve Wharps Sub-division drainage problems	*Catchment Community:* • Cost of drainage reparation works	*Individual landowners* • Reduction in loss of cane production due to poor drainage *Catchment Community:* • Reduction in adverse impacts of inappropriate drainage infrastructure on other land-owners and habitats • Reduced social conflicts and reduction in litigation and transaction costs associated with negotiation over drainage management

Issue	HRCCC Activity	Potential Costs of Activity	Potential Benefits
Management of wetlands	• Raising awareness of ecological importance of retaining natural wetlands on farm • Fostering the development of artificial wetlands on cane farms	*Individual landowners:* • Opportunity cost of land • Construction costs of wetland vary according to size and site of area to be constructed and availability of suitable areas for disposal of soil (eg. Cost of 0.3ha lagoon up to 3m deep range from $15K to $20K) *Catchment Community:* • Contribution to salary and on-costs for DNR extension officer	*Individual landowners:* • Improvement to on-farm drainage • Source of water in dry periods • Aesthetic attraction of habitat etc. *Catchment Community:* • Retention of significant natural habitats on the Herbert floodplain for fish and wildlife • Providing a retention basin for nutrients and sediments in wetland leading to improved water quality downstream • Improve recharge of groundwater • Aesthetic benefits
Management of acid sulfate soils	• Raising farmer awareness of potential problems of acid sulfate soils	*Individual landowners:* • Estimated opportunity cost of land (eg. decision not to convert grazing land to caneland) for area 'at risk' in catchment (approx. 787ha) is approx. $1,772K per annum. *Catchment Community:* • Costs of media releases and distribution of literature to "at risk" farmers	*Individual landowners:* • Avoided costs of loss of cane production (eg. 1% reduction in yield on current caneland in ASS prone areas is approx. $20K per annum) varies with size of area of potential impact *Catchment Community:* • Avoided costs (eg. Avoidance of fish kills and degradation of estuarine habitat)) varies with size of area of potential impact
Strategic river bank protection	• Joint project with Herbert River Improvement Trust at Long Pocket	*Catchment Community:* • Cost of works (eg. bank stablisation using vegetation and rock protection as well as land use changes)	*Individual landowners:* • Avoided costs of loss of cane production *Catchment Community:* • Protection of existing infrastructure (eg. cane railway link to mill and road bridge across river) • Prevention of river bank erosion upstream causing loss of riparian vegetation and adjacent productive cane land • Reduction in siltation downstream
Stabilising relict mining dams in the upper catchment	• Inventory of derelict tin dams in upper catchment to assess risk and prioritise work needed • Fostering of coordinated action between government agencies and landowners	*Individual landowners:* • In-kind contribution of time and earth moving equipment *Catchment Community:* • NLP Project grant of $21K p.a. for dam wall stabilisation	*Individual landowners:* • Improved water supply to property owners *Catchment Community:* • Improved water quality downstream • Avoidance of risk of dam failure

5. EVALUATION OF ICM IN THE HERBERT RIVER CATCHMENT

The evaluation of the ICM process in the Herbert River catchment presented below uses the framework identified previously in Table 2 and presents a synthesis of the findings of the eleven project activities, which are presented in summary form in Appendix 1 to this report. The reports and other publications relating to each of these research activities are also identified in Appendix 1.

5.1 Characterisation of NRM Issues in the Catchment

5.1.1 Extent and severity of resource use problems and progress of management responses in the catchment

The Herbert River catchment is a rural catchment of approximately 10,000 sq km in the wet tropics area of north-eastern Queensland. It does not have a single compelling natural resource management issue of the magnitude of salinity to focus community attention to catchment scale issues. Rather it has a range of significant land and water management issues relating to land clearing, flood protection and drainage management for rural land use over a long time frame of development.

Land use and cover
Agricultural and pastoral production are the largest uses of land in the catchment. In terms of arable agricultural production, the sugar industry located in the lower catchment is dominant, with approximately 65000 ha of sugarcane under cultivation (6.5% of the total catchment area). Other important industries are plantation forestry (1.3%) and small crops such as pineapple, melon and pumpkin (1%). Less important crops include papaya, banana, lychee and mango. Lands not used for arable agriculture or forestry are mainly under native vegetation or improved pastures for beef cattle production (90% of the area). This is especially the case in the upper catchment. Small areas are utilised for mining (in the upper catchment only) and industrial activities, or are alienated for urban development.

There have been substantial changes in land cover and land use in the Herbert River catchment since European settlement, particularly in the lower catchment. Prior to European settlement in the 1860's, the area was dominated by open grassland, rainforest, mangrove s, Eucalypt woodlands and *Melaleuca* communities. However, by the 1940's large losses of rainforest and *Melaleuca* dominated patterns had occurred and much of the native grassland had been converted either to grazing or sugarcane. Land cover remained relatively stable throughout the 1960's and early 1970's. However, the period between 1977 and 1996 saw a rapid expansion in the area of land under sugarcane from 27000 ha in 1977 to approximately 65000 ha in 1996. The consequences of this expansion have been a decrease of approximately 65% in the area of *Melaleuca* dominated patterns when compared to pre-European estimates, a 60 % decrease in the area of beachside vegetation, a 20% decrease in the area of Eucalypt woodland; and a 10% decrease in the areas of rainforest patterns. The area of mangrove communities and open water has remained relatively stable since 1943, while the area of sugarcane has more than tripled between 1943 and 1996. However the total area alienated for urban and industrial land in the catchment is small within the context of the total catchment area (ie <1%). Land cover and land use in the upper catchment (predominantly extensive grazing of unimproved pastures) has remained relatively constant since the 1940s.

Chemical usage
Total fertiliser N (nitrogen) and P (phosphorus) use in the catchment has increased with time, however it is important that these increases are placed in the context of changes in land

use. The total area of rural land fertilised is approximately 7.5% of the total catchment area, with the majority of this (ie. 6.5% of the total area fertilised) for sugarcane cultivation. As the area of sugarcane cultivated has continued to increase, N fertiliser inputs (kg ha^{-1}) has also increased, reaching a peak in the late 1980's. Early indications are that this trend may be declining as sales of fertiliser post 1990 have declined and current Bureau of Sugar Experimental Stations (BSES) fertiliser recommendations for the Herbert River district advocate reduced rates of N. P fertiliser inputs (kg ha^{-1}) have also increased, although both rates and total use declined for a period in the 1970's coinciding with the removal of the government fertiliser subsidy and the energy crisis. Inputs of N and P to improved pastures increased dramatically during the 1980's, however their relative contribution to total catchment inputs was small. Subsequent conversion of pastures to sugar cane has meant that the area of this land type fertilised has declined to negligible levels by 1998. The area of exotic pine plantations has increased since their establishment in the 1970's, although additions of N and P (kg ha^{-1}) have decreased since the late 1980's. The area of horticulture and small crops in the catchment has varied with time, although N and P usage (kg ha^{-1}) has remained relatively stable.

A large number of agrochemicals have been applied in the Herbert River catchment since European settlement. In 1995 approximately 7% of the total catchment area was receiving pesticide applications, with approximately 95% of total applications (by volume) occurring in cane growing areas of the lower catchment. With an increasing land area under sugarcane and other crops, total agrochemical use in the catchment has increased with time and it provides a potential source of contaminants to the adjacent water of the Great Barrier Reef Marine Park (GBRMP). While many of the highly persistent pesticides were withdrawn from usage in the late 1980's and early 1990's, their fate in aquatic and marine environments of the Herbert River and adjacent GBRMP are unknown.

Integration for natural resource management
Established social networks and interactions, fundamental social values, legal and institutional frameworks and historical influences have shaped the current human/community association with the natural resource environment in the Herbert River catchment and will inevitably continue to influence the pattern in future. At the inception of ICM in the Herbert in 1992, a broad range of community, industry and local and state government organisations with some level of responsibility or an interest in resource use management and planning were present in the Herbert River Catchment. However, there was a clear lack of integration or formal linkages between these organisations on natural resource management that would support an integrated approach to the management of the land and water resources of the catchment.

5.1.2 Diversity of stakeholder knowledge, attitudes and values on natur al resource use and management

At the commencement of ICM in 1992 in the Herbert River catchment there was a relatively low level of awareness of ICM issues in industry, local government and the broader community, except for the compelling issues of flooding and drainage in the lower catchment. Since ICM's inception in 1992, rural drainage, flooding, river management and sugar industry expansion and related land clearing have remained key issues in the catchment. However, emerging issues since 1995 are water quality (particularly relating to fish kills), riparian vegetation and wetlands management, integrated pest and weed management and a coordinated approach to land use planning and resource management in the catchment. With closer linkages with the upper catchment community particularly since 1998, grazing land degradation/erosion and water availability are also identified by HRCCC members as key issues of concern.

The focus of the issues identified by the new upper catchment sub-committee of the HRCCC formed in early 1999 relate largely to specific land and water management issues (eg. weeds, soil erosion, land clearing). This contrasts with the current views of the lower catchment-dominated HRCCC, which is now more focussed on broader planning and public good issues (eg. land use planning, coordinated drainage management, and riparian and wetland management).

Opinions in relation to key resource management issues and constraints are impacted significantly by understanding. Although there is good agreement among HRCCC members on the key catchment resource management issues, individual stakeholder/member diagnosis of their causes and possible solutions varies significantly. The decision context is also perceived to vary with the type of catchment issue. In 1998, members identified that three catchment issues - water quality (particularly relating to fish kills), waterways management and flooding, and floodplain drainage coordination – had both a high to very high degree of technical complexity and a high to very high intensity of community conflict. While industry expansion, land/vegetation clearing and land use planning had a moderate level of technical complexity but a high to very high intensity of community conflict in the decision context. In contrast, riparian management and wetland degradation have a low to moderate level of technical complexity and a moderate intensity of conflict. This situation has distinct implications for the type of community involvement required for each issue in seeking their resolution (eg. consensual, consultative).

HRCCC members perceive that the key catchment issues are difficult for ICM to address because of (a) 'institutional failure' (eg. slow government responses and strategies, departmental conflicts, lack of government commitment to a 'whole of government' approach) and (b) economic issues (eg. high costs of solutions and lack of financial capacity in the community).

5.1.3 Scientific understanding, feasibility and acceptability of technical solutions to natural resource problems

Concern over flooding has been a community issue in the lower catchment since the 1880s. However flood mitigation works and the development of uncoordinated drainage systems have been the cause of considerable community conflict. Since the late 1970s, there have been five major technical studies commissioned by the Herbert River Improvement Trust (HRIT) and the Hinchinbrook Shire Council in collaboration with state government agencies that have examined water management related issues with respect to flooding management, rural drainage planning, and stream management planning. Continuing conflict over these predominantly engineering-based technical solutions was perceived to be impeding economic and social development for the Herbert River catchment community and prompted the call for an ICM process from key actors in the catchment in 1992. Importantly, at the time of inception of ICM in the catchment, technical information and understanding of the catchment resources was either not widely shared or in an inaccessible form for key decision-makers.

Since the establishment of an ICM process in the catchment, water quality has increasingly become recognised within the local community as a major issue of concern. These concerns relate to the quality of town water supplies in the lower catchment, several significant fish kills since 1998 in streams draining the lower floodplain and the potential detrimental impact on the adjacent the estuarine and marine environments of the Great Barrier Reef lagoon.

Understanding of cause-effect relationships and 'solutions' to major issues in the Herbert River catchment have varied along a scale of 'speculative' (eg. fish kills) to 'uncontested' (eg. acid sulfate soils). The lack of technically uncontested 'solutions' for highly sensitive issues in the catchment at times has led to substantial community conflict and lack of confidence in government, research and other relevant agencies and therefore has inhibited progress on these issues. The resolution of such sensitive issues requires clear local interpretation supported by appropriate and locally credible data.

5.1.4 Extent of problem recognition and acceptance of change required and by whom

Land allocation

Inappropriate land allocation is identified in the Herbert River Catchment Management Strategy as the major land use issue for the catchment. Its major impacts are lost opportunity for other uses, loss of prime agricultural land, excessive soil erosion and downstream sedimentation, water quality issues (surface and groundwater), loss of significant native vegetation and wildlife habitats and conflicts between adjacent incompatible land users. Past land and water management practices in the catchment (eg. land clearing and expansion of intensive agriculture by rural producers, and reactive, ad hoc floodplain drainage and flood mitigation works) were encouraged and/or inadvertently promoted under a past development ethos by both government and industry alike without an overall systemic or catchment planning approach or full knowledge or understanding of the environmental or social consequences. Changes to existing institutional arrangements for land development/allocation and in particular caneland assignment are required if sustainable development is to be achieved.

Riparian and wetland management

The impact of these issues has been an extensive decline of riparian and wetland ecosystems and a rise in total use of agrochemicals in the lower Herbert River catchment with long term implications for the sustainability of riverine, coastal and marine ecosystems. The mangroves and wetlands of the Herbert River Catchment are of national and local significance. Riparian vegetation management and wetland destruction have been identified by the community as major issues needing to be addressed at a catchment level. This issue came to a high point in 1996 with a significant conflict within the community and at a State level over the clearing of Pomona Station, an area perceived to be Mahogany glider habitat. This community conflict was reflected in a failure to reach agreement on action within the HRCCC. Members of the HRCCC have reported that they considered that there was enough information to know there was a problem, but not enough to precipitate a solution. Furthermore, access to information was reported as a problem as was the apparently conflicting advice coming from different agencies. As a consequence, personal opinions and local politics dominated the issue. Significant issues underpinning the conflict included:

- agreement on the definition of a water course and swamp or lake;
- basic inventory data about water resources in the area;
- understanding of mahogany glider habitat; and
- poor understanding of the legislation associated with these issues.

The Pomona issue did precipitate changes within the HRCCC specifically and in the catchment more broadly in seeking better ways to resolve resource use conflicts. Thus the HRCCC agreed that the issue had been exacerbated by inadequate basic information and successfully lobbied the Minister for a water resources extension officer to be based in the catchment, thereby extending the expertise available locally.

To-date the conservation of riparian vegetation, wetlands and mangroves has been ineffective in the Herbert floodplain because of fragmented management arrangements, a failure to address environmental issues in the rural land development process and limited ability of government authorities to control harmful land management practices particularly on freehold land. This potentially could lead to high transaction costs in negotiating the appropriate management of riparian areas with relevant authorities and individual land managers.

Water quality
Water quality has increasingly been recognised within the local community as a major issue of concern. Tin mining dams in the upper catchment, some of which were abandoned in the late 1890s, are perceived to pose a hazard to downstream water-users, natural drainage in the Lower Herbert, and the biodiversity of aquatic habitats. This was initially a divisive issue between the upper and lower catchment communities due poor domestic water quality at certain times in the lower catchment, as well as concerns that increased sedimentation from abandoned mine waste was reducing the river capacity and contributing to greater flooding problems. It requires remedial works to stabilise these dams and mining waste through collaborative efforts of local government and a limited number of relevant landowners in the upper catchment. Disturbance of wetlands as a result of drainage works and agricultural development in the Herbert coastal wetlands has led to acidification of adjacent waters (with pH levels as low as 2 or 3) and have been locally linked to fish kills. Areas prone to risk of acid sulfate soils are confined to a limited number of properties adjacent to coastal lowland wetland and mangrove areas. Diffuse source pollution of waterways from intensive agricultural production however continues to be a problem of significant social conflict both within the Herbert community and between the community and relevant government agencies. It has been highlighted in 1998 with the high profile fish kills in streams draining the floodplain.

Rural producers/land managers (and in particular cane growers) are the principal responsible groups requiring change in behaviour to a more precautionary approach, in particular in regard to land clearing and nutrient enrichment of waterways. However, long term solutions are frequently not in a landowners self-interest financially to undertake. These issues therefore require the political commitment and will of relevant local and state government agencies to apply their relevant powers in land development decision-making and approval processes to ensure ICM principles are taken into account and to establish cost-sharing arrangements.

5.2 Implementation Context for the ICM Policy Initiative in the Herbert River Catchment

5.2.1 Rationale and motivation for the commencement and on-going development of the Herbert River ICM initiative

The prominent history of flooding and drainage issues in the catchment has created significant social conflict over a long timeframe. Previous local and state government responses were to undertake 5 major technical studies since the late 1970s. However, there was concern within the local catchment community that (a) despite the major public and private investment in these studies, government had failed to achieve on-ground outcomes on drainage management, and (b) the local community needed a greater influence on decision-making on these issues. To this end, prominent actors in the catchment from the sugar industry and local government lobbied the State Government for the initiation of an ICM process in the catchment in 1992.

The steering committee for ICM set up in July 1992 identified key stakeholder organisations with a responsibility or interest in natural resource management in the Herbert catchment and in February 1993 invited them to nominate representatives to form the HRCCC. Since then the HRCCC has opportunistically invited additional stakeholder groups to participate in the HRCCC as they saw fit. The number of members on the HRCCC therefore has fluctuated between 13 and 17 members since it was formally established in March 1993. Current representation on the HRCCC is diverse involving local industry (sugar, cattle, fishing, horticulture), local government and other statutory bodies, conservation and community interests. However, the HRCCC has been dominated by the lower catchment with only one representative from the upper catchment. State government have not been formally represented until early 1999 with the appointment of a representative from the EPA for the first time. Informally DNR officers have provided technical advice on a regular basis.

Over its life, the HRCCC membership has been remarkably stable with approx. 60% of the members in 1999 being the original foundation members. All members are active community leaders who belong to a wide range of different organisations in the catchment holding executive and other leadership positions. They therefore have multiple allegiances and interests.

The lower Herbert catchment is topographically, hydrologically, socially and politically 'divorced' from the upper catchment. This means that at the catchment scale inclusiveness of all interests, integrated solutions, and communication are major challenges for a whole of catchment ICM process. A Sub-Committee of the HRCCC was formed for the upper catchment in December 1998 to discuss and raise issues of particular relevance to the upper catchment. This sub-committee, the Upper Herbert River Catchment Group, arose because community members in the upper catchment felt that they were not equally represented on the HRCCC. The HRCCC membership has been overwhelmingly dominated by members from the lower catchment and has inevitably tended to have a focus on issues affecting the lower floodplain. In addition, there were logistical issues relating to the long distance between the upper and lower catchments (ie. a 4-5 hour drive) in attending meetings and activities.

5.2.2 Socio-economic conditions and use of technology

Socio-demographic profile

The population of the catchment was 18,615 persons in 1996 with approximately 70% living in the lower catchment. The growth rate between 1991 to 1996 was approximately 3% with most of this increase being in the upper catchment. Approximately 20% of those employed in the catchment are employed in the agriculture, forestry, fishing industries, 18% in community services, 14% in wholesale and retail and 13% in manufacturing industries.

A lack of financial resources in the community is considered an issue by the Herbert catchment community for both solutions to natural resource problems and for personal planning. The economy of the lower catchment is heavily dependent on the sugar industry and the economy of the upper catchment is dependent on the cattle industry. The economic impact of these industries on the regional economy of North Queensland shows that, together, these industries make a significant contribution (both direct and flow-on effects) to gross output and employment in the catchment:

- *Output*: the sugar industry of the lower Herbert River catchment in 1996 contributed to over $354m of output in the regional economy, including $206m of output from sugar production and a further $148m in flow-on impacts from other industries in the region. The cattle industry in the upper Herbert River catchment contributed $16m in output to

the regional economy, including $13m in output from cattle production and a further $3m in flow-on impacts.

- *Regional employment*: the sugar industry of the lower Herbert River catchment provided employment for over 3,300 people in the Northern statistical division in 1996. Over 1,300 of these people are estimated to be employed directly in the production of sugar with a further 1,936 people employed in industries supporting the sugar industry. The cattle industry in the upper Herbert River catchment is estimated to provide employment for 170 people, which includes 120 people employed directly in cattle production and a further 49 in support industries.

The economic sustainability of these industries therefore is critical to the catchment economy. However, the financial viability of both cane farmers and beef producers in the future is not optimistic. The possibility of reduced financial viability could result in reluctance, on the part of farmers, to engage in farm management practices which, though regarded as improving the state of the environment, would not directly improve the financial status of individual framers.

Use of technology

Lack of relevant information is not perceived by HRCCC members as a constraint for ICM in the Herbert. Since 1995, there has been an emergence in the catchment of a number of collaborative ventures between local government, industry and state and federal government agencies to improve the capture of relevant data on NRM issues (eg. Herbert Mapping Project and a Catchment Atlas) and provide locally accessible mechanisms for integrating data and information delivery or service provision (ie. Herbert Resource Information Centre). The HRCCC to-date has not made extensive use of the available Information Technology in its own right. Nevertheless, the availability to other stakeholders of technologies to underpin resource management has been important to the HRCCC, which has, therefore, fostered the further adoption of such technologies. The most significant example of this in the Herbert has been the HRCCC's support for the establishment of the Herbert Resource Information Centre (HRIC), a collaborative GIS venture for the management and use of spatial resource data for the catchment. The HRCCC is not a partner to the HRIC per se (the HRIC is a joint venture between Hinchinbrook Shire Council, CSR Ltd., the Herbert Cane Protection and Productivity Board, CANEGROWERS Herbert River District, CSIRO and the Queensland Department of Natural Resources), nor is it a significant user of the HRIC's data sets or services. Nevertheless, the HRCCC has had a role to play in facilitating and encouraging the use of those data and services by resource managers and planners.

The HRCCC was also instrumental in bringing about the Herbert River Catchment Atlas in collaboration with CSIRO and the Herbert River CANEGROWERS. The Atlas was created by CSIRO and was extensively used by HRCCC members in the development of the Herbert Catchment Management Strategy. The HRCCC has contributed funding for production costs and it has been instrumental in the broad dissemination of the Atlas, particularly to schools, TAFE and for other awareness raising and educational purposes.

5.2.3 Community attitudes and support for ICM

Awareness of ICM

At a project workshop of key stakeholders on the ICM process held in April 1995, it was argued that in order to gain a long term commitment to the ICM process amongst the community, it was necessary to create a common and widespread understanding of the ICM conceptual process. At that stage, it was argued by the workshop participants that the development of a Catchment Management Strategy was a critical process in gaining

community consensus on key issues and the role of ICM. The Catchment Management Strategy that was subsequently developed explicitly acknowledged this role and is being used to seek a consensus on key resource use issues amongst community leaders. The Community Survey in 1998 demonstrated that improved community awareness of ICM through exposure to the Strategy has been limited to-date with only approximately 40% of community respondents either aware of ICM or the Strategy.

However this awareness level is increasing. In particular, over the period 1995-98, HRCCC members considered that the rural community's *awareness* on natural resource issues and the HRCCC organisation itself had improved substantially largely due to the occurrence of specific well publicised or controversial issues/events (such as land conversion from cattle-to-cane, land clearing for cane land expansion, Mahogany glider habitat destruction, owl boxes activity, fish kills in the river, damming of streams and acid sulfate soils).

Support for ICM

In principle there is considerable support for ICM in the community with all ICM activities being seen as of moderate to high importance in the Community survey. Community perceptions of the priority responsibilities for ICM were:

- encouraging joint projects between government, industry and research;
- raising local awareness of natural resource management;
- gaining a better understanding of environmental problems;
- developing solutions for environmental problems;
- encouraging research; and
- communicating on this work to the community.

The Community surveys in 1995 and 1998 showed that people were generally satisfied with many aspects of living in the Herbert River catchment and perceived many advantages of living in the area. The majority of respondents would therefore possibly not support any changes threatening these aspects of their community. The most important issues identified by respondents were: unemployment; a lack of opportunities for young people; and a lack of diversity in industry. Further issues related to land and water management and included clearing of marginal land, flooding, drainage, water quantity issues (ie. lack of water), fishing issues, the impact of weather and changing weather conditions on primary industry, and environmental issues. The awareness within the community of land and water problems and the perception that these issues are important, both personally and on a catchment scale, signifies general support for ICM to tackle land and water management on a number of fronts. However, land and water management issues were not uppermost in people's minds which suggests that there needs to be awareness and acknowledgment by ICM that while people may support land and water management of various kinds, their first priorities lie with 'life issues'.

Perceived impediments to ICM

For those catchment community respondents involved in ICM, the major issues were the environment in general, ineffective decision making processes and communication, water quality, and flooding, drainage and their management. However, for those not involved in ICM, flooding, drainage and their management were of greatest concern.

While there was community interest in issues for the Herbert, the influence people felt was not particularly high, it appeared that there may be some conflict and not all respondents often thought about local community issues. These factors may hinder community participation in ICM. With regard to how manageable (or practical) catchment management might be, there were a number of impediments to effectively managing land and water in the catchment identified including slow government strategies, slow reactions of government to

new problems, the catchment's large area, the cost of solutions, a lack of easy solutions, low trust of government programs, and insufficient understanding of relevant problems. It will be important for ICM to address these perceptions of impediments, perhaps by encouraging timely responses from government, encouraging financial support for ICM, developing and promoting solutions, encouraging improved formal and information communication between the government and the community, and improving understanding of land and water management problems.

5.2.4 Attitudes and resources of local constituency groups

An examination of documentation has shown that there has been a broadening of the focus of industry organisations (eg. CANEGROWERS, Herbert Pest and Productivity Board) in the catchment from an almost exclusive concern with productivity and efficiency issues and impacts at the inception of ICM in 1992 to a recognition and even promotion of the importance of natural resource management to the long term sustainability of the industry.

HRCCC members consistently identified rural producers, industry organisations, the Herbert River Improvement Trust and the Drainage Board as having an effective to very effective involvement in ICM. These groups also were reasonably active attendees at HRCCC meetings. In contrast, local environment organisations were represented by one member who was very effective when available to participate in meetings and highly respected for that contribution by other members. However, due to many other commitments the conservation representative has had a very low attendance rate and there was an apparent lack of an alternative representative to act as a proxy.

5.2.5 Support from politicians

Local government politicians have had an active and influential involvement with ICM process with 2 Councillors from the lower catchment and one other from the upper catchment regularly participating in the HRCCC. In addition, the lower catchment Mayor is now the Deputy Chair of the HRCCC. However State government and Federal government politicians have had little input or involvement such that HRCCC members identified them as having an ineffective to very ineffective involvement.

5.2.6 Media coverage and attention to NRM issues and ICM

The 1995 Community survey found that *The Herbert River Express,* the local newspaper for the lower Herbert catchment was used more frequently than any other source of information (60%) on catchment issues, including friends and colleagues (54%) and personal experience (39%). In the lower catchment it was the source of information for 84% of those surveyed.

An assessment of the representation of natural resource management issues in general, and integrated catchment management in particular, as they were presented by the *Herbert River Express* from 1990 to 1998 found that natural resource management issues became increasingly prominent in the *Herbert River Express* with 1995-96 and 1996-97 exhibiting the highest levels of prominence. The river/stream/water management theme comprised 36% of all natural resource management articles, while political controversies comprised 20% of the articles and pest/feral species 15%. The occurrence of these articles in the *Herbert River Express* clearly reflects that the Herbert River Catchment Coordinating Committee (HRCCC) has a profile in the lower catchment community. However, the analysis does indicate a lag in the time between the inception of ICM in the Herbert River catchment in March 1993 and the HRCCC developing a profile in the community and also possibly influencing the presentation of natural resource management issues in the community. For example, over

the eight year time frame studied, 1996-97 and 1997-98 were the years where river, stream and water management issues were the most prominent.

Although the actual number of articles on river, stream and water management issues appearing each year peaked in 1995-96 there is a tendency for the prominence of these issues to increase over time. This suggests an increasing community interest in, or focus, on river/stream and water management issues. The *Herbert River Express* also provided information on the role and function of the HRCCC and at times emphasised the importance of community involvement in natural resource decision making.

5.3 Adequacy of Policy Frameworks and Institutional Arrangements for ICM at State and Local Catchment Levels

5.3.1 Adequacy and effectiveness of policies, plans and decision rules of ICM and other responsible agencies/groups for NRM

The ICM Policy

The integrated management of land and water in Queensland is addressed through the Integrated Catchment Management Policy (1991) and the emerging system of regional resource management strategies promoted through DNR's community resource management program. A substantial source of funding for these programs is the National Landcare Program (NLP) and, more recently, the Natural Heritage Trust (NHT). There is no legislative basis for integrated resource management in Queensland to compare with the NSW Total Catchment Act or the Victorian Catchment Management Act and little statutory guidance for management of steep lands, floodplains, riparian zones and other key landscapes for ICM.

The implementation of ICM in Queensland is based on the establishment of Catchment Coordinating Committees (CCC). A CCC comprises representatives of the major sectors of the community and government that are involved in, or influenced by the management of land and water resources in the catchment. While considerable progress has been achieved in some catchments and in some regions, the depth, coverage, and effectiveness of the ICM in Queensland is very patchy. Specifically, there are as yet no regional resource management plans to guide ICM activities and only a minority of river basins covered by Integrated Catchment Management (ICM) plans. The consequence is that at this time there is no statutory or policy framework to guide landholder and local resource management plans with respect to water, vegetation and land management. There is no set of priorities or codes of practice for on-ground works, vegetation management, soil conservation, riparian zones and other key areas.

Implementation of strategies for resource management by individual ICM organisations in Queensland requires the voluntary cooperation of the community, local government and government agencies. The ICM organisation does not have the authority to legislate or pass laws to regulate resource use. The organisation is only able to influence the regulation of resource use through an organisation, such as local government, which does have this authority. Alternatively, where regulations are not enforceable, for example on freehold land, the voluntary support of the community may be the only alternative.

Since the inception of ICM in Queensland implementation has been hindered by the inability of catchment management groups to influence land use planning and management. Traditionally ICM principles and catchment management issues have not been incorporated into or addressed by local planning schemes. A recent legislative approach towards promoting ecologically sustainable development in Queensland, the *Integrated Planning Act*

(1997), does not specifically identify a role for ICM organisations in the planning and management of natural resources. The *IPA* allows local government to require landholders wishing to conduct intensive agricultural activities, such as cane farming, to obtain it's approval. While this mechanism could provide benefits, it appears to be focused on development control rather than strategic planning. Indeed, the intent of the Integrated Development Approval System within IPA appears to be primarily focused on streamlining decision-making processes, rather than enhancing their effectiveness.

The HRCCC
The approach to selection of members/stakeholder representatives on the HRCCC has been to ask for a nomination from the organisation concerned. Representatives have tended to be community leaders or 'committee people' who are often already over-committed. There is some concern among HRCCC members that there are no clear rules for managing the HRCCC's representational structure and processes (eg. use of proxies, reviewing membership, election of office bearers). To-date the approach has been largely an ad hoc process that may in time reflect on its credibility.

Land use planning in the Herbert Catchment
Clearing of native vegetation (particularly land close to stream and watercourses) remains one of the most contentious issues impinging on land and water resources management in the Herbert River catchment. Much current decision-making in relation to the granting of caneland assignment occurs in the absence of clearly agreed catchment based plans for land, water and vegetation resources. For the period 1993-96, 525 applications for caneland assignment covering an approximate area of15,013ha were submitted to the Victoria and Macknade Local Boards for approval. Of these, 12,165ha were awarded, representing an 81% approval rate. Over 70% (8,655ha) of the awards granted were on land that both the Local Cane Assignment Boards and Environmental Advisory Committee (EAC) deemed suitable. About 7% (741ha) was granted on land that both groups perceived as unsuitable and another 20% (2,768ha) was granted on land over which there was clear disagreement between the Local Boards and EAC over drainage and habitat issues.

As a step towards addressing these issues, a recent development in 1998 in the lower Herbert catchment is the process that requires farmers opening up new areas for intensive agriculture or seeking a change of use will require Hinchinbrook Shire Council approval (for conditions) under the new Shire Plan. This process seeks advice from a range of responsible agencies including ICM in the decision-making process. Although local government in the lower catchment now does have enormous scope to achieving catchment management objectives, it is limited by the fact that it can only implement these strategies when a development application is triggered by the planning scheme. The regulation of new developments through the planning process will not effectively deal with existing resource management problems because planning controls have little power to control existing unsustainable land uses or minor variations in those uses. Ultimately this development requires the Council to have both the technical capacity and political will to implement their statutory powers. Therefore to effectively achieve ICM, planning schemes and development assessment need to be integrated with other forms of institutional arrangements to deal with existing use rights.

5.3.2 Clarity and consistency of roles and objectives of ICM and other responsible agencies/groups for NRM

The ICM Program in Principle
Queensland's ICM program has very broad, and from a community point of view, somewhat nebulous goals. The stated purpose of ICM as outlined in the Queensland ICM Strategy

(QDPI 1991), is to integrate the management of land, water and related biological resources in order to achieve the sustainable and balanced use of these resources. The fundamental assumptions that underpin this policy are that the objective of ICM will be achieved by:

- generating a better understanding of ecosystem interactions at a catchment scale by the community and Government; and, thereby
- moving towards common or agreed goals through development of a catchment management strategy; and
- facilitating co-ordination and co-operation within and between Government agencies and the Community to enable the prioritisation of actions; and
- joint or independent action to seek solutions to problems.

The strategy also differentiated clear roles for the community, and local, state and federal governments. As such, the role of the community in ICM was identified as:

- Establishing and supporting Catchment Committees as needed to address land and water issues.
- Identifying interrelated land and water issues that should be addressed, and contributing to the development of solutions.
- Participating in the development of catchment management strategies.
- Influencing the community and individuals through local action groups to achieve results on the ground;
- Promoting within the local community the concepts and principles of sustainable and balanced use of land and water resources; and
- Contributing funds to develop and implement catchment management strategies.

The role of local government is identified as:

- Fostering community awareness and the formation of Catchment Groups;
- Contributing technical and financial support to Catchment Groups and Committees, on a voluntary basis and as resources permit;
- Participating in the development of catchment management strategies; and
- Contributing voluntarily to the implementation of catchment management strategies by considering incorporating relevant parts of these strategies in local authority plans, by-laws and administrative procedures and in their own field activities

The roles of the State Government is identified as:

- Fostering community awareness and the provision of educational material and services;
- Participating in the development of catchment management strategies;
- Contributing technical and financial support to Catchment Coordinating Committees as resources permit;
- Establishing policies, institutional arrangements and necessary legislation to facilitate the implementation of integrated catchment management;
- Contributing to the implementation of catchment management strategies by considering the incorporation of relevant parts of these strategies in appropriate legislation, regulations and administrative procedures, and in the management of public land and water resources and the provision of infrastructure and services;
- Developing State-side catchment management strategies and programs and monitoring their progress; and
- Ensuring interdepartmental coordination of land and water resource programs.

The roles of the Commonwealth Government is identified as:

- Participating in the development of catchment management strategies
- Adopting catchment management strategies on land used or managed by the Commonwealth Government or its agencies
- Providing financial support to priority catchment projects where national interests apply

- Providing taxation and other financial incentives for expenditure on land and water conservation

ICM in Practice
The State-wide survey of Catchment Coordinators and Chairs revealed, however, that although there is general agreement on the ultimate purpose of ICM and stakeholder roles, there is a wide spread of opinions as to the purpose and operation of CCC among the various individuals and catchments in the State. This is not to be perceived as a deficiency of the program, given that it is intended to be community based. Over the ten years of the ICM initiative in Queensland it has been surprisingly robust. While it has evolved, its essential philosophies and implementation have remained constant.

In the Herbert River catchment, there was considerable uncertainty initially amongst HRCCC members on the roles and objectives of the HRCCC and ICM in general. It took over 3 years before a draft Catchment Management Strategy (CMS) was developed that identified a clear set of objectives for ICM in the Herbert for the first time. These objectives are:

- Co-ordinate government agencies and the community to pursue common goals
- Seek community involvement in catchment management
- Reflect the requirements of the wider community within the Catchment
- Identify and rectify natural resource degradation
- Promote ways to prevent and reduce natural resource degradation
- Promote the wise use of all natural resources within the Catchment
- Identify key indicators of biodiversity and monitor as a measure of catchment health
- Encourage the retention of significant natural habitats within the Catchment.

These objectives of the HRCCC are caste in general terms, which encompass both its role as a coordinator between the catchment community and government agencies as well as its role as a monitor of catchment health.

5.3.3 Adequacy of financial resources for ICM

Financial resources for a program with such ambitious goals as the ICM policy have been erratic and low. A key source of funds has been the NLP, without which ICM would struggle to survive. CCCs are required to find funding on their own initiative rather than use established revenue sources as do most public programs. DNR provides significant levels of funding, especially for start-up, the employment of Coordinators and related administrative costs. At present however CCC have no revenue raising capacities and there is a lack of confidence in government funding for implementation, which is of particular concern given that once CCCs have been established and created strategies, their requirement for funds for on-ground works will increase their financial requirements. Planning is inexpensive relative to action.

Although seed money provided by the lead state agency for ICM has been pivotal to the successful formation of the HRCCC and a catalyst for it to leverage other sources of funding (eg. NLP/NHT), the short term nature of funding and political cycles has not been conducive to long term environmental/sustainable development solutions. In addition, much of the funding is administratively burdensome to apply for and to manage and takes up a lot of the HRCCC's resources (eg. the Catchment Coordinators time). The extent and speed with which the HRCCC can implement its strategy is largely determined by the level of funding that it can attract.

5.3.4 Coordination among ICM and other responsible agencies/groups for NRM

ICM at the state level
DNR is the lead agency for ICM in Queensland which was perceived by most Chairs and Catchment Coordinators in the state-wide surveys in 1995 and 1997 to be a successful partnership between DNR and the rural land owner interests and not much more than that. There was a widely held view that local governments, both politically and at officer level have not been involved effectively in the ICM process. Involvement of other key state agencies such as Lands and Environment is less applauded.

In Queensland in general most CCCs have not so far had effective involvement from local governments nor from key agencies with statutory resources and management responsibilities. As the coordinating process for mainstream decisions affecting natural resources, ICM have not yet been universally successful. Lack of co-ordination between state agencies has been a major obstacle for ICM. There is no whole of government or even whole of DNR commitment evident. For example, the Water Infrastructure Taskforce kargely ignored ICM, as has the Water Allocation Management Planning (WAMP) process and the Sugar Infrastructure Planning (SSIP) initiative.

ICM in the Herbert River catchment
Effective state government involvement is critical to the success of ICM in the Herbert through the provision of financial resources, technical support, and its power to endorse the Catchment Management Strategy. An endorsed strategy is the basis for leveraging funding for projects. However, a high turnover has occurred in state-agency personnel at regional/catchment and state policy levels relevant to ICM, which has meant a loss of expertise on what is essentially an experimental policy process. This poses particular challenges for ICM groups like the HRCCC in terms of maintaining effective networks, the loss of corporate memory on previous decisions and what needs to happen with regard to a particular ICM initiative.

There have been significant changes in the system of organisational linkages on NRM in the Herbert River catchment since the inception of ICM:

- Increased number of linkages (both regulatory and non-regulatory) between (a) local government and related statutory bodies and industry and other community organisations in the Herbert catchment and (b) these Herbert River organisations and state and federal agencies.
- The emergence of a number of successful coordinative, collaborative and/or joint funding initiatives for NRM purposes (eg. the Herbert Mapping Project and the establishment of the HRCCC in 1993) which are now the catalyst for further collaborative ventures relevant to catchment management (eg. the Herbert Resources Information Centre or HRIC).

Within this system, the HRCCC however is moving towards being a legitimate coordinative and informative forum on NRM (at least within the lower catchment) for facilitating information exchange and more inclusive debate on NRM issues with a level of legitimacy that had not existed before in the catchment.

5.3.5 Commitment and skill of staff in ICM and other responsible agencies/groups for NRM

Commitment
One of the big challenges for ICM is keeping up the momentum in a process where tangible outcomes are slow to emerge and may well be attributed to others influenced by ICM rather

than the ICM process itself. A strong, active, credible and enduring Chair has been essential for driving the ICM process in the Herbert and progressing issues. The HRCCC has also been fortunate in having only two Catchment Coordinators in its lifetime – both being very capable and the first being there for 4 years. This situation is in sharp contrast to many ICM initiatives in Queensland where, in the 2-year period 1995 to 1997, there was less than 25% of both Catchment Coordinators and Chairs being retained.

Participants of a community forum held in 1995 in the catchment identified Government as being the hardest to get on-side and committed to ICM. Besides providing continuity in support through providing resources (eg. funds, personnel, technical advice) to effect action, a key requirement from government for successful ICM is the commitment of top officials to ensure effective participation by agencies as well as the continuity of political commitment (ie. of all tiers of government).

Qualities of ICM personnel

In 1998, based on their experience in ICM, HRCCC members identified the important qualities of a Catchment Committee member as: open-minded with a broad vision (including benefit of the community at heart, recognises needs of others, sees other point of view, prepared to compromise, able to give a little); genuinely concerned about NRM/ICM issues; good communication skills and can contribute to group discussion and take information back to their own stakeholder group; understands and is prepared to put forward the views of own interest group; good interpersonal skills (including willingness to listen to others views); vast local experience and aware of what is going on in the catchment; progressive attitude (including willingness to accept change, learn things all the time); and with available time to commit to ICM.

Members also identified a number of important qualities of a Catchment Coordinator as: experience with and knowledge of NRM issues and agricultural systems (ie. technical skills, understanding across disciplines, problem solving, eye for myths and legends); good communicator; highly developed interpersonal skills and able to handle a diverse group of people; broad minded with an ability to look at the big picture; tactful; confident and prepared to stand up and be accounted for; good conflict resolution skills; and a good listener.

5.3.6 Opportunities for formal access by wider community

The state ICM program is community based and, at least formally, provides adequate opportunity for involvement by all in the community. This has mostly been achieved through representation of groups of specific interests including industry and conservation. The pattern of actual access differs widely between regions.

However, there is a lack of a clear mechanism for initiating involvement in ICM outside the formal representative structure of the HRCCC. Importantly, through this formal mechanism a sub-committee of the HRCCC for the upper catchment involving 16 representatives of a broad range of stakeholders from the community, industry and government was formally formed in December 1998 to discuss and raise issues of particular relevance to the upper catchment. Community members in the upper catchment felt that they were not equally represented on the HRCCC (only one representative), there was a predominant focus of the HRCCC on issues affecting the lower floodplain and that there were logistical difficulties relating to the long distance between the upper and lower catchments to attend meetings (ie. a 4-5 hour drive). This new group is also facilitated by the HRCCC's Coordinator and regularly reports to the HRCCC. The upper catchment also maintains a representative on the HRCCC.

5.4 Adequacy and Equity of the Herbert River ICM Processes

5.4.1 Knowledge and expectations of the process by stakeholders

The 1995 and 1998 Community surveys showed that awareness levels of ICM, the HRCCC and its main purpose were relatively high (42%, 42% and 39% respectively). These could be improved, particularly in urban areas and the upper catchment. Detailed awareness of ICM's effectiveness however was low. Nevertheless Herbert community priorities for the role of ICM were identified in 1998 as:

- working closely with local government;
- encouraging joint projects;
- raising local awareness; gaining better understanding of environmental problems;
- developing solutions for these problems; and
- encouraging research.

Within the HRCCC there has been a clear improvement in member's awareness of catchment issues and expectations of ICM. Initially, the HRCCC had a focus on undertaking on-ground activities and works. Now members see their role as being more strategic and influential on others to undertake projects and catchment management planning processes.

5.4.2 Degree of coordination of resources to address catchment issues

Coordination of government resources to address issues of community conflict relating to land and water resources management from a whole of government approach has consistently been seen as a major blockage to an effective ICM process. Experience with major resource management issues with significant social conflict in the Herbert River catchment supports this concern (eg. the failure for over 5 years to reach agreement on the Sugar Industry Infrastructure Package with the local sugar industry bodies; Mahogany Glider conflict at Pomona; and fish kills controversy).

The HRCCC has adopted a lead role as the key broker in the catchment for external funding of community projects to address natural resource management problems in the catchment. For example, the HRCCC acted as the broker and coordinator for all new proposals from the catchment submitted for federal government funding through the National Heritage Trust initiative. This is providing the catalyst for community activity in federal and state-funded natural resource management initiatives in a more strategic way than in the past.

The 1998 Community survey identified that residents in the catchment considered coordination of efforts by ICM and local government as extremely important, ie local government planning taking ICM into account and a local government role in ICM. While Government agencies were perceived to often give conflicting information on land and water management issues. It can be difficult for community members to obtain information from government agencies and also a lack of internal communication often leads to mixed messages emanating from the Government to the community.

The Communication study found that a matrix of contacts existed between key stakeholders of ICM in the Herbert River catchment. In particular, there was direct contact and therefore linkages between all major groups of stakeholders. Therefore the basis for a communication network was present, although the strength of links was variable. Most communication was categorised as "mutual" which indicated that the informal contacts made during meetings and other gatherings are important to the functioning of ICM. The predominant reasons

supplied by respondents for their communication, and the primary contacts associated with those reasons, were:

- policy/planning/decision making with local government and Brisbane state government;
- environmental issues with local government;
- research/project work with the HRCCC; and
- follow up on catchment/strategy issues with the HRCCC.

5.4.3 Degree of motivation, commitment, cooperation and support for the process

State-level

CCCs have to contend with low awareness in the general public about resources management issues and a general resistance to external intervention. A surprising, consistent and very significant result from the state-wide survey of Chairs and Catchment Coordinators was the universal view that there is too much government regulation. People in rural Australia resent government controls on land use whether they arise from World Heritage listing and conservation generally, tree clearing regulations, water and land management regulations, changes to land tenure and land rights laws. There is a clear message here that landholders in particular will resist any solution to ICM problems that involve state and national government regulations.

Perhaps for the reason that ICM requires a complex process of learning, there was a disturbing low level of satisfaction with progress on ICM amongst the respondents at the state level (especially the Coordinators). Less than half the coordinators in 1995 were satisfied with progress in their CCC and three were unsatisfied, one to the point of resigning over it. The Chairs were generally more satisfied with progress, and while none was actually dissatisfied, almost half were ambivalent. Although satisfaction levels and support improved during the period 1995-98, they remained relatively low.

Most Chairs and Catchment Coordinators believed that support from the general public was low due largely to the public's low level of awareness about natural resource management issues. Importantly only 35% of Coordinators are satisfied with the acceptance of their CCCs by other government agencies. Chairs were more positive on this point. A wide range of factors generate support from industry and community organisations, especially the efforts of the CCC Chairs. Respondents however were commonly unhappy with political support and of the acceptance of local government at both the agency and political levels. As in many other results of the survey there are regular exceptions to common patterns. Other community groups rating as important include Landcare groups, Recreational fishing, Commercial Fisherman's Association, Aboriginal Council, Sugar Industry (Mills), Tourism and environmental organisations.

Clearly and not surprisingly, the dominant effective partnership is between the CCCs, the DPI (now DNR) and rural producer groups. Coordinators were not in general impressed with the involvement of the Departments of Lands, Local Government and Planning or Environment.

The Herbert Catchment

The membership of the HRCCC has ranged from between a total of 13 and 17 representatives since it was established in 1993. There has been varied commitment to the ICM process by these representatives over time (ie 1993-98) as reflected in attendance at monthly meetings (eg. about 9 members on average attend each meeting). The representatives of the sugar industry/agencies, local government, upper catchment and

Landcare have been the most consistent participants, while the Conservation representative, local Development Bureau and a local community group had the lowest involvement.

The time commitment of HRCCC members to ICM matters has increased between 1995 and 1998. Until 1997, the majority of members (over 70%) spent less than 10 hours per month on ICM matters but, by 1998, nearly 50% of members identified a commitment of more than 16 hours per month to ICM.

HRCCC member's motivation for involvement in ICM was identified in 1997 as being personally rewarding (eg. because they could contribute to the community), they cared about the environment, and that they could meet other members of the community who could influence resource management decision-making. However, in some instances (eg. contentious or 'hot' issues), some members have appeared to be protecting their own sectoral or personal interests rather than acting for the betterment of the overall catchment community and the sustainability of resource use. Most members have become positive over time (1995-98) about the HRCCC's achievements and the group's overall direction. They also perceive an improvement in the level of community support for ICM from a low to a moderate level. However, there are some concerns with the slow rate of progress and in particular the slowness of the overall process in general.

Local government involvement has been perceived by the HRCCC to be of critical importance to the success of ICM in the Herbert, and that, effectively, ICM could not really function well without that involvement.

At the Herbert catchment community level, the majority of residents surveyed in 1998 who were aware of the HRCCC supported its general direction and effectiveness and were satisfied with the speed of its progress. Personal benefits of involvement in group activities were perceived by 31%, preparedness of respondents to become involved in land and water issues was around 40%, preparedness to assist in local projects was around 42% and intentions to become involved were around 22%. The level of involvement in local community groups or associations was 44% in the 1995 survey and 32% in 1998. Most respondents agreed there was an urgent need to address environmental problems, signifying the basis for a high degree of motivation to deal with problems. Time was an important factor preventing involvement in local community issues for 36% of respondents. While support for ICM was implicit in the high degree of support shown for all of the proposed activities of ICM.

5.4.4 Efficiency and effectiveness of process

HRCCC Achievements

The major achievements of the Herbert River ICM process as identified by HRCCC members can be summarised as:

- Providing a forum that brings very different people in the catchment together to exchange ideas and providing a catalyst for change;
- Developing a Herbert River Catchment Management Strategy (CMS);
- Supporting a range of projects on natural resource management;
- Raising community awareness of catchment issues; and
- Gaining legitimacy as an influential group on NRM in the catchment.

The present value of the costs associated with the establishment and on-going administration of the HRCCC over a period of 20 years is estimated to be approximately $974,000. To offset this cost, the HRCCC has undertaken a number of specific activities in the catchment. These activities have been funded from both the public purse as well as from the catchment

community. They relate to: (i) management of riparian vegetation, (ii) preservation of natural habitats, (iii) management of drainage problems, (iv) management of wetlands, (v) management of acid sulfate soils, (vi) strategic river bank protection and (vii) the stabilisation of relict mining dams. These activities have the potential to significantly improve or preserve the condition of natural resources in the catchment.

Catchment Management Strategy
Due to a lack of continuity and security of funding for ICM, HRCCC activities and progress has been largely opportunistic and dictated by state and federal government political imperatives and opportunities, funding options and technical understanding rather than by the priorities identified in the Herbert Catchment Management Strategy (CMS). Thus, for example, action has often been dictated by NHT funding priorities and opportunities as expressed by the Regional Advisory Panel rather than the priority needs expressed by the HRCCC. This has meant that the HRCCC has been fairly reactive in its approach in implementing the CMS (rather than setting its own agenda), and that it is tending to follow a circuitous course towards reaching its stated goals.

The HRCCC released a draft Herbert River Catchment Management Strategy in May 1996 for public comment that was important to HRCCC members because (a) it provided a future direction to the group and a guide for future actions (e.g. identified issues, prioritised needs, identified stakeholders and their roles, provided a reference point to start from); and (b) it helped to get resources and support for ICM in the Herbert (e.g. funding for Catchment Coordinator and natural resource projects, and gaining in principle commitment of State Government to undertake projects). The Catchment Management Strategy development process proved to be valuable to the HRCCC members involved because (a) the process was seen to be inclusive and transparent within the Committee, (b) it raised awareness of issues and others viewpoints within the HRCCC membership, (c) it identified areas of agreement, and (d) helped to focus the HRCCC and establish an overall direction.

The issues relating to the development process for the catchment strategy are the lack of resolution on some key issues, speculation whether it will assist in resolving resource management conflicts in the catchment, and the apparent failure of the strategy to have a significant impact on what the Committee was actually doing to-date.

Progress
The HRCCC in general takes a consensual approach to decision making or at least an approach based on a process that seeks consensus. However, this has meant that on some issues in the catchment, the HRCCC has taken 'minimal' decisions rather than perhaps what might be called 'better' decisions for the catchment. In addition, this approach has kept some more contentious but critical problems from being addressed by ICM (eg. drainage coordination).

From 1995 to 1998 there has been a general improvement in the overall level of satisfaction of HRCCC members with progress. However they identified a number of ways that could improve their performance (including the level of stakeholder group involvement in the HRCCC) by:

- Raising the profile of ICM and the HRCCC in the community through more targeted publicity and promotion of the HRCCC and its activities;
- Ensuring the security of tenure for a Catchment Coordinator and the adequacy of funding for HRCCC activities;
- Maintaining legitimacy through broad stakeholder representation on the HRCCC (eg. direct involvement of local business through the Chamber of Commerce; more active

involvement of environment interests; representation of government technical expertise from the EPA and DNR);
- Greater use of proxies by representatives;
- A more proactive (versus opportunistic) approach; and
- More effective government agency involvement in the ICM process (including government agencies being required to consult with the HRCCC on all their programs in the catchment).

The HRCCC is constrained in undertaking its roles both financially, in terms of funding to carry out specific activities, as well as institutionally, in terms of its legislative or statutory power to regulate resource management. In particular in 1998, HRCCC members considered that the implementation of ICM in the Herbert River catchment was difficult because of the large size of the catchment, the lack of financial resources within the community (particularly in the upper catchment), the lack of cooperation between State government agencies, and the lack of coordination between state government agencies in addressing issues.

Communication
Communication on NRM relies predominantly on existing social networks. Local media is also a highly important source of information for a community.

In the communication study, with the exception of local landholders, most perceived their communications in relation to ICM to be satisfactory. Satisfaction was highest, however, for communication with the HRCCC and local government, which indicates a greater satisfaction when communication was with local bodies. In general, outcomes from communication were very positive, the most commonly identified being progress on issue, understanding of issues, information exchange, resolution of issues/decision, gained information, changed their outlook, specific action taken; and coordinate/collaborate.

Information needs
In principle, in order to be successful, an ICM initiative has massive information needs from biophysical through socio-economic to procedural. However in practice in the Herbert River ICM process, most information sharing, management and analysis has been informal and verbal through Committee meetings, presentations by researchers and special interest groups and so on. The Catchment Co-ordinator did circulate information to HRCCC members and their has been exchange of information between members at meetings, but most data access was reactive. Information was mainly pushed out to the community via the media. Inadequate access to biophysical and socio-economic information was not perceived to overly constrain the HRCCC's activities, although inadequate procedural information probably did.

The HRCCC continues to see the value of information and push for support for information-based programs. Thus, the HRCCC played a role in the establishment of the Herbert Resource Information Centre (HRIC) but has, in practice, itself made little use directly of the resources available through the HRIC. Local knowledge and expertise is a primary source of information applied within the ICM process. This is consistent with the nature and intent of ICM. Major ICM-based initiatives in the formal collection, collation and management of information relevant to the ICM process seem both inappropriate and unrealistic.

Importantly, the specific information needs facing the ICM initiative in the Herbert have been unpredictable, or at least difficult to predict. Thus, the Committee's information requirements have been context specific in response to changing priorities and circumstances

in the catchment. Furthermore, the information requirements have changed with the state of development of the ICM initiative and the maturity of the processes underpinning it. The HRCCC therefore has had to be adaptive and responsive and, despite the strategic nature of the Catchment Management Strategy does not have the resources or mandate to plan major initiatives, whether on-ground or in relation to the design, collation and management of key natural resource management data. As a consequence, ICM in the Herbert has relied predominately on the corporate knowledge and expertise of members of the HRCCC and opportunities to access additional expertise from others on a needs basis – including researchers and State Government resource managers.

5.4.5 Equity and procedural justice and perceptions of trust in process

Difficulties of ICM

In the state-wide survey, Coordinators believe that some of the most significant difficulties for ICM are due to the wide variety of beliefs amongst CCC members; a perception that the program has been forced on the catchment by the State Government in communities without financial resources to respond, and a lack of trust in the public in government sponsored initiatives. The Chairs hold similar views differing significantly as a group only in relation to the significance of the wide variety of beliefs and values of CCC members and to a lesser extent on the difficulties posed by the large size of catchments. Both groups believe that the CCCs have the important groups represented. There are some potentially fatal problems identified here, although many can be overcome in time as the ICM process matures and achieves ownership and clearer common perceptions.

In the Herbert Community survey in 1998, some of the major difficulties in managing land and water were seen to be caused by slow government strategies, slow reactions of government to new problems, and a low trust of government programs. Importantly, respondents did not find government strategies to be highly useful to them on a personal level. Many respondents felt the government needed to give more resources to voluntary groups and give incentives for landholders to address environmental issues.

In the Herbert River catchment, there has been a clear shift of opinion by HRCCC members over time (1995-1998) from agreement to disagreement on whether the ICM implementation process was difficult because of:

- the public's lack of trust in state/local government-sponsored initiatives;
- the absence of a single acute resource management problem (eg. of the magnitude of salinity); and
- the wide variety of values and beliefs among HRCCC members seriously detracted from an effective level of cooperation developing; or

In 1998 they also clearly disagreed that ICM was difficult because of a community perception that ICM has been forced on the catchment by the state government. These changes suggest both an increase in the confidence of HRCCC members in the ICM approach and a greater acceptance/tolerance of the diversity of views amongst members.

There is also a clear perception within the HRCCC of the importance of procedural fairness (eg. in land allocation and planning decisions) and the need for better incentives for landholders and greater resourcing of community groups for catchment management.

Overall HRCCC members considered that all parties (ie. all three tiers of government, industry and individual farmers) should contribute to catchment management. However on average members felt that the Commonwealth and State Governments should contribute considerably more than other parties (ie 30% each), local government (17%) marginally more

than industry (14%) with individual farmers contributing the least (10%). The community survey revealed a very similar order and distribution of contributions, except that it was perceived that federal government should contribute more (ie. 34%) than state government (27%). In sum, the overall system was perceived to be reasonably fair and there was an overall preference from all stakeholders for a partnership approach between government, industry and the community rather than responsibility going primarily to government or the community.

All of the potential benefits resulting from investment in ICM activities are not equitably distributed among those incurring the cost and those who do not contribute to the cost can not realistically be excluded from enjoying the benefits. In effect, the positive externalities resulting from on-farm investment in improving the condition of the environment cannot be internalised. In an economic climate where the financial viability of farmers is generally deteriorating, the ability, and therefore the willingness, of farmers to invest in improved resource management is likely to be considerably reduced.

For the successful implementation of a number of activities undertaken by the HRCCC, notably management of riparian vegetation, management of acid sulfate soils and management of wetlands, private property owners would incur considerable financial expense, but many of the benefits accrue to the community in general. Specifically the *potential costs* of the activities undertaken by the HRCCC are incurred by both individual landowners (eg. opportunity cost of land, restoration or remediation works, materials and construction costs, in-kind contributions of time and equipment) and the catchment community (eg. cost of reparation or remedial works, construction costs, wages and publicisation). Similarly *potential benefits* will accrue to both landowners (eg. avoided costs of lost production, aesthetic attraction of improved habitat, reduced production costs, improved water supply) and the catchment community (eg. improved downstream water quality, retention and improvement of natural habitats, reduced social conflicts, reduced litigation and transaction costs, aesthetic benefits, avoided costs of resource degradation and damage to infrastructure).

5.4.6 Influence of ICM in the catchment

Community Involvement

For the major natural resource management activities in the catchment (ie. land use planning, environmental protection, land clearing guidelines drainage coordination), HRCCC members consider that that there should be much greater community influence in decision-making than what occurs at present. However, they also consider that the level of community involvement/public participation in decision-making needs to vary depending on the particular issue of concern between 'Consulting', 'Involving', and 'Shared planning and decision making'. Importantly, they were not in support of the community or the government alone making decisions on these issues. Rather decision making should be a partnership between government, industry and the community.

The ICM process has contributed to increased community awareness and involvement in natural resource management issues in the catchment. In particular, the presence of the HRCCC and its activities has helped to focus community attention on natural resource management issues. However, to-date it has not been possible to assess the extent this awareness has been translated into better land management practices by landowners.

Local Government Planning

The active involvement of local government in the HRCCC emerged as a key strategy for the HRCCC to influence decision-making processes in the Herbert particularly relating to land

development planning. Local government is an important information source for the ICM process, it recognises HRCCC with its broad stakeholder representation as a legitimate referral and advisory group in the catchment, it is actively seeking HRCCC's advice on catchment issues, and it is seen as an important mechanism for providing ICM with "teeth for implementation".

ICM has had a substantial influence on local government in a relatively short period of time. Some of these changes include an improved awareness of ICM, better coordination between authorities in extending the reach of town planning to achieve ICM strategies as well as the actual implementation of ICM in the local planning scheme. Positive benefits also include improved communication between local government and previously unconnected stakeholder groups to provide a wider range of perspectives on resource management issues. Now local authorities in the lower Herbert are regulating land uses to achieve catchment management objectives. The upper catchment is significantly behind the lower catchment in terms of the understanding of planning and ICM issues, open communication between stakeholder groups and level of commitment to resource management.

Communication

In the Communication study involving key stakeholders of ICM in the Herbert, influence related to how much the communication was thought to have changed the outlook of those involved. Respondents reported the greatest change in outlook (for themselves and the contact) in communications with the HRCCC and with people on an individual basis. This is an important result to utilise in situations where attitude change is seen to be important. The main ways in which *respondents* reported that *their outlook had changed* were: gaining greater awareness, understanding or knowledge or to share what is happening and ideas. Areas in which *respondents* felt the *outlook of contacts had change*d were: understanding/knowledge; greater awareness; and acceptance of ICM.

The Media

The dominant community values regarding natural resource management and integrated catchment management as presented in the local newspaper for the lower catchment, the Herbert River Express, were life support values. The sample of articles exhibited no intrinsic values held about river/stream water management issues in the Herbert River Express. Life support values were found in 65% of the articles, economic or utilitarian values in 26% and aesthetic values in the remaining 9%. These life support values focus on issues of flood mitigation, water course management and ensuring the viability of the sugar industry, but more in terms of the way of life it represents. That is, the identity of the district as a sugar cane production area is strong.

The term *'Integrated Catchment Management* 'specifically appears from mid 1996 and is stressed as an important issue for the community. The HRCCC is portrayed as a contributor to achieving the goals of productivity, development and sustainability of the local community. The media representation of the HRCCC is positive and is clearly linked with integrated catchment management in almost all articles involving the HRCCC. Extrinsic, 'life support' values were the predominant values presented in natural resource management issues in *The Herbert River Express*. The community's identity and well being is dependent on the health and sustainability of their natural resources, and is clearly evident from the manner in which the local newspaper presents issues.

5.4.7 Agreed responsibilities and roles

The Catchment Coordinating Committee
In 1998, HRCCC members prioritised the roles for ICM in the Herbert River catchment (in priority order from very high to moderate) as:

- Encourage Local Government to take an active role in environmental management issues
- Encourage joint projects between community, industry and state and local government
- Provide a continuing source of advice to local government on catchment issues
- Encourage discussion between community interest groups on environmental issues
- Raise the level of local awareness and knowledge of environmental issues on the catchment
- Encourage coordination of state government programs
- Encourage research
- Develop solutions for, and better understanding of, environmental problems in the Herbert catchment.
- Undertake specific on-ground projects with other bodies.

Respondents reported a wide range of activities reflecting largely the age and maturity of the CCCs. Some have been in operation effectively since 1988, whereas some are still in the process of being formed. A progression of activities can be recognised from organisational activities - public awareness and involvement - issues generation - catchment planning - technical studies. The range of activities are all envisaged in the Queensland ICM Policy which now requires the preparation of catchment strategies before funding is provided for projects (QDPI 1991)

Perhaps the most interesting feature of these results is the wide spread of opinions as to the purpose and operation of CCC among the various individuals and catchments in the State. Coordinators for example are not in clear agreement as to what they and their CCCs should do - some believe that Coordinators and CCCs should coordinate activities and give advice to landowners, others do not. Significant differences in opinion exist as to whether the objectives of the local ICM programs are clear to all members and to the level of participation of their CCC members in meetings. They too do not always agree as to whether the CCC should give advice to landholders.

There has been a significant increase in the number and diversity of projects engaged in by the HRCCC - from a tin mining dam inventory in 1995 to include by 1999 a joint project with the HRIT on bank stabilisation, the owl nesting box program, a Catchment Atlas, several restoration and revegetation projects, riparian vegetation mapping study, weed control activities, a riparian "community" forum, acid sulphate soils awareness, and a cooperative project to link ICM and local government planning.

While the majority of members agreed that an HRCCC member's role is to represent the resource management views of their constituent group at meetings, there was a divergence of opinion on whether an HRCCC member's role is also to provide either their personal views on resource management issues or a catchment-wide perspective of natural resource management issues at CCC meetings.

The reliance on local expertise and knowledge has clear implications for the management of ICM to ensure its effective contribution to improved natural resource management including:

- the HRCCC needs to provide not only for effective representation of key stakeholder groups but also to provide as broad a base of expertise locally available as can be achieved.
- The Catchment Coordinator must have a key role to play in providing a stream of information to Committee members so that they can continue to expand their expertise in relation to ICM relevant issues.
- Relevant State agencies and other key stakeholder groups have a clear responsibility for effective communication of available information to members of the CCC.

Local Government
Since the inception of ICM in the Herbert catchment, a significant increase has occurred in the role and responsibility of local government in catchment management and planning. This has emerged through (a) an influential role based on active membership on the HRCCC and (b) regulatory and statutory processes (including major changes to the Hinchinbrook Shires Planning Scheme and HRIT activities).

Industry
The industry must take a leadership role if the importance placed on the environment and sustainability is to be realised. Present Conditions of Assignment suggest that failure to comply with restrictions may see the award revoked. This places increased responsibility for enforcement on the Local Board (Cane Production Board). These are new roles for these organisations. Leadership by the Local Board (Cane Production Board), CANEGROWERS and mills can establish an expectation that compliance is expected and required by all farmers. This type of widely based, voluntary action could engender very strong public support. ICM clearly has a role to play here. In its absence, public support will be nurtured through compliance and enforcement. The recommended audit should provide insight into both voluntary compliance and enforcement measures. Those findings will reflect on the leadership qualities of the sugar industry, and identify the need for evolutionary and revolutionary change in its management of natural resources.

The Community
Members clearly feel that the community also had a responsibility regarding land and water management and that ICM should remain a voluntary activity by community members. Similarly, many community members felt that individual landholders had a role to play in land and water management and that there were ways they and their local communities could assist. To do this, they saw the need for support from the government in terms of resources and incentives. Overall, there was a high sense of self responsibility for dealing with land and water management issues.

5.4.8 Integration (of processes in structure and context)

The system of organisational structures and linkages on natural resource management in the Herbert River Catchment has evolved to be more coordinated and more inclusive of key stakeholder groups since the establishment of the HRCCC in 1993. Significantly, the HRCCC is providing a key integrating and informing functional role on NRM within this system. In particular, CCC meetings provide a forum for networking and responding to community needs, a central 'pool' of information on the catchment, and a link between local government, state government agencies and various industry and community interest groups that did not exist before ICM.

Despite the need for ICM to integrate across government agencies the state-wide survey of Catchment Corrdinators and Chairs revealed there is a clear absence of a "whole of government" approach, commitment or involvement in ICM. State politicians seem to ignore ICM and there has been ineffective, even counter productive involvement of some

state agencies. While there was no reported hostility from politicians, agency staff and community groups, it seems that CCCs must create these supporting links themselves with little support from outside.

Similarly, concern was continually expressed by some HRCCC members of the on-going failure of State Government agencies to effectively use their statutory powers and authority to substantively address land and water development and management through a whole of government approach within the catchment (eg. land conversion from grazing to intensive agriculture, caneland expansion through tree clearing, and construction of levees on the floodplain). State agencies continue to make decisions on NRM issues in the catchment independently of each other and local interest groups and often fail to advise or consult local agencies or groups on new programs or activities to be commenced in the catchment. For example, some important catchment initiatives (eg. Water Infrastructure package) have 'by-passed' ICM.. In particular, the apparent lack of sharing of information between agencies has led to contradictory or conflicting information being presented to the community by different government agencies with regard to important issues in the Herbert. This situation has often exacerbated the community conflict.

There is a strong and complementary relationship between Landcare and ICM in the Herbert River catchment. The Catchment Coordinator also acts as the Landcare coordinator and has encouraged the re-establishment of a group in the lower catchment.

On the basis that establishing effective communications on ICM is a fundamental element of systems implementation in ICM, understanding the communication network is essential. Most communications amongst stakeholders of ICM in the Herbert were found to be *mutual* (through a mutual contact, meeting or other event) which indicates the importance of mutual or informal ways of meeting to the functioning of ICM.

5.5 Methods for Supporting ICM

In the course of the evaluation of the ICM process in the Herbert River Catchment, a range of different methods for supporting ICM implementation processes were identified and trialed. These methods and their potential role in ICM are briefly outlined below.

Evaluating ICM Policy Initiatives
The challenge to create policy processes, institutional arrangements and NRM practices that can contribute towards achieving sustainable and equitable resource use outcomes requires rigorous evaluation as part of the change process. Monitoring and evaluation is fundamental to identifying change, supporting an adaptive approach that is flexible enough to meet the challenge of this change, and enabling learning at individual, community, institutional and policy levels. Natural resource management policy and planning initiatives need to be evaluated as a system that links the initiative's objectives and rationale to performance 'on the ground'. The integrated systems evaluation strategy developed by the project provides:

- a basis for an integrated evaluation of the different perspectives (i.e. social, economic, environmental, policy and institutional) on the performance of the policy process;
- a framework for guiding its implementation; and
- a rigorous basis for synthesising findings (Bellamy *et al.* 1999a, 1999b).

Catchment Atlas
The Herbert River Catchment Atlas (Johnson and Murray 1997) provided essential natural resource information for supporting and promoting ICM in the Herbert River Catchment. The Atlas has been distributed widely by the Herbert Catchment Coordinating Committee and used as an important means of raising awareness of catchment stakeholders (eg. high

school children, local government and cane farmers) of the natural resources and related issues of the catchment.

Assessing land use change

ICM processes frequently are required to deal with intractable issues that are embedded in past land use decision making behaviour and land management practices. In facilitating an effective ICM process, Catchment Committees and supporting government and industry agencies should place a priority on the collection of essential natural resource use data to understand past and present resource use. In particular, a focus on providing data that enables ICM groups to understand the spatial and temporal distribution of key indicators such as land use change and agrochemical usage is essential. Doing this helps to raise awareness of catchment resources and the potential implications of land management practices, and thus informs the debate on the nature and extent of both future resources use and the level of behavioural change required to meet these aspirations. It has a valuable bi-product of providing a vehicle for cooperation as was the case with the HRIC.

Assessing local knowledge

Investigation of changes in local knowledge over time provide a powerful tool for evaluating some of the key impacts of an ICM process (Walker and Meesham 1999). In particular, the assessment of local knowledge provides an effective means of identifying gaps in local understanding in relation to management options and in evaluating fundamental assumptions that underpin local management practices and may thereby provide an appropriate basis for prioritising research. An approach based on 'landscape literacy' allowed the characterisation of resource user perceptions and to determine significant differences amongst stakeholders to the principles underpinning ICM.

Institutional analysis

Regular monitoring of the evolving legislative, administrative and financial arrangements for ICM and related policy areas (including natural resource, environmental, planning legislation and programs at the local, state and Commonwealth level) developed an understanding of the broader policy, administrative and financial context impinging on the Herbert ICM process. The Herbert is not an island. While local commitment drove the HRCCC, without local and state government support little would probably have been achieved. Queensland's ICM policy remained unchanged for a decade, but erratic finances, advent of the project funding opportunities of the NHT, emergence of improved conservation and environmental programs all played a critical role in what happened in one catchment.

Assessing organisational linkages

A broad range of community, industry and government organisations with some level of responsibility or an interest in resource use management and planning function in catchments or at a regional level. The system of organisational structures and linkages is a critical mechanism for facilitating the exchange of information and supporting a coordinated and inclusive approach to catchment management decision-making (Bellamy and Horsley 1999). An assessment of the change in the system of organisational structures and linkages on natural resource management provided an indicator of progress on ICM and a basis for monitoring a key factor underlying the effectiveness and fairness of the outcomes of the process.

Monitoring community attitudes and values

Attitudinal surveys of catchment residents extend social profiles beyond a demographic focus to perceptions, a better understanding of tractability, identifying how effective ICM is perceived to be, and identifying priorities for investigation (ie. where to focus effort in regard to specific issues, such as opportunities for use of the media). The community survey

examined landholder's behaviours and attitudes toward land and water management in the Herbert River catchment, and provided an understanding of social factors that might influence the implementation of ICM in the Herbert catchment (McCreddin and Syme 1999a, 199b).

Assessing communication networks

The effectiveness of communications provides an important measure of whether coordination is happening, and also identifies where there are gaps in the system and the effectiveness of specific/different linkages on ICM. Measuring this effectiveness should be a routine part of any ICM evaluation, particularly in the early stages. A simple questionnaire investigation provided a methodological basis on which to evaluate the adequacy of communications at a system level for ICM (McCreddin *et al.* 1999). The study also demonstrated the feasibility of monitoring communication networks and their adequacy over time.

Media representation of NRM

The use of a media as an unobtrusive source of data for research on the social context is becoming more popular as the data is becoming more readily available in 'on-line' databases. The analysis of newspaper coverage provides a useful and unobtrusive means of gauging community values about natural resource management issues (Cottrell and Rowbotham 1999). The method of content analysis that focuses on the article as the unit of analysis allowed a greater consideration of the broader social context within which the issues occur.

Economic assessment of ICM

Cost-benefit analysis (CBA) could provide a consistent and reliable evaluation of the ICM organisation that addressed the social costs and social benefits arising from the implementation of the policy initiative although formidable problems of measuring intangible benefits make the ideal difficult to achieve. To undertake a CBA, a number of simplifying assumptions are required including those concerning the causal relationship between the activities of the ICM initiative and potential improvement in the condition of natural resources and about the shifting baselines for almost all variables – economic, environmental and social. While acknowledging the problems and limitations underlying CBA, it provides valuable information for an ICM organisation to guide the ICM implementation process regarding the efficiency of investment as well as the distribution of the costs and benefits from its activities (Robinson *et al.* 1998, 1999). These contributions relate to the resource management questions, such as the value of riparian zones or clean water and to the more obscure question as to the efficiency of Catchment Coordinating Committee processes themselves. For example, does the relatively small cash outlay on ICM, plus the larger in-kind contributions of members generate real benefits in resource use?

6. FACTORS INFLUENCING THE SUCCESS OF ICM IN THE HERBERT RIVER CATCHMENT

6.1 Importance of Context

Within the Herbert River catchment community, established social networks and interactions, societal values, legal policy frameworks and historical influences have shaped the human association with the natural resource environment and will inevitably continue to influence that association and pattern of behaviour in the future. At the time of inception of ICM in the Herbert River Catchment in 1992 there was a low level of awareness of natural resource management issues in industry, local government and the general Herbert catchment community except for the compelling issue of flooding and drainage. Linkages on natural resource management between state government, local government and industry organisations were non-existent. In general, there was even a lack of cooperation within and between government agencies or sections of departments and ICM was seen as an initiative of the Resource Management section of the Department of Primary Industries rather than a whole of government initiative. There was low industry awareness and commitment to the environment and resource management beyond immediate production impacts and a lack of incentives for industry to develop environmental objectives. In addition, understanding of the resources in the catchment was fragmented across a myriad of agencies with relevant technical information not widely shared or available in an accessible form to key stakeholders and decision-makers for addressing catchment issues.

Since the establishment of the HRCCC in 1993, ICM has been only one of many changes occurring in the Herbert catchment. The social, economic, institutional, technological and environmental context has evolved independently. Some of these external influences on the ICM process and catchment issues include an increasing commitment by state and federal governments to devolve responsibility for natural resource management to the local level, a sugar industry environmental audit, the introduction of the *Integrated Planning Act*, the establishment of the Herbert Resources Information Centre (HRIC), a State of the Rivers study of the catchment, the Mahogany glider controversy at Pomona, several highly publicised fish kills in floodplain rivers, and in general growing community awareness of natural resource management across the country. The tractability of catchment issues therefore has changed markedly during the life of the HRCCC.

The implementation of the ICM process in the Herbert River Catchment is context sensitive and a wide range of environmental, economic, social, policy/institutional and technological factors have influenced its implementation and impact (Bellamy *et al.* 1999a). Based on the evaluation of the Herbert ICM process presented in Section 5 of this report, the next section identifies the environmental, economic, social, institutional and technological factors that fostered and hindered the implementation of ICM in the Herbert River catchment.

6.2 Factors Fostering the ICM Process in the Herbert River Catchment

6.2.1 NRM Issue Characterisation in the Catchment

- Lack of accessible information and technical understanding of some of the key issues is not seen as an inhibiting factor in the Herbert River catchment. There are clear enough technical solutions to many of the natural resources management problems in the Herbert River catchment in some cases for decades and longer (eg. floodplain management, soil erosion control and acid sulfate soils). In addition there has been an emergence of a number of collaborative ventures between local government, industry and state and federal government agencies to improve the capture of relevant data on

NRM issues (eg. Herbert Mapping Project and a Catchment Atlas) and provide locally accessible mechanisms for integrating data and information delivery or service provision (ie. Herbert Resource Information Centre).

- Understanding the history of land use change within the catchment helped in understanding the causes of some issues, to identify the target/client group and helped also to target strategies to resolve the problem.
- Accessibility and availability of the local knowledge and expertise on catchment issues from a diversity of catchment stakeholder groups/interests represented on the HRCCC has been critical to successful progress in the ICM process.
- Successful ICM requires a high degree of community awareness that there are important environmental problems that require timely action. Although awareness of ICM in the Herbert community is comparatively modest, it is clearly improving from a low base.
- A high level of support for community responsibility was evident within the Herbert River community by general agreement that many environmental problems come from the way individuals manage their properties. This is an advantage for ICM in gaining community participation but it will be very important for ICM to recognise the need for behavioural change at property level when working with the community and developing policies.

6.2.2 Implementational Context of the Herbert River ICM Process

- The inception of ICM in the Herbert was a voluntary process that was actively negotiated by key actors in the catchment in local government and industry organisations. As such it has attained a certain degree of credibility within the catchment because it has not been seen to have been forced on them by government or other 'outsiders'.
- The social context in which an ICM initiative operates can have an important influence on its progress. Importantly how resource management issues and ICM processes in particular are presented in the local media can reflect, and in turn, influence a community's values on these issues. The local newspaper for the lower catchment community has increased its presentation of natural resource management issues (ie. in terms of the number of published articles on NRM and the prominence of articles) since 1995. It has also identified the ICM process to the Herbert community and emphasised the importance of community involvement in natural resource management decision-making.
- There has been a broadening of the focus of local industry organisations in the catchment from an almost exclusive concern with productivity and efficiency issues and impacts at the inception of ICM in 1992 to a recognition and even promotion of the importance of natural resource management to the long term sustainability of the industry.
- Involvement in ICM is facilitated by an appreciation of personal benefits from becoming involved in group activities to help manage land and water. This was demonstrated by positive attitudes towards group involvement in the Herbert and the reported group activities of a substantial proportion of the community.

6.2.3 Policy Frameworks and Institutional Frameworks for ICM processes

- The long term consistency of the goals for ICM and commitment of its primary promoter, the Queensland Department of Natural Resources, has contributed to the survival and success of ICM in Queensland. A critical factor is the level of commitment through funding and staffing. ICM has survived using a mixture of state program and core funds and, most importantly through the National Landcare Program and its successor, the Natural Heritage Trust. Most significantly, the host Department, DPI

then DNR (from 1995), provide in-kind support centrally and in the regions in the form of staff time and operational expenses.

- At the State level, acceptance of the need for better coordination of government programs has assisted ICM. This has occurred through the acceptance of the need to develop regional resource management strategies (few have been finalised at time of writing), the increasing adoption of the *Integrated Planning Act 1997* as a framework for local and regional integration of planning and development assessment and, less tangibly, the expanded understanding in State Government of the demands of integration to achieve sustainable development.
- The ICM program in Queensland has been experimental, evolutionary and incremental. The early pilot studies informed the expansion and maturing process to the point that over 35 catchments are now formally included in the program. Catchment Coordinating Committees are formally endorsed by the (now) Landcare and Catchment Management Council. There is a growing group of experienced facilitators and catchment coordinators who contributed to this effort. Since 1995, the Queensland ICM program has organised a number of conferences and forums – especially targeted at the chairs of committees and the catchment coordinators with first hand experience of the operation of the program. They reviewed achievements and shared experiences as a learning opportunity for those catchments representatives and facilitators without the same level of experience.
- State seed money for the HRCCC (eg. for organisational start-up and development, capacity building, general operational costs, and leveraging other sources of funding for undertaking projects) was crucial to making the local/community side of the partnership work.
- Project funding successes (e.g. NLP/NHT), the appointment of an innovative and active Chair of the HRCCC, development of strong linkages with Local Government and the Herbert River Improvement Trust (HRIT), collaborative projects with other local stakeholder/interest groups, improvement in general in the cooperation amongst collaborating government agencies on ICM, and the appointment of additional DNR extension staff in the catchment are key factors raising the profile of ICM in the community and gaining a certain degree of confidence in the process and credibility amongst stakeholder groups.
- Skilled committed and long term staffing of the HRCCC has been critical to an effective and influential ICM process. In particular, a well funded Catchment Coordinator was essential to "drive" the process and perform administrative and other "burn-out" producing tasks (eg. communication/media, grant writing, coordination of activities).
- The HRCCC's representational structure and the perceived inclusiveness of the key catchment stakeholders on the committee has been important to ICM gaining credibility with other groups and processes in the catchment. In providing a representative community forum, the HRCCC has facilitated (a) exchange of information between stakeholder organisations on NRM issues, (b) the development of an appreciation of other's viewpoints, and (c) a more informed debate on catchment issues.
- There is a strong and complementary relationship between Landcare and ICM in the Herbert River catchment. The Catchment Coordinator also acts as the Landcare coordinator and has encouraged the re-establishment of a group in the lower catchment.

6.2.4 ICM Processes

- Increasing community awareness, concern and commitment to improving natural resource and environmental conditions is a major challenge for ICM in the Herbert River catchment. The acuteness or perceived social importance of the resource management problems and the ability to link these problems to ICM related solutions

(eg. habitat protection, water quality) have helped ICM gain a certain degree of legitimacy in the community.

- There has been a clear improvement in HRCCC member's awareness of catchment issues and expectations of ICM. Initially, the HRCCC had a focus on undertaking on-ground activities and works. Now members see their role as being more strategic and influential on others to undertake projects and catchment management planning processes.
- Achieving a truly representative ICM process is in part dependent on the identification of an appropriate "scale" for the ICM initiative, ie. one that is relevant to the key catchment management problems and meaningful to the local "community of interest". With a clearly differentiated upper and lower catchment context (socially, topographically and economically) in the Herbert River catchment, the formation of a new sub-committee in the upper catchment provides the basis for a more inclusive and integrated approach to catchment problems that was not perceived to be the case with one initial lower catchment dominated HRCCC.
- HRCCC meetings have provided an effective on-going forum for networking and responding to community needs in the catchment. Importantly they provide a central 'pool' of information to address issues, and they operate as a link between local government, state government agencies and various catchment stakeholders groups for NRM.
- The emphasis of the ICM process on fostering a partnership approach between government and the community is seen as one of its key strengths. Many of the HRCCC members were not in favour of an approach to NRM issues and planning based on the community alone making the decision. Concern was expressed that decisions would be based on the vested interests of particular dominant stakeholder groups rather than for the benefit of the catchment community as a whole.
- There is strong support within the Herbert community for a close a relationship between local government and ICM. This has been established by the HRCCC.
- ICM has had a substantial influence on local government planning in a relatively short period of time in the lower catchment. Importantly, a partnership has formed between the HRCCC and local government with local government taking greater responsibility for the implementation of ICM principles and strategies. This partnership is the result of improved communication between the catchment committee and local government, a better understanding of the principles and objectives of ICM within local government and because of an improved recognition of the role of local government in the management of natural resources by the HRCCC. Importantly, local government involvement has been of critical importance to the success of ICM in the Herbert. Effectively, ICM could not really have had the impact that it has without this strong partnership with local government.
- It is important that the community understands and supports what ICM is trying to achieve. Community perceptions of the main purpose of ICM appear to match closely with HRCCC objectives and their priority activities.
- Particularly in its initial stages, ICM may be more process than product and therefore may lack tangible outcomes for a considerable time. Focussed high profile activities that are small, topical, measurable and have visible outcomes (eg. owl nesting boxes, Catchment Atlas) have provided a win-win illustration of the importance of NRM in the community and providing clear evidence of progress on ICM in the catchment. They have also been important in raising community awareness of the ICM process and fostering on-going commitment of HRCCC members to a slow evolving process.
- The HRCCC developed a lead role as the key broker in the catchment for external funding of community projects to address natural resource management problems in the catchment (eg. NHT). This has provided the catalyst for community activity in

federal and state-funded natural resource management initiatives in a more strategic way than in the past.

- An inclusive and participative approach to developing the Herbert River Catchment Management Strategy substantially raised awareness of issues and others viewpoints within the HRCCC, it identified that there were substantial areas of common agreement amongst stakeholders on many key issues where there was a clear divergence of opinion and helped to establish an overall direction for the group.
- The improvement in the system of organisational networks and formal linkages in the catchment on NRM has provided opportunities for more coordinated and inclusive collaborative projects and ventures on NRM in which ICM has been a key player. These linkages have been fundamental in helping the ICM process have an influential role in catchment management and planning processes.
- Effective linkages and communication network among catchment stakeholders provide opportunities for improved coordination of resources. Existing communication networks among Herbert catchment stakeholders are providing for mutual benefits (such as information exchange, progress or ensuing action on the issue of communication, better understanding of issues) and mutual influence (eg. changed views, acknowledgment of problems, increased awareness of problems, sharing of ideas, increased acceptance and awareness of icm).
- The capacity and a willingness within an ICM organisation to collaborate with other groups, agencies or individual experts with particular understanding of the issues is essential for raising awareness of ICM issues and precipitating appropriate action. This appears to be occurring to an acceptable extent in the Herbert River ICM context.

6.3 Factors Hindering the ICM Process in the Herbert River Catchment

6.3.1 NRM Issue Characterisation in the Catchment

- ICM in the Herbert River catchment has been required to deal with intractable issues that are embedded in past land use and resource management decision making behaviour and established ways of doing things that were based to a large extent on:
  - a history of 'ignorance' of the incremental, cumulative and insidious nature of environmental degradation (eg. as exemplified in the Herbert River catchment by extensive land clearing of lowland forest and coastal wetland vegetation for agricultural development); and
  - a past developmental ethos actively promoted by governments and rural industry alike.
- Technical issues have been a hindrance in the case of some emergent problems in the Herbert catchment. For example, biodiversity conservation and nutrient enrichment of waterways are not so well defined in technical terms, and the HRCCC has experienced difficulty focusing its priorities and activities on these issues. They need research information to gain a greater understanding of the processes involved and to demonstrate the necessity and effectiveness of technological solutions.
- Understanding of cause-effect relationships and 'solutions' to major issues in the Herbert River catchment have varied along a scale of 'speculative' (eg. fish kills) to 'uncontested' (eg. acid sulfate soils). The lack of technically uncontested 'solutions' for highly sensitive issues in the catchment at times has led to substantial community conflict and lack of confidence in government, research and other relevant agencies and therefore has inhibited progress on these issues.
- Feelings of personal and community control are also related to feelings of tractability of the problem. All possible impediments to managing land and water as presented in the questionnaires in the Herbert were perceived to exist at least to some extent. Greatest

impediments were seen to be with government, in particular a lack of responsiveness and low trust in government programs.
- The key catchment issues are perceived by HRCCC members to be difficult for ICM to address because of (a) 'institutional failure' (eg. slow government responses and strategies, departmental conflicts, lack of government commitment to a 'whole of government' approach) and (b) economic issues (eg. high costs of solutions and lack of financial capacity in the community).
- Rural producers/land managers (particularly on the lower floodplain) are the principal responsible groups requiring change in behaviour to a more precautionary approach, in particular in regard to land clearing and nutrient enrichment of waterways. However, long term solutions are frequently not in a landowners self-interest financially to undertake.

6.3.2 Implementational Context of the Herbert River ICM Process

- The lower Herbert catchment is topographically, hydrologically, socially and politically 'divorced' from the upper catchment. This means that at the catchment scale inclusiveness of all interests, integrated solutions, and communication are major challenges for a whole of catchment ICM process.
- At the inception of ICM in the Herbert in 1992, a broad range of community, industry and local and state government organisations with some level of responsibility or an interest in resource use management and planning were present in the Herbert River Catchment. However, there was a clear lack of integration or formal linkages between these organisations on natural resource management that would support an integrated approach to the management of the land and water resources of the catchment.
- Successful ICM requires a high degree of community awareness that there are important environmental problems that require timely action. Those who were unaware of ICM and other related strategies on the catchment may be wary of these programs.
- A high personal sense of control in dealing with environmental problems, or a belief that individuals can help motivate the community to improve the environment will promote ICM. Unfortunately in the Herbert a large percentage of the community felt they had a low influence over what happens in their community.
- Government strategies are not perceived to be highly useful to many community members at a personal level and therefore not seen to be highly relevant at that scale.
- The effectiveness of communication of existing information between state and other relevant bodies is critical to informing the ICM process. At the inception of ICM in 1992, there was a lack of both formal linkages between organisations on natural resource management and a capacity to share information.
- Despite the need for ICM to integrate across government agencies there is a clear absence of a "whole of government" approach, commitment or involvement in ICM. State politicians seem to ignore ICM and there has been ineffective, even counter productive involvement of some state agencies on some contentious issues.

6.3.3 Policy Frameworks and Institutional Frameworks for ICM processes

- There has been an increasing commitment within federal and state governments to devolve responsibility for natural resource management to the local level without a concomitant devolution of resources to local authorities to do so. Initially, there was a lack of capacity (ie. knowledge, resources, skills) in local government in the Herbert River catchment to implement natural resource management objectives.
- The frequent lack of effective cost-sharing and other incentive systems to encourage and support changes in land manager behaviour, and in some cases reparation of

ecosystems, is a major hindrance to ICM in the Herbert in addressing key issues such as riparian vegetation clearance and nutrient enrichment of waterways.

- The relatively erratic and low level of funding available to ICM has been a major hindrance to ICM. It is still a marginal program, compared say with infrastructure development, health care or other social services. It receives some regular annual support from DNR budgets but uncertain and short term project funding from this source and from the NHT has not allowed any certainty of program development and employment in the process. This is especially an issue for a program that is intrinsically evolutionary and dependent on awareness, planning and action cycles that take longer than a few years to establish. In particular in the Herbert catchment, the lack of continuity and security of funding for a Catchment Coordinator has been a major concern to members and at times has inhibited progress on ICM.
- Inadequate resources for an ICM initiative and lack of a mandate to plan major initiatives has meant that ICM activities (eg. awareness raising and on-ground action) have been largely opportunistic and often dictated by political imperatives and opportunities, funding options and existing technical understanding rather than the priorities identified in the Herbert Catchment Management Strategy.
- ICM is a essentially an experimental program with participants on a steep learning curve. There was therefore considerable uncertainty and disagreement initially amongst HRCCC members on the roles and objectives of the HRCCC and ICM in general. It took over 3 years before a draft Catchment Management Strategy (CMS) was developed that identified a clear set of objectives for ICM in the Herbert for the first time.
- Moving from identifying and prioritising issues and developing a catchment strategy to precipitating action on that strategy has been a major challenge for the HRCCC. Guidelines that identify practical options or strategies for addressing specific natural resource issues on the ground have generally been lacking.
- There has been a high turnover in state-agency personnel at regional/catchment and state policy levels relevant to ICM, which has meant a loss of expertise on what is essentially an experimental policy process. This has posed particular challenges for the HRCCC in terms of maintaining effective networks, the loss of corporate memory on previous decisions and what needs to happen next.
- Many existing regulatory mechanisms for resource use and management focus on development control rather than strategic integrated planning and therefore have provided only limited opportunity for ICM to influence decision-making (eg. the granting of cane assignment). In addition there was poor integration of land use and management planning processes (such as the caneland assignment process with Local Government planning schemes). Through the new Integrated Planning Act, the new Hinchinbrook Shire Planning Scheme will address this issue but only for new development applications or changes of existing right of use. Government authorities still have limited ability to control potentially harmful land management practices particularly on freehold land. These issues mean that there is a potential for high transaction costs in the negotiation of the appropriate management of riparian areas and coastal wetlands with relevant authorities and individual land owners.
- Lack of an open and accountable process of cane assignment so that all parties with an interest can understand the assumptions and processes leading to decisions being made has fostered considerable social conflict in relation to the granting of caneland assignment.
- There is a lack of agreed catchment based management plans for land, water and vegetation resources for the catchment that can be used in the assessment of cumulative or potential downstream impacts of development proposals and caneland assignment applications.

6.3.4 ICM Processes

- Coordination of information flow from state government agencies was considered to be low in relation to environmental topics or ICM related matters.
- Lack of coordination of government resources to address issues of community conflict relating to land and water resources management from a whole of government approach has consistently been seen as a major blockage to an effective ICM process in the Herbert.
- A major challenge for an ICM organisation like the HRCCC in progressing action on issues is how to deal with a range of conflicts that exist between catchment stakeholders. Such conflicts existed in the Herbert between different state government agencies and even sections within a department in providing contradictory or conflicting information, within the catchment community about development (eg. growers, conservationists), in relation to individual versus community rights, and among experts about biophysical processes (eg. fish kills) or which mechanisms to use (eg. statutory).
- Although there has been consensus amongst stakeholders in identifying the key catchment issues, much greater difficulty and even strong conflict occurred in gaining agreement on the prioritisation of issues and the best ways or strategies for the ICM initiative to address them. This is complicated further by the situation that many representatives on the HRCCC frequently wear several 'hats' or roles during their engagement with particular catchment issues.
- The approach to selection of members/stakeholder representatives on the HRCCC has been to ask for a nomination from the organisation concerned. Representatives have tended to be community leaders or 'committee people' who have "too many hats" and are often already over-committed. Loss of motivation and burnout are a high risk amongst members. Also unless there are clear rules and strategies agreed upon regarding election of office bearers and renewal of representatives periodically there may be stagnation in the ICM implementation process and even dissatisfaction amongst members.
- The HRCCC mostly takes a consensual approach to decision making or at least an approach based on a process that seeks consensus. However, this has meant that on some issues in the catchment, the HRCCC has taken 'minimal' decisions rather than perhaps what might be called 'better' decisions for the catchment. In addition, this approach has contributed to some more contentious but critical problems from being addressed by ICM (eg. drainage coordination).
- In relation to some contentious or 'hot' issues arising, some HRCCC members have appeared to be protecting their own sectoral or personal interests rather than acting for the betterment of the overall catchment community and the sustainability of resource use.
- All of the potential benefits resulting from investment in ICM activities are not equitably distributed among those incurring the cost and those who do not contribute to the cost can not realistically be excluded from enjoying the benefits. In effect, the positive externalities resulting from on-farm investment in improving the condition of the environment cannot be internalised. In an economic climate where the financial viability of farmers is generally deteriorating, the ability, and therefore the willingness, of farmers to invest in improved resource management is likely to be considerably reduced.
- Obviously programs which are perceived to be well resourced both in terms of money and time are likely to be successful. Even though people thought current financial contributions from locals and government sources to be relatively equitable the surveys demonstrated worry about local people lacking money to spend on solutions. There was also concern arising from lack of finances about an inability for landholders to plan more than a year ahead. Reservations were expressed about government willingness to spend money on solutions in the longer term. In addition there was a perceived need

for more government resources for voluntary groups and better incentives for landholders to address environmental issues/problems in the future. Finally, over a third of respondents felt that they had little time to become involved in local community issues.

- Communication issues and related problems identified by Herbert stakeholders which inhibit an effective ICM process include:
  - Difficulties in getting acknowledgment of problems by all stakeholders;
  - Perceptions that issues are too politicised and too big to deal with and that there is lack of resourcing and true commitment to ICM both within government and the community;
  - Difficulty some stakeholders have in explaining concepts of ICM to others;
  - The assumption by many stakeholders that they are influencing others outlooks much more than they may be in reality.
- The specific information needs facing the ICM initiative in the Herbert have been unpredictable, or at least difficult to predict. The HRCCC therefore has had to be adaptive and responsive and, despite the strategic nature of the Catchment Management Strategy does not have the resources or mandate to plan major initiatives, whether on-ground or in relation to the design, collation and management of key natural resource management data. As a consequence, ICM in the Herbert has had to rely predominately on the corporate knowledge and expertise of members of the HRCCC and opportunities to access additional expertise from others on a needs basis – including researchers and State Government resource managers.

7. ROLE OF ICM IN NATURAL RESOURCE USE MANAGEMENT AND PLANNING

7.1 A Process of Influence

Although the Herbert River ICM process is only one case study of the ICM policy initiative in Queensland, fortuitously it is an exemplary one. It is a process that has continued to slowly evolve in a context of substantial change in regard to community values and expectations of natural resource management and planning within the catchment. However, it is a process that at times has been inhibited by a considerable degree of uncertainty and confusion on the intent of the process and on what was required or expected of those involved. It has also been subject to internal and external conflicts between its diverse stakeholders that at times have constrained progress, as has indifference, inertia, self-interest and even gate-keeping by key participants and proponents on some issues. This is not surprising given the complexity of the issues being addressed and the inherent multi-stakeholder and multi-objective nature of the ICM policy initiative. Significantly, ICM has had a substantial influence on NRM in the catchment, but there is still a long way to go to ensure a sustainable future for the Herbert River catchment.

The process by which ICM has influenced NRM in the Herbert River catchment is shown simplistically in Figure 1. Given that actual NRM decisions are mostly made by individual landowners and public agencies, ICM has only an indirect role in NRM. It achieves its core objectives primarily by influencing the behaviour of these decision-makers. To do so it has had to change values and attitudes of those with statutory and other rights and powers over natural resources. That process is one of social learning, awareness raising and political influence, operating in part by affecting the whole community's awareness and supporting the incorporation of ICM principles and objectives in resource management and planning processes occurring in the catchment.

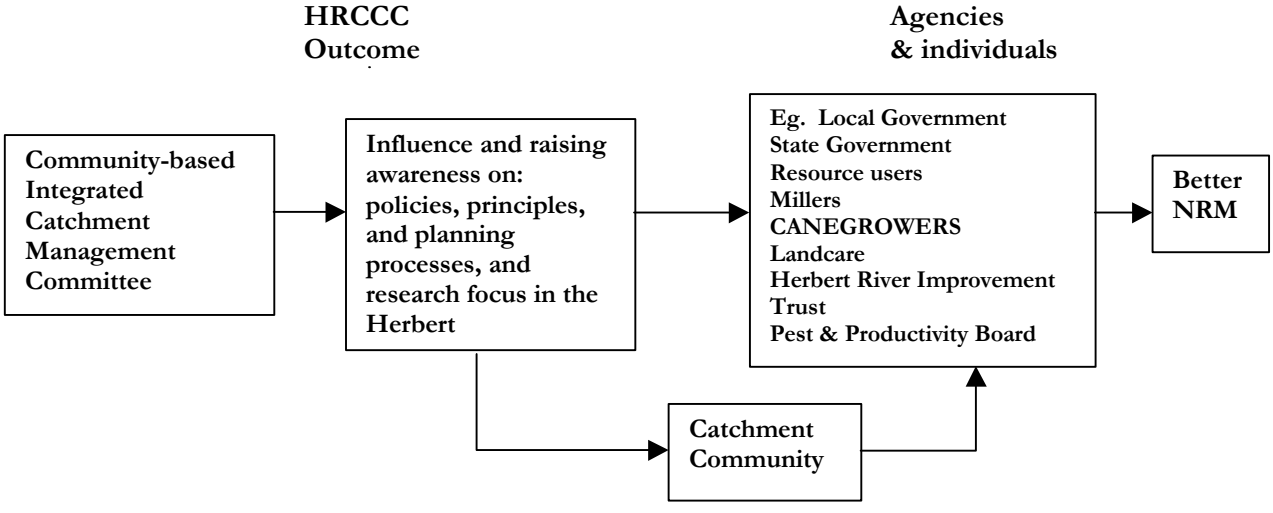

Figure 1. The ICM Process of influence on NRM in the Herbert River catchment

The Queensland Government's ICM policy initiative triggered this process in the Herbert River catchment by funding the HRCCC as a catalytic group. In Queensland, the ICM policy relies on community-level processes to promote the ICM principles in the local community and industry as well as local government without any statutory powers and only limited finances. In this context, the HRCCC has certainly succeeded in raising community and industry awareness of NRM issues, had noticeable success influencing land use planning

and development assessment at local government level, and was a voice for an integrated approach to Coastal Zone management and planning, integrated pest management and sugar industry expansion in the catchment. The HRCCC was also the driving force and principal broker negotiating funding for NRM research and resource management projects undertaken by other agencies and groups in the catchment such as Landcare, local government the Herbert River Improvement Trust and the Herbert Resources Information Centre.

7.2 Principles for the Role of Community-based Catchment Management Initiatives

The experience of the Herbert River Catchment ICM process revealed a number of fundamental principles relating to community-based catchment management policy initiatives. In particular form our perspective, a successful ICM process requires ICM to have the following roles:

- *To be a process of influence.* As a multi-stakeholder mechanism for community participation in natural resource management, ICM should not be seen as a vehicle for radical shifts in power relations within the community, but rather a vehicle for influencing policy agendas and the system of planning processes on NRM within government (local, state and federal), industry and the broader catchment community.
- *To support community learning.* ICM needs to be recognised as a program of community learning that requires a significant period of time before substantial on-ground results can be expected. Community learning at all levels, including the State level, implies:
  - the parallel increase in awareness of the significance of long term resource management problems;
  - appreciation of the need for integrated as opposed to piecemeal approaches;
  - maturing of community cooperation to address the problems;
  - creation of plans and actions that are agreed by the community;
  - political support; and
  - eventually substantial on-ground change.

  This process can easily stall and even reverse at any time along the path.
- *To be a partnership between government, industry and the community.* The ICM initiative relies on existing authorities and various programs and planning processes of state and local governments and private and non-government sectoral activities to implement their plans and achieve their objectives. ICM requires a partnership approach between different levels of government (particularly local government), industry, landholders and the broader community. There is a responsibility for landholders to do things on the ground, which is widely supported by the community and needs to be recognised and promoted in this approach. At the same time, both incentives for their efforts and resources for voluntary groups need to be provided by government rather than through regulation alone. An important way to implement this will be joint on-ground projects. This includes ensuring consistency of the information that is provided for the community from government. In doing so, there needs to be agreement on the exact roles of community and government, ie. clear roles will need to be established at the commencement of any activity.
- *To ensure legitimate representation.* For the partnership to work and gain credibility within the catchment community, representation in the ICM process must be legitimate, inclusive and accountable. Representatives must keep their constituents informed of the ICM process, interact actively with their constituents to understand their perspectives, and represent their constituency's interests to the partnership.
- *To provide a community forum for coordination of effort, networking and social learning.* Community-based ICM meetings can provide an effective and legitimate community forum for networking, both within the community and between government and the community,

as well as a vehicle for the exchange of information and more informed and inclusive discussion on NRM issues and planning processes that links state government, local government and various key catchment stakeholder groups. Decision-making in this forum needs therefore to be based on negotiated accommodation of explicitly stated interests and social learning of new shared perspectives rather than entrenched positions.

- *To build trust and effective interactions amongst stakeholders.* The success of ICM in precipitating action on catchment issues depends on the willingness of the participating individuals to build trust, deal sensitively with conflicts in the catchment community and work on maintaining productive interactions within the context of workable institutional arrangements. In this, local leaders play a substantially influential role.
- *To ensure fairness of process.* A key determinant of broader community acceptance of decision-making on catchment issues and related planning outcomes is the perceived fairness of NRM process and procedures and relatedly the fairness of outcomes that people receive. An ICM process can foster fairness through: (a) establishing a legitimate system of representation for the ICM initiative (eg. ensuring inclusiveness of membership and the supporting representatives to adequately represent their group's interests in the ICM process), (b) working towards the development of acceptable cost-sharing arrangements for NRM infrastructure and on-ground works and (c) establishing a decision-making approach for ICM that is based on a process that seeks consensus amongst stakeholders, while respecting and accommodating on-going differences.
- *To identify and broker project funding opportunities*. ICM needs to develop a lead role as coordinator and the principal broker in the catchment for external funding of community projects to address natural resource management problems in the catchment (eg. NHT).
- *To provide an influential voice on NRM at the regional level.* An ICM initiative has a key role of linking NRM principles and objectives into regional processes such as regional economic development, regional planning, cultural heritage and conservation management programs and processes.
- *To demand long term government agency commitment to the process.* The success of ICM is in part dependent on government agencies resolving bureaucratic gridlock among the array of fragmented but inter-dependent agency-based policies, plans and programs and (b) ensuring long term agency commitment to the ICM process (ie. clear upper management commitment within government agencies, political support, financial and administrative resources, establishment of workable institutional arrangements).
- *To provide a vehicle for integrating information relevant to NRM.* The two primary sources of information for the ICM process are local knowledge and expertise and existing technical information held by state and other relevant bodies. ICM meetings provide a central pooling of local knowledge through the wide diversity of stakeholder representatives involved in the ICM decision-making processes and related activities. Agencies are also repositories of technical information on the catchment but this information is fragmented and needs to be "shared" with other agencies and local interest groups. A key role of ICM is to foster the capture of relevant data on NRM issues and the development of locally accessible mechanisms for integrating data and delivering information.

Finally ICM implementation is acutely context-dependent. Established social networks and interactions, fundamental social values, institutional frameworks, historical problems and past actions and experiences have influenced and will continue to shape the current human association with the natural resource environment in a catchment. An ICM process therefore needs to recognise these and work towards achieving a sustainable future for the catchment by influencing existing networks, value systems and institutional frameworks rather than creating a new set of structural arrangements.

1. ANALYSIS OF RESOURCE USE IN THE HERBERT RIVER CATCHMENT

OBJECTIVE

This project activity aimed to quantify and document the natural resource context and aspects of the evolution of natural resource use and management in the Herbert River catchment. It focused on two key activities:

1. Integrating existing natural resource information into a form easily accessible to catchment stakeholders.
2. Quantifying changes over time in two key indicators of the resource use context, namely:
   - Land cover and land use change; and
   - Inputs of agrochemicals.

RELATIONSHIP TO OVERALL PROJECT STRUCTURE

This component provides key data on the historical context in which natural resource management has evolved in the Herbert River catchment and thus contributes to an understanding of the factors that influence the success of the ICM. In particular it examines aspects of the following specific elements of the evaluation framework:

Natural Resource Management Issue Characterisation

- Evolution of NRM in the catchment
- Extent of behavioural change required

METHODS

The analysis of resource use in the Herbert River catchment was addressed through three different approaches:

(i) *Spatial and temporal analysis of land cover and land use in the Herbert River catchment.* This involved the visually interpretation of the land cover of the lower Herbert River catchment from scanned and rectified 1:25,000 aerial photography acquired for 1943, 1961, 1970, 1977, 1988 and 1992 and 1:10,000 digital orthophotography acquired in 1993, 1994 and 1995. Land cover boundaries were then mapped onto a geo-referenced digital base in ARCINFO GIS. The classification drew on previous vegetation and soil surveys. Validation of 1996 mapping units and boundaries was conducted by vehicle and foot traverse. Approximately 150 sites were visited during inspections. Classification of units and boundaries not inspected was completed by extrapolation from equivalent photographic units. Data on land use was obtained from the Bureau of Census and Statistics (pre-1972) and the Australian Bureau of Statistics (ABS), and was cross-referenced with the land cover data. These data were augmented (particularly for the pre-1948 period) from records held by the two local sugar mills and the Queensland Department of Primary Industries.

(ii) *Preparation of a Herbert River Catchment Atlas.* This involved the thematic compilation of data relating to soils, ground and surface water hydrology, climate, geology, land use, demography and vegetation from a range of local, state and federal government agencies. The Atlas is available digitally (CD-Rom and Web-site access) and as a hard copy publication.

(iii) *Spatial and temporal analysis of nutrient and pesticide usage in the Herbert River catchment.* Quantities of pesticide used in infrastructure maintenance pest and weed control on government and leasehold lands, and government forestry plantations were obtained from historical records maintained by the relevant state or local government agency. Data for fertiliser and insecticide usage in the sugar industry was obtained from historical records held by the Herbert Cane Protection and Productivity Board. Fertiliser and pesticide usage for crops other than sugarcane was estimated by combining data collected at 4 levels:

- statistical divisions and local government boundaries;
- the original sales areas of chemical companies (these correspond in the Herbert River catchment to the sugar mill areas);
- individual dealer records for sales districts of fertiliser companies; and
- semi-structured interviews with individual agricultural producers.

Nutrient and chemical allocations were developed on a crop basis (i.e. the known area of each crop multiplied by the rate of usage), and then summed for the catchment over time. Allocations of sales area data to the catchment were confirmed in discussions with industry staff.

KEY FINDINGS

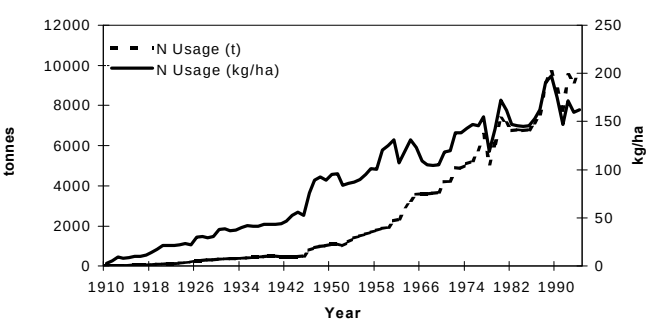
Evolution of Natural Resource Use and Management in the Herbert River Catchment

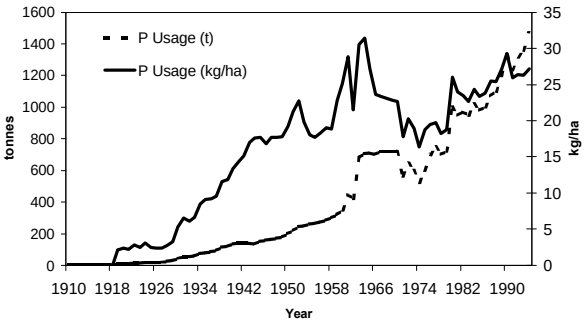
Land cover and land use

- Land cover and land use in the Herbert River catchment has changed substantially since European settlement, particularly in the lower catchment. Prior to European settlement in the 1860's, the area was dominated by open grassland, rainforest patterns, mangrove patterns, Eucalypt woodlands and *Melaleuca* communities. However, by the 1940's large losses of rainforest patterns and *Melaleuca* dominated patterns had occurred and much of the native grassland had been converted either to grazing or sugarcane. Land cover remained relatively stable throughout the 1960's and early 1970's. However, the period between 1977 and 1996 saw a rapid expansion in the area of land under sugarcane from 27000 ha in 1977 to approximately 65000 ha in 1996. The consequences of this expansion have been:
  - a decrease of approximately 65% in the area of *Melaleuca* dominated patterns;
  - a 60 % decrease in the area of beachside vegetation;
  - a 20% decrease in the area of Eucalypt woodland; and
  - a 10% decrease in the areas of rainforest patterns when compared to pre-European estimates.
- The area of mangrove communities and open water has remained relatively stable since 1943, while the area of sugarcane has more than tripled between 1943 and 1996. As expected the area of urban and industrial land cover has increased since European settlement, however the total area alienated is small within the context of total catchment area (ie <1%). In contrast, land cover and land use (predominantly extensive grazing of unimproved pastures) in the upper catchment has remained relatively constant over this time.

Nutrient Usage.

- Total fertiliser N and P use in the catchment has increased with time, however it is important that these increases are placed in the context of changes in land use. The total area of rural land fertilised is approximately 7.5% of the total catchment area, with the majority of this (ie. 6.5% of the total area fertilised) for sugarcane cultivation. As the area of sugarcane cultivated has continued to increase, N fertiliser inputs (kg ha^{-1}) increased with time, reaching a peak in the late 1980's. Early indications are that this trend may be declining as sales of fertiliser post 1990 have declined and current Bureau of Sugar Experimental Stations (BSES) fertiliser recommendations for the Herbert River district advocate reduced rates of N.
- P fertiliser inputs (kg ha^{-1}) have increased over time as the area of cultivated land has increased, although both rates and total use declined for a period in the 1970's coinciding with the removal of the government fertiliser subsidy and the energy crisis.





- Inputs of N and P to improved pastures increased dramatically during the 1980's, however their relative contribution to total catchment inputs was small. Subsequent conversion of pastures to sugar cane meant that the area of this land type fertilised has declined to negligible levels by 1998. The area of exotic pine plantations has increased since their establishment in the 1970's,

although additions of N and P (kg ha^{-1}) have decreased since the late 1980's. The area of horticulture and small crops in the catchment has varied with time, although N and P usage (kg ha^{-1}) has remained relatively stable.

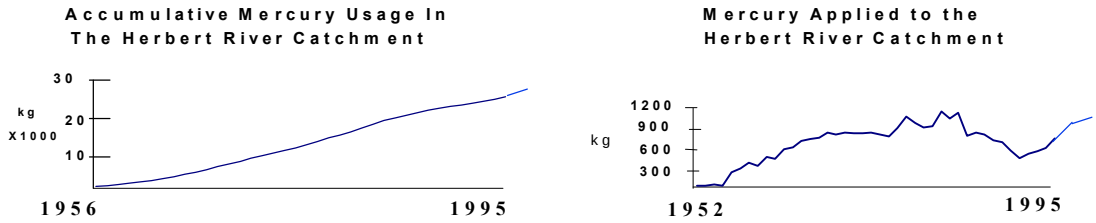
Pesticide Usage.

- A large number of agrochemicals have been applied in the Herbert River catchment since European settlement. In 1995 approximately 7% of the total catchment area was receiving pesticide applications, with approximately 95% of total applications (by volume) occurring in cane growing areas of the lower catchment. With an increasing land area under sugarcane and other crops, total agrochemical use in the catchment has increased with time and it provides a potential source of contaminants to the adjacent water of the Great Barrier Reef Marine Park (GBRMP).
- Significant quantities of organochlorine pesticide have been applied in the catchment. In general these chemicals are highly persistent, sorb strongly to particulate matter, are toxic to aquatic and marine organisms and have a tendency to bioaccumulate. While many of these were withdrawn from usage in the late 1980's and early 1990's, their fate in aquatic and marine environments of the Herbert River and adjacent GBRMP are unknown.
- Large volumes of the organophospate insecticide Chlorpyrifos continue to be applied in the catchment. Chlorpyrifos has become the dominant chemical for control of cane grubs in the sugar industry. Recent increases in total volumes correspond closely in relative magnitude to the increasing area of sugarcane production. Given the significant impact that cane grub damage has on the sugar industry, this trend is likely to continue unless an effective substitute can be found. Chlorpyrifos is persistent but effectively immobile in the soil, hence it poses little threat to ground water. However it does have the potential to contaminate aquatic and marine environments, particularly where soil erosion occurs.
- The volume of the herbicides Atrazine, Diuron and 2-4,D applied in the Herbert also increased rapidly between 1985 and 1995. Very little is known of the residual behaviour of Diuron and 2-4,D under north Australian conditions and no information is available in terms of their persistence in ground or surface waters in these areas. Diuron is persistent but not highly mobile while 2-4,D is less persistent but more mobile. Given the large volumes applied of both Diuron and 2-4,D, they do have ecotoxicological potential. Atrazine, which is both highly persistent and mobile, has been detected in ground water in the Burdekin River delta and similarly, has a high ecotox potential.
- Usage of Azole group fungicides has increased rapidly since 1982 as cane growers used these products as a substitute to Mercury based fungicides. However, the small volumes used mean that a low ecotoxicological potential exists. Large volumes of methoxymethlymercury chloride (MEMC) have been applied in the catchment since 1953. MEMC has the longest continuous record of known pesticide application in the Herbert catchment. Farmers perceptions of the greater efficacy of MEMC in comparison to Azole group fungicides has meant that its use has increased in the 1990's following a period of declining use in the 1980's. The environmental fate of MEMC is not well documented in the literature, however recent studies have shown a close correspondence between known history of MEMC application, and its subsequent appearance in the Herbert River estuary and associated coastal embayments of the GBRMP.

Extent of Behavioural Change

- The results of these studies demonstrate the magnitude of the tasks facing planners and natural resource managers in the Herbert River catchment in relation to the extensive historical decline of riparian and wetland ecosystems and the rise in use of agrochemicals in the lower Herbert River catchment and their long term implications for the sustainability of coastal and marine ecosystems. It identifies rural producers/land managers (and in particular cane growers) as the responsible groups requiring change in behaviour to a more precautionary approach, in particular in regard to land clearing and chemical usage.
- It also identifies considerable challenges for an ICM process in dealing effectively with the issues of accountability and 'user-pays' in the context of an emerging public good issue arising from past land and water management practices (eg. land clearing and expansion of intensive agriculture by rural producers). These were encouraged and/or inadvertently promoted under a past development ethos by both government and industry alike without the full knowledge or

understanding of the environmental consequences.



METHODS FOR SUPPORTING ICM IMPLEMENTATION PROCESSES

- The *Herbert River Catchment Atlas* provided essential natural resource information for supporting and promoting ICM in the Herbert River Catchment. The Atlas has been distributed widely by the Herbert Catchment Coordinating Committee and used as an important means of raising awareness of catchment stakeholders (eg high school children and cane farmers) of the natural resources and related issues of the catchment.
- The methods used to assess spatial and temporal variation in land cover and land use practices have generic application to other catchments in Australia. They have been published in a number of forms. Their robustness, rigour and simplicity would enable their application by most ICM groups.

FACTORS THAT INFLUENCE THE SUCCESS OF ICM

- ICM processes frequently are required to deal with intractable issues that are embedded in past land use decision making behaviour and land management practices that they have had no opportunity to have influence over but which were based to a large extent on:
  - a history of 'ignorance' of the incremental, cumulative and insidious nature of environmental degradation (eg. as exemplified in the Herbert River catchment by land clearing of lowland forest and coastal wetland vegetation); and
  - a past developmental ethos actively promoted by governments and rural industry alike.
- The frequent lack of effective cost-sharing and other incentive systems to encourage and support changes in land manager behaviour, and in some cases reparation of ecosystems, is a major hindrance to the success of ICM processes.

RECOMMENDATIONS

- In facilitating an effective ICM process, Catchment Committees and supporting government and industry agencies should place a priority on the collection of key natural resource use data to understand past and present resource use. In particular, a focus on providing data that enables ICM groups to understand the spatial and temporal distribution of key indicators such as land use change and agrochemical usage is essential. In so doing this helps to raise awareness of catchment resources and the potential implications of land management practices, and thus informs the debate on the nature and extent of both future resources use and the level of behavioural change required to meet these aspirations.

2. LOCAL KNOWLEDGE AND INTEGRATED CATCHMENT MANAGEMENT

OBJECTIVE

This project activity considers local understanding about catchment processes and its potential contribution to the progress of Integrated Catchment Management (ICM). The work specifically reports on some trial exercises undertaken with sugar producers and resource professionals:

- to investigate the potential role that local knowledge has in the context of ICM;
- to consider different approaches to local knowledge elicitation and analysis; and
- to investigate practical issues involved in the elicitation and analysis of local knowledge.

RELATIONSHIP TO OVERALL PROJECT STRUCTURE

This activity provides key data and insights on the social and technological contextual factors that influence the implementation of an ICM process. In particular, it examined aspects of the following particular elements o the evaluation framework :

NRM Issue Characterisation:

- Status of technical solutions
- Perspectives on natural resource use and management

METHODS

The methods for the project included three primary components:

(i) A Review of literature was undertaken to:

- Consider why local knowledge is relevant to ICM;
- Investigate the difference between 'indigenous knowledge', 'local knowledge' and 'land literacy'; and
- Investigate what would be required to implement a large scale local knowledge study.

(ii) Trial interviews conducted with individuals to investigate operational aspects of eliciting local knowledge.

These trials were designed to explore a range of approaches to eliciting technical knowledge relating to catchment management (with an initial focus on characterisation of the physical nature of issues/ problems) in order to scope out some of the operational issues that would be involved in the design of a large scale research project. The emphasis in ICM is on integration of issues such as water quality; water quantity (availability); drainage; flood protection; riparian zone management; habitat management and protection; soil erosion and sedimentation; and pest management. These trials reflected this diverse set of issues rather than treating them in isolation.

For the individual interviews, three techniques to knowledge elicitation, representation and analysis were investigated:

- questionnaire survey;
- semi-structured interview; and
- scenario-based approaches.

Two farmers, two researchers and one drainage engineer were interviewed. Each completed all three parts of the trial in a single interview of between one and one and a half hours.

(iii) Trial workshops to investigate differences between groups (eg. on the basis of age).

The use of small groups was investigated as a means of eliciting local knowledge using a number of different (but preferably related) scenario selection exercises that considered different management options in a fictitious catchment. Maps of the topography and hydrology of the hypothetical

catchment, current land use and tenure, soils and land use suitability for sugar cane were prepared to support the exercise, and a scenario description was also prepared. Two groups of 8 farmers each were approached, each representing different demographic characteristics and different levels of experience in sugar farming. The first consisted of farmers over 50 with more than 20 years cane farming experience. The second consisted of farmers under 40, all of whom were at least second-generation cane farmers.

KEY FINDINGS

This research activity focussed on an examination of the role of local knowledge as an input into the ICM process and the potential assessment of change in local knowledge as a means of tracking the impact of an ICM process. As such, local knowledge was identified as having the potential for a significant role in ICM, particularly in regard to:

- targeting research priorities;
- determining whether research programs are likely to be adopted by catchment communities;
- evaluating the impact of ICM implementation programs through tracking changes in perceptions and attitudes.

Status of Technical Solutions

- Assessment of local knowledge may provide an effective means of identifying key gaps in local understanding in relation to management options and in evaluating fundamental assumptions that underpin local management practice and may thereby provide an appropriate basis for prioritising research.

Perspectives on Natural Resource use and Management

Opinions in relation to key resource management issues and constraints are impacted significantly by understanding. As a consequence, investigation of local knowledge may provide key insights into differing values and opinions.

Methods

- The review of literature revealed that an approach termed 'landscape literacy' was most likely to be useful in the context of ICM. It allows researchers to characterise resource user perceptions and to determine significant differences to the principles underpinning ICM. This approach is also more suitable to tracking changes in resource user behaviour and attitudes providing a potential indicator of the success of ICM programs.
- The practical trials revealed some significant operational issues associated with knowledge elicitation and analysis. Principally, some participants were uncomfortable with certain aspects of interviews. In addition, many remained focussed at the level of their own farm, and had difficulty relating to hypothetical situations for the purposes of drawing out common themes amongst groups of participants.
- The two trial workshops resulted in considerable and heated discussion, thereby providing a considerable insight into farmers' perceptions of catchment scale issues. While the scenario provided a useful point of departure and reference for this discussion, it proved hard to keep the discussion focussed on the scenario, such that it proved impossible to get a clear justification for the group for selection of a particular scenario. It is anticipated that altering the scenario rules and moving towards a scenario selection and vote at the end of this workshop would mitigate this problem. On the basis of the trial only, it was difficult to clearly delineate differences between groups of farmers.
- In summary, efficient and effective formal approaches to eliciting and assessing local knowledge that would be operationally relevant to an ICM process have yet to be developed.

RECOMMENDATIONS

- Investigation of changes in local knowledge over time provide a powerful tool for evaluating some of the key impacts of an ICM process.
- Investigation of local knowledge may be achieved with a variety, and preferably a mix, of methods. The valuation of methods in this study reinforced the general observation that questionnaire based approaches to eliciting local knowledge are much more effective than semi-structured interview and scenario-based group workshop processes.
- The study revealed some convincing arguments for the inclusion of a local knowledge component in ICM implementation programs. It is recommended that a larger scale study be pursued to clarify details of how local knowledge can be incorporated into ICM strategies, and to develop methods for the analysis of 'landscape' literacy in the context of ICM

3. INSTITUTIONAL ARRANGEMENTS FOR THE ICM PROGRAM IN QUEENSLAND

OBJECTIVE

As part of the state system of institutional arrangements for Integrated Catchment Management, and resource management more generally in Queensland, performance of a specific ICM initiative, such as the HRCCC, depends substantially on state structures, processes and support to that process. This project component therefore focussed on developing an understanding of the broader policy, administrative and financial context of ICM policy initiative at the state-level to provide:

- an understanding of the essential institutional context in which ICM in the Herbert River catchment has been conducted including legal, administrative and financial factors;
- key baselines for the assessment of the institutional factors that influence the success of an effective ICM process in the Herbert River catchment; and
- key information for the assessment of the technical needs for effective ICM.

RELATIONSHIP TO OVERALL PROJECT STRUCTURE

In relation to the evaluation framework of the research program, the institutional arrangements at the Statewide level are important as a baseline or contextual matrix for evaluating activities in the Herbert River catchment. In particular, it examined aspects of the following particular elements of the evaluation framework :

Adequacy of Policy Frameworks and Institutional Arrangements for ICM at state and local catchment levels

- Clarity and consistency of roles and objectives of ICM and other responsible agencies/groups for NRM
- Adequacy of financial resources for ICM
- Coordination among ICM and other responsible agencies/groups for NRM
- Adequacy and effectiveness of policies, plans and decision rules of ICM and other responsible agencies/groups for NRM
- Opportunities for formal access by wider community

Adequacy and Equity of the Herbert River ICM Processes

- Knowledge and expectations of the process by stakeholders (inside and outside the catchment)
- Degree of coordination of resources to address catchment issues
- Degree of motivation, commitment , cooperation and support for the process
- Efficiency and effectiveness of process
- Equity and procedural justice and perceptions of trust in the process (by those whose activities are affected).
- Influence of ICM on planning activities in the catchment
- Agreed responsibilities and roles of important individuals and agencies
- Integration - degree of incorporation of processes in structure and context.

METHODS

The assessment of the institutional arrangements for the ICM policy initiative in Queensland was addressed through two different approaches:

Statewide Survey of ICM Officials

A comprehensive mail-out survey of all ICM coordinators and CCC Chairpersons in the State was conducted in December 1995 and repeated in November 1997. The response rate for 1995 survey was excellent. All coordinators (14 at that time) and 78% of Chairs returned the survey in most cases with useful additional comments. The results are reported in McDonald and Shrubsole (1996).

The 1997 questionnaire was based on the one used in the 1995 survey with some additions and deletions. The response rate was modest , 61% of incumbent Coordinators (28) and 50% of Chairs (26). The results are reported in McDonald, Bellamy and Laredo (1998) which contains a full description of the survey and its results.

Regular Monitoring of Legislation and ICM Programs
Regular monitoring of the evolving legislative and administrative arrangements that affect ICM in the Herbert including natural resource, environmental, planning legislation and programs at the local, state and Commonwealth level that impinge on the Herbert. This was achieved by regular interviews with key government officials in Brisbane, Townsville and Ingham and by compiling documentary sources on legislation, programs, finance, etc. One of the team (G. McDonald) was appointed Chair of the Natural Heritage Trust Assessment Panel in 1998, which provided additional opportunity to observe NRM in Queensland close at hand.

KEY FINDINGS

Clarity and consistency of roles and objectives of ICM and other responsible agencies/groups for NRM

- Queenslands ICM program has very broad, and from a community point of view, somewhat nebulous goals. There is general agreement on the ultimate purpose of ICM, but also a wide spread of opinions as to the purpose and operation of CCC among the various individuals and catchments in the State. This is not to be perceived as a deficiency of the program, given that it is intended to be community based. Over the ten years of the ICM initiative in Queensland it has been surprisingly robust. While it has evolved, its essential philosophies and implementation have remained constant.

Adequacy and effectiveness of policies, plans and decision rules of ICM and other responsible agencies/groups for NRM

.

- The integrated management of land and water in Queensland is addressed through the Integrated Catchment Policy (1991) and the emerging system of regional resource management strategies promoted through DNR's community resource management program. A substantial source of funding for these programs is the Natural Heritage Trust. There is no legislative basis for integrated resource management in Queensland to compare with the NSW Total Catchment Act or the Victorian Catchment Management Act and little statutory guidance for management of steep lands, floodplains, riparian zones and other key landscapes for ICM.
- While considerable progress has been achieved in some catchments and in some regions, the depth, coverage, and effectiveness of the Queensland integrated resource management system is very patchy. Specifically, there are as yet no regional resource management plans to guide ICM activities and only a minority of river basins covered by Integrated Catchment Management (ICM) plans.
- The consequence is that at this time there is no statutory or policy framework to guide landholder and local resource management plans with respect to water, vegetation and land management. There is no set of priorities or codes of practice for on-ground works, vegetation management, soil conservation, riparian zones and other key areas.

Coordination among ICM and other responsible agencies/groups for NRM

- DNR is the lead agency for ICM which was perceived by most respondents to be a successful partnership between DNR and the rural land owner interests and not much more than that. There was a widely held view that local governments, both politically and at officer level have not been involved effectively in the ICM process. Involvement of other key state agencies such as Lands and Environment is less applauded.
- CCCs have not so far had effective involvement from local governments nor from key agencies with statutory resources and management responsibilities but the problem is understood and action being taken (DNR 1996; Vella 1999). As coordinating focus for mainstream decisions affecting resources, ICM have not yet been universally successful.

Adequacy of financial resources for ICM

- Financial resources for a program with such ambitious goals has been erratic and low. A key source of funds has been the NLP, without which ICM would struggle to survive. CCCs are required to find funding on their own initiative rather than use established revenue sources as do most public programs. DNR provides significant levels of funding, especially for the employment of coordinators.
- At present CCC have no revenue raising capacities and there is a lack of confidence in government funding for implementation, which is of particular concern given that once CCCs have been established and created strategies, their requirement for funds for on-ground works will increase their financial requirements. Planning is inexpensive relative to action.

Opportunities for formal access by wider community in ICM at state level

- The state ICM program is community based and, at least formally, provides adequate opportunity for involvement by all in the community. This has mostly been achieved through representation of groups of specific interests including industry and conservation. The pattern of actual access differs widely between regions.

Degree of motivation, commitment, cooperation and support for the process

- CCCs have to contend with low awareness in the general public about resources management issues and a general resistance to external intervention. A surprising, consistent and very significant result from the survey was respondents universal view that there is too much government regulation. People in rural Australia resent government controls on land use whether they arise from World Heritage listing and conservation generally, tree clearing regulations, water and land management regulations, changes to land tenure and land rights laws. There is a clear message here that landholders in particular will resist any solution to ICM problems that involve state and national government regulations.
- Perhaps for the reason that ICM requires a complex process of learning, there was a disturbing low level of satisfaction amongst the respondents at the state level (especially the Coordinators). Less than half the coordinators in 1995 were satisfied with progress in their CCC and three were unsatisfied, one to the point of resigning over it. The Chairs were generally more satisfied with progress, and while none was actually dissatisfied, almost half were ambivalent. Satisfaction levels and support improved during the period 1995-98.
- Most respondents believed that support from the general public was low due largely to the public's low level of awareness about natural resource management issues. Only 35% of Coordinators are satisfied with the acceptance of their CCCs by other government agencies. Chairs are more positive on this point.
- A wide range of factors generate support from industry and community organisations, especially the efforts of the CCC Chairs. Again both groups of respondents were commonly unhappy with political support and of the acceptance of local government at both the agency and political levels. As in many other results of the survey there are regular exceptions to common patterns. Other community groups rating as important include Landcare groups, Recreational fishing, Commercial Fisherman's Association, Aboriginal. Council, Sugar Industry (Mills), Tourism. Environmental organisations considered to be valuable for CCC groups included ACF, QCC, Regional Environmental Council, Marine Conservation Society (although there was ambivalence on this, some respondents believed that these groups were obstructionist).
- Clearly and not surprisingly, the dominant effective partnership is between the CCCs, the DPI (now DNR) and rural producer groups. There was less agreement between the Chairs and Coordinators on the effectiveness of the involvement of local government and even some ambivalence on the involvement of others such as the Department of the Environment. Coordinators did not in general seem impressed with the involvement of Lands and Local Government.

Agreed responsibilities and roles of important individuals and agencies

- Respondents reported a wide range of activities reflecting largely the age and maturity of the CCCs. Some have been in operation effectively since 1988, whereas some are still in the process of being formed. A progression of activities can be recognised from organisational activities - public awareness and involvement - issues generation - catchment planning - technical studies. The range of activities are all envisaged in the Queensland ICM Policy which now requires the preparation of catchment strategies before funding is provided for projects (Queensland Department of Primary Industries, 1991)
- Perhaps the most interesting feature of these results is the wide spread of opinions as to the purpose and operation of CCC among the various individuals and catchments in the State. Coordinators for example are not in clear agreement as to what they and their CCCs should do - some believe that Coordinators and CCCs should coordinate activities and give advice to landowners, others do not. Significant differences in opinion exist as to whether the objectives of the local ICM programs are clear to all members and to the level of participation of their CCC members in meetings. They too do not always agree as to whether the CCC should give advice to landholders.

Equity and procedural justice and perceptions of trust in process by those affected

- Coordinators believe that some of the most significant difficulties are due to the wide variety of beliefs amongst CCC members, a view not so strongly held by Chairs; a perception that the program has been forced on the catchment by the State Government in communities without finical resources to respond, and a lack of trust in the public in government sponsored initiatives. The Chairs hold similar views differing significantly as a group only in relation to the significance of the wide variety of beliefs and values of CCC members and to a lesser extent on the difficulties posed by the large size of catchments. Both groups believe that the CCCs have the important groups represented. There are some potentially fatal problems identified here, although many can be overcome in time as the ICM process matures and achieves ownership and clearer common perceptions.

Integration – the degree of incorporation of processes in structure and context

- Despite the need for ICM to integrate across government agencies there is a clear absence of a "whole of government" approach, commitment or involvement in ICM. State politicians seemed to ignore ICM and there was ineffective, even counter productive involvement of some state agencies. While there was no reported hostility from politicians, agency staff and community groups, it seems that CCCs must create these supporting links themselves with little support from outside.

Conclusions

It is crucial to the evaluation of the ICM process to identify what is *the problem* and how it affects the implementation process. From a *technical* point of view resource management is finding effective mechanisms to address specific well defined problems such as soil erosion, flooding, nutrient enrichment, unreliable water supplies, loss of biodiversity. The solutions are defined in terms of land management practices, engineering structures, input usage and similar hard technological matters. From a *socio-economic* point of view, resources management is a matter of designing and implementing socially acceptable and effective solutions and preventative actions to these same problems through awareness raising and education, economic, administrative and legal measures

All the respondents acknowledged the difficulty of promoting a program with relatively few immediate benefits but often with immediate cost implications for land holders. This problem is intrinsic to ICM, and can only be alleviated by a change in ethics in the community as a whole. It would be assisted by technical and economic data that demonstrated the severity of the problems and reality of the long term benefits. Those catchments with more apparent and visible resource issues (such as water shortages or acute soil erosion) will have a better chance of focussing

community attention.

The Queensland ICM program is part of the struggle to move from sectoral approaches to resources management to an integrated whole of landscape approach. The survey revealed that the biggest obstacle to ICM is the *process* within the community and within government to redress and prevent resource management problems - political and social processes to apply technological solutions. Not surprisingly, this change of philosophy is accompanied by uncertainty and resistance especially when the way forward is not signposted. As yet there is no well tested solution to this problem as a guide to action, although significant progress is being made with regional plans and better integration of local governments.

The move towards an integrated approach to natural resources management has come at a time when community expectations about environment and resources issues have increased. In some cases these changes have been rapid and the shift in resource management and economic goals magnifies the extent of attitude and behaviour change required. For example, twenty years ago, farmers were encouraged to develop natural resources such as irrigation, tree clearing for grazing, clearing and drainage for agriculture. Recently, they have been asked to revise their practices substantially. These changing requirements for resource management have been isolated to a considerable extent from the economic development decision making process although there are promising signs that the merger of resource and environmental issues with economic development issues is beginning to occur in rural areas of the State. For example decisions on water resources development, agricultural expansion, water control, use rights and land tenure, resources extraction are becoming the concern of ICM groups. In order to do this successfully, further changes will be required by the major players in natural resources management. At present the ICM program is largely limited in scope to a relationship between farmers and the Department of Natural resources (formerly Primary Industries). Sustainable development requires a whole of government and a whole of community approach to decision about resources and economic issues.

The Queensland ICM program has been active only since 1990. Consequently a major constraint to any evaluation is the relatively short period of time that CCCs have been in existence and the limited opportunities they have to bring about change. A progression of activities was recognised from organisational activities - public awareness and involvement - issues generation - catchment planning - technical studies - implementation. Judging from the diversity of responses, it requires approximately five years before a CCC will reach maturity along this spectrum. A considerable amount of time is taken establishing the CCC, creating some coherence amongst its members, learning the challenges and opportunities and having the platform for planning and implementation.

FACTORS THAT INFLUENCE THE SUCCESS OF ICM

- The long term consistency of the goals for ICM and the commitment of its primary promoter, the Queensland Department of Natural Resources, are the most important factors influencing the success of ICM in Queensland.
- The relatively erratic and low level of funding available to ICM has been a major hindrance to ICM. It is still a marginal program, compared say with infrastructure development or health care. It receives some regular annual support from DNR budgets but uncertain and short term project funding from this source and from the NHT has not allowed any certainty of program development and employment in the process. This is especially an issue for a program which is intrinsically evolutionary and dependent on awareness, planning and action cycles that take longer than a few years to establish.
- Critical to the survival and success of any program is the level of commitment through funding and staffing. ICM has survived using a mixture of state program and core funds and, most importantly through the National Landcare Program and its successor, the Natural Heritage Trust. It is difficult to define accurately just what resources have been available for the ICM program and the Catchment Committees. Most significantly, the host Department, DPI then DNR (from 1995), provide in-kind support centrally and in the regions in the form of staff time and operational expenses. Because catchment related research, planning and implementation

support are closely interconnected with many programs. Disentangling specific ICM related expenditures (eg river improvement, water allocation) is difficult and conceptually dangerous.

- The ICM program in Queensland has been experimental, evolutionary and incremental. The early pilot studies informed the expansion and maturing process to the point that over 35 catchments are now formally included in the program. Catchment Coordinating Committees are formally endorsed by the (now) Landcare and Catchment Management Council. There is a growing group of experienced facilitators and catchment coordinators who contributed to this effort. Since 1995, the Queensland ICM program has organised a number of conferences and forums – especially targeted at the chairs of committees and the catchment coordinators with first hand experience of the operation of the program. They reviewed achievements and shared experiences as a learning opportunity for those catchments representatives and facilitators without the same level of experience.
- This developmental process has depended on improved understanding of community-based processes, acceptance and adoption of the need for strategies to guide catchment action, and more recently scaling up to the regional level in the form of regional NRM strategies.
- Increasing community awareness, concern and commitment to improving natural resource and environmental conditions in their areas is a major factor promoting ICM. The acuteness of the resource management problems and the ability to link these problems to ICM related solutions, (eg water quality) helps ICM gain legitimacy in the community.
- Technical issues have been a hindrance in the case of some issues but not others. The research revealed that there are clear enough technical solutions to many of the natural resources management problems in Queensland in some cases for decades and longer - eg floodplain management, soil erosion control, groundwater depletion and acidification. The proposed technical solutions have been similar in each case, but the resources management problem still exists. Other emergent problems, such as biodiversity conservation and nutrient enrichment of waterways are not so well defined in technical terms, and ICM groups where these are key issues have greater difficulty focusing their priorities and activities. They need research information to gain a greater understanding of the processes involved and to demonstrate the necessity and effectiveness of technological solutions.
- The lack of support from State politicians for ICM has been a major hindrance to ICM. This is slowly changing. Also the relationship with local government, though highly variable, is improving to the benefit of ICM in the long term.
- There was wide agreement about the supportive role of the media and of the essential role that the CCCs, its Chairs and Coordinators play in gaining support from the stakeholders. Clearly, the ability of these people is critical to the success of individual ICM programs. The study could not assess these abilities and what skills are essential, personal or technical.
- At the State level, acceptance of the need for better coordination of government programs has assisted ICM. This has occurred through the acceptance of the need to develop regional resource management strategies (few have been finalised at time of writing), the increasing adoption of the *Integrated Planning Act 1997* as a framework for local and regional integration of planning and development assessment and, less tangibly, the expanded understanding in State Government of the demands of integration to achieve sustainable development.

RECOMMENDATIONS

- That ICM be recognised as a program of community learning and that it requires a significant period of time before substantial on-ground results can be expected. Community learning at all levels, including the State level, implies the parallel increase in awareness of the significance of long term resource management problems, appreciation of the need for integrated as opposed to piecemeal approaches, maturing of community cooperation to address the problems, creation of plans and actions that are agreed by the community, political support and eventually substantial on-ground change. This process can easily stall and even reverse at any time along the path.
- The regional resource management and integrated catchment management strategies prepared under the DNR's community resource management program be strengthened by a statutory basis and coordinated with the regional planning process under the Integrated Planing Act 1997 and other resource management legislation. More specifically the regional resource management plans and the regional conservation strategies could become the formal agreed strategies for that

component of regional plans. Such a development would bring Queensland into line with Victoria and with emerging trends in NSW.

- Accompanying the need for a firmer statutory basis for ICM in local and regional planning is the need for more reliable financial support. At the State level ICM finance has come from a mixture of source including state and NHT funds. Coordinators and CCCs live with uncertainty and short time horizons. This is not conducive to commitment and effective staffing nor to long term incentives for successful CCCs. (This is not a recommendation that funding be guaranteed but that a more stable source of funding be provided to staff CCCs and to allow reasonable expectations of competitive project support – say as applies to RITs, local roads etc.

4. MONITORING THE IMPLEMENTATION OF ICM IN THE HERBERT RIVER CATCHMENT

OBJECTIVE

Monitoring and evaluation are fundamental to identifying change and enabling learning (eg. at individual, community, institutional and policy levels). As part of the development of an understanding of both the factors that foster and hinder community-based ICM policy initiatives and their likely impact, this project activity focussed on monitoring and evaluating the context, practice and progress of the ICM process in the Herbert River Catchment to provide:

- an understanding of the essential social and institutional context in which ICM in the Herbert River catchment has been conducted;
- key baselines for the assessment of the social and institutional factors that influence the success of an effective ICM process in the Herbert River catchment; and
- key information for the assessment of the technical needs for effective ICM.

RELATIONSHIP TO OVERALL PROJECT STRUCTURE

In relation to the research project's evaluation framework, an assessment was made of the historical context of resource use in the catchment, the local institutional arrangements, and implementation process for the ICM initiative in the Herbert River catchment to identify (a) the social and institutional factors that influence an ICM process and (b) what might be realistically expected of the ICM process. In particular, this component examined aspects of the following particular elements of the evaluation framework:

Characterisation of NRM Issues in the Catchment

- Diversity of stakeholder knowledge, attitudes and values on natural resource use and management

Implementation Context for the ICM Policy Initiative in the Herbert River Catchment

- Rationale and motivation for the commencement and on-going development of the Herbert River ICM initiative
- Socio-economic conditions and use of technology
- Community attitudes and support for ICM
- Attitudes and resources of local constituency groups
- Support from politicians

Adequacy of Policy Frameworks and Institutional Arrangements for ICM at state and local catchment levels

- Clarity and consistency of roles and objectives of ICM and other responsible agencies/groups for NRM
- Coordination among ICM and other responsible agencies/groups for NRM
- Adequacy and effectiveness of policies, plans and decision rules of ICM and other responsible agencies/groups for NRM
- Commitment and skill of staff in ICM and other responsible agencies/groups for NRM
- Opportunities for formal access by wider community

Adequacy and Equity of the Herbert River ICM Processes

- Degree of coordination of resources to address catchment issues
- Degree of motivation, commitment , cooperation and support for the process
- Efficiency and effectiveness of process
- Agreed influence (eg. of ICM initiative in the catchment)
- Agreed responsibilities and roles of important individuals and agencies
- Integration – degree of incorporation of processes in structure and context

METHODS

The assessment of the social and institutional context, local institutional arrangements and the implementation process for the ICM policy initiative in the Herbert River catchment was

addressed through multiple methods:

(i) Bench-marking attitudes, values and behaviour through semi-structured interviews of HRCCC members in 1995, 1997 and 1998. The questionnaires covered members' views on the nature and tractability of catchment management issues, roles and responsibilities of CCCs, HRCCC activities and achievements, Herbert River Catchment Management Strategy –development process and influence, the ICM program in Queensland - suitability and needs, public awareness, community support and involvement in ICM, stakeholder/sector involvement and influence in the ICM process, information needs and use, factors influencing ICM implementation, personal demands and motivation, and personal background information, group/organisational involvement (McDonald and Shrubsole 1996; Shrubsole 1996; Bellamy *et al.* 1998, 1999).

(ii) Catchment stakeholder workshop to benchmark attitudes and values on natural resource issues and ICM in 1995 (Bellamy *et al.* 1995).

(iii) Interactive annual forums with HRCCC members as a group to interactively discuss issues arising in the ICM process..

(iv) On-going monitoring and analysis of documentation relevant to the ICM process including consultancy reports, HRCCC meeting minutes, stakeholder organisation annual reports (eg. McDonald and Bellamy 1997; Bellamy and Johnson 1997; Bellamy and Horsley 1999).

(v) Review of ICM and Local Government Planning schemes based on review of legislation, consultancy reports and documentation on institutional and administrative arrangements as well as semi-structured interviews with key informants in the Herbert River catchment (Vella 1997, 1999).

(vi) Mapping of change in the system of organisational structures and linkages on NRM in the Herbert catchment from 1993 to 1998 based on interviews of key informants and a review of organisational documentation including annual reports (Bellamy and Horsley 1999).

(vii) Development of a catchment socio-demographic profile through the analysis of ABS Census data for 1991 and 1996 for the catchment.

KEY FINDINGS

Rationale and motivation for the commencement and on-going development of the Herbert River ICM initiative

- There is a prominent history of flooding and drainage issues in the catchment, which has created significant social conflict over a long timeframe. Previous local and state government responses were to undertake 5 major technical studies since the late 1970s. However, there was concern within the local catchment community that (a) despite the major public and private investment in these studies, government had failed to achieve on-ground outcomes on drainage management, and (b) the local community needed a greater influence on decision-making on these issues. To this end, prominent actors in the catchment from the sugar industry and local government lobbied the State Government for the initiation of an ICM process in the catchment in 1992.
- The HRCCC has a representational structure. The steering committee set up in July 1992 identified key stakeholder organisations in the Herbert with a responsibility or interest in natural resource management in the catchment and in February 1993 invited them to nominate representatives for the HRCCC. Since then the HRCCC has opportunistically invited additional stakeholder groups to participate in the HRCCC as they saw fit. The number of members on the HRCCC therefore has fluctuated between 13 and 17 members since it was formally established in March 1993. Current representation on the HRCCC is diverse involving local industry (sugar, cattle, fishing, horticulture), local government and other statutory bodies, conservation and community interests. However, the HRCCC has been dominated by the lower catchment with only one representative from the upper catchment. State government had not been formally represented until 1999 with the appointment of a representative from the EPA for the first time. Informally DNR officers have provided technical advice on a regular basis.
- HRCCC membership has been remarkably stable with approx. 60% of current members (1999) being the original foundation members. All members are active community leaders who belong to a wide range of different organisations in the catchment holding executive and other leadership positions. They therefore have multiple allegiances and interests.

Socio-economic conditions and use of technology

- The lower Herbert catchment is topographically, hydrologically, socially and politically 'divorced' from the upper catchment. This means that at the catchment scale inclusiveness of all interests, integrated solutions, and communication are major challenges for a whole of catchment ICM process.
- Lack of relevant information is not perceived by HRCCC members as a constraint for ICM in the Herbert. Since 1995, there has been an emergence in the catchment of a number of collaborative ventures between local government, industry and state and federal government agencies to improve the capture of relevant data on NRM issues (eg. Herbert Mapping Project and a Catchment Atlas) and provide locally accessible mechanisms for integrating data and information delivery or service provision (ie. Herbert Resource Information Centre).

Diversity of stakeholder knowledge, attitudes and values on natural resource use and management

- In 1997, the HRCCC identified that managing land and water resources in the Herbert was perceived to be difficult because of (a) 'institutional failure' (eg. slow government responses and strategies, departmental conflicts, lack of government commitment to a 'whole of government' approach) and (b) economic issues (eg. high costs of solutions and lack of financial capacity in the community).
- HRCCC member's views on the key catchment resource management issues have evolved since 1995 and are now more strategic and inclusive in scope. Rural drainage, flooding, river management and sugar industry expansion and related land clearing have remained key issues in the catchment. Since 1997, emerging issues are water quality (particularly relating to fish kills), riparian vegetation and wetlands management, integrated pest and weed management, a coordinated approach to land use planning and resource management in the catchment. With closer linkages developed with the upper catchment community since 1998 grazing land degradation/erosion and water availability are also identified as key issues of concern.
- The focus of the issues identified by the new upper catchment sub-committee of the HRCCC formed in early 1999 largely related to specific "on-site" land and water management issues (eg. grazing land degradation, soil erosion). This contrasts with the current views of the lower catchment-dominated HRCCC, which is now more focussed on broader planning and public good issues (eg. land use planning, coordinated drainage, riparian and wetland management).
- Although there is good agreement among HRCCC members on the key catchment resource management issues, individual stakeholder/member understanding of those issues and in particular the diagnosis of their causes and possible solutions can vary significantly. This means that identifying mechanisms and strategies to address these issues needs to be a participatory process involving all stakeholders and to take account of the decision context. (eg. the level of problem/technical complexity and the intensity of community conflict associated with the decision). In 1998, members identified that three catchment issues - water quality (particularly relating to fish kills), waterways management and flooding, and floodplain drainage coordination – had both a high to very high degree of technical complexity and a high to very high intensity of community conflict. While industry expansion, land/vegetation clearing and land use planning had a moderate level of technical complexity but a high to very high intensity of community conflict in the decision context. In contrast, riparian management and wetland degradation have a low to moderate level of technical complexity and a moderate intensity of conflict. The participatory approach for dealing with these issues needs to be selected with close consideration to the particular decision context.

Community attitudes and support for ICM

- Over the period 1995-98, HRCCC members considered that the rural community's *awareness* on natural resource issues and the HRCCC organisation itself had improved substantially largely due to the occurrence of specific well publicised or controversial issues/events (such as land conversion from cattle-to-cane, land clearing for cane land expansion, owl boxes activity, fish kills in the river, damming of streams and acid sulfate soils).

Attitudes and resources of local constituency groups

- There has been a broadening of the focus of industry organisations in the catchment from an almost exclusive concern with productivity and efficiency issues and impacts at the inception of ICM in 1992 to a recognition and even promotion of the importance of natural resource management to the long term sustainability of the industry.

Support from politicians

- Local government politicians have had an active and influential involvement with ICM process with 2 Councillors regularly participating in the HRCCC and the lower catchment Mayor being the Deputy Chair of the HRCCC. However State government and Federal government politicians have had little input or involvement such that HRCCC members identified them as having an ineffective to very ineffective involvement.

Adequacy and effectiveness of policies, plans and decision rules of ICM and other responsible agencies/groups for NRM

- The HRCCC released a draft Herbert River Catchment Management Strategy in May 1996 for public comment that was important to HRCCC members because (a) it provided a future direction to the group and a guide for future actions (e.g. identified issues, prioritised needs, identified stakeholders and their roles, provided a reference point to start from); and (b) it helped to get resources and support for ICM in the Herbert (e.g. funding for Catchment Coordinator and natural resource projects, and gaining in principle commitment of State Government to undertake projects).
- Since the inception of ICM in Queensland implementation has been hindered by the inability of catchment management groups to influence land use planning and management. Traditionally ICM principles and catchment management issues have not been incorporated into or addressed by local planning schemes. A recent development (1998) in the lower Herbert catchment is the process that requires farmers opening up new areas for intensive agriculture or requiring a change of use will require Hinchinbrook Shire Council approval (for conditions) under the new Shire Plan. This process seeks advice from a range of responsible agencies including ICM in the decision-making process. Ultimately this development requires the Council to have both the technical capacity and political will to implement their statutory powers.
- While local government in the lower catchment does have enormous scope in achieving catchment management objectives, it is limited by the fact that it can only implement these strategies when a development application is triggered by the planning scheme. The regulation of new developments through the planning process will not effectively deal with existing resource management problems because planning controls have little power to control existing unsustainable land uses or minor variations in those uses. Therefore to effectively achieve ICM, planning schemes and development assessment may need to be integrated with other forms of institutional arrangements to deal with existing use rights.
- The approach to selection of members/stakeholder representatives on the HRCCC has been to ask for a nomination from the organisation concerned. Representatives have tended to be community leaders or 'committee people' who are often already over-committed.
- There is some concern among HRCCC members that there are no clear rules for managing the HRCCC's representational structure and processes (eg. use of proxies, reviewing membership, election of office bearers). To-date the approach has been largely an ad hoc process that may in time reflect on its credibility.

Coordination among ICM and other responsible agencies/groups for NRM

- The HRCCC has emerged as a coordinative and informative forum (particularly within the lower catchment) for facilitating information exchange and more inclusive debate on NRM issues with a level of legitimacy that had not existed before in the catchment.
- There have been significant changes in the system of organisational linkages on NRM in the catchment since the inception of ICM. (1) Increased number of linkages (both regulatory and

non-regulatory) between (a) local government and related statutory bodies and industry and other community organisations in the Herbert catchment and (b) these Herbert River organisations and state and federal agencies. (2) the emergence of a number of successful coordinative, collaborative and/or joint funding initiatives for NRM purposes (eg. the Herbert Mapping Project and the establishment of the HRCCC in 1993) which are now the catalyst for further collaborative ventures relevant to catchment management (eg. the Herbert Resources Information Centre or HRIC).

- A high turnover has occurred in state-agency personnel at regional/catchment and state policy levels relevant to ICM, which has meant a loss of expertise on what is essentially an experimental policy process. This poses particular challenges for ICM groups like the HRCCC in terms of maintaining effective networks, the loss of corporate memory on previous decisions and what needs to happen with regard to a particular ICM initiative.
- Effective state government involvement is critical to the success of ICM in the Herbert through the provision of financial resources, technical support, and its power to endorse the Catchment Management Strategy.

Clarity and consistency of roles and objectives of ICM and other responsible agencies/groups for NRM

- Initially there was considerable uncertainty amongst HRCCC members on the roles and objectives of the HRCCC and ICM in general. It took over 3 years before a draft Catchment Management Strategy (CMS) was developed that identified HRCCC objectives for the first time and indicated a degree of consensus on issues and respect for others views within the HRCCC.
- In 1997, The HRCCC launched a draft Herbert River Catchment Management Strategy for public comment which formally identified a clear set of objectives for ICM in the Herbert for the first time:
  - Co-ordinate government agencies and the community to pursue common goals
  - Seek community involvement in catchment management
  - Reflect the requirements of the wider community within the Catchment
  - Identify and rectify natural resource degradation
  - Promote ways to prevent and reduce natural resource degradation
  - Promote the wise use of all natural resources within the Catchment
  - Identify key indicators of biodiversity and monitor as a measure of catchment health
  - Encourage the retention of significant natural habitats within the Catchment.

Adequacy of financial resources for ICM

- Although seed money provided by the lead state agency for ICM has been pivotal to the successful formation of the HRCCC and a catalyst for it to leverage other sources of funding (eg. NLP/NHT), the short term nature of funding and political cycles is not conducive to long term environmental/sustainable development solutions. In addition, much of the funding is administratively burdensome to apply for and to manage and takes up a lot of the HRCCC's resources (eg. the Catchment Coordinators time).

Commitment and skill of staff in ICM and other responsible agencies/groups for NRM

- One of the big challenges for ICM is keeping up the momentum in a process where tangible outcomes are slow to emerge and may well be attributed to others influenced by the ICM process. A strong, active and credible Chair has been essential for driving the ICM process in the Herbert and progressing issues.
- Participants of a community forum held in 1995 in the catchment identified Government as being the hardest to get on-side and committed to ICM. Besides providing continuity in support through providing resources (eg. funds, personnel, technical advice) to effect action, a key requirement from government for successful ICM is the commitment of top officials to ensure real participation by agencies as well as the continuity of political commitment (ie. at all tiers of government).
- In 1998, members identified the important qualities of a Catchment Committee member as: open-minded with a broad vision (including benefit of the community at heart, recognises needs

of others, sees other point of view, prepared to compromise, able to give a little); genuinely concerned about NRM/ICM issues; good communication skills and can contribute to group discussion and take information back to their own stakeholder group; understands and is prepared to put forward the views of own interest group; good interpersonal skills (including willingness to listen to others views); vast local experience and aware of what is going on in the catchment; progressive attitude (including willingness to accept change, learn things all the time); and with available time to commit to ICM.

- Members also identified the a number of important qualities of a Catchment Coordinator as: experience with and knowledge of NRM issues and agricultural systems (ie. technical skills, understanding across disciplines, problem solving, eye for myths and legends); good communicator; highly developed interpersonal skills and able to handle a diverse group of people; broad minded with an ability to look at the big picture; tactful; confident and prepared to stand up and be accounted for; good conflict resolution skills; and a good listener.

Opportunities for formal access by wider community

- Although ICM is a community-based process, there is a lack of a clear mechanism for initiating involvement in ICM outside the formal representative structure of the HRCCC. Importantly, through this formal mechanism a sub-committee of the HRCCC involving 16 representatives of a broad range of stakeholders from the community, industry and government was formally formed for the upper catchment in December 1998 to discuss and raise issues of particular relevance to the upper catchment. Community members in the upper catchment felt that they were not equally represented on the HRCCC (only one representative), there was a predominant focus of the HRCCC on issues affecting the lower floodplain and that there were logistical difficulties relating to the long distance between the upper and lower catchments to attend meetings (ie. a 4-5 hour drive). This new group is also facilitated by the HRCCC's Coordinator and regularly reports to the HRCCC.

Degree of coordination of resources to address catchment issues

- Coordination of government resources to address issues of community conflict relating to land and water resources management from a whole of government approach has consistently been seen as a major blockage to an effective ICM process and experience with major resource management issues with significant social conflict in the catchment supports this concern (eg. the failure for over 5 years to reach agreement on the Sugar Industry Infrastructure Package with the local sugar industry bodies; Mahogany Glider conflict at Pomona; and fish kills controversy).
- The HRCCC has adopted a lead role as the key broker in the catchment for external funding of community projects to address natural resource management problems in the catchment. For example, the HRCCC acted as the broker and coordinator for all new proposals from the catchment submitted for federal government funding through the new National Heritage Trust initiative. This is providing the catalyst for community activity in federal and state-funded natural resource management initiatives in a more strategic way than in the past.

Degree of motivation, commitment, cooperation and support for the process

- The membership of the HRCCC has ranged from between a total of 13 and 17 representatives since it was established in 1993. There has been varied commitment to the ICM process by these representatives over time (ie 1993-98) as reflected in attendance at monthly meetings (eg. about 9 members on average attend each meeting). The representatives of the sugar industry/agencies, local government, upper catchment and Landcare have been the most consistent participants, while the Conservation representative, local Development Bureau and a local community had the lowest involvement.
- The time commitment of HRCCC members to ICM matters has increased between 1995 and 1998. Until 1997, the majority of members (over 70%) spent 10 hours or less per month on ICM matters but, by 1998, nearly 50% of members reported committing more than 16 hours per month to ICM.
- HRCCC member's motivation for involvement in ICM was identified in 1997 as being personally rewarding (eg. because they could contribute to the community), they cared about the

environment, and that they could meet other members of the community who could influence resource management decision-making. However, in some instances (eg. contentious or 'hot' issues), some members have appeared to be protecting their own sectoral or personal interests rather than acting for the betterment of the overall catchment community and the sustainability of resource use.

- Most members have become positive over time (1995-98) about the HRCCC's achievements and the group's overall direction. They also perceive an improvement in the level of community support for ICM from a low to a moderate level. However, there are some concerns with the rate of progress and the slowness of the overall process in general.
- Local government involvement has been perceived by the HRCCC to be of critical importance to the success of ICM in the Herbert, and that, effectively, ICM could not really function well without that involvement.

Efficiency and effectiveness of process

- Due to a lack of continuity and security of funding for ICM, HRCCC activities and progress has been driven opportunistically by state and federal government funding processes and schemes rather than by the priorities identified in the Herbert Catchment Management Strategy (CMS). This has meant that the HRCCC has been fairly reactive in its approach in implementing the CMS (rather than setting own agenda), and that it is tending to follow a circuitous course towards reaching its stated goals.
- The major achievements of the Herbert River ICM process are summarised as:
  - Providing a forum that brings very different people in the catchment together to exchange ideas and providing a catalyst for change;
  - Supporting a range of projects on natural resource management;
  - Raising community awareness of catchment RM issues; and
  - Gaining legitimacy as an influential group on NRM in the catchment.
- The HRCCC in general takes a consensual approach to decision making or at least an approach based on a process that seeks consensus. However, this has meant that on some issues in the catchment, the HRCCC has taken 'minimal' decisions rather than perhaps what might be called 'better' decisions for the catchment. In addition, this approach has kept some more contentious but critical problems from being addressed by ICM (eg. drainage coordination).
- From 1995 to 1998 there has been a general improvement in the overall level of satisfaction of HRCCC members with progress. However they identified a number of ways that could improve their performance (including the level of stakeholder group involvement in the HRCCC) by:
  - Raising the profile of ICM and the HRCCC in the community through more targeted publicity and promotion of the HRCCC and its activities;
  - Ensuring the security of tenure for a Catchment Coordinator and the adequacy of funding for HRCCC activities;
  - Maintaining legitimacy through broad stakeholder representation on the HRCCC (eg. direct involvement of local business through the Chamber of Commerce; more active involvement of environment interests; representation of government technical expertise from the EPA and DNR);
  - Greater use of proxies by representatives;
  - A more proactive (versus opportunistic) approach; and
  - More effective government agency involvement in the ICM process (including government agencies being required to consult with the HRCCC on all their programs in the catchment).
- The Catchment Management Strategy development process proved to be valuable to the HRCCC members involved because (a) the process was seen to be inclusive and transparent within the Committee, (b) it raised awareness of issues and others viewpoints within the HRCCC membership, (c) it identified areas of agreement, and (d) helped to focus the HRCCC and establish an overall direction.
- The issues relating to the development process for the catchment strategy are the lack of resolution on some key issues, speculation whether it will assist in resolving resource management conflicts in the catchment, and the apparent failure of the strategy to have a significant impact on what the Committee was actually doing.
- In 1998, HRCCC members considered that the implementation of ICM in the Herbert River catchment was difficult because of the large size of the catchment, the lack of financial resources

within the community in the upper catchment, the lack of cooperation between State government agencies, and the lack of coordination between state government agencies in addressing issues.

Agreed Influence of ICM in the catchment

- The system of organisational structures and linkages on natural resource management in the Herbert River Catchment has evolved to be more coordinated and more inclusive of key stakeholder groups since the establishment of the HRCCC in 1993. Significantly, the HRCCC is providing a key integrating and informing functional role on NRM within this system.
- Overall HRCCC members considered that for major natural resource management activities in the catchment (ie. land use planning, environmental protection, land clearing guidelines drainage coordination) that there should be much greater community influence in decision-making than what occurs at present. However, they also in general considered that the level of community involvement/public participation in decision-making needs to vary depending on the particular issue of concern between 'Consulting', 'Involving', and 'Shared planning and decision making'. Importantly, they were not in support of the community alone making decisions on these issues.
- The active involvement of local government in the HRCCC emerged as a key strategy for the HRCCC to influence decision-making processes in the Herbert particularly relating to land development planning. Local government is an important information source for the ICM process, it recognised HRCCC with its broad stakeholder representation as a legitimate referral and advisory group in the catchment, it is actively seeking HRCCC's advice on issues, and it is seen as an important mechanism for providing ICM with "teeth for implementation".
- Integrated catchment management has had a substantial influence on local government in a relatively short period of time. Some of these changes include an improved awareness of ICM, better coordination between authorities in extending the reach of town planning to achieve ICM strategies as well as the actual implementation of ICM in the local planning scheme. Positive benefits also include improved communication between local government and previously unconnected stakeholder groups to provide a wider range of perspectives on resource management issues. Now local authorities in the lower Herbert are regulating land uses to achieve catchment management objectives. The upper catchment is significantly behind the lower catchment in terms of the understanding of planning and ICM issues, open communication between stakeholder groups and level of commitment to resource management.
- The ICM process has contributed to increased community awareness and involvement in natural resource management issues in the catchment. In particular, the presence of the HRCCC and its activities has helped to focus community attention on natural resource management issues. However, to-date it has been difficult to assess the extent this awareness has been translated into better land management practices by land owners.

Agreed responsibilities and roles

- In 1998, HRCCC members prioritised the roles for ICM in the Herbert as:
  - Encourage Local Government to take an active role in environmental management issues
  - Encourage joint projects between community, industry and state and local government
  - Provide a continuing source of advice to local government on catchment issues
  - Encourage discussion between community interest groups on environmental issues
  - Raise the level of local awareness and knowledge of environmental issues on the catchment
  - Encourage coordination of state government programs
  - Encourage research
  - Develop solutions for, and better understanding of, environmental problems in the Herbert catchment.
  - Undertake specific on-ground projects with other bodies.
- Since the inception of ICM in the Herbert catchment, a significant increase has occurred in the role and responsibility of local government in catchment management and planning. This has emerged through (a) an influential role based on active membership on the HRCCC and (b) regulatory and statutory processes (including major changes to the Hinchinbrook Shires Planning Scheme and HRIT activities).
- While the majority of members agreed that an HRCCC member's role is to represent the

resource management views of their constituent group at meetings, there was a divergence of opinion on whether an HRCCC member's role is to provide either their personal views on resource management issues or a catchment-wide perspective of natural resource management issues at CCC meetings.

- Members clearly feel that the community also had a responsibility regarding land and water management and that ICM should remain a voluntary activity by community members.
- There has been a significant increase in the number and diversity of projects engaged in by the HRCCC - from a tin mining dam inventory in 1995 to include by 1999 a joint project with the HRIT on bank stabilisation, the owl nesting box program, a Catchment Atlas, several restoration and revegetation projects, riparian vegetation mapping study, weed control activities, a riparian "community" forum, acid sulphate soils awareness, and a cooperative project to link ICM and local government planning.

Integration – the degree of incorporation of processes in structure and context

- Concern was continually expressed by some HRCCC members of the on-going failure of State Government agencies to effectively use their statutory powers and authority to substantively address land and water development and management through a whole of government approach within the catchment (eg. land conversion from grazing to intensive agriculture, caneland expansion through tree clearing, and construction of levees on the floodplain). State agencies continue to make decisions on NRM issues in the catchment independently of each other and local interest groups. In particular, the apparent lack of sharing of information between agencies has led to contradictory or conflicting information being presented to the community by different government agencies with regard to important issues in the Herbert. This situation has often exacerbated the community conflict.
- Government agencies have often failed to consult local agencies or groups on new programs or activities to be commenced in the catchment. For example, some important initiatives have 'by-passed' ICM (eg. Water Infrastructure package).
- There is a strong and complementary relationship between Landcare and ICM in the Herbert River catchment. The Catchment Coordinator also acts as the Landcare coordinator and has encouraged the re-establishment of a group in the lower catchment.

Equity and procedural justice and perceptions of trust in process

- Overall members considered that all parties (ie. all three tiers of government, industry and individual farmers) should contribute to catchment management. However on average members felt that the Commonwealth and State Governments should contribute considerably more than other parties (ie 30% each) with individual farmers contributing the least (10%).
- There was clear perception within the HRCCC of the importance of procedural fairness (eg. in land allocation and planning decisions) and the need for better incentives for landholders and greater resourcing of community groups for catchment management.
- In 1998, most members considered that ICM was *not made difficult* because of:
  - The public's general lack of trust in government-sponsored initiatives;
  - The wide variety of values and beliefs among HRCCC members seriously detracting from an effective level of cooperation developing among them; or
  - A community perception that ICM has been forced on the catchment by the state government.
- Significantly, there has been a clear shift of opinion by members over time (1995-1998) from agreement to disagreement on whether the ICM implementation process was difficult because of:
  - the public's lack of trust in state/local government-sponsored initiatives;
  - the absence of a single acute resource management problem (eg. of the magnitude of salinity); and
  - the wide variety of values and beliefs among HRCCC members seriously detracted from an effective level of cooperation developing,

These changes suggest both an increase in the confidence of HRCCC members in the ICM approach and a greater acceptance/tolerance of the diversity of views amongst members.

FACTORS THAT INFLUENCE THE SUCCESS OF ICM

Establishing confidence and credibility in the process

- The inception of ICM in the Herbert was a voluntary process that was actively negotiated by key actors in the catchment in local government and industry organisations. As such it has attained a certain degree of credibility within the catchment because it has not been seen to have been forced on them by government or other 'outsiders'.
- The HRCCC has a representational structure and the perceived inclusiveness of the key catchment stakeholders on the committee has been important to its credibility with other groups and processes in the catchment. In providing a truly representative community forum a CCC can facilitate (a) exchange of information between stakeholder organisations on NRM issues, (b) the development of an appreciation of other viewpoints, and (c) a more informed debate on catchment issues.
- Achieving a truly representative ICM process is in part dependent on the identification of an appropriate "scale of catchment" for the ICM initiative, ie. one that is relevant to the key catchment management problems and meaningful to the "community of interest". With a clearly differentiated upper and lower catchment context (socially, topographically and economically) in the Herbert River catchment, the formation of a new sub-committee in the upper catchment provides the basis for a more inclusive and integrated approach to catchment problems that was not perceived to be the case with one initial lower catchment dominated HRCCC.
- Project funding successes (e.g. NLP/NHT), the appointment of an innovative and active Chair of the HRCCC, development of strong linkages with Local Government and the Herbert River Improvement Trust (HRIT), collaborative projects with other local stakeholder/interest groups, improvement in general in the cooperation amongst collaborating government agencies on ICM, and the appointment of additional DNR extension staff in the catchment are key factors raising the profile of ICM in the community and gaining a certain degree of confidence in the process and credibility amongst stakeholder groups.
- Understanding of cause-effect relationships and 'solutions' to major issues in the Herbert River catchment have varied along a scale of 'speculative' (eg. fish kills) to 'uncontested' (eg. acid sulfate soils). The lack of technically uncontested 'solutions' for highly sensitive issues in the catchment at times has led to substantial community conflict and lack of confidence in government, research and other relevant agencies and therefore has inhibited progress on these issues.

Creating awareness of issues and the ICM process

- Particular in its initial stages, ICM may be more process than product and therefore may lack tangible outcomes for a considerable time. Focussed high profile activities that are small, topical, measurable and have visible outcomes (eg. owl nesting boxes, Catchment Atlas) have provided a win-win illustration of progress. They have also been important in raising community awareness of the ICM process and fostering on-going commitment of HRCCC members to a slow evolving process.
- An inclusive and participative approach to developing a Catchment Management Strategy substantially raised awareness of issues and others viewpoints within the HRCCC, it identified that there were substantial areas of common agreement amongst stakeholders on so key issues, and thus helped to establish an overall direction for the group.

Precipitating action

- The success of ICM in precipitating action on catchment issues depends on the willingness of the participating individuals to build trust, resolve/deal with conflicts in the catchment community and work on maintaining productive interactions within the context of workable institutional arrangements.
- Understanding the history of land use change within the catchment helped in understanding the causes of some issues, to identify the target/client group and helped also to target strategies to resolve the problem.
- Moving from identifying and prioritising issues and developing a catchment strategy to precipitating action on that strategy has been a major challenge for the HRCCC. Guidelines that identify practical options or strategies for helping the CCC address specific natural resource

issues on the ground have generally been lacking.

Acting to resolve conflict

- A major challenge for an ICM organisation like the HRCCC in progressing action on issues is how to deal with a range of conflicts that exist between catchment stakeholders. Such conflicts existed in the Herbert between different state government agencies and even sections within a department in providing contradictory or conflicting information, within the catchment community about development (eg. growers, conservationists), in relation to individual versus community rights, and among experts about biophysical processes (eg. fish kills) or which mechanisms to use (eg. statutory).
- Although there may be consensus amongst stakeholders in identifying the key catchment issues, much greater difficulty and even strong conflict may occur in gaining agreement on the prioritisation of issues and the best ways or strategies for the ICM initiative to address them. This may be even more complicated by the common situation that representatives on the CCC frequently wear several 'hats' or roles during their engagement with particular catchment issues.

Ensuring continuity

- HRCCC meetings have provided an effective on-going forum for networking and responding to community needs by providing a central "pool' of information to be available to address business, and operating as a link between local government, state government agencies and various catchment stakeholders groups for NRM.
- State seed money for ICM is crucial to making the local/community side of the partnership work (eg. for organisational start-up and development, capacity building and general operational costs, and leveraging other sources of funding for undertaking projects).
- A well funded Catchment Coordinator was essential to "drive" the process and perform administrative and other "burn-out" producing tasks (eg. communication/media, grant writing, coordination of activities). The lack of continuity and security of funding for a Catchment Coordinator has been a major concern to members and at times has inhibited progress on ICM.

Maintaining commitment to the process

- CCC members are frequently active and committed community leaders or 'committee people' who may have "too many hats". Loss of motivation and burnout are a high risk amongst members.
- The approach to selection of members/stakeholder representatives on the HRCCC has been to ask for a nomination from the organisation concerned. Representatives have tended to be community leaders or 'committee people' who are often already over-committed. Also unless there are clear rules and strategies agreed upon regarding election of office bearers and renewal of representatives periodically there may be stagnation in the ICM implementation process and even dissatisfaction amongst members.

Establishing an influential role

- The emphasis of the ICM process on fostering a partnership approach between government and the community is seen as one of its key strengths. Many of the HRCCC members were not in favour of an approach to NRM issues and planning based on the community alone making the decision. Concern was expressed that decisions would be based on the vested interests of particular dominant catchment stakeholder groups rather than for the benefit of the catchment community as a whole.
- ICM has had a substantial influence on local government planning in a relatively short period of time in the lower catchment. Importantly, a partnerships has formed between the HRCCC and local government with local government taking greater responsibility for the implementation of ICM principles and strategies. This partnership is the result of improved communication between catchment committee and local government, a better understanding of the principles and objectives of ICM within local government and because of an improved recognition of the role of local government in the management of natural resources by the HRCCC. Importantly, local government involvement has been of critical importance to the success of ICM in the Herbert. Effectively, ICM could not really have had the impact that it has without this strong partnership with local government.
- The improvement in the system of organisational networks and formal linkages has provided

opportunities for more coordinated and inclusive collaborative projects and ventures on NRM in which ICM has been a key player. These linkages have been fundamental in helping the ICM process take an influential role in catchment management.

RECOMMENDATIONS

- The ICM process provides a multi-stakeholder mechanism for community participation in ESD that should not be seen as a vehicle for radical shifts in power relations within the community but a vehicle for influencing policy agendas on NRM.
- Established social networks and interactions, fundamental social values, legal/institutional frameworks and historical influences have shaped the current human association with the natural resource environment in the Herbert and will continue to influence the pattern in future. An ICM process needs to recognise these and work towards achieving ESD by influencing existing networks, value systems and institutional frameworks rather than creating a new set of structures and processes.
- In choosing the method of community engagement and a strategy for action for a particular catchment problem, attention needs to be given to the decision context relating to that problem (ie the level of technical complexity and the intensity of community conflict associated with the decision).
- Local government has enormous scope in achieving catchment management objectives through the incorporation of ICM principles into planning schemes. However local government land use planning is not the answer alone. It is limited in that it can only implement these strategies in Queensland when a development application is triggered by the planning scheme. Therefore to effectively achieve integrated catchment management, planning schemes and development assessment will need to be integrated with other land management arrangements that can deal more effectively with existing unsustainable use rights.
- Government agencies need to resolve bureaucratic gridlock and ensure long term agency commitment to the ICM process. The complex and often confusing array of Acts, programs, and policies that impact on resource management at the local, watershed, state and national levels need to be rationalised to ensure a truly integrated approach to catchment management. Examples of were this could occur through legislation at a State level in Queensland include the River Improvement Trust Act, Water Resources Act, Nature Conservation Act, Environmental Protection Act and the Land Act.
- Government agencies and other technical advisers or experts need to be careful not to push highly speculative solutions that may create greater social conflict and loss of trust in policy processes.
- An ICM process needs to establish clear and agreed ground rules on how the CCC will operate (ie. purpose, structure, composition, process). Some of the key questions that need to be addressed are:
  - What is the appropriate scope and scale of the ICM initiative – this requires defining the community of interest.
  - Who should be involved – this raises the issues of inclusiveness vs effective group size
  - How representatives are to be selected.
  - How office bearers are to be appointed and for how long
  - How decision will be made (eg. by vote or consensual decision)
  - What is the role of a representatives (eg. protecting own or sectoral interests, communication needs)
  - Ensuring legitimacy of representativeness (eg. use of proxies, review of membership).
- CCC members are frequently active and committed community leaders or 'committee people' who may have "too many hats". Efficient use of proxies and turn over of representatives are essential for an inclusive, enthusiastic and actively influential ICM process.

5. ANALYSIS OF THE SUGAR CANE ASSIGNMENT PROCESS IN THE HERBERT RIVER CATCHMENT

OBJECTIVE

Since the early 1990s, significant expansion in both growing area and milling capacity has occurred in the Australian sugar industry and in the Herbert River catchment in particular. Knowledge about the nature and processes that operate within the sugar industry are central in understanding both problems and solutions. The institutional arrangements that are often perceived to be part of the problem, as well as a part of the solution, are generally poorly understood.

The cane land allocation process arguably has the greatest influence on the use of natural resources in the lower Herbert River catchment. ICM has traditionally played a minor role in the cane land allocation process, however changes in sugar industry policy and increasing capacity within ICM groups represent an opportunity for this situation to change. As a contribution to the assessment of the institutional factors that influence the success of an effective ICM process, this Activity aims to evaluate the cane land allocation process in the Herbert River catchment in relation to its compliance with the objectives of ICM.

RELATIONSHIP TO OVERALL PROJECT STRUCTURE

This component contributes to the identification and assessment of factors that influence the success of an ICM implementation process. In particular it examines aspects of the following specific elements of the evaluation framework:

NRM Issue Characterisation

- Evolution of NRM in the catchment
- Extent of behavioural change required

Institutional Structures for ICM

- Policies, plans and decision rules of implementing agencies
- Coordination among implementing agencies

Analysis of Process

- Efficiency and effectiveness of process
- Equity and procedural justice
- Integration (degree of incorporation of process in structure and context)
- Agreed responsibilities and roles

METHODS

This activity involved a detailed evaluation of the cane land allocation process in terms of efficiency, equity and performance in relation to the objectives of Integrated Catchment Management in the lower Herbert River catchment during the period 1993-1996.. This analysis was addressed through five different methodological approaches:

(i) Review of written records of applications for assignment;
(ii) Analysis of spatial data on the biophysical and land use characteristics of the lower Herbert River district (see Activity 1 of this study);
(iii) A statistical analysis of the relationship between the granting or rejection of assignment applications and key biophysical, economic and social parameters;
(iv) A geo-statistical analysis of the relationship between the granting or rejection of assignment applications and key locational parameters; and
(v) Semi-structured interviews with key sugar industry and government respondents at local and state levels.

KEY FINDINGS

Evolution of NRM in ihe catchment

- During the study period, 525 applications for assignment, covering an approximate area of 16,000 ha, were submitted to the Victoria and Macknade Local Boards for approval. It was feasible to link information from complete application forms with a companion spatial database for 472 applications (89.9%) of the total application pool. These applications encompassed an area of 15,013ha or about 94% of the total 15,994ha area applied for. During the study period, 472 applications were spatially represented and comprised an area of 15,013ha. From this total, 355 (75%) applicants were awarded their entire request, 92 (20%) were awarded less than their request, and 22 (5%) were denied. Of the 15,013ha applied for, 12,165ha were awarded, representing an 81% approval rate. 1,962ha were not awarded on the basis of an applicant being granted less than 100% of their request. In addition, 887ha were denied an award. All applications that were denied occurred in 1996 and represented an area of 2,736ha. Since the 1996 application pool contains applications that were denied, the analysis pays particular attention to it.
- Over 70% (8,655ha) of the awards granted during the study period occurred on land that both the Local Cane Assignment Boards and Environmental Advisory Committee (EAC) were deemed suitable by both bodies. About 7% (741ha) was granted on land that both groups perceived as unsuitable. Of concern is the 2,768ha of development that occurred in the area of disagreement. This represented about 20% of development during the entire study period. More importantly, in 1996, over 1,400ha of the total assignment of 3,601.5ha (38.8%) were located in this region. In the absence of an open and transparent decision-making process and effective conflict resolution mechanisms, cane expansion in these areas may alarm government officials (and interested members of the public) who are concerned with drainage and habitat issues. It is these considerations that the Local Boards and EAC disagree on.

Extent of behavioural change required

- These data and development patterns raise concerns about how effectively the sugarcane assignment process supports the objectives of ESD in general and ICM in particular. Changes to existing institutional arrangements are required if sustainable development is to be achieved.

Policies, plans and decision rules of implementing agencies

- Many of the recent changes, such as regulations under the *Fisheries Protection Act 1994* and the development of Codes of Practice and Environmental Protection Policies, are focused at the operational level of planning. However, they are often perceived as reactive rather than proactive. Their frequent use, particularly on newly assigned lands has prompted the question; "Why was this land assigned in the first place"? *Environmental Protection Policies* and *Codes of Practice* are an important part of the solution that ensures that an appropriate "duty of care" is achieved. However, they are only part of a package that must also incorporate strategic and normative level responses.
- There have been a number of advances at normative and strategic levels. All levels of government have supported the need for ecologically sustainable development with legislation and/or strategic planning initiatives. For example, in the Herbert District, the draft Cardwell/Hinchinbrook Coastal Management Plan aims to provide legislative support for ESD initiatives. Similar activities are underway in other cane growing catchments. It is also likely that catchment management strategies developed by Integrated Catchment Management groups will have a very significant influence on land use planning and development in local government areas in the future. The intent is to implement many of the provisions contained in these documents in local government Strategic Plans. This first step has happened in the lower Herbert River catchment with the incorporation of ICM principles in the new planning scheme (see Vella 1999).
- Much current decision-making in relation to the granting of "assignment" occurs in the absence of agreed catchment based plans for land, water and vegetation resources. Hence it is extremely

difficult to assess cumulative or potential downstream impacts of assignment applications/proposals.

- Clearing of native vegetation (particularly land close to stream and watercourses) remains one of the most contentious issues impinging on cane expansion activities. A number of options are available to the sugar industry:
  - Motivational and voluntary incentives including activities such as ICM must be a core mechanism for improved natural resource management eg. to reduce the clearing of valued habitats.
  - Although some protection for natural resources is currently afforded by planning controls embedded within a number of State *Acts,* problems exist in areas subject to the provisions of the *Water Resources Act 1989*, or on land with freehold tenure. An increasing regulatory role for Local Government (eg through the invocation of planning controls if consent is required for subdivision, zone change and drainage development) provides some opportunity for improved natural resource management. Some of these issues are presently being addressed in the planning schemes of Hinchinbrook Shire in the lower Herbert catchment and the HRCCC has had an important influence in this development (see Vella 1999).
- The introduction of the *Integrated Planning Act 1997* (IPA) and the reformulation of many Queensland local government Strategic Plans are fundamental guides for future resource management activities. The *IPA* allows local government to require landholders wishing to conduct intensive agricultural activities, such as cane farming, to obtain it's approval. While this mechanism could provide benefits, it appears to be focused on development control rather than strategic planning. Indeed, the intent of the Integrated Development Approval System within IPA appears to be primarily focused on streamlining decision-making processes, rather than enhancing their effectiveness.

Coordination among Responsible agencies

- The establishment of an EAC provides a mechanism for more formal communication between Local Boards and those government, industry and community representatives who have an interest in natural resource issues. However, this mechanism has many shortcomings. Members of an EAC can feel betrayed and frustrated when their recommendations are not acted upon, because there is an ineffective two-way process of communication. In cases where there are differences of opinion between the EAC and the Local Board, the latter is under no obligation to inform the former of why it rejected its recommendation. These differences of opinion can occur at two levels and pertain to: (i) areas that are suitable for cane expansion; and (ii) individual applications. A one-way exchange of information is supported through the present referral process.

Integration

- The essence of balanced decision making is to integrate economic, social and environmental considerations. Current assignment mechanisms provide very limited opportunity to support balanced decision making. Formation of an EAC and the development of the conditions of assignment reflect Local Boards' primary responses to the requirement that it and the Queensland Sugar Corporation are satisfied that assigned land is "prepared and used for the growing of sugar cane without undue damage to the environment". In practice, EAC's provide only modest opportunities to significantly influence decision-making. If decisions are to be more balanced, there is a need for the cane allocation process to introduce environmental and social issues earlier in the cane assignment process and to have the "assignment" process underpinned by a strategic planning outcome which represents the views of both sugar industry and non sugar industry stakeholders.

Equity and procedural justice

- More needs to be done to support the application of the precautionary principle through transferring more responsibility to proponents. Issues related to the management of Mahogany Glider habitat and acid sulphate soils in the Herbert River Catchment, for example, have

demonstrated the challenges of moving the management system towards the precautionary principle. Mechanisms need to be developed that place more responsibility on applicants and Local Boards for determining the nature and extent of threatening activities before the review of an individual application. In response, action will be required of CANEGROWERS, mills, and the BSES to determine: (i) the need for industry sponsored collection of essential data which further the existing information base; and (ii) the need for and basis of cost-sharing arrangements which support appropriate analysis during the application process.

Efficiency and effectiveness of process

- Effective responses to the changes, uncertainties, complexities and conflicts that will continue to be part of the sugar industry's future lie in innovative administrative mechanisms, planning initiatives, and scientific research. Thus, there are conceptual and practical shortcomings in present responses that suggest the need for changes to the cane land allocation process. While the industry is currently in a phase of reduced expansions, it needs to be adequately prepared for future expansions when economic conditions become more favourable. We argue that ESD in the sugar industry requires a better integration of economic, social and environmental considerations. ICM can play a key role in supporting the achievement of this goal.

Agreed Responsibilities and Roles

- The industry must take a leadership role if the importance placed on the environment and sustainability is to be realised. Present Conditions of Assignment suggest that failure to comply with restrictions may see the award revoked. This places increased responsibility for enforcement on the Local Board (Cane Production Board). These are new roles for these organisations. Leadership by the Local Board (Cane Production Board), CANEGROWERS and mills can establish an expectation that compliance is expected and required by all farmers. This type of widely based, voluntary action could engender very strong public support. ICM clearly has a role to play here. In its absence, public support will be nurtured through compliance and enforcement. The recommended audit should provide insight into both voluntary compliance and enforcement measures. Those findings will reflect on the leadership qualities of the sugar industry, and identify the need for evolutionary and revolutionary change in its management of natural resources.

FACTORS THAT INFLUENCE THE SUCCESS OF ICM

- ICM has had limited opportunity for influence on decision-making on the granting of cane assignment in the past.
- The focus of many existing regulatory mechanisms on development control rather than strategic integrated planning.
- Lack of an open and accountable process of cane assignment so that all parties with an interest can understand the assumptions and processes leading to decisions being made.
- Poor integration of the caneland assignment process with other land use and management planning processes, especially Local Government planning schemes.
- Lack of agreed catchment based management plans for land, water and vegetation resources that can be used in the assessment of cumulative or potential downstream impacts of assignment applications/proposals.
- Lack of time to undertake an effective open and accountable process that is effectively informed by appropriate and available information.
- Historical socio-cultural context in the catchment with established ways of doing things and a past history of encouragement by both government and industry alike of a development ethos in ignorance of the incremental and cumulative impacts of environmental degradation.

RECOMMENDATIONS

- The policy environment for ESD will continue to respond to changing political, economic, social and environmental considerations. While the manner in which resources are managed will vary, public expectations for, and support of, effective environmental management policies will

remain. In this regard, the principles for ESD will form the basis for the development of new and improved initiatives. ICM needs to take a key role in influencing these developments.

- The challenge for the sugar industry is to embrace, rather than resist, the inevitable trend toward greater public intervention in its affairs. In response, government must provide a stable environment in which locally relevant decision-making can occur and in which appropriate and viable monitoring, cost-sharing and regulatory arrangements can be supported. The Australian sugar industry must continue to develop its own capacity to plan for expansion (and contraction). Such planning must be a continuous activity rather than a single exercise. Further, the industry must develop its own strategic view on where and how sugarcane will be grown – both at regional and whole of industry levels. This view will need to be based on the best available scientific information and full utilisation of the products of its substantial investment in environmental R&D.
- In facing the significant challenges of balancing the dual goals of economic efficiency and environmental conservation in relation to cane expansion, the sugar industry in collaboration with ICM, can reflect on its own experience and that of other agricultural industries and move to a sustainable future by playing a key role in jointly:
  - *Developing structures and related processes and procedures that foster cooperation* between the industry and other industry, community groups and government organisations and paves the way for more equitable decision making and more sustainable natural resource outcomes on the ground;
  - *Ensuring open and accountable decision-making processes on caneland allocation* so that all parties with an interest can understand the assumptions and processes leading to a assignment recommendation or proposal and provide appropriate advice; and
  - *Supporting the integration* of resource management principles (including Codes of Practice for Sustainable Cane Growing) into Local Government planning schemes and decision-making processes.

6. COMMUNITY SURVEY

OBJECTIVE

The goals for managing catchment land and water resources need to be informed by the views and behaviours of those - whether seen as individuals or group and community members - within the catchment. The aims of the Community Survey Component therefore were as follows.

- To examine, longitudinally, landholders' behaviours and attitudes towards land and water management in the Herbert River Catchment.
- To provide an understanding of social factors that might influence the implementation of ICM in the Herbert.
- To provide an understanding of whether and how such factors vary according to where people live and what their interests are.

RELATIONSHIP TO OVERALL PROJECT STRUCTURE

This component will provide key baselines for the assessment of factors that hinder or foster an effective ICM process in the Herbert River catchment, and in particular examine aspects of the following specific elements of the evaluation framework:

Analysis of Processes:

- Knowledge and expectations of ICM
- Responsibilities and roles in ICM
- Degree of motivation, commitment and support
- Coordination of resources
- Equity and procedural justice/trust in the process

Context of ICM

- Attitudes of constituents
- Community support
- Socio-economic conditions

METHODS

This project component was designed as a longitudinal study of the attitudes and behaviour of Herbert River catchment residents based on 2 mail-out surveys. The sampling framework for these two surveys was stratified on geographic location - upper or lower catchment and rural or urban. In both surveys initially 800 people were phoned to ask their willingness to participate in the survey. There were 477 respondents to the initial baseline survey conducted in 1995 and 401 respondents to the second survey in 1998. The second survey included 44% repeat respondents.

KEY FINDINGS

Knowledge and expectations of ICM

- Awareness levels of ICM, the HRCCC and its main purpose were relatively high (42%, 42% and 39% respectively). These could be improved, particularly in urban areas and the upper catchment. Detailed awareness of their effectiveness was low.
- Priorities for ICM were considered to be: working closely with local government; encouraging joint projects; raising local awareness; gaining better understanding of environmental problems; developing solutions for these problems; and encouraging research.

Responsibilities and roles

- There was a high sense of self-responsibility for dealing with land and water management issues.
- Many community members felt that individual landholders had a role to play in land and water management and that there were ways they and their local communities could assist. To do this, they saw the need for support from the government in terms of resources and incentives.

Degree of motivation, commitment and support

- The majority of those who were aware of the HRCCC supported its general direction and effectiveness and were satisfied with the speed of its progress.
- Personal benefits of involvement in group activities were perceived by 31%, preparedness of respondents to become involved in land and water issues was around 40%, preparedness to assist in local projects was around 42% and intentions to become involved were around 22%.
- The level of involvement in local community groups or associations was 44% in the 1995 survey and 32% in 1998.
- Most respondents agreed there was an urgent need to address environmental problems, signifying the basis for a high degree of motivation to deal with problems.
- Time was an important factor preventing involvement in local community issues for 36% of respondents. A finding of the urban catchment management study (Nancarrow *et al.* 1998) was that people have commitments which impact on their time available for voluntary work.
- Support for ICM was implicit in the high degree of support shown for all of the proposed activities of ICM.

Coordination of resources

- Coordination of efforts by ICM and local government was seen to be extremely important, ie local government planning taking ICM into account and a local government role in ICM.
- Government agencies were perceived to often give conflicting information on land and water management issues, similar to the finding by Nancarrow at al (1998) that it can be difficult for community members to obtain information from government agencies and that a lack of internal communication often leads to mixed messages emanating from the Government to the community.
- Encouragement of joint projects was seen to be one of the main priorities for ICM.

Equity and procedural justice/trust in the process

- Funding contributions to ICM made by the three levels of government, industry and farmers were perceived to be relatively equitable.
- Respondents did not find government strategies to be highly useful to them on a personal level.
- Many respondents felt the government needed to give more resources to voluntary groups and give incentives for landholders to address environmental issues.
- Some of the major difficulties in managing land and water were seen to be caused by slow government strategies, slow reactions of government to new problems, and a low trust of government programs.
- There were split opinions regarding government and community roles in catchment management (eg whether or not: catchment management should be funded and run by the government; ICM should remain a voluntary activity; the government expects too much from local communities in catchment management; and programs like ICM interfere with people's rights to make their own decisions).

Attitudes of constituents to resource use issues and management

- People were generally satisfied with many aspects of living in the Herbert River catchment and perceived many advantages of living in the area. The majority of respondents would therefore possibly not support any changes threatening these aspects of their community.
- The most important issues identified by respondents were: unemployment; a lack of opportunities for young people; and a lack of diversity in industry. Further issues related to land and water management and included: clearing of marginal land; flooding; drainage; water quantity issues (ie. lack of water); fishing issues; the impact of weather and changing weather conditions on primary industry; and environmental issues.
- The awareness within the community of land and water problems and the perception that these issues are important, both personally and on a catchment scale, signifies general support for ICM to tackle land and water management on a number of fronts. However, land and water

management issues were not uppermost in people's minds which suggests that there needs to be awareness and acknowledgment by ICM that while people may support land and water management of various kinds, their first priorities lie with 'life issues'.

- While there was community interest in issues for the Herbert, the influence people felt was not particularly high, it appeared that there may be some conflict and not all respondents often thought about local community issues. These factors may hinder community participation in ICM.
- With regard to how manageable (or practical) catchment management might be, there were a number of impediments to effectively managing land and water in the catchment identified:
  - slow government strategies;
  - slow reactions of government to new problems;
  - the catchment's large area;
  - the cost of solutions;
  - a lack of easy solutions;
  - low trust of government programs; and
  - insufficient understanding of relevant problems.
- It will be important for ICM to address these perceptions of impediments, perhaps by:
  - encouraging timely responses from government;
  - encouraging financial support for ICM;
  - developing and promoting solutions;
  - encouraging improved formal and information communication between the government and the community; and
  - improving understanding of land and water management problems.

Community Support

- ICM activities were all seen as of moderate to high importance which suggests there is considerable support for ICM in the community. Community perceptions of the priority responsibilities for ICM were:
  - encouraging joint projects between government, industry and research;
  - raising local awareness of natural resource management;
  - gaining a better understanding of environmental problems;
  - developing solutions for environmental problems;
  - encouraging research; and
  - communicating on this work to the community.

Socio-economic conditions

- A lack of financial resources in the community were considered an issue for both solutions to natural resource problems and for personal planning.
- The largest impacts on the Herbert were seen to be from a loss of farm productivity, higher taxes, and higher production costs.

FACTORS THAT INFLUENCE THE SUCCESS OF ICM

This social research has demonstrated a number of factors which are crucial in positively or negatively motivating community involvement in ICM as summarised below.

Awareness

- Successful ICM requires a high degree of community awareness that there are important environmental problems that require timely action. Awareness of ICM in the Herbert was comparatively modest from the surveys. Those who were unaware of ICM and other related strategies on the catchment may be wary of these programs.

Control and Tractability

- A high personal sense of control in dealing with environmental problems, or a belief that individuals can help motivate the community to improve the environment will promote ICM. Unfortunately in the Herbert a large percentage of respondents felt they had a low influence over what happens in their community.
- Feelings of personal and community control are also related to feelings of tractability of the problem. All possible impediments to managing land and water as presented in the questionnaires in the Herbert were perceived to exist at least to some extent. Greatest impediments were seen to be with government: a lack of responsiveness and low trust in government programs.

Responsibility

- High level of support for community responsibility was shown by general agreement that many environmental problems come from the way individuals manage their properties. This is an advantage for ICM in gaining community participation but it will be very important for ICM to recognise the need for behavioural change at property level when working with the community and developing policies.

Perceived Personal Benefits

- Involvement in ICM is facilitated by an appreciation of personal benefits from becoming involved in group activities to help manage land and water. This was demonstrated by positive attitudes towards group involvement in the Herbert and the reported group activities of a substantial proportion of the community. Unfortunately, Government strategies were not perceived to be highly useful to respondents at a personal level and therefore not seen to be highly relevant at that scale.

Support for the Activities of the Catchment Coordinating Committee

- It is important that the community understands and supports what is trying to be achieved. The surveys showed that community perceptions of the main purpose of ICM matched closely with HRCCC objectives and their priority activities.

Coordination of ICM with Local and State Government Functions

- There was strong community support for a close a relationship between local government and ICM. This has already been established by the HRCCC. Unfortunately coordination of information flow from state government agencies was considered to be low in relation to environmental topics or ICM related matters.

Resources

- Obviously programs which are perceived to be well resourced both in terms of money and time are likely to be successful. Even though people thought current financial contributions from locals and government sources to be relatively equitable the surveys demonstrated worry about local people lacking money to spend on solutions. There was also concern arising from lack of finances about an inability for landholders to plan more than a year ahead. Reservations were expressed about government willingness to spend money on solutions in the longer term. In addition there was a perceived need for more government resources for voluntary groups and better incentives for landholders to address environmental issues/problems in the future.
- Finally, over a third of respondents felt that they had little time to become involved in local community issues.

RECOMMENDATIONS

Communication with the community

- The widespread community recognition of the importance, urgency and impacts of land and water issues can be exploited. Communication with the community can therefore focus instead on those issues where there was low awareness and a desire to know more, including possible solutions for environmental problems and ensuring there is something provided that the community can start working with immediately. Concentrating on solutions and actions can help to prevent a negative "doom and gloom" image sometimes perceived.
- Information and education should use the results showing which dimensions heighten the likelihood of participating and be presented with the local community in mind, responding to community needs and interests. Therefore, it will be important to emphasise those issues shown to increase intentions to participate by: encouraging an interest in local community issues; demonstrating the importance of land degradation to individuals; emphasising that the size of the Herbert does not make land and water management too difficult; and explaining in which ways government strategies are useful to individuals.

Working with the community

- In working with the community, it will be important to understand and acknowledge the historical issues that have been frustrating for the community in order to move forward in working with the community, gaining support and involvement. Related to this is the need to address the lack of influence felt by the community by showing that they have influence and demonstrating the ways in which they can influence land and water management. An important first step will be to respond to the issues in the community survey.
- Recognise money constraints and the limitations on people's time to become involved in local land and water management activities and promote solutions and activities for the broader community that can save them time or take very little extra time or effort.
- Use a partnership approach, between ICM, different levels of government (particularly local government), industry, landholders and the broader community. There is a responsibility for landholders to do things on the ground, which is widely supported by the community and needs to be recognised in this approach. At the same time, incentives for their efforts and resources for voluntary groups need to be provided by government rather than regulation. An important way to implement this will be joint on-ground projects. This includes ensuring consistency of the information that is provided for the community from government. In doing so, as there is little agreement on the exact roles of community and government, clear roles will need to be established at the commencement of any work. It was found in a National Review of Whole Catchment Management that giving groups more autonomy acts to increase motivation and a positive outlook (Syme et al. 1993).
- The perceived impediments to managing land and water need to be addressed by: speeding up government responses and strategies and communicating regularly about what is happening. This will assist in improving relations with the community and heightening trust in government. In addition, promote solutions to problems and, if possible, low cost solutions; clearly explain how the difficulties arising from the large area of the catchment are being addressed.
- Acknowledge the importance of employment and financial issues in working with the community and assist in the issues of financial management and productivity and start to identify, and publicise, employment opportunities in the solutions that are developed for land and water management. ICM therefore needs to include market and productivity issues as well as environmental issues to ensure relevance.

Research methods

- This relates not so much to the development of methods but to the value of attitudinal surveys to ICM. This type of survey extends social profiles beyond a demographic focus to:
  - perceptions;
  - a better understanding of tractability;
  - how effective ICM is perceived to be;

- identifying priorities for investigation, ie where to focus efforts in regard to specific issues, eg opportunities for use of the media).

7. ORGANISATIONAL COMMUNICATION AMONG ICM STAKEHOLDERS

OBJECTIVE

Whatever the precise aims of Integrated Catchment Management (ICM), success by definition depends on coordination of inputs from the multiple stakeholders and communication of the interpretation of these inputs between all parties. Effective communication both within and between stakeholder organisations is a prerequisite for trust to be developed and integration to occur. To-date, however, very little research has been conducted on how to measure the degree of communication between stakeholders of ICM and the effectiveness of the communication.

The principal objectives of this pilot study were:

- to develop and test a simple tool or approach for measuring the quantity, and various characteristics, of communication occurring on ICM and environmental issues among ICM stakeholders; and
- to shed some insights on the effectiveness of the organisational communication network on ICM in the Herbert Catchment in particular.

For the purposes of this study, communications include:

- formal (eg. a letter or e-mail) or informal (eg. a conversation or meeting at a social occasion);
- for one particular reason or for a number of reasons;
- personal (ie. individuals representing themselves) or official (ie. individuals representing their organisation); or
- 'one off' or a 'group' of communications with the same contact.

RELATIONSHIP TO OVERALL PROJECT STRUCTURE

This component contributes to the assessment of factors that hinder or foster an effective ICM process in the Herbert River catchment and, in particular, examines aspects of the following elements of the evaluation framework:

Analysis of Process

- Coordination of resources
- Influence
- Systems implementation
- Effectiveness of process

Context of ICM

- Attitudes of constituency groups

METHODS

A pilot study was conducted to measure communications about ICM and environmental issues between all significant stakeholder groups of the Herbert River ICM process. This was done to establish whether an effective communication system had been attained.

Stakeholders included:

- State Public Servants (Brisbane);
- State Public Servants (Regional);
- Regional participants in ICM in nearby catchments;
- Researchers
- HRCCC
- Landholders (not HRCCC)
- Prominent local people.

Across these groups, a total of 80 people were contacted to ask if they would participate in this pilot study and 60 agreed. In less organised categories of people respondents were gathered in a "snowball" sampling manner. Those who agreed to participate were interviewed by telephone using

a questionnaire to measure the following aspects of communication:

- frequency of communication with contacts over the past year;
- the topics of communication;
- who initiated the contact;
- whether respondents represented themselves or an organisation;
- the outcomes;
- the degree of satisfaction with the communication;
- any resultant change in the respondent's outlook; and
- the respondent's opinion about resultant change in the contact's outlook.

KEY FINDINGS

Coordination of resources

A matrix of contacts revealed that that there was direct contact and therefore linkages between all major groups of stakeholders. Therefore the basis for a communication network was present, although the strength of links was variable. Most communication was categorised as "mutual" which indicated that the informal contacts made during meetings and other gatherings are important to the functioning of ICM.

The predominant reasons supplied by respondents for their communication, and the primary contacts associated with those reasons, were:

- policy/planning/decision making with local government and Brisbane state government;
- environmental issues with local government;
- research/project work with the HRCCC; and
- follow up on catchment/strategy issues with the HRCCC.

Influence

Influence in this study related to how much the communication was thought to have changed the outlook of those involved.

There was a tendency for respondents to report that they had influenced the outlook of others more than others had influenced them. This may be true but the result may have more to do with the tendency people have to describe their own activities more positively than they describe others, in other words, 'self-others biasing' (Kurman & Eshel, 1998).

Respondents reported the most change in outlook (for themselves and the contact) in communications with the HRCCC and with people on an individual basis. This is an important result to utilise in situations where attitude change is seen to be important.

The main ways in which *respondents* reported that *their outlook had changed* were: gaining greater awareness, understanding or knowledge or to share what is happening and ideas. Areas in which *respondents* felt the *outlook of contacts had change*d were: understanding/knowledge; greater awareness; and acceptance of ICM.

Systems Implementation

On the basis that establishing effective communications on ICM is a fundamental element of systems implementation in ICM, understanding the communication network is essential. In this study therefore, 'contacts' were categorised into *outward* (the respondent initiated the communication), *mutual* (through a mutual contact, meeting or other event) and *inward* (the contact initiated communication with the respondent). Most communications were found to be "mutual" which indicates the importance of mutual or informal ways of meeting to the functioning of ICM.

Respondents reported having initiated the communication (outward communication) more than contacts initiated the communication (inward communication). As noted above this may be due to

self-others biasing.

Effectiveness of process

In the communication study, effectiveness of process was looked at in terms of the outcomes of the communication as well as perceived satisfaction with the communication event. In general, outcomes from communication were very positive, the most commonly identified being:

- progress;
- understanding of issues;
- information exchange;
- resolution of issues/decision;
- gained information;
- changed their outlook;
- specific action taken; and
- coordinate/collaborate.

With the exception of local landholders, most perceived their communications in relation to ICM to be satisfactory. Satisfaction was highest, however, for communication with the HRCCC and local government, which indicates a greater satisfaction when communication was with local bodies.

Attitudes of constituency groups

Major concerns for those involved in ICM were:

- the environment in general;
- ineffective decision making processes and communication;
- water quality; and
- flooding, drainage and their management.

For those not involved in ICM, however, flooding, drainage and their management were of greatest concern.

Methods

- The simple questionnaire investigation provided a methodological basis on which to evaluate the adequacy of communications at a system level for ICM. The study also demonstrated the feasibility of monitoring communication networks and their adequacy over time.
- To improve this research face-to-face rather than telephone interviewing should be adopted to ensure greater rapport and information exchange between the researcher and the interviewee.
- The pilot questionnaire took some time to complete for more "central" stakeholders in the ICM process because of their large number of pertinent communications. Efforts should be made to streamline the measurement of communications for these individuals by identifying major strengths and weaknesses rather than attempting to enumerate individual communications.

FACTORS THAT INFLUENCE THE SUCCESS OF ICM

- The existing linkages and communication network among stakeholders of a catchment provide opportunities for improved coordination of resources (such as information, knowledge, and understanding of issues) particularly through mutual or informal contact.
- Effective communication networks among catchment stakeholders provide for mutual benefits (such as information exchange, progress or ensuing action on the issue of communication, better understanding of issues) and mutual influence (eg. changed views, acknowledgment of problems, increased awareness of problems, sharing of ideas, increased acceptance and awareness of ICM). These outcomes seem to be occurring to an acceptable extent in the Herbert situation.
- Communication issues and related problems which may inhibit an effective ICM process include:
  - Difficulties in getting acknowledgment of problems by all stakeholders;
  - Perceptions that issues are too politicised and too big to deal with and that there is lack of

resourcing and true commitment to ICM both within government and the community;
- Difficulty some stakeholders have in explaining concepts of ICM to others;
- The assumption by many stakeholders that they are influencing others outlooks much more than they may be in reality.

RECOMMENDATIONS

Implementing an ICM initiative

- The effectiveness of communications provides an important measure of whether coordination is happening, and also identifies where there are gaps in the system and the effectiveness of specific/different linkages on ICM. Measuring this effectiveness should be a routine part of any ICM evaluation, particularly in the early stages.
- Communication between groups and individuals are potentially an important means of influence in terms of changing outlook of others on ICM or environmental issues. In particular communication is effective in increasing awareness and gaining understanding and knowledge. Nevertheless, there should be caution in assuming how much perceived influence people are having on others, and it is therefore important for ICM to evaluate this.
- The importance of 'mutual' communication should be recognised. Opportunities should be created for mutual and informal contact and information exchange. If considered successful, such contacts are likely to be self-perpetuating.
- An effective overall system of communication on ICM across all stakeholder groups should be designed to facilitate significant outcomes including:
  - *mutual benefits* (such as information exchange, progress or ensuing action on the issue of communication, better understanding of issues).
  - *mutual influence* or changed outlook (including changed views, acknowledgment of problems, increased awareness of problems, sharing of ideas, increased acceptance and awareness of ICM).

Methods for ICM Evaluation

- The simple questionnaire investigation demonstrated the feasibility of monitoring communication networks and their adequacy over time. As such it provides a mechanism for measuring an indicator of the transaction costs or communication "effort" required to keep a system such as ICM operating. This questionnaire should be applied both during the development of ICM and from time to time during it mature operating phase.

PRINCIPAL RESEARCHER(S):

Geoff Syme and Janet McCreddin

FURTHER READING

McCreddin, J.A., Syme, G.J. & Porter, N.B. 1999. *Integrated Catchment Management Communication Study: The Herbert River Catchment, Queensland.* CSIRO Land and Water Consultancy Report No. 99-18.

8. MEDIA STUDY

OBJECTIVE

This project activity focuses on how natural resource management issues in general and integrated catchment management in particular were presented in the media. In a survey of the catchment conducted by Butterworth *et al.* (1997) various media were found to be important sources of information about land and water resource issues. *The Herbert River Express,* the local newspaper for the lower Herbert catchment was used more frequently than any other source of information (60%), including friends and colleagues (54%) and personal experience (39%). In the lower catchment it was the source of information for 84% of those surveyed.

This component therefore focussed on a content analysis of the *Herbert River Express* as a key source of information for the loer Herbert River catchment community. Specifically, it involved an assessment of the representation of natural resource management issues in general, and integrated catchment management in particular, as they were presented by the *Herbert River Express* over the time frame of July 1990 to June 1998 to provide an overview of:

- Changes in emphasis on natural resource management issues over an eight year time frame;
- Changes in emphasis on Integrated Catchment Management issues over an eight year time frame; and
- The dominant community values regarding natural resource management and Integrated Catchment Management as presented in a local newspaper.

RELATIONSHIP TO OVERALL PROJECT STRUCTURE

This component contributes to the assessment of the social context in which the ICM process in the Herbert River catchment occurs as well as the assessment of factors that influence the success of the ICM process in the Herbert River catchment. In particular it examines aspects of the following specific elements of the evaluation framework:

Context of ICM

- Media coverage and attention

Analysis of Process

- Influence

METHODS

A quantitative and qualitative analysis was made of articles and Letters to the Editor covering natural resource management issues published in the *Herbert River Express* from 1990-1998. Because this newspaper is not available on line or on microfiche, it was necessary to physically handle each issue of the newspaper to assess the content. Conducting only a quantitative analysis of these issues would have provided a limited view of the social context in which integrated catchment management was occurring. Whilst a qualitative analysis is time consuming, it provides a more detailed understanding of the nature of community values held about natural resource management. The quantitative analysis used Gregory and Williams (1981) point score framework and the qualitative analysis was based on extrinsic (ie. economic, life support and aesthetic) and intrinsic (ie. moral/spiritual) values after Xu and Bengston (1997) and Callicott (1989).

The aim was to examine articles on environmental and natural resource management issues in *The Herbert River Express* to provide a view of local perspectives on integrated catchment management in particular. *The Herbert River Express* is a paid tabloid with a circulation of approximately 3,200 and published three times a week.

KEY FINDINGS

Media Coverage/Attention

- Over the eight year time frame of 1990-1998 natural resource management issues were increasingly prominent in the *Herbert River Express* with 1995-96 and 1996-97 exhibiting the highest levels of prominence. Themes identified within natural resource management issues included: sugar industry; forestry industry; tourism industry; waste management; land resources; fisheries; pest/feral species; world heritage; river/stream/water management; soil conservation; flora/fauna issues; government initiatives; and other. River/stream/water management issues were the most prominent over time comprising 36% of all natural resource management articles. Political controversies comprised 20% of the articles and pest/feral species 15%.
- The occurrence of articles in the *Herbert River Express* clearly reflects that the Herbert River Catchment Coordinating Committee (HRCCC) has a profile in the lower catchment community. However, the analysis does indicate a lag in the time between the inception of ICM in the Herbert River catchment in March 1993 and the HRCCC developing a profile in the community and also possibly influencing the presentation of natural resource management issues in the community. For example, over the eight year time frame, 1996-97 and 1997-98 were the years where river, stream and water management issues were the most prominent.
- Although the actual number of articles on river, stream and water management issues appearing each year peaked in 1995-96 there is a tendency for the prominence of these issues to increase over time. This suggests an increasing community interest in, or focus, on river/stream and water management issues. The *Herbert River Express* also provided information on the role and function of the HRCCC and at times emphasised the importance of community involvement in natural resource decision making.

Influence

- The dominant community values regarding natural resource management and integrated catchment management as presented in the local newspaper were life support values. The sample of articles exhibited no intrinsic values held about river/stream water management issues in the Herbert River Express. Life support values were found in 65% of the articles, economic or utilitarian values in 26% and aesthetic values in the remaining 9%. These life support values focus on issues of flood mitigation, water course management and ensuring the viability of the sugar industry, but more in terms of the way of life it represents. That is, the identity of the district as a sugar cane production area is strong.
- The term 'Integrated *Catchment Management* 'specifically appears from mid 1996 and is stressed as an important issue for the community. The HRCCC is portrayed as a contributor to achieving the goals of productivity, development and sustainability of the local community. The media representation of the HRCCC is positive and is clearly linked with integrated catchment management in almost all articles involving the HRCCC.
- Extrinsic, '*life* support' values were the predominant values presented in natural resource management issues in *The Herbert River Express*. This seems fitting as the community in the Herbert River region is agriculturally based and located on a flood plain. The community's identity and well being is dependent on the health and sustainability of their natural resources, and is clearly evident from the manner in which the local newspaper presents issues. Intrinsic values were not apparent.
- An *important* issue is that it seems that *The Herbert River Express* editorial policy appears to operate in a manner that excludes views that do not adhere to the dominant social values locally. However, once an item is accepted for publication there appears to be so little editorial interference that the material can be accepted as representing the dominant values held.

Research Methods

- The use of a media as an unobtrusive source of data for research on the social context is becoming more popular as the data is becoming more readily available in 'on-line' data bases. For national media this provides a useful perspective on changing attitudes to environmental issues (Bengston *et. al.*, 1999). On the basis of the results of this research we suggest that despite

the difficulties of data collection and analysis, local newspapers such as *The Herbert River Express* are rich sources of data for social context on resource management issues.

- There are two main methods used to conduct content analyses of media. There are those which focus on individual words, a method primarily employed by social psychologists. We found that the method which focuses on the article as the unit of analysis allowed a greater consideration of the broader social context within which the issues occur. In the context of this study we felt the latter approach more appropriate. There are other research contexts in which the former approach is more appropriate, particularly where the data are already 'on-line'.

FACTORS THAT INFLUENCE THE SUCCESS OF ICM

- The social context in which an ICM initiative operates may have an important influence on its progress. How resource management issues and ICM processes in particular are presented in the local media may reflect, and in turn, influence a community's values on these issues.

RECOMMENDATIONS

- The number and frequency of articles on natural resource management issues and ICM in particular show that local media such as local newspapers can contribute to community discourse on natural resource management issues and can be exploited to bring attention to an ICM approach within a catchment community.
- Analysis of newspaper coverage provides a useful and unobtrusive means of gauging community values about natural resource management issues. In future studies of these issues newspaper coverage might be a useful starting point for assessing community values and attitudes.

9. AN ECONOMIC EVALUATION OF ICM IN THE HERBERT RIVER CATCHMENT

OBJECTIVE

The role of ICM organisations is to provide a vehicle for the implementation of natural resource management in an integrated way at a catchment scale. The objectives of this project activity were:

- To identify an appropriate methodology for the economic evaluation of ICM organisation in the Herbert River catchment (ie. Herbert River Catchment Coordinating Committee or HRCCC)
- To establish the economic context for the ICM organisation in the Herbert, and
- To undertake an economic evaluation of the Herbert River ICM organisation to provide information to decision-makers about the efficiency of public sector investment in these organisations and about the possible distribution of identified costs and benefits.

RELATIONSHIP TO OVERALL PROJECT STRUCTURE

This component contributes to the identification and assessment of (a) the implementation context of the ICM process in the Herbert River catchment, (b) factors that influence the success of that process from achieving stated objectives, and (c) potential impacts of an ICM initiative. In particular it examines aspects of the following specific elements of the evaluation framework:

Implementation Context of ICM

- Socio-economic conditions

Adequacy of Policy Frameworks and Institutional Arrangements for ICM

- Adequacy and effectiveness of policies, plans and decision rules of ICM and other responsible agencies/groups for NRM
- Adequacy of financial resources for ICM

Analysis of Process

- Efficiency and effectiveness of process
- Equity and procedural justice

METHOD

The economic evaluation of the ICM organisation in the Herbert River catchment had three methodological components:

(i) A review of the literature to identify economic evaluation techniques that would be appropriate to evaluate ICM organisations and to identify their strengths and weaknesses.

(ii) An economic profile of the sub-regional economy was developed using land-use data, historical employment data as well input-output techniques.

(iii) An economic evaluation of the HRCCC was undertaken based on a cost-benefit analysis using an outcome-scenario approach (Robinson *et al.* 1998). Initially, the costs associated with establishing and administering the organisation were estimated. A number of the activities undertaken by the HRCCC to implement its stated strategy were then evaluated to determine whether the potential benefits associated with these activities would meet the costs of the organisation.

KEY FINDINGS

Implementation Context for ICM Initiative

- The economy of the lower catchment is heavily dependent on the sugar industry and the economy of the upper catchment is dependent on the cattle industry. The economic impact of these industries on the regional economy of North Queensland shows that, together, these industries make a significant contribution (both direct and flow-on effects) to gross output and employment in the region:
  - *Output*: the sugar industry of the lower Herbert River catchment contributed to over $354m of output in the regional economy, including $206m of output from sugar production and a

further $148m in flow-on impacts from other industries in the region. The cattle industry in the upper Herbert River catchment contributed $16m in output to the regional economy, including $13m in output from Cattle production and a further $3m in flow-on impacts.

- *Regional employment*: the sugar industry of the lower Herbert River catchment provided employment for over 3,300 people in the Northern statistical division in 1995. Over 1,300 of these people are estimated to be employed directly in the production of sugar with a further 1,936 people employed in industries supporting the sugar industry. The cattle industry in the upper Herbert River catchment is estimated to provide employment for 170 people, which includes 120 people employed directly in cattle production and a further 49 in support industries.

- The economic sustainability of these industries therefore is critical to the regional economy.
- The financial viability of cane farmers in the future is not optimistic. The possibility of reduced financial viability could result in reluctance, on the part of farmers, to engage in farm management practices which, though regarded as improving the state of the environment, would not directly improve the financial status of individual framers.

Adequacy and effectiveness of policies, plans and decision rules of ICM and other responsible agencies/groups for NRM

- Implementation of strategies for resource management by individual ICM organisations in Queensland requires the voluntary cooperation of the community, local government and government agencies. The ICM organisation does not have the authority to legislate or pass laws to regulate resource use. The organisation is only able to influence the regulation of resource use through an organisation, such as local government, which does have this authority. Alternatively, where regulations are not enforceable, for example on freehold land, the voluntary support of the community may be the only alternative.
- A more recent legislative approach towards promoting ecologically sustainable development in Queensland, the *Integrated Planning Act* (1997), does not specifically identify a role for ICM organisations in the planning and management of natural resources.

Adequacy of financial resources for ICM

- The HRCCC is financially constrained. Apart from the catchment coordinator, who has been funded through the federal government's National Landcare Program (NLP) and supported in terms of administrative and office accommodation by the Department of Natural Resources (DNR), the organisation is staffed and supported by local stakeholder bodies such as the local council and sugar industry bodies. No formal cost-sharing of resource management activities is in place.
- For the most part, HRCCC activities, including data collection research activities as well as specific projects and programs, are funded by grants from state and federal governments as well as industry support organisations which are awarded through a competitive bidding process. The extent and speed with which the organisation can implement its strategy is largely determined by the level of funding it can attract.

Efficiency and effectiveness of process

- The objectives of the HRCCC are caste in general terms which encompass both its role as a coordinator between the catchment community and government agencies as well as its role as a monitor of catchment health. The HRCCC is constrained in undertaking these roles both financially, in terms of funding to carry out specific activities, as well as institutionally, in terms of its legislative or statutory power to regulate resource management.
- The present value of the costs associated with the establishment and on-going administration of the HRCCC over a period of 20 years is estimated to be approximately $974,000. To offset this cost, the HRCCC has undertaken a number of specific activities in the catchment. These activities have been funded from both the public purse as well as from the catchment community. They relate to: (i) management of riparian vegetation, (ii) preservation of natural habitats, (iii) management of drainage problems, (iv) management of wetlands, (v) management

of acid sulfate soils, (vi) strategic river bank protection and (vii) the stabilisation of relict mining dams.

- The activities undertaken by the HRCCC have the potential to significantly improve or preserve the condition of natural resources in the catchment. The *potential costs* of these activities are incurred by both individual landowners (eg. opportunity cost of land, restoration or remediation works, materials and construction costs, in-kind contributions of time and equipment) and the catchment community (eg. cost of reparation or remedial works, construction costs, wages and publicisation). Similarly *potential benefits* will accrue to both landowners (eg. avoided costs of lost production, aesthetic attraction of improved habitat, reduced production costs, improved water supply) and the catchment community (eg. improved downstream water quality, retention and improvement of natural habitats, reduced social conflicts, reduced litigation and transaction costs, aesthetic benefits, avoided costs of resource degradation and damage to infrastructure).

Equity and procedural justice

- For the successful implementation of a number of activities undertaken by the HRCCC, notably management of riparian vegetation, management of acid sulfate soils and management of wetlands, private property owners would incur considerable financial expense, but many of the benefits accrue to the community in general.
- All of the potential benefits resulting from investment in ICM activities are not equitably distributed among farmers incurring the cost and those who do not contribute to the cost can not realistically be excluded from enjoying the benefits. In effect, the positive externalities resulting from on-farm investment in improving the condition of the environment cannot be internalised. In an economic climate where the financial viability of farmers is generally deteriorating, the ability, and therefore the willingness, of farmers to invest in improved resource management is likely to be considerably reduced.

Methods for Supporting ICM Processes

- Economic evaluations are not routinely undertaken for natural resource management policy initiatives, and where they have been undertaken they do not generally address the social costs and social benefits arising from the implementation of the policy initiative. In addition, there is no consistent methodology for measuring and valuing a change in the condition of natural resources.
- Cost-benefit analysis has the potential to provide a consistent and reliable evaluation of an ICM organisation. To undertake a CBA of the HRCCC, a number of simplifying assumptions were required including those concerning the causal relationship between the activities of the HRCCC and potential improvement in the condition of natural resources.
- Insufficient data was available to provide an estimated NPV of the investment in the HRCCC, that is to establish, measure and value causal relationships between the condition of the natural resources in the catchment and the activities of the HRCCC. In particular, there was: (i) limited data available to identify the "without project" scenario; (ii) lack of on-going data collection to determine any improvements in the condition of the natural resources in the catchment and (iii) limited data to enable credible valuation of any deterioration in the condition of the environment or of the benefits resulting from improvements in the condition of the environment.

RECOMMENDATIONS

- Because ICM organisations in Queensland cannot rely on the legislature to introduce and enforce property rights which would be environmentally appropriate, informal and frequently less reliable methods to encourage the adoption of norms of good behaviour need to be adopted. Implementation of strategies for resource management by individual ICM organisations therefore requires the voluntary cooperation of the community, local government and government agencies.
- Community-based organisations, which rely on the voluntary cooperation of individual resource managers, may need to consider the financial viability of managers and offer financial incentives to improve the effectiveness of their strategies. Specifically, ICM organisations will need to address the problem of encouraging farmers to take on farm management practices that could

result in improvements to the land and water resources when to do so could result in a shortfall in their income and limited personal benefits. Educating farmers is not necessarily going to result in a change in behaviour. Financial incentives may need to be introduced if a change in attitude is going to lead to a change in behaviour that will result in an improvement in the condition of natural resources.

- While acknowledging the problems and limitations underlying cost benefit analysis (CBA), CBA can provide valuable information for an ICM organisations that can guide the ICM implementation process regarding the efficiency of its investments as well as the distribution of the costs and benefits resulting from its activities. To facilitate such evaluations, indicators measuring the condition of natural resources need to be identified and monitored to enable substantiation of claims of natural resource improvement.

10. INFORMATION NEEDS FOR ICM

OBJECTIVE

The purpose of this activity was to explore key issues and considerations for planning and managing information needs and provision to support community-based approaches to integrated resource management through case study investigation of ICM in Queensland, and the Herbert River ICM process in particular.

In particular, the activity aimed to review information needs associated with the following four tasks and to make recommendations on their management:

- Developing a catchment management strategy that identifies and prioritises land and water management issues and develops recommendations;
- Raising awareness of catchment issues;
- Influencing resource managers' activities, including precipitating/catalysing action; and
- Implementing an effective ICM program.

RELATIONSHIP TO OVERALL PROJECT STRUCTURE

This activity contributed to the identification and assessment of the implementation context of the ICM process in the Herbert River catchment and factors that influence the success of that process. In particular it examines aspects of the following specific elements of the evaluation framework:

Implementation Context for the ICM Policy Initiative in the Herbert River Catchment

- Socio-economic condition and use of technology

Adequacy and Equity of the Herbert River ICM Processes

- Efficiency and effectiveness of process
- Agreed responsibilities and roles

METHOD

(i) Collation and review of multiple data sources:

- Policy documentation on ICM;
- Lead agency documentation supplied to a Catchment Coordinating Committee (CCC);
- R&D findings and related documents from the CTC7 research project;
- Minutes of HRCCC meetings;
- Targeted semi-structured interviews with three key informants in the Herbert River ICM process;
- On-going interviews and discussions with key informant/participants of ICM; and
- The collective experience of the research team.

(ii) Data analysis using qualitative assessment techniques

Information that was asserted or predicted to be relevant in the various documents available to an ICM CCC was compared to evidence for what information was actually used in the context of the Herbert initiative for each of the four tasks identified (ie. catchment strategy development, awareness raising, influencing resource managers and precipitating action and running an effective ICM program). Explanations for, and the implications of, the difference between the two were then explored.

KEY FINDINGS

Socio-economic condition and use of technology

- Given the consensus that the HRCCC has a primary role in awareness raising, improving communication on catchment management issues and lobbying for action, it is not surprising

that the HRCCC has not made extensive use of Information Technology in its own right. Nevertheless, the availability to other stakeholders of technologies to underpin resource management has been important to the HRCCC, which has, therefore, fostered the further adoption of such technologies. The most significant example of this in the Herbert has been the HRCCC's support for the establishment of the Herbert Resource Information Centre, a collaborative GIS venture for the management and use of spatial resource data for the catchment. The HRCCC is not a partner to the HRIC per se (the HRIC is a joint venture between Hinchinbrook Shire Council, CSR Ltd., the Herbert Cane Protection and Productivity Board, CANEGROWERS Herbert River District, CSIRO and the Queensland Department of Natural Resources), nor is it a significant user of the HRIC's data sets or services. Nevertheless, the HRCCC has had a role to play in facilitating and encouraging the use of those data and services by resource managers and planners.

- The HRCCC was also instrumental in bringing about the Herbert River Catchment Atlas in collaboration with CSIRO and the Herbert River CANEGROWERS. The Atlas was created by CSIRO and was extensively used in the development of the Catchment Management Strategy. The HRCCC has been instrumental in the broad dissemination of the Atlas, partricularly to schools, TAFE and for other awareness raising and educational purposes."

Efficiency and effectiveness of process

- In principle, in order to be successful, an ICM initiative has massive information needs from biophysical through socio-economic to procedural. However in practice in the Herbert River ICM process, most information sharing, management and analysis has been informal and verbal through Committee meetings, presentations by researchers and special interest groups and so on. The Catchment Co-ordinator did circulate information to HRCCC members and their has been exchange of information between members at meetings, but most data access was reactive. Information was mainly pushed out to the community via the media. Inadequate access to biophysical and socio-economic information was not perceived to overly constrain the HRCCC's activities, although inadequate procedural information probably did.
- The HRCCC continues to see the value of information and push for support for information-based programs. Thus, the HRCCC played a role in the establishment of the Herbert Resource Information Centre (HRIC) but has, in practice, itself made little use directly of the resources available through the HRIC.
- The specific information needs facing the ICM initiative in the Herbert have been unpredictable, or at least difficult to predict. Thus, the Committee's information requirements have been context specific in response to changing priorities and circumstances in the catchment. Furthermore, the information requirements have changed with the state of development of the ICM initiative and the maturity of the processes underpinning it.
- The specific awareness raising initiatives and involvement in instigating on-ground management that the HRCC has been involved in has been largely opportunistic and dictated by political imperatives and opportunities, funding options and technical understanding. Thus, for example, action has often been dictated by NHT funding priorities and opportunities as expressed by the Regional Advisory Panel rather than the priority needs expressed by the HRCCC.
- The HRCCC has had to be adaptive and responsive and, despite the strategic nature of the Catchment Management Strategy does not have the resources or mandate to plan major initiatives, whether on-ground or in relation to the design, collation and management of key natural resource management data. As a consequence, ICM in the Herbert has relied predominately on the corporate knowledge and expertise of members of the HRCCC and opportunities to access additional expertise from others on a needs basis – including researchers and State Government resource managers.
- Local knowledge and expertise is a primary source of information applied within the ICM process. This is consistent with the nature and intent of ICM. Major ICM-based initiatives in the formal collection, collation and management of information relevant to the ICM process seem both inappropriate and unrealistic.

Agreed responsibilities and roles

- The reliance on local expertise and knowledge has clear implications for the management of

ICM to ensure its effective contribution to improved natural resource management including:

- the HRCCC needs to provide not only for effective representation of key stakeholder groups but also to provide as broad a base of expertise locally available as can be achieved.
- the Catchment Coordinator must have a key role to play in providing a stream of information to Committee members so that they can continue to expand their expertise in relation to ICM relevant issues.
- Relevant State agencies and other key stakeholder groups have a clear responsibility for effective communication of available information to members of the CCC.

FACTORS THAT INFLUENCE THE SUCCESS OF ICM

- Inadequate resources for an ICM initiative and lack of a mandate to plan major initiatives may mean that ICM activities (eg. awareness raising and on-ground action) will be largely opportunistic and often dictated by political imperatives and opportunities, funding options and existing technical understanding.
- Accessibility and availability of the local knowledge and expertise on catchment issues from as broad a range as possible of catchment stakeholder groups/interests is critical to a successful ICM process.
- Informal and verbal communication through social networks and existing institutional arrangements are critical for information sharing and analysis within the ICM process.
- Inadequate procedural information may constrain the focus and diversity of the activities of an ICM process
- Given that formal collection, collation and management of information relevant to an ICM process may be both inappropriate and unrealistic for a specific ICM initiative, the effectiveness of communication of existing information between state and other relevant bodies is critical.
- Capacity and a willingness within an ICM organisation to collaborate with other groups, agencies or individual experts with particular understanding of the issues may be essential for raising awareness of ICM issues and precipitating appropriate action.
- Adequacy of the skills and commitment of the staff ICM groups and other relevant agencies are critical to an effective and influential ICM process.

RECOMMENDATIONS

Planning Information Needs in Support of an ICM Process

- The specific information provisions required in order for ICM to contribute to the solution of problems are diverse from biophysical through socio-economic to procedural; variable with the stage of implementation of the ICM process; and in any specific instance, context specific; and unpredictable in response to changing circumstances and priorities in the catchment including political imperitives and opportunities, funding options and technical understanding.
- Information needs associated with an ICM initiative can be usefully considered and managed in relation to the following discrete tasks: developing a Catchment Management Strategy; raising awareness of ICM and issues that ICM is tackling; influencing and precipitating action and planning by others; and managing an effective ICM program.
- Local corporate knowledge and expertise is likely to be a primary source of information applied within the ICM process. It is imperative that the ICM committee provides not only for effective representation of key stakeholder groups but also provides as broad a base of expertise locally available as can be achieved.
- The Catchment Co-ordinator must have a key role to play in providing a stream of information to Committee members so that they can continue to expand their expertise in relation to ICM relevant issues.
- Major ICM based initiatives in the formal collection, collation and management of information relevant to the ICM process may be both inappropriate and unrealistic for a community-based ICM group to undertake. However it is imperative that effective communication of information is possible between relevant State agencies and other key stakeholder groups and members of the CCC.

Developing a Catchment Management Strategy

- Generically, the structure and content of the Catchment Management Strategy is dictated by State level policy. However, the local expertise of the members of the Catchment Coordinating Committee and other stakeholders consulted during the process of developing the Strategy need to be used to develop a Strategy within this general framework that meets local needs.
- The Strategy can not rely solely on local expertise. Extensive use of documented information and knowledge needs to be used to validate, 'reality check' and develop the structures and issues generated by the Catchment Coordinating Committee. This material should be properly referenced within the document.
- Because the Catchment Strategy is intended to be a living document, it is important that, as well as being referenced, the data and information that underpin the document are maintained by the Committee and that on-going process of continue to collection and collate key information continues so that future versions of the document can reflect an increasing documented resource base.

Raising Awareness of ICM

- Awareness raising is likely to be more productive in relation to issues that are well understood scientifically rather than remaining fundamentally contentious.
- Awareness raising on issues is likely to be opportunistic, so information collection for awareness raising must be rapid and responsive to opportunities.
- Effective awareness raising depends on a reasonable knowledge of the current level of awareness in the community, on the sources of information most widely used by people in the area etc. Collection of this type of information may be a worthwhile investment for a CCC.

Influencing and Precipitating Action

- As with raising awareness, influencing resource managers and planning processes and precipitating on-ground action will fall into the broad strategic direction set by the Catchment Management strategy. However, it is likely to be opportunistic and therefore not easy to plan for in terms of information provision.
- The expertise of members of the Catchment Coordinating Committee is often critical in identifying opportunities for influencing resource managers and planning processes as well as precipitating action.
- Collaboration with other groups, agencies or individual experts with particular understanding of the issues involved is often the most expedient way of precipitating appropriate action.

Implementing an effective ICM program

- Implementing an effective ICM program places a number of information needs on the Catchment Coordinating Committee. However, most information sharing, management and analysis was informal and verbal through Committee meetings, presentations by researchers and special interest groups and so on
- The State level coordinators of ICM need to ensure a regular and consistent flow of information to local groups.
- The Catchment Coordinator and Committee Chair need to ensure close and effective communication with policy level people.
- The management skills of the Coordinator and Committee members is important - appropriate people should be picked on this basis and additional training may be merited.

1.0 INTRODUCTION

Integrated Catchment Management (ICM) is an example of the significant investments that are being made throughout Australia in approaches to natural resource management through the integration of community involvement, technical knowledge, and organisational structure and policy objectives. The purpose of this report is to explore key issues and considerations for planning and managing information needs and provision to support community-based approaches to integrated resource management through case study investigation of ICM in Queensland, and the Herbert River ICM process in particular. While based on an assessment in relation to ICM, the findings presented in this report are of direct relevance to other integrated resource management initiatives across Australia.

The report briefly considers the background to ICM in Queensland and identifies four fundamental tasks faced by an ICM initiative. In the subsequent sections, the information needs associated with each of these tasks is considered in some detail. Finally we draw together the material and make recommendations in relation to planning for the information needs associated with an ICM initiative.

1.1 BACKGROUND

ICM in Queensland is being implemented as a partnership between catchment communities (as represented by Catchment Coordinating Committees, CCCs) and the Queensland Government. It is a policy initiative based on voluntary participation from the community and does not have a statutory underpinning per se (see McDonald *et al.* 1999).

The key elements of this ICM policy initiative promoted in Queensland were (Rowland and Begbie 1997):

- *Voluntary program.* Participation in ICM was to be voluntary for both community and government.
- *Community based*, meaning that all structures were to have a majority of community members. Formation of catchment coordinating committees (CCCs) was dependent on interest from the community and other sectors.
- *Partnership* between the levels of government, industry and the community. All sectors and key stakeholders are to be involved. As the CCCs do not have statutory "teeth", implementation of strategies relies on negotiated and voluntary action by responsible agencies and individuals.
- *Processes* used by the committees in coordinating and integrating management of the catchment are to be *participative and consultative.*
- ICM is about taking a *strategic and planned* approach to tackling important issues. This should be a feature of the actions of all catchment management groups.

The implementation of ICM in Queensland is based on the establishment of Catchment Coordinating Committees. The Queensland Integrated Catchment management Strategy (QDPI 1991) identifies that:

> *Catchment Coordinating Committees are established to address complex catchment management issues that involve many community groups and government agencies. Catchment Coordinating Committees comprise representatives of the major sectors of the community and government that are involved in, or influenced by the management of land and water resources in the catchment. Their major roles are to provide a forum for community input and discussion, to prioritise the issues and to develop and promote the adoption of catchment management strategies.*

One of the seven principles espoused in the Queensland Integrated Catchment Management Strategy (QDPI, 1991) is that "*Land and water resource management decisions must be based on the best available information*." This principle is elaborated in the same document with the observation that "*Information on land and water resources, particularly on the interactions between these resources, is often deficient or not readily accessible. While additional information is often desired, management decisions will need to be made using available data to avoid unacceptable delays.*" (QDPI, 1991)

The stated purpose of ICM as outlined in the Queensland ICM Strategy (QDPI 1991), is to integrate the management of land, water and related biological resources in order to achieve the sustainable and balanced use of these resources. The "key elements" identified in the ICM Strategy are : awareness; community action; and Government action and support.

The fundamental assumptions that underpin the ICM policy are that the objectives ICM initiatives will be achieved by:

- generating a better understanding of ecosystem interactions at a catchment scale by the community and Government; and, thereby
- moving towards common or agreed goals through development of a catchment management strategy; and
- facilitating coordination and cooperation within and between Government agencies and the Community to enable the prioritisation of actions; and
- joint or independent action to seek solutions to problems.

In order for these objectives of awareness and action to be achieved, the ICM Catchment Coordinating Committees, facilitators and other managers also need to be able to manage a successful ICM program.

1.2 TASKS FOR ICM

On the basis of these observations on the background to ICM, we propose that an ICM initiative faces four fundamental tasks: the requirement to develop a catchment strategy; the need to raise awareness of catchment scale issues and solutions; the need to precipitate action to bring about solutions; and the need to run an effective program in order to achieve the first three objectives.

Each of these fundamental tasks imposes particular information needs on the ICM initiative. Furthermore, these information needs have to be addressed with due recognition of the participatory nature of the ICM process. The role of communication in ICM as a basis for seeking consensus and building the capacity of stakeholders to contribute to integrated resource management means that information needs cannot be addressed as a technical issue independently from participatory processes.

Task 1 : Develop a catchment management strategy that identifies and prioritises land and water management issues and develops recommendations.

As identified above, the Queensland ICM Strategy (DPI 1991) identifies the development and promotion of a catchment management strategy as a fundamental requirement placed on all ICM groups. The process of developing a strategy demands some element of resource audit, issue identification, issue prioritisation and the identification of targets and responsibilities for action. Fulfilling these requirements involves accessing or creating and then integrating diverse information from a range of sources.

Task 2 : Raising Awareness of Issues

ICM aims to raise awareness amongst all stakeholders about issues of land and water management at a catchment scale, and the interactions between them. The focus on awareness is justified in the Queensland ICM Strategy as follows.

> *"The sustainable and balanced use of land and water resources depends on landholders and other resource users, the community in general, and government agencies and authorities having a sound understanding of the interactions between land and water, and of the need for a coordinated catchment-wide approach for addressing issues affecting these resources. A good understanding of these principles will enable all people and organisations involved to identify the need to change existing practices and adopt practices best suited to their own situation, without damaging other parts of the ecosystem."* (QDPI, 1991)

Thus, one of the key functions of the Catchment Coordinating Committee is to raise awareness of issues across the community. Similarly, one of the key roles identified for the State Government in the Queensland ICM Strategy is "*Fostering community awareness and the provision of educational material and services*".

In many contexts, raising awareness is not simply a question of promulgating existing understanding. Issues at a catchment scale are often not well understood by any individual or group, thus the challenge may be to identify issues and seek consensus and then disseminate consensus to the broader community. This is a demanding process and will call on information and insight from a range of sources.

Task 3: Precipitating / catalysing action
It is implicit in the Queensland Integrated Catchment Management Strategy that ICM is intended as a means of raising awareness about the need to manage natural resources strategically across a catchment (as discussed above) and, thereby, enable appropriate action by appropriate stakeholders. Thus the 'Guidelines for the Formation of a Catchment Coordinating Committee' (DPI 1994) states that "*The CCC will initiate change in practices, procedures and policies through goodwill and influence on the relevant authorities and groups. The committee does not make decisions which are the statutory responsibility of other bodies. … The success of CCC depends on its ability to take a catchment perspective and to influence other bodies, rather than the exercise of power and statutory responsibility.*" (p.14). This places ICM in contrast with Landcare which often has a greater role in identifying and implementing specific solutions to particular resource management issues. This view is broadly consistent throughout the material on ICM, although in places it is implied that ICM is also aimed at directly tackling problems rather than facilitating their resolution.

For the purpose of this document, we have assumed that technical solutions to particular problems remains the domain of stakeholders in the ICM process (whether individual landholders, local government or State Government agencies) and that the role of ICM is to identify and raise awareness of issues and precipitate their resolution by resource managers. Thus the Queensland ICM Strategy document (QDPI, 1991) states that "*CCCs foster the voluntary implementation of catchment management strategies through existing government and community organisations*". Nevertheless, given the objective of seeking integrated solutions, an ICM initiative may have a significant role to play in facilitating information access for resource managers. Given that better outcomes stem from better understanding not just better information, the exchange of information cannot reasonably be seen independently from the provision of training and skills, which may therefore also be an appropriate role for ICM.

Task 4: Implementing an effective ICM program
Relationships, roles and personal skills are probably the most critical factor in achieving the effective collaboration and participation that underpins an effective ICM initiative. However, there are also a number of information requirements that relate to the CCC's fundamental role in influencing other bodies. These include information on the ICM policy and related policies and statutory arrangements, on the broader institutional environment, on the roles and relationships of key partners, the expectations of key partners and on the biophysical and socio- economic context. They will also include a range of information to enable those involved in implementing the initiative to track progress and modify actions accordingly, thus enabling the ICM policy and program to be effective as an adaptive learning process.

2.0 METHOD

In this report, we address the information needs associated with the fundamental tasks outlined above by considering experience in the Herbert ICM in relation to each task.

For each task, we identify what information was asserted or predicted to be relevant in the various documents available to an ICM CCC and compare this to evidence for what information was actually used in the context of the Herbert initiative. We then consider explanations for, and the implications of, the difference between the two.

Given the need to integrate information across a range of issues and domains and from a range of perspectives and stakeholders, it is reasonable to assume that ICM groups face challenges in collecting, storing and managing data. We therefore explore these processes for each of the tasks in relation to the Herbert experiences.

Given the participating and community-oriented nature of ICM, it is reasonable to suppose that knowledge and expertise held by members of the catchment community (termed here as local knowledge in contrast to professional knowledge) are critical in the ICM process. Furthermore, given the complex nature of some of the natural resource issues being tackled, it is reasonable to assume that research projects and resource use inventory and survey may be a key source of information. These two sources are therefore considered in relation to each of the four tasks.

2.1 DATA SOURCES

The data sources used are referenced throughout the report. In summary, they include:-

- Policy documentation on ICM;
- Documents provided by the lead agency to guide CCCs;
- R&D findings/documents from the CTC7 research project;
- HRCCC minutes;
- Targeted interviews with 3 key informants in the Herbert River ICM process;
- Participant observation, on-going interviews and discussions with key informants
- The collective experience of the research team.

3.0 EVALUATIVE CONTEXT: ICM IN THE HERBERT

ICM in the Herbert River catchment is a community-led and voluntary process in a formative stage initiated by key interests in the catchment. The impetus for the establishment of the Herbert River Catchment Coordinating Committee (HRCCC) in 1993 related to two key factors. Firstly, broad community-based concern over the ineffectiveness of fragmented government decision-making on river management issues, and the failure of past studies to move beyond the development of plans and lead to action on the ground to resolve these issues. Secondly, the perceived need within the catchment for more active and meaningful community involvement in decision-making on these issues, that is beyond a basic consultative approach (Bellamy et al. 1998, 1999).

The objectives of the ICM process in the Herbert Catchment have been identified by the HRCCC in its draft Catchment Management Strategy (HRCCC 1996, p.i) as:

- Co-ordinate government agencies and the community to pursue common goals
- Seek community involvement in catchment management
- Reflect the requirements of the wider community within the Catchment
- Identify and rectify natural resource degradation
- Promote ways to prevent and reduce natural resource degradation
- Promote the wise use of all natural resources within the Catchment
- Identify key indicators of biodiversity and monitor as a measure of catchment health
- Encourage the retention of significant natural habitats within the Catchment.

Although these broad objectives are couched in terms that suggest an overall policy framework for the catchment, ICM has no legislative jurisdiction in Queensland. Success therefore will depend to a considerable extent on the degree to which the Herbert ICM process can engage public and private interests in a substantive way to voluntarily effect required action.

The HRCCC involves representatives of a broad range of rural industry, community and local government and other statutory organisations that have an interest and/or role in natural resource management in the catchment (Bellamy *et al.* 1999). As such, the membership reflects the influential groups, power structures, and prominent community interests in the catchment. In 1998, the HRCCC had a local Chairman and 16 other members representing community, industry and local government and statutory bodies in the catchment. A full-time Catchment Coordinator facilitates the process. Nine of the current members (50%) have been involved with the HRCCC since its inception in March 1993. Most of the members are active community members with multiple sectoral interests or 'hats'. Eleven of the seventeen HRCCC members are either sugarcane farmers or employed within the sugar industry reflecting the economic, social and cultural importance of the sugar industry in the lower Herbert catchment community.

4.0 TASK 1: DEVELOPMENT OF A CATCHMENT MANAGEMENT STRATEGY

4.1 INTRODUCTION

All ICM initiatives in Queensland are required to develop a catchment management strategy. The same is true of many equivalent regional or catchment resource management initiatives in other States.

In the context of ICM in Queensland, a catchment management strategy "*should provide a framework or blueprint for resolving key issues of catchment wide importance in a catchment. It should be useful to groups and organisations within the catchment as well as to others outside (like funding bodies, State Government etc.) the catchment*" (Rowlands, 1995). Furthermore, "*Catchment management strategies provide a broad assessment of the priority land wand water issues in the catchment and contain recommended actions to address particular issues*" (DPI, 1991, p. 20).

Given the number of Catchment Management Strategies (CMS) or equivalent documents that have been developed by community groups in recent years or are under development, it is perhaps not surprising that an increasing number of documents have been generated to provide guidance for this process. These include:

- Catchment Management Strategies : Draft Notes Philip Rowland, 22 February 1995 – Maleny Forum
- Essential Characteristics of Regional and Catchment Management Strategies: Michael O'Brien: Queensland Department of Natural Resources, March 1999 - Draft document
- Australian Local Government Association. 1997. Regional Environmental Strategies: How to prepare and implement them;
- Greening Australia. 1997. Regional Strategy Checklist: Essential Characteristics of Natural Resources Management Strategies; and
- DNR. 1998. Interim Guidelines for the Development of Natural Resources and Biodiversity Conservation Regional Strategies

While the broad principles discussed in these documents have a good deal in common, the specifics of the recommended contents for Strategy documents vary. Table 1 presents a generic Strategy structure derived from Rowland (1995).

Table 1: Key components of a Catchment management strategy (After Rowland 1995)

Setting the Scene	Description of the physical, economic, biological and social attributes of the catchment and the use and management of natural resources in the catchment.
The Vision	A statement or series of statements describing a vision for the catchment or principles to guide use of resources that have broad stakeholder support.
Identifying Issues	Identification, analysis and ranking of the key natural resource management issues.
Outcomes	Statements of the proposed outcomes resulting from the implementation of the Strategy
Objectives	Specific, measurable, achievable, relevant and timely objectives to address each issue.
Strategies	Strategies to achieve the objectives. Major components of these strategies include: Activities to be carried out Organisations, government departments or agencies, local authorities and other key stakeholders that need to be involved. Resources (time, money, manpower) needed to carry out the activities
Performance Indicators	Attributes that should be measured or determined to assess progress toward the objectives.
Outputs	For example : Policies for use by local and state government, industry groups and other agencies. Guidelines for the use and management of natural resources in the catchment. Operational plans to redress or prevent degradation of loss of value with natural resources in the catchment. Institutional arrangements necessary to achieve better use and management of natural resources.
Implementation	Mechanisms and structures to be used in implementing the strategy.

Evaluation and Review	How the implementation of the strategy will be monitored so that appropriate changes can be made if necessary.

4.2 METHOD

In this section we assess information needs by comparing the guidelines and requirements provided to ICM initiatives by State Government with the practice as illustrated by the Herbert River case study. Given that information management and content is significantly impacted by the purpose for which the document is put together we first consider purpose. We then address processes for accessing and managing information before addressing the actual information content in the Strategy. In each case we compare:

- **Principles** - the direction provided by State Government;
- **Assessment Criteria** - the assessment criteria proposed by State Government for assessing Strategies (which therefore provide a measure of the Government's views on how principles should be operationalised); and
- **Practice** – from consideration of the Herbert case study.

This comparison provides insights into the information needs and challenges for ICM initiatives but is based on the assumption that the State Government policy, while evolving, has been broadly consistent over the life of the whole ICM Program and that the Herbert Catchment is an appropriate example of an ICM initiative that represents the best efforts of the Catchment Coordinating Committee. While at the time of writing the Herbert CMS has yet to be endorsed, it has received interim endorsement twice. Furthermore, continued funding support suggests continued State Government approval of process in the catchment.

4.3 THE PURPOSE OF THE CATCHMENT STRATEGY

The Catchment Management Strategy has two generic functions.

It fulfils a 'due process' requirement. ICM Catchment Strategies need to be endorsed by State Government in order to receive and maintain funding inputs and other support. As a consequence, criteria for assessing such strategies have been developed (see O'Brien 1999 for assessment criteria under development for use by the Queensland LCMC for the assessment of ICM Catchment Management Strategies).

As well as meeting the requirements for 'due procedure' the Strategy is clearly intended to provide a focus for the ICM initiative and a point of reference through its subsequent development.

These two generic functions are apparent in both principle and in practice, but with important differences in interpretation and application.

In Principle
In notes prepared for the Catchment Management Forum at Maleny in February 1995, Philip Rowland identified three basic purposes for Catchment Management Strategies:

- Formal recognition by State government (through Cabinet), local government and industry.
- Providing "*a clear message to these bodies [funding sources in Government and elsewhere] about what needs to be done*".
- A tool for local stakeholders by "Acting as a framework or blueprint for resolving key issues of *catchment wide* importance in a catchment".

The notes place considerable emphasis on following standard structures for Catchment Management Strategies in order to ensure that they are appropriate for endorsement and provide a sound basis for communication with Agencies beyond the catchment. Similarly notes on "*Essential characteristics of regional and catchment management strategies*" (O'Brien, 1999) state that "*A key element in the preparation and implementation of resource management strategies is the need to gain endorsement at a State Government level*".

These and similar documents contain limited discussion on the structure of the Strategy in relation to its role in local management of resource use strategies. Nevertheless, the emphasis on

standardisation is reflected in the stringent criteria for Strategy endorsement that have been developed (O'Brien, 1999) and the requirement to have a Strategy submitted and endorsed in order to continue to receive recognition and funding support.

In Practice
Surveys of HRCCC members in 1997 and 1999 (Bellamy & MacDonald, 1998; Bellamy et al., 1999) demonstrate that the Herbert River Catchment Coordinating Committee have similar views to those being presented by State Government. Most members agreed that the HRCCC prepared a catchment strategy to ensure future funding support and that it was the main driver for its preparation.

However, they also stated that the development of the strategy helped to focus the HRCCC, and that the catchment strategy would contribute to more effective resource management in the Herbert. However, there was a wide range of views amongst the members on whether the catchment strategy would assist in resolving resource management conflicts or whether the Catchment Management Strategy provides an effective blueprint for the HRCCC activities.
Importantly, the development of the Catchment Management Strategy is perceived by members to have been of value because of a number of qualities and outcomes of the development process that include:

1. *inclusive and transparent* to all members involved; bringing all viewpoints across organisations on issues together and out into the open.
2. *establishing a clear direction* for the HRCCC; helping to focus the HRCCC as an organisation and providing an overall vision for the catchment.
3. *raising awareness* of catchment issues; especially improving Committee member's awareness of issues as well as other stakeholder's viewpoints on those issues.
4. *highlighting areas of common ground*; by identifying areas of agreement across diverse sector groups on some catchment issues, it provided a basis for the Committee to move ahead and develop better natural resource management and planning projects.

4.4 ACCESSING AND MANAGING INFORMATION

The development of a catchment management strategy is a major undertaking for a CCC. The process of developing a strategy demands some element of catchment resource audit, issue identification, issue prioritisation and the identification of targets and responsibilities for action. Fulfilling these requirements involves some level of accessing or creating and then integrating diverse information from a range of sources.

In Principle
The ICM Program has specific expectations of the approaches to information collection, collation, integration and interpretation that underpin the Catchment Management Strategy development if it is to receive formal endorsement. Some of the criteria provided for CCCs to guide the development and assessment of their strategies (O'Brien, 1999) are presented in Box 1.

Meeting these criteria demands significant skills in terms of accessing and analysing quantitative data sources, literature review and community consultation. Development of the Catchment Management Strategy requires access to "historical" material in terms of grey literature in the form of previous reports and studies etc. as well as accessing the formal literature in relation to fundamental principles to resource management issues relevant to their catchments. They will also need significant skills and expertise to effectively access community perceptions, priorities and values.

In Practice
The HRCCC has been involved in developing a CMS twice, the initial CMS was developed and launched by the HRCCC in 1996. In 1998, a major revision was undertaken to obtain endorsement. While endorsement has been seen as a significant target, it has not been treated as the 'end of the road'. The Strategy has been envisaged as becoming an enduring 'living document'.

Box 1. Criteria for developing and accessing strategies (After O'Brien, 1999)

PRINCIPLES

Is the strategy consistent with the overarching principles of effective resource management (eg. ICM, ESD)?

STAKEHOLDERS

- Have all the relevant stakeholders been identified (eg. community interest groups, NGOs, Government agencies, Indigenous groups etc …)
- Was the stakeholder input reflective of the importance of developing a regional strategy?
- Have the responsibilities of the various stakeholder groups been clearly defined and endorsed (signed off) by them?
- Has a lead agent been identified and accepted by the stakeholders as responsible for coordinating and promoting the endorse strategy?
- Has the stakeholder involvement been consistent and facilitated through appropriate methods through all stages of the strategic plan (ie. planning, implementation, review phases)
- Do community members respect the creditability of organisations and agencies involved in the strategy?
- Have the stakeholder groups that already deal with particular issues (if they exist) been identified?

INFORMATION BASE

- Have information gaps been identified?
- Has the opportunity to fill information gaps by utilising the knowledge of stakeholders as a resource been investigated?
- Has the integrity of the various data sources for economic, social, cultural and ecolo9gical processes been documented?
- Has the current understanding of processes been documented?
- Is there confidence in the integrity of the information contained in the strategy, and in information used in its development?

SYSTEMATIC REGIONAL APPROACH

- Have external impacts or flow on effects resulting from the strategy been identified?
- Has compromise been made between the social, cultural, ecological and environmental objectives to ensure acceptance by the community?
- Does there need to be a systematic and systematic perspective of the region?
- Does the strategy focus on a variety of regional issues?

INTEGRATED

- Have all other plans and strategies (all scales) appropriate to the management of the region been identified and their role integrated into the strategy?
- Has the hierarchy of the related plans been identified? (consider the priority of implementing the strategy in relation to other regional plans)
- What are the existing priorities and strategies within the organisations that are required to support the implementation of the strategy?
- Have the constraints, difficulties and limitations in linking this strategy with other plans been identified?
- Have possible resolutions to these been suggested?
- Does the NRM strategy conform to the statutory plans used by local and state government when dealing with development pressures?

SCALE

- Does the strategy address the issues at an appropriate scale to ensure effective management?
- Have mechanisms been provided to address issues across legal boundaries?
- Has the future role of the strategy in the management of the region been identified?

GENERATION & EVALUATION OF OPTIONS

- Have a variety of options and alternatives for addressing issues been identified?
- Have the positives and negatives of each alternative been documented and evaluated?
- Have the costs and benefits of each option (as they relate to environmental, social and economic resources) been considered?
- Have options been prioritised in an appropriate yet flexible manner?

COMMUNITY CONSULTATION

- Has sufficient and effective consultation been carried out throughout the planning, implementation and evaluation stages?
- *Consider:* appropriate time and resources committed, suggestion and promotion of mechanisms to facilitate feedback throughout the life of strategy.
- Was the method of community consultation appropriate for the various stakeholder groups involved?
- *Consider*: education and literacy levels, knowledge of topics, facilitation and promotion method, potential conflicts, objectives of consultation made clear from onset, local relevance of issues, representatives for stakeholder groups communicated outcomes effectively
- To what degree have the consultation methods fostered an atmosphere of community ownership and commitment? (Reflected in the stakeholder signatures in the Endorsement Section and in acceptance of responsibilities for carrying out actions)
- Has justification been provided for those issues where public participation was not used?

Formal interviews and informal discussions with participants suggest that it was generally agreed that local knowledge was a key information source for catchment management strategy development. There was strong consensus and agreement within the HRCCC that local expertise was not often in

conflict. It was widely held that the expertise held by members of the Catchment Coordinating Committee (including their knowledge of, or involvement in, previous studies and reports) was the dominate information source. The Catchment Coordinator stated that formal and documented information had been relied on where available and interpreted in the light of local knowledge. Local knowledge had only been used in its own right where there was no documented information to be used instead.

The development of the first Catchment Management Strategy had little or no input from State Government. This was perceived to have been a deficiency and the second round development has included significant involvement from State Government agencies, representative bodies and local government. Anecdotal information and undocumented experience or expertise was only used in the Strategy if it was widely held (the same did not apply to technical documents from which data was included even if it was not supported by the committee members experience).

The Catchment Co-ordinator was active in seeking out published information of relevance to the development of the Strategy and circulating this material to Committee members. It was clear that for some areas (eg. the upper Herbert River Catchment) documented information was very sparse. For the lower Herbert there was more documentation to back up (or refute) local knowledge. The Catchment Co-ordinator reported some significant differences between local perspectives and documented technical information.

Some participants noted that it had became clear that the Strategy was really just a document to obtain Government funding and was therefore constrained by what government wanted, particularly during the second revision.

Prioritisation of issues and strategies was based entirely on Catchment Coordinating Committee consensus and discussion. There was limited if any 'reality checking' of the importance of issues or viability of strategies.

When asked how they would change the development of the strategy if they were tackling it again, the three key participants interviewed said that they would bring in more agencies and other perspectives earlier in the process. They also said that they would invest time in looking into research and experience beyond the catchment boundaries and interstate. The close to exclusive reliance on local expertise and research or other technical documentation specific to the catchment was clearly seen as a missed opportunity.

4.5 INFORMATION CONTENT FOR THE STRATEGY

In Princi ple
The proposed or required structure for a Catchment Management Strategy and the required contents (as expressed in the evaluative criteria, O'Brien, 1999 and Box 1) provide some clear guidance on the content required.

Context. Description of the physical, economic, biological and social attributes of the catchment and the use and management of natural resources in the catchment provides critical context for the remainder of the strategy. A comprehensive description of context at a catchment scale is a significant task. This process requires accessing previous documents, which may be out of date, may cover an overlapping but different physical area and may have a particular perspective that covering a particular issue requires. Furthermore, statistical data and other primary data such as State of the Environment reports and ABS population census data may need to be accessed and analysed.

Vision. The development of a vision statement that represents reasonable community consensus requires significant consultation and negotiation. Clearly, consideration of negotiation processes is beyond the scope of consideration of 'information needs', however, the consultation process is essentially a data gather exercise. This demands a clear identification of representatives of key stakeholder groups and the use of appropriate methods to support those groups in reaching their own consensus on their vision and articulating this to other groups as a basis for negotiating a community vision. Furthermore, given that endorsement of a Catchment Management Strategy by

the LCMC requires '*strong evidence of community input*' appropriate methods for recording these inputs and making them available for later consideration might be necessary.

Values. Development of the vision requires consideration of the social, economic, environmental and cultural values associated with the area. Some of these values will be directly quantifiable while others might only be measurable through surrogates and many might not realistically be described in anything other than qualitative terms. Furthermore, the values considered need to go beyond the immediate stakeholder groups and have some cognisance of the regional, state, national and international values associated with the area.

Key issues. Identifying key natural resource management issues facing a region with due recognition of their economic, cultural, environmental and social dimensions is a significant challenge. Issues need to be considered not only in their local context but also as they relate to state, national and international issues. Similarly, multiple timeframes need to be integrated. Achieving community consensus on the comparative priorities of these key issues is possibly harder still. Rowlands (1995) makes the point that scientific (qualitative and quantitative) as well as local knowledge should be used in the description and analysis of the issues. This is a big ask for Catchment Coordinating Committees.

Objectives & strategies Devising a set of objectives and strategies for the resolution of the key issues identified may be a relatively straight forward process. Nevertheless, objectives need to be based on Committee (and by implication community) consensus, be clearly communicated and demonstrably contribute to the achievement of the vision. They also need to be tractable and consistent with legislation, policy and other natural resource management frameworks. The strategies that underpin objectives also need to be technically feasible and tractable in terms of resource availability. They also need to demonstrably be an appropriate means of achieving the objective. Thus, as with any planning activity, the greatest challenge facing the Committee in drafting objectives and strategies is to be able to analysis their feasibility and tractability. This 'reality check' process demands considerably more information than drafting objectives and strategies in the first instance.

In Practice
In a broad sense, both the first and second editions of the Herbert Catchment Management Strategy cover the material proposed by the State level program.

It is clear from the Strategy and, in particular the use of specific figures on particular issues, that extensive use was made of published material. The Strategy itself contains reference to the meetings, field inspections, literature reviews and general contact with the community that underpinned the development of the Strategy.

The introductory section provides an excellent audit / situation statement with a significant use of figures. The Herbert River Catchment Atlas (Johnson *et al.*, 1999) was clearly a key document and receives its own section in the Introductory material. The only other specific references in the document are to DPI and DEH vegetation assessment and mapping and to the Nature Conservation (Wildlife) Regulation 1994. Similarly, the local statements of issues, values, strategies and so on are not referenced to source. This lack of referencing makes analysis of the use of information difficult. More significantly, it makes it difficult to judge the validity of the contents of the document. Furthermore, one of the Committee members pointed out during interview that a failure to reference adequately meant that the document could not practically be maintained as a 'living' or evolving document.

All three of the key participants in the development of the strategy who were interviewed argued that the key information gap they faced during the development of the document related to the spatial location and distribution of issues and resources. Specific issues included :

- the extent and significance of vegetation types;
- mahogany glider habitat;
- the extent of tree clearing in the upper catchment;
- up-to-date land use information;

- weed distribution;
- land use suitability;
- groundwater quality and quantity;
- water licensing and allocations.

4.6 CONCLUSIONS – INFORMATION NEEDS FOR STRATEGY DEVELOPMENT

This comparison of the information needs associated with the development of a Catchment Management Strategy in principle and practice raises a number of issues.

The development of a Catchment is a substantial and challenging task. It may often prove to be a significant test of the capacity of members of a Catchment Coordinating Committee to access, analyse and synthesis diverse data sources. Furthermore, it may frequently be constrained by the resources (in terms of direct funding, indirect support from external agencies and the voluntary time from CCC members) available.

These observations raise four issues of particularly note, as follows.

How much is enough?
The guidance provided to CCCs and the stringent assessment criteria applied in relation to endorsement provide a high standard for Catchment Management Strategies, as witnessed by the problems that many groups (including the Herbert) have had in receiving endorsement.

However, no information seems to be available on how much information analysis and synthesis is adequate to result in a Catchment Management Strategy that will adequately fulfil its role. This issue is complicated by the reality of the dual roles of a strategy - facilitating action within the catchment and receiving endorsement (and therefore further funding) from the State Government and by the level of consensus that is deemed to be necessary.

Responsibility for information provision
A catchment Management Strategy requires significant base information from biophysical to social. Much of this information is patchy, dispersed and difficult to access.

The CCC play a key role in accessing and integrating local expertise, values and knowledge but also have the primary responsibility for initiating and supporting approaches to collecting and collating base data. At the CCC Forum in Rockhampton in 1994 an expectation was clearly articulated that it was up to State and Federal Government to provide the information base required by the CCCs and Local Governments to prepare plans.

Maintaining the information base
This issue of responsibility for the management of the core information base is particularly significant given the need to maintain and update the information base that underpins the Catchment Management Strategy so that it remains a 'living document' which evolves to reflect changes in knowledge, understanding, attitudes and issues. This is a significant role for CCCs and one for which they may be poorly equipped.

Assessing tractability and feasibility
Little is said in the guidelines to CCCs about the information and analysis required to assess the tractability and feasibility of the objectives and strategies in the Catchment Management Strategies. This process of reality check is both demanding and important.

5.0 TASK 2: INFORMATION NEEDS FOR RAISING AWARENESS OF ISSUES

5.1 INTRODUCTION

HRCCC members stated during interview that one of the fundamental roles of an ICM initiative is raising awareness of issues in order to get others to act on them. This view is consistent with the ethos espoused in the Herbert Catchment Management Strategy that the intended role of the ICM initiative is to recommend actions and processes on the basis of issues identified and to be responsible for implementation through pushing adoption of its recommendations by the relevant management agencies and other stakeholders. Thus, one of the key outcomes of implementation of the strategy is identified as informed land holders.

It is clear from the material on the Herbert ICM process that in the first instance the challenge was to raise awareness amongst members of the HRCCC. Committee members represent a range of perspectives and interest groups. Committee members can, therefore, represent their constituents' interests to other stakeholders groups and can, in principle, raise awareness within their constituency of the issues of other groups. In order to implement substantial action, the CCC also needs to raise awareness of issues amongst key management agencies at the Federal, State and Local Government level, within industry and amongst landholders and the broader community.

In order to undertake these roles the CCC may need to tackle a number of issues such as:

- What appropriate information (i.e. of demonstrably local & personal relevance) is available for raising awareness on issues?
- What is the existing level of awareness?
- What is the necessary / desirable level of awareness?
- How are people likely to process and respond to issues?

These questions build on more generic issues relating to information management in ICM such as:

- What are the sources of information that people make use of?
- How do those sources present information?
- To what extent is the information from those sources trusted?
- How is the information from those sources used?
- How has local experience identified issues that require resolution?

5.2 CASE STUDIES

In order to address consideration of these and related issues in the Herbert ICM process the data sources used by the HRCCC to raise awareness were reviewed and assessed. This assessment focussed on the ICM initiative itself and four additional case studies:

- The management of acid sulfate soils within the Herbert River Catchment
- The assessment of the status of riparian vegetation within the Herbert River Catchment
- An inventory of the legacy of historic tin mining in the upper catchment
- A community oriented program to erect owl boxes for integrated pest management

As with the information used in developing the CMS, the information base used for raising awareness in the Herbert was a mixture of the 'corporate knowledge' of Committee members, documented information and other expert sources.

Raising awareness about the ICM initiative itself

At a workshop of key stakeholders in the ICM process held in 1995 (Bellamy et al., 1995) it was argued that in order to gain a long term commitment to the ICM process amongst the community, it was necessary to create a common and widespread understanding of the ICM conceptual process. At that stage (April 1995), it was argued by participants at the workshop that the development of the Catchment Management Strategy was a critical process in gaining community consensus on key issues and the role of ICM. The Catchment Management Strategy that was subsequently developed explicitly acknowledged this role and is being used to seek a consensus on key resource use issues amongst community leaders. The Community Surveys (Butterworth et al., 1998; McCreddin et al.,

1999) demonstrate that this broad community awareness of ICM through exposure to the Strategy has not yet been achieved in that there was limited awareness of ICM or the Strategy amongst the broader community.

Raising awareness about Acid Sulfate Soils
Acid sulfate soils have emerged as a potentially significant issue for the Herbert Catchment during the life of the ICM initiative. The HRCCC played a significant role in raising community awareness of this problem through the local media (Cottrell and Rowbotham 1999).

Several members of the HRCCC were aware of growing concern about acid sulfate soils in other sugar growing districts, particularly in NSW, through general media coverage and brochures and other literature prepared by the NSW Government. Subsequent developments of two low lying areas of land raised local concerns within State Government Departments and precipitated wider local interest. As a consequence, the HRCCC decided to take specific action in raising awareness. Through consultation with the Queensland Department of Natural Resources they established that acid sulfate soils were a particular issue at less than 3m AHD. The HRCCC then commissioned CSIRO to develop a map of land lower than 3m AHD in the catchment that was published with an accompanying article in the local press. This was perceived to have significantly broadened awareness of acid sulfate soils and their implications amongst the community.

Members of the HRCCC report that they found much of the information then available from Queensland State Government Departments to be vague and overly general. As a consequence the group relied heavily on the NSW literature that defines the problems and management requirements- but with some concern about its relevance to North Queensland. The ability to generate a map of local risk areas was critical to the success of awareness raising as it provided local context.

Raising awareness about ripari an vegetation
Riparian vegetation and its management has become a significant natural resource management issue in the Herbert over the course of the ICM initiative. Objectives, options and responabilities for management remain contentious. However, early in the life of the ICM initiative, the current state of riparian vegetation in the catchment was a major source of uncertainty.

The HRCCC supported student research work that mapped and assessed the state of riparian vegetation along major water courses in the lower catchment (Petroeschevsky, 1997). The HRCCC did not want botanical mapping or general level 'state of rivers' type assessments but needed information of relevance to land holders, allowing them to compare the state of their riparian vegetation to that of others. The inventory resulting from the student project was deemed to have fulfilled this role very well. The then Catchment Coordinator was of the opinion that it resulted in better and cheaper information than the State Government State of the Rivers report.

The exercise was reported as having been a very important catalyst in raising awareness of issues in relation to the state of riparian vegetation amongst members of the HRCCC. The data has been widely distributed. It is held by the Herbert Resource Information Centre (HRIC) and was, for some time, one of their most accessed data layers, having attracted broad interest including from Government departments and researchers. The data was a key input into the Joint Board Catchment Rehabilitation Plan for the Herbert River catchment and, in turn, also influenced the Herbert River Improvement Trust (HRIT) and the Hinchinbrook Shire Council's priorities.

Raising awareness about the impact of legacy tin mines
One of the enduring land and water management issues in terms of strength of feeling amongst community members prior to the establishment of the HRCCC was the impact of abandoned tin mines in the upper catchment. The dams were abandoned in the late 1980's and were regarded by Herberton Shire Council as a threat to the surrounding community and to the downstream quality of water in the Herbert River. Concern arose from the lack of maintenance of the earth-filled dams and the possible increasing risk of failure through erosion. The HRCCC's activities in addressing this issue are discussed in the next section, however, this action followed the building of a consensus amongst the HRCCC that this was an issue that merited HRCCC involvement. The HRCCC

therefore undertook a field visit to the upper catchment to view the sites. This proved to be a constructive means of building awareness and consensus among committee members.

Raising awareness about Owl boxes
One of the highest profile activities that the HRCCC has been involved in has been the promotion of owl nest boxes. Owl populations on the Ingham coastal lowlands have dropped noticeably over the last five years. Reduced populations have been attributed to the clearing of native vegetation to accommodate the expanding sugar industry resulting in the destruction of nesting habitats and hunting perches. In addition, the possibility of secondary poisoning linked to rat baits has been suggested (Robinson *et al.* 1999). Establishing nesting boxes and hunting perches for owls in cane growing areas increases the owls' hunting range and improves the chance of survival in a changed habitat. Robinson *et al.* (1999) reports that a single owl family can eat over 2,000 rats per year. Aside from the number of rats an owl family can physically remove from the environment, there is some potential for owls to disrupt the breeding cycle of rats, further reducing their population. Rat damage to cane in the Herbert River District has been estimated by the Herbert Cane Protection and Productivity Broad (HCPPB) to range from 28,265 tonnes in 1993 to 6,576 tonnes in 1997.

The owl nest box project is seen by HRCCC members as having been an important achievement that served in promoting principles of integrated pest management within the sugar industry, encouraging the retention of old growth trees in riparian areas and raising the profile of ICM in the catchment (through, for example, a Landline feature).

Interviews with HRCCC members reveal that this initiative came about as a consequence of a number of coincidental issues and triggers.

A local wildlife expert Mr John Young, ran an owl spotting tour that was attended by some HRCCC members and commented on the numbers of rats consumed by owls, the decline in owl numbers and the critical importance of nest sites in maintaining population levels. That damage has always been a significant issue for canegrowers and deregistering of key rodenticides at the time was forcing consideration of integrated approaches to pest management. Considerable work by the Bureau of Sugar Experiment Stations (BSES) rodent control research on habitat management was receiving attention. The HRCCC brought together this information and felt that promoting owl nest boxes was a potential win-win situation for the industry and environment that was unlikely to be contentious.

The expertise provided by John Young and the BSES researchers as well as information on the economic value of rat damage provided by the HCPPB provided the HRCCC with all the information they need to launch this simple but significant initiative.

5.3 INFORMATION NEEDS FOR RAISING AWARENESS – IMPLICATIONS FOR AN ICM PROGRAM

Focus on improving the flow of existing information – particularly within the CCC
During interviews with HRCCC members, it was argued that raising awareness was an issue of information flow between the HRCCC, agencies and the community and that, while as much information as could be available would be useful, the fundamental constraint on awareness raising was one of cooperation and information flow with management agencies and stakeholder groups rather than information gaps per se. Review of the case studies bears out that much of the awareness raising was indeed based on improving the flow of information. This was probably most clearly demonstrated in relation to awareness raising amongst the members of the HRCCC where discussions, presentations and field trips proved to be of considerable value.

Focus on awareness raising in relation to well understood issues on which there is broad technical consensus
Review of the case studies and other issues in which the HRCCC has become involved also demonstrates that issues that were well understood and on which there is broad consensus were a more effective basis for raising awareness than less well understood issues. Thus the HRCCC can claim a significant role in raising awareness about Acid Sulfate Soils and the decline in owl

populations but has had more trouble in dealing with the poorly understood and contentious fish kill issue.

6.0 TASK 3: INFORMATION NEEDS FOR PRECIPITATING ACTION

6.1 INTRODUCTION

As has been discussed, a consensus has emerged that the role of the HRCCC is to strategically precipitate action or influence planning by those with management responsibilities in Local and State Government, industry and amongst landholders on key natural resource management issues from the catchment perspective. Thus one of the foundations documents for the ICM program states that "*The CCC will initiate change in practices, procedures and policies through goodwill and influence on the relevant authorities and groups. The committee does not make decisions which are the statutory responsibility of other bodies. … The success of a CCC depends on its ability to take a catchment perspective and to influence other bodies, rather than exercise of power and statutory authority.*" (QDPI, 1994)

The HRCCC is faced with a variety of information and information management needs in precipitating or enabling appropriate and timely management intervention and adoption of appropriate practices and with influencing statutory planning processes. Can the specific information needs that might be associated with enabling action aimed at the resolution of resource management issues be predicted and, if so, at what stage? When surveyed in 1997, HRCCC members stated that catchment natural resources, land use, options for funding of ICM and other community activities, government policies and regulations on natural resources and related issues and government institutional arrangements for ICM, Landcare, natural resource management and related issues were the categories of information that were most useful in supporting the Herbert ICM program and its activities (Bellamy & Macdonald, 1998). When surveyed in 1998, most members disagreed that managing land and water resources in the Herbert was difficult because people on the catchment lacked access to information needed to respond to/deal with new catchment issues or problems. Members did not perceive a lack of relevant information as a significant constraint for ICM in the Herbert (Bellamy et al., 1999).

This section addresses these issues by looking at what was used by the HRCCC in practice and what the group would have liked to have used but did not have access to and comparing this to the early thinking on key issues. This comparison enabled consideration of the extent to which relevant issues might have been predicted. It is concluded that the specific information provisions required in order for ICM to contribute to the solution of problems are diverse; variable with the stage of implementation; in any specific instance, context specific; and unpredictable.

6.2 PREDICTING INFORMATION NEEDS FOR PRECIPITATING ACTION

The HRCCC raised four issues when it was formally recognised in March 1993:

1. River Management/River Improvement work
2. Need for improved Land Management/Land Use Planning
3. Mining Dams in the Herberton Shire
4. Drainage in the floodplain delta

At the Catchment Coordinating Committees Forum in Rockhampton in 1994, the HRCC identified the following as its key challenges over the next five years:

- To have direct consultation with the local authority(s) in the development of the Shire(s) Strategic Plan in coordination with the Department of Housing, Local Government and Planning
- To encourage the establishment of a Decision Support System (DSS) between industry, agriculture, local and state Government to better manage the catchment
- Industry endorsement of Property Management Planning consistent with Floodplain Management Guidelines.
- To address river Management Issues (Siltation, Water quality, River capacity) and liaise closely with, and assist the Herbert River Improvement Trust, in implementing the key recommendations of its Strategic Plan.

- To address Land Use Planning issues (Land utilisation, Land use plans, Land management plans) and work with local authorities and government departments to *effectively* use geographical data which is becoming available. Use land use planning to allocate appropriate land for cane expansion and other uses.
- To address Drainage issues (Water availability, drainage/irrigation, ground water, stream water, Coordinated drainage)

Concern over flooding has been a community issue in the lower catchment since the 1880s. However flood mitigation works and the development of uncoordinated drainage systems have been the cause of considerable community conflict. Between 1976 and 1993, there were a number of major studies commissioned by the Herbert River Improvement Trust (HRIT) and the Hinchinbrook Shire Council in collaboration with state government agencies that have examined water management related issues with respect to flooding management, rural drainage planning, and stream management planning. These technical studies focussed on "engineering-based" solutions.

In contrast, the most important resource management issues in the catchment identified by HRCCC members in 1995, 1997 and 1998 are compared in Table 1. In general, member's perspectives on catchment management issues broadened and became more strategic. Rural drainage, flooding, river management and sugar industry expansion and related land clearing have remained key issues for the HRCCC members across all surveys. However, since 1997 additional issues identified were water quality (particularly relating to fish kills, and stream sedimentation), riparian vegetation and wetlands management, pest and weed management, land use planning and a coordinated approach to catchment management. In 1998, with closer linkages to the upper catchment community, two further issues were also identified; grazing land degradation/erosion and water availability issues.

Importantly, perceived impacts of these issues have evolved from an initial focus in the technical studies on productivity and infrastructure impacts to encompass also loss of alternative use opportunities and environmental and ecological factors. Perceptions of the key mechanisms for resolution have also evolved from the initial focus on "engineering based" approaches to include policy incentives, individual action, the development of local industry codes of practice, and the use local government planning and development controls.

Table 1. Perceived Key Resource Management Issues by the HRCCC 1993-1998.

November 1995	November 1997	November 1998
Rural drainage	Rural drainage	Drainage coordination/ management
Stream bed/bank erosion	River management	on floodplains
Urban flooding		Waterways management and flooding
Allocation of sugar caneland	Caneland expansion	Sugar industry expansion
Land clearing		Land clearing
	Water quality	Water quality
	Riparian management	Riparian vegetation management
	Wetland degradation	Wetland degradation/ management
	Pest and weed management	Weed management
	Coordinated extension approach	
	Catchment planning	
		Land use planning, catchment management
		Grazing land degradation/erosion
		Water quantity/availability (upper)

In early 1999 a sub-committee of the HRCCC was formed in the upper catchment. This new group identified and prioritised the key issues for the upper catchment as detailed in Box 2. Although there are some commonalities with those issues identified by the formal HRCCC, the focus of the issues identified by the upper catchment sub-committee is quite different in that they are largely concerned with specific land and water management issues rather than including broader planning and public good issues.

Box 2. Key natural resource management issues for the upper catchment group

Weeds in general (ie. noxious weeds, ponded pastures, stream blockers)
Erosion (ie. cost effective measures)
Water conservation (ie. crop water requirements, changed water requirements (eg. for dairy, cane), best practices water harvesting, storage)
Water quality (ie. turbidity, chemical, sediment)
Land clearing (ie. best practice in native forest, management (fire, grazing, timber), potential cropping areas)
Soil fertility (ie. potential for cropping – forage and fruit, salinity, manganese, nitrification)
Wetland/wildlife preservation (ie. birds/maintenance of habitat (natural, artificial), feral animals)
Land subdivision (ie. more and larger approvals, water quality implications, licensing, multiplier effects of dams)
Creek and river restoration (ie. repair and cleaning)

A reasonable consistency in perception of key issues is apparent from this brief review. While these statements of key issues are generic, they arguably provide a reasonably solid basis for planning a program of information collection and collation. Some of the information that has been actually used is reviewed in the next section.

6.3 INFORMATION USED IN PRACTICE IN PRECIPITATING ACTION

Review of some of the activities that the HRCCC has been involved in in practice reveals that, the understanding, values and perceptions held by members of the HRCCC have proved to be a key information input into HRCCC activities designed to precipitate action. The HRCCC have, therefore, seemed to have had limited requirements for collating technical data beyond their existing expertise and have, instead, sought to involve the people with that expertise into the process, as illustrated in the following two case studies.

Stabilising tin mining remains

One of the early issues tackled by the HRCCC was an inventory and evaluation of abandoned tin mines on water quality downstream. The HRCCC targeted this issue in response to widespread community concern over many years of the impact on water quality, causing discolouration and possible impacts on the quality of drinking water extracted from the Herbert for the Ingham water supply. An HRCCC fieldtrip heightened awareness amongst committee members and lead to significant lobbying for action by HRCCC members from the lower catchment, principally directed at the HRCCC member from the upper catchment.

In response to the perceived issue, the Catchment Co-ordinator lobbied the State Government Mines Department to map and assess the old tin mining structures, particularly the dams associated with the mines. Following the inventory of major dam structures, material was sent to a dam safety engineer for assessment so that the extent of the problem, dams at risk and priorities for works could be identified. Funding applications had been knocked back for years but an HRCCC sponsored project with significant in-kind support from local lease holders, Shire Council and others was funded and remedial works were undertaken. This project was supported by NLP funding and was brokered in collaboration with State Government Department of Mining and Exploration and Herberton Shire Council. The project therefore resulted in on-ground remedial works. It also precipitated the development of an active Landcare group in the upper catchment which provided the impetus for the development of a Catchment Coordinating Committee in the upper catchment.

In this instance, the information required by the HRCCC was simply identification of the issue in the first instance. The Committee and Coordinator played an important facilitating role in bringing parties together and seeking funding but effectively out-sourced information requirements by contracting engineering consultants.

Influencing the modification of the Shire planning scheme

This initiative was part of a statewide project (Lusis, 1999). It was fortuitous that the Hinchinbrook Shire Council was undertaking a review of its planning scheme at this same time as the project team was looking for case studies. The HRCCC became involved in this project following an invitation

from the Mayor and came to contribute half of the members of the Committee. The HRCCC members played a key role in identifying and communicating issues and in driving much of the local project work. One of the aspects of the project was to locate key wetlands. This was of particular interest to the HRCCC and was facilitated by the mapping and analysis facilities offered by the Herbert Resource Information Centre. The project was not felt to have been information constrained.

The project itself lead to a significant change in the Shire strategic plan in that intensive agriculture was removed as an 'as of right' use such that proposed development of scheduled wetlands areas now trigger an impact assessment process.

Other initiatives

The same general observation that the HRCCC has relied predominantly on the expertise of members of the Committee applied to some of the more contentious and less productive issues that the HRCCC has been involved in. Thus the clearing of Pomona Station was a significant source of conflict within the community and at a State level. This conflict was reflected in a failure to reach agreement on action within the HRCCC. Members of the HRCCC have reported that they considered that there was enough information to know there was a problem, but not enough to precipitate a solution. Furthermore, access to information was reported as a problem as was the apparently conflicting advice coming from different agencies. As a consequence, personal opinions and local politics dominated the issue. Significant issues included :

- agreement on the definition of a water course and swamp or lake;
- basic inventory data about water resources in the area;
- understanding of mahogany glider habitat
- poor understanding of the legislation associated with these issues

The contrast between this issue and the two case studies outlined above clearly illustrates some of the limitations associated with relying predominately on expertise held within the Committee.

The Pomona issue did precipitate changes within the HRCCC specifically and in the catchment more broadly in seeking better ways to resolve resource use conflicts. Thus the HRCCC agreed that the issue had been exacerbated by inadequate basic information. However, instead of seeking to build the information base held by the Committee, the HRCCC successfully lobbied the Minister for a water resources extension officer to be based in the catchment, thereby extending the expertise available locally.

Other examples of significant differences of opinion on points of fact and interpretation of fact between members of the HRCCC are reported by key informants. These include views on the series of high profile fish kills that occurred in 1998 and on the SIIP (Sugar Industry Infrastructure Package) works in the Herbert

6.4 SUMMARY

In a general sense, perceptions of key natural resource management issues in the Herbert Catchment have been relatively stable over the life to date of the ICM initiative. In principle, this therefore provides a basis for planning the collection, collation and management of a range of base data for the catchment and research and other information pertinent to the key issues of concern. This has not happened and, in practice, reliance on the expertise of the members of the HRCCC and leveraging the expertise of other people where that expertise is inadequate has proved to be a reasonably effective approach to precipitating action. This approach has failed in relation to some poorly understood and highly contentious issues. However, in these circumstances the HRCCC has successfully sought to increase the level of expertise available locally through lobbying for additional state government staff and through promoting and encouraging research initiatives.

7.0 TASK 4: INFORMATION NEEDS FOR IMPLEMENTING AN EFFECTIVE ICM PROGRAM

In the introduction it was argued that one of the key information needs facing an ICM initiative related to design, implementation and management of a successful ICM program. In this section, the information needs facing a CCC in establishing and implementing an effective ICM program are reviewed. This information includes: contextual material, for example the State Government policy on ICM; implementational information such as legal requirements and funding options; and evaluative information (e.g. are the key stakeholder groups adequately involved in ICM). As with previous sections of this report, predicted needs and actual experience in the Herbert are compared and contrasted.

7.1 INFORMATION NEEDS THAT A CCC MIGHT BE EXPECTED TO HAVE IN ORDER TO MANAGE AN EFFECTIVE ICM PROCESS

Implementational information needs will clearly vary according to the stages of the ICM initiative. Much of the information provided by the State Government to guide the implementation of ICM process at a local level has been presented on a stage-by-stage basis and indeed has apparently evolved as ICM experience in Queensland evolves and pilot groups reach a new stage of development.

The information needs for implementation of an ICM program on the basis of stage in the process are summarised in Table 2.

Table 2. Information needs and information provision techniques for instigating and managing an ICM program (Adapted from QDPI 1994).

Stage	Objective	Information Needs	Suggested Techniques
Stimulate interest in a CCC	Stimulate interest in key issues associated with natural resources and Integrated Catchment Management as a way of tackling those issues	Overview of catchment issues, , techniques for stimulating interest in forming a CCC	Using media, video, clean up days, public/information meetings, issue scoping surveys, inviting speakers from other catchments or different interest sectors, leaflets etc.
Identify and inform key groups, organisations and individuals	membership will affect the credibility of the committee and *how* the committee is formed is also important.	local groups /organisations in catchment with interest / stake in NRM	personal contact, surveys, informed persons interviews, RRA.
Form a CCC steering group	Credibility and a community mandate	Relevant individuals, organisations and agencies; and how to communicate with the community	public workshops, focussed group workshops, nominations by interest groups)
The steering group in action	Obtain establishment grant, prepare brief *overview of important issues and problems*, inform community about ICM, determine *geographical area* of interest (may include adjacent catchments where inter-basin transfers etc); *become incorporated* (info on incorporation), determine size and composition of CCC.	Team / group management	
Form a CCC			
The CCC in action	Tasks: elect a chairperson, decision on incorporation, solicit support for the operation of CCC, obtain technical support (eg. from local govts, industry groups, unis, research orgs), apply for	Team / group management. Consensus building. Conflict resolution techniques. Financial management. Funding	

Stage	Objective	Information Needs	Suggested Techniques
	endorsement (to foster close relationship with govt and obtain establishment and operating grants), get started (eg. understand catchment including resources, changes occurring, key players; finalise major catch. Management issues, prepare an action plan, form subcommittees to oversee strategy devpt on major issues)	sources. Social / community networks. Information sources. Time management.	

As has been discussed previously, endorsement is a key step in the life of an ICM initiative. It gives a CCC formal recognition by Government under the Queensland Integrated Catchment Management (ICM) Strategy and provides access specific support available from the ICM initiative of the Queensland Government including public liability and personal accident insurance, operating grants and project grants (QDPI 1995). A number of guidelines are available to CCCs on the requirements for endorsement (see eg Box 3).

Box 3. Requirements for obtaining endorsement of a Catchment Management Strategy (QDPI 1995)

Catchment coordinating committees should have the following features to be eligible for endorsement under the Queensland ICM Strategy:

- They should cover an entire named river basin or a major sub-basin covering significant parts of at least two local government areas.
- Membership should reflect the interests of the major sectors of the community including:
- Local governments
- Key relevant primary industry organisations (for example, Canegrowers, Graingrowers, fruit and vegetable cooperatives, commercial fishing organisations)
- Landholders in proportion to the range of land uses in the catchment (for example, cane, fruit, hobby, urban, grazing)
- State Government agencies
- Community groups and organisations (for example landcare groups and service clubs)
- Recreation and conservation interests (including recreational fishing)
- Secondary industry (for example, millers, processors, light and heavy industry)
- Major stakeholders outside the catchment where relevant (for example the Great Barrier Reef Marine Park Authority, downstream users, out of catchment users,)
- Membership should be determined by open election or through nomination by community groups, agencies and the general public.
- Achievable objectives should be set that are consistent with the functions of a CCC as outlined in the *Queensland Integrated Catchment Management Strategy*.
- A whole catchment perspective should be taken rather than being restricted to a single issues such as soil erosion or stream bank revegetation
- A demonstrated ability to be accountable for the administration of funds and the management of projects is important. This can be indicated by the committee being incorporated and having an active executive.

7.2 ACTUAL EXPERIENCE OF THE HRCCC

Not withstanding the availability of guidelines such as those outlined in the previous section, one of the consistent themes from interviews with the participants in the Herbert initiative, the Mercure workshop (Bellamy et al., 1995) and the HRCCC surveys (Bellamy and Macdonald, 1998; Bellamy et al., 1999) was uncertainty about "*what the LCMC really want*" and doubts about continued support and resources from Government. This was closely related to continued uncertainty expressed about roles and responsibilities, lead agencies and co-ordination

Participants in the HRCCC spoke of inadequate communication with the LCMC but stated that where there was contact it was "patronising and dictatorial, but arbitrary". Some spoke of working in a policy and leadership vacuum. Furthermore, it was stated that many of the guidelines that were available simply stated what the Government wanted rather than helping the community to take a leadership role and achieve its ambitions.

In terms of tracking their own progress, some information had a significant impact on participants. Thus the survey of community views and perspectives (Butterworth et al., 1996, McCreddin et al., 1999) and HRCCC surveys (Bellamy and Macdonald, 1998; Bellamy et al., 1999) revealed a low awareness about ICM amongst the broader community and some internal problems within the Committee. The HRCCC were apparently initially surprised and defensive about both but subsequently took a proactive role in improving external communication and addressing Committee structure.

Participants reported that the key inputs into the ICM initiative in the Herbert were experience in other catchments and the experience of members of the committee. Both these inputs were critical in identifying and negotiating roles and realities for the HRCCC itself and members of the Committee. The process was therefore perceived as being only as good as the Committee, making appropriate representation critical. Thus, one key participant stated that "*A healthy committee with solid constitution and reasonable turn-over and involving [State Government] Departments has the information needed to develop a strategy. The committee can work out issues as well as anyone.*"

8.0 SUMMARY

In principle, in order to be successful an ICM initiative has massive information needs from biophysical through socio-economic to procedural. Our review of experience in the Herbert catchment however illustrates that most information sharing, management and analysis was informal and verbal through Committee meetings, presentations by researchers and special interest groups and so on. The Catchment Co-ordinator did circulate information to HRCCC members but most data access was reactive. Information was mainly pushed out to the community via the media. Inadequate access to biophysical and socio-economic information was nor perceived to overly constrained the HRCCC's activities, although inadequate procedural information probably did.

Despite these assertions, the HRCCC continues to see the value of information and push for support for information-based programs. Thus, the HRCCC played a role in the establishment of the Herbert Resource Information Centre (HRIC) but has, in practice, itself made little use directly of the resources available through the HRIC.

However, the specific information needs facing the ICM initiative in the Herbert have been unpredictable, or at least difficult to predict. Thus, the Committees information requirements have been context specific in response to changing prioritise and circumstances in the catchment. Furthermore, the information requirements have changed with the state of development of the ICM initiative and the maturity of the processes underpinning it.

The specific awareness raising initiatives and involvement in instigating on-ground management that the HRCC has been involved in has been opportunistic and dictated by political imperatives and opportunities, funding options and technical understanding. Thus, for example, action has often been dictated by NHT funding priorities and opportunities as expressed by the Regional Advisory Panel rather than the priority needs expressed by the HRCCC.

For all these reasons, the HRCCC has had to be adaptive and responsive and, despite the strategic nature of the Catchment Management Strategy does not have the resources or mandate to plan major initiatives, whether on-ground or in relation to the design, collation and management of key natural resource management data. As a consequence, ICM in the Herbert has relied predominately on the corporate knowledge and expertise of members of the HRCCC and opportunities to access additional expertise from others on a needs basis – including researchers and State Government resource managers.

In conclusion, local knowledge and expertise is a primary source of information applied within the ICM process. This is consistent with the nature and intent of ICM. Major ICM based initiatives in the formal collection, collation and management of information relevant to the ICM process seem both inappropriate and unrealistic. However, the reliance on local expertise and knowledge has implications for the management of ICM. It makes it imperative that the HRCCC provides not only

for effective representation of key stakeholder groups but also provides as broad a base of expertise locally available as can be achieved. Furthermore, the Catchment Coordinator must have a key role to play in providing a stream of information to Committee members so that they can continue to expand their expertise in relation to ICM relevant issues. The same responsibility applies to relevant State agencies and other key stakeholder groups – effective communication of information to members of the CCC will be critical for its effective contribution to improved natural resource management.

9.0 FACTORS THAT INFLUENCE THE SUCCESS OF ICM

- Inadequate resources for an ICM initiative and lack of a mandate to plan major initiatives may mean that ICM activities (eg. awareness raising and on-ground action) will be largely opportunistic and often dictated by political imperatives and opportunities, funding options and existing technical understanding.
- Accessibility and availability of the local knowledge and expertise on catchment issues from as broad a range as possible of catchment stakeholder groups/interests is critical to a successful ICM process.
- Informal and verbal communication through social networks and existing institutional arrangements are critical for information sharing and analysis within the ICM process.
- Inadequate procedural information may constrain the focus and diversity of the activities of an ICM process
- Given that formal collection, collation and management of information relevant to an ICM process may be both inappropriate and unrealistic for a specific ICM initiative, the effectiveness of communication of existing information between state and other relevant bodies is critical.
- Capacity and a willingness within an ICM organisation to collaborate with other groups, agencies or individual experts with particular understanding of the issues may be essential for raising awareness of ICM issues and precipitating appropriate action.
- Adequacy of the skills and commitment of the staff ICM groups and other relevant agencies are critical to an effective and influential ICM process.

10.0 RECOMMENDATIONS

10.1 PLANNING INFORMATION NEEDS IN SUPPORT OF AN ICM PROCESS

- The specific information provisions required in order for ICM to contribute to the solution of problems are diverse from biophysical through socio-economic to procedural; variable with the stage of implementation of the ICM process; and in any specific instance, context specific; and unpredictable in response to changing circumstances and priorities in the catchment including political imperitives and opportunities, funding options and technical understanding.
- Information needs associated with an ICM initiative can be usefully considered and managed in relation to the following discrete tasks: developing a Catchment Management Strategy; raising awareness of ICM and issues that ICM is tackling; influencing and precipitating action and planning by others; and managing an effective ICM program.
- Local corporate knowledge and expertise is likely to be a primary source of information applied within the ICM process. It is imperative that the ICM committee provides not only for effective representation of key stakeholder groups but also provides as broad a base of expertise locally available as can be achieved.
- The Catchment Co-ordinator must have a key role to play in providing a stream of information to Committee members so that they can continue to expand their expertise in relation to ICM relevant issues.
- Major ICM based initiatives in the formal collection, collation and management of information relevant to the ICM process may be both inappropriate and unrealistic for a community-based ICM group to undertake. However it is imperative that effective communication of information is possible between relevant State agencies and other key stakeholder groups and members of the CCC.

10.2 DEVELOPING A CATCHMENT MANAGEMENT STRATEGY

- Generically, the structure and content of the Catchment Management Strategy is dictated by State level policy. However, the local expertise of the members of the Catchment Coordinating Committee and other stakeholders consulted during the process of developing the Strategy need to be used to develop a Strategy within this general framework that meets local needs.
- The Strategy can not rely solely on local expertise. Extensive use of documented information and knowledge needs to be used to validate, 'reality check' and develop the structures and issues generated by the Catchment Coordinating Committee. This material should be properly referenced within the document.
- Because the Catchment Strategy is intended to be a living document, it is important that, as well as being referenced, the data and information that underpin the document are maintained by the Committee and that on-going process of continue to collection and collate key information continues so that future versions of the document can reflect an increasing documented resource base.

10.3 RAISING AWARENESS OF ICM

- Awareness raising is likely to be more productive in relation to issues that are well understood scientifically rather than remaining fundamentally contentious.
- Awareness raising on issues is likely to be opportunistic, so information collection for awareness raising must be rapid and responsive to opportunities.
- Effective awareness raising depends on a reasonable knowledge of the current level of awareness in the community, on the sources of information most widely used by people in the area etc. Collection of this type of information may be a worthwhile investment for a CCC.

10.4 INFLUENCING AND PRECIPITATING ACTION

- As with raising awareness, influencing resource managers and planning processes and precipitating on-ground action will fall into the broad strategic direction set by the Catchment Management strategy. However, it is likely to be opportunistic and therefore not easy to plan for in terms of information provision.
- The expertise of members of the Catchment Coordinating Committee is often critical in identifying opportunities for influencing resource managers and planning processes as well as precipitating action.
- Collaboration with other groups, agencies or individual experts with particular understanding of the issues involved is often the most expedient way of precipitating appropriate action.

10.5 IMPLEMENTING AN EFFECTIVE ICM PROGRAM

- Implementing an effective ICM program places a number of information needs on the Catchment Coordinating Committee. However, most information sharing, management and analysis was informal and verbal through Committee meetings, presentations by researchers and special interest groups and so on
- The State level coordinators of ICM need to ensure a regular and consistent flow of information to local groups.
- The Catchment Coordinator and Committee Chair need to ensure close and effective communication with policy level people.
- The management skills of the Coordinator and Committee members is important - appropriate people should be picked on this basis and additional training may be merited.

1. INTRODUCTION

Approaches to natural resource management based on the integration of community involvement, technical knowledge, and organisational structure and policy objectives are endorsed throughout Australia. All State Governments have adopted programs of integrated catchment management (ICM) under a variety of names and using a variety of policy and legislative frameworks. At present the application of ICM varies widely throughout Australia, with some states such as New South Wales having established legislation, whilst others such as Western Australia and Queensland have no generic legislative powers.

The fundamental challenge of these policy initiatives is to improve the way our natural resources are used and managed with a long-term perspective. However, the translation of the concept of an integrated approach to resource use and management at a catchment scale into practice is proving difficult. ICM is an evolving concept that lacks a well-defined body of guiding principles capable of general application.

This report identifies guiding principles for the role of community-based ICM, identifies factors that are likely to influence its success and makes recommendations on its planning and implementation. These principles and recommendations are based on a five-year study to investigate factors that influence the success of a community-based approach to ICM in the Herbert River Catchment of north Queensland[1]. Although many will not be necessarily surprising, their significance lies in that they are backed-up by comprehensive and rigorous interdisciplinary research (see 'Further Reading').

2. THE ROLE OF COMMUNITY-BASED ICM

2.1 To be a process of influence.

As a multi-stakeholder mechanism for community participation in natural resource management, ICM should not be seen as a vehicle for radical shifts in power relations within the community, but rather a vehicle for influencing policy agendas and the system of planning processes on NRM within government (local, state and federal), industry and the broader catchment community.

2.2 To support community learning.

ICM needs to be recognised as a program of community learning that requires a significant period of time before substantial on-ground results can be expected. Community learning at all levels, including the State level, implies:

- the parallel increase in awareness of the significance of long term resource management problems;
- appreciation of the need for integrated as opposed to piecemeal approaches;
- maturing of community cooperation to address the problems;
- creation of plans and actions that are agreed by the community;
- political support; and
- eventually, substantial on-ground change.

This process can easily stall and even reverse at any time along the path.

2.3 To be a partnership between government, industry and the community.

The ICM initiative relies on existing authorities and various programs and planning processes of state and local governments and private and non-government sectoral activities to implement their plans and achieve their objectives. ICM requires a

[1] LWRRDC R&D Project CTC7 – Evaluation of Integrated Catchment Management in a Wet Tropical Environment.

partnership approach between different levels of government (particularly local government), industry, landholders and the broader community. There is a responsibility for landholders to do things on the ground, which are widely supported by the community. At the same time, both incentives for their efforts and resources for voluntary groups need to be provided by government rather than through regulation alone. An important way to implement this will be joint on-ground projects. This includes ensuring consistency of the information that is provided for the community from government. In doing so, there needs to be agreement on the exact roles of community and government, ie. clear roles will need to be established at the commencement of any activity.

2.4 To ensure legitimate representation.

For the partnership to work and gain credibility within the catchment community, representation in the ICM process must be legitimate, inclusive and accountable. Representatives must keep their constituents informed of the ICM process, interact actively with their constituents to understand their perspectives, and adequately represent their constituency's interests to the partnership.

2.5 To provide a community forum for coordination of effort, networking and social learning.

Community-based ICM meetings can provide an effective and legitimate community forum for networking, both within the community and between government and the community, as well as a vehicle for the exchange of information and more informed and inclusive discussion on NRM issues and planning processes that links state government, local government and various key catchment stakeholder groups. Decision-making in this forum needs therefore to be based on negotiated accommodation of explicitly stated interests and social learning of new shared perspectives rather than entrenched positions.

2.6 To build trust and effective interactions amongst stakeholders.

The success of ICM in precipitating action on catchment issues depends on the willingness of the participating individuals to build trust, deal sensitively with conflicts in the catchment community and work on maintaining productive interactions within the context of workable institutional arrangements. In this, local leaders play a substantially influential role.

2.7 To ensure fairness of process.

A key determinant of broader community acceptance of decision-making on catchment issues and related planning outcomes is the perceived fairness of NRM process and procedures and relatedly the fairness of outcomes that people receive. An ICM process can foster fairness through: (a) establishing a legitimate system of representation for the ICM initiative (eg. ensuring inclusiveness of membership and the supporting representatives to adequately represent their group's interests in the ICM process), (b) working towards the development of acceptable cost-sharing arrangements for NRM infrastructure and on-ground works and (c) establishing a decision-making approach for ICM that is based on a process that seeks consensus amongst stakeholders, while respecting and accommodating on-going differences.

2.8 To identify and broker project funding opportunities.

ICM needs to develop a lead role as the principal broker in the catchment for external funding of community projects to address natural resource management problems in the catchment (eg. NHT). This role can provide the catalyst for community activity in federal and state-funded natural resource management initiatives in a more strategic way than in the past.

2.9 To provide an influential voice on NRM at the regional level.

An ICM initiative has a key role of linking NRM principles and objectives into regional processes such as regional economic development, regional planning, cultural heritage and conservation management programs and processes.

2.10 To demand long term government agency commitment to the process.

The success of ICM is in part dependent on government agencies resolving bureaucratic gridlock among the array of fragmented but inter-dependent agency-based policies, plans and programs and, in particular. ensuring long term agency commitment to the ICM process (ie. clear upper management commitment within government agencies, political support, financial and administrative resources, establishment of workable institutional arrangements).

2.11 To provide a vehicle for integrating information relevant to NRM.

The two primary sources of information for the ICM process are local knowledge and expertise and existing technical information held by state and other relevant bodies. ICM meetings provide a central pooling of local knowledge through the wide diversity of stakeholder representatives involved in the ICM decision-making processes and related activities. Agencies are also repositories of technical information on the catchment but this information is fragmented and needs to be "shared" with other agencies and local interest groups. A key role of ICM is to foster the capture of relevant data on NRM issues and the development of locally accessible mechanisms for integrating data and delivering information.

3. FACTORS THAT INFLUENCE ICM OUTCOMES

3.1 Characterisation of NRM Issues in the Catchment

Historical context and evolution of resource use

- The level of understanding relating to the history of land use change and resource use within the catchment that can help to identify the causes of some issues, to identify the target/client groups and to target strategies to resolve the problem.

Diversity of stakeholder knowledge, attitudes and values on natural resource use and management

- Degree of catchment community awareness of the importance of environmental problems and the need for behavioural change and timely action.
- Degree of recognition across stakeholder groups of community responsibility to address natural resource use and management problems.

Extent of problem recognition and acceptance of change required by different stakeholders

- The history of stakeholder 'ignorance' of the incremental, cumulative and insidious nature of environmental degradation in the catchment, as well as the existence of a past developmental ethos supported by both governments and rural industry that actively promoted land clearing and intensification of land use.

Scientific understanding, feasibility and acceptability of technical solutions to natural resource problems

- The availability and level of accessibility to all stakeholders of local knowledge, scientific data and technical understanding on natural resource issues in the catchment.

- The availability and acceptability to stakeholders of technical 'solutions' for sensitive issues in the catchment.

3.2 Local Attitudes, Values and Behaviours on NRM

Evolution of on-ground policy or program implementation

- The degree to which the catchment community perceived the ICM process as a voluntary one or one forced on the community by government.
- The degree of perceived personal and community control or influence on the management of land and water issues in the catchment.
- The appropriateness of the 'scale' of the ICM initiative to the local community, that is the degree of perceived relevance and meaningfulness of the catchment 'scale' to the local community of interest.

Socio-economic conditions and trends of context of implementation

- Stakeholder perceptions of the costs of solutions and the level of financial capacity within the catchment community to address natural resource issues.

Media coverage and attention

- The degree of coverage and the way in which resource management issues and an ICM initiative are presented in the local media.

Support from catchment community leaders

- The degree of support and promotion of natural resource management within local industry groups.
- The degree of support and promotion of natural resource management from politicians in local and state governments.

Attitudes and resources of local constituents

- The level and intensity of formal linkages and interaction between community, industry and government organisations with a responsibility or an interest in resource use management and planning within the catchment.
- The level of perceived personal and community benefit from becoming involved in NRM policy processes and related activities.
- Degree of perceived relevance of government strategies at a catchment scale and perceptions of their usefulness to community members at a personal level.

3.3 Adequacy of Policy Frameworks and Institutional Arrangements for ICM

Clarity and consistency of roles and objectives of the ICM initiative and other responsible groups

- The degree of consistency of the goals and objectives of an ICM policy initiative in the long term.
- Degree of integration of legislative frameworks on natural resource management across local, state and federal levels.
- The clarity of roles and responsibilities of implementing and other responsible bodies for ICM across stakeholder groups.

Coordination among implementing agencies and stakeholders on NRM

- The level of commitment of upper and other key management in state agencies to both ICM and a 'whole of government' approach, and their preparedness to commit resources to support the process in the long term.

- The degree of opportunity for those actively involved in the implementation of ICM to share knowledge experiences, and concerns relating to the process.
- The degree of support and closeness of the relationship between local government and ICM.
- The complementarity of the relationship between the ICM process and Landcare and the degree of coordination of their activities in the catchment.

Adequacy of financial resources for the policy initiative

- The level and security of government funding to support an ICM initiative (eg. for organisational start up, general operational costs, capacity building and leveraging other funding sources).

Commitment and skill of implementing staff

- The availability of a committed, skilled and well-funded catchment coordinator to drive the process and undertake a range of essential tasks.
- The level of commitment, amount of available time, and degree of strategic vision of the local chair of the ICM organisation.

Adequacy of policies, plans and decision rules of implementing agencies

- The degree to which the devolution of responsibilities for natural resource management to the local level is matched by a concomitant devolution of resources and capacity to local authorities.
- The degree of inclusiveness of the representation of interests on the ICM organisation.
- The availability and equity of cost-sharing and other incentive systems to encourage and support changes in land manager behaviour.
- The availability to the ICM organisation of guidelines and practical options for taking action on specific problems on the ground.
- The degree of focus of regulatory mechanisms on strategic integrated planning rather than development control.
- Availability of agreed management plans for land, water and vegetation resources in the catchment.

3.4 Sustainability and Equity of Processes for ICM

Knowledge and expectations of the process by stakeholders

- The degree and diversity of stakeholder awareness of catchment issues and their expectations of ICM.
- The community perception of the acuteness or perceived social importance of resource management problems and their ability to link these perceptions to ICM related solutions.
- The degree of matching of the views and understanding on the aims of ICM between the overall catchment community and those of the members of the ICM organisation.

Degree of coordination of resources to address catchment issues

- The degree of coordination of government resources and level and intensity of commitment to a whole of government approach across relevant agencies.
- The degree of contradiction and conflict in the flow of information and advice from different state government agencies.
- The effectiveness of communication networks between state agencies as well as between these agencies and other relevant organisations in the catchment.

Degree of motivation, commitment, cooperation and support for the process

- The capacity and willingness within an ICM organisation to collaborate with other groups and agencies or individual experts with a particular understanding of the issues.
- The degree of 'over-commitment' of key players, and the diversity and compatibility of the different 'hats' they wear.
- The degree of self-interest and gate-keeping by stakeholder representatives on the ICM organisation particularly regarding controversial or 'hot' issues for the catchment.
- Perceived degree of politicisation of natural resource management issues by the catchment community.

Efficiency and effectiveness of process

- The effectiveness of the ICM organisation in providing a representative community forum for informed debate on catchment issues, including linking state government, local government and other community groups, fostering the exchange of information amongst stakeholders, and the development of an appreciation of the nature and diversity of other stakeholder's viewpoints on particular issues.
- The degree to which the ICM initiative is perceived to be fostering a partnership approach between local government, state government and the community.
- The degree to which local government incorporates ICM principles into local government planning processes and takes responsibility for implementing them.
- The degree to which the ICM initiative is able to identify opportunities to undertake high profile activities that are topical, measurable and have visible outcomes to the catchment community in the short term.
- The frequency of turnover of staff and degree of retention of expertise on ICM within state agencies with roles and responsibilities relating to natural resource management in the catchment.
- Accessibility and availability of the local knowledge and expertise on catchment issues from a diversity of catchment stakeholder groups/interests to the ICM process.
- Timely targeting of appropriate inforamtion.

Perceptions of equity and procedural justice/trust in process

- The perceived inclusiveness of the selection process for stakeholder representation on the catchment committee and the adequacy of the rules and strategies underpinning this process.
- The perceived adequacy and fairness of the cost-sharing arrangements amongst potential beneficiaries of the investment in NRM activities in the catchment
- The degree of inclusiveness and level of participation of stakeholders in the development of the catchment management strategy.
- The degree of willingness and capacity of relevant government agencies and community organisations to share information.

4. RECOMMENDATIONS FOR PLANNING AND IMPLEMENTING ICM

4.1 Establishing Local Relevance

The implementation of an ICM initiative is inherently context sensitive and a wide range of environmental, economic, social, policy/institutional and technological factors will influence its implementation and impact. In any particular instance, the human association with the natural resource environment in a catchment is embedded in established social networks and interactions, fundamental social values, institutional frameworks, historical problems, past experiences and established ways of doing things and it will continue to be shaped by them in the future.

- ***Recommendation 1:***

  To ensure community acceptability and establish relevance to the local context, an ICM process should focus on achieving a sustainable future for the catchment by working with, influencing and improving the effectiveness of existing social networks and institutional frameworks rather than creating a completely new set of structural arrangements that supplant the old.

4.2 Establishing Supportive Institutional Arrangements

Although the development and implementation of strategies for catchment resource management should be encouraged through the voluntary cooperation of the community, industry groups, local government and state government agencies, the effective implementation of ICM objectives at the local level requires legislative support.

- ***Recommendation 2:***

  An ICM initiative needs to be initiated and its implementation supported as a voluntary partnership between the community and government. However its on-ground implementation also requires the balanced support of incentive systems (to encourage voluntary action in the community) and legislative backing (to enforce compliance where necessary).

Local government has substantial scope to achieve catchment management objectives through the incorporation of ICM principles into planning schemes. However local government land use planning is not the answer alone as it may only have powers to influence decision-making in limited situations (eg. to variations to existing use rights or new development applications).

- ***Recommendation 3:***

  ICM needs to foster strong linkages with and involvement of local government in the ICM process and to ensure the integration of ICM principles into local government planning schemes. However it also needs to support the integration of local government planning schemes and development assessment procedures with other resource management arrangements that may deal more effectively with existing use rights on both leasehold and freehold lands.

Although there has been an increasing commitment within federal and state governments to devolve responsibility for natural resource management to the local level, in general there has not been a concomitant devolution of resources to local authorities to support them doing so.

- ***Recommendation 4:***

  The ICM initiative itself, and state government in particular, need to actively address the lack of capacity (ie. knowledge, resources, skills) in local authorities to identify opportunities and to implement ICM objectives.

The common short-term nature of ICM funding and political cycles is not conducive to the development of long term sustainable solutions, or to the long-term commitment of staffing necessary for a successful ICM organisation. This is especially an issue for a program that is intrinsically evolutionary and dependent on awareness, planning and action cycles that take longer than a few years to establish. Importantly, once an ICM organisation is established and catchment management strategies developed, the requirement for funds for on-ground works will increase substantially as planning is inexpensive relative to action. There is also a risk that ICM activity and progress will be entirely opportunistic and dictated by state and federal government political imperatives and competitive funding opportunities rather than being directed by the community priorities identified in the catchment management strategy.

- ***Recommendation 5:***

  An ICM initiative requires adequacy and long term security of financial resources for both start-up and on-going operational support of the ICM organisation and to have reasonable expectations of competitive project support. The ICM organisation also needs to adopt a lead role as the key broker in the catchment for coordinating external funding of community projects to ensure that natural resource management problems in the catchment are addressed in a more strategic way.

Coordination of government resources to address issues of community conflict relating to land and water resources management from a whole of government approach within the catchment is essential to an effective ICM process. State agencies often make decisions on NRM issues independently of each other and local interest groups. In particular, a lack of sharing of information between agencies can lead to contradictory or conflicting information being presented to the community by different government agencies with regard to important catchment issues which exacerbates the community conflict. In addition, many existing regulatory mechanisms for resource use and management focus on development control rather than strategic integrated planning and therefore provided only limited opportunity for ICM to influence decision-making

- ***Recommendation 6:***

  The complex and often confusing array of Acts, programs, and policies that impact on resource management at the local, catchment, state and national levels require rationalisation to support a more strategic, integrated and coordinated approach to catchment management. In particular, a key requirement from government for successful ICM is the clear commitment of key officials to ensure effective participation, coordination of effort and consistency of advice by all relevant agencies as well as the continuity of political commitment (ie. all tiers of government) on a long-term basis.

ICM is promoted as a partnership approach to catchment management between government, industry and the community. However, specific roles and responsibilities for the different partners are frequently couched in very general terms, which may lead to confusion and slow progress or even in-action on important or challenging catchment strategies in some situations.

- ***Recommendation 7:***
  At the commencement of any work or activity of an ICM process, clear roles and responsibilities need to be negotiated and agreed upon between the responsible government, industry and community bodies.

4.3 Establishing Legitimacy

ICM as implemented in Australia is essentially an experimental program with participants on a steep learning curve. Community learning at all levels, including the State level, implies the parallel increase in awareness of the significance of long term resource management problems, appreciation of the need for integrated as opposed to piecemeal approaches, maturing of community cooperation to address the problems, political support, creation of agreed plans and actions and eventually substantial on-ground behavioural change. This process takes a long time to evolve and can easily stall and even reverse at any time along the path.

- ***Recommendation 8*:**
  ICM needs to be recognised, promoted and supported as a program of community learning that requires a significant period of time before substantial on-ground results can be expected.

Understanding of cause-effect relationships and 'solutions' to major issues in a catchment can vary along a scale of 'speculative' to 'uncontested'. The lack of technically uncontested 'solutions' for highly sensitive issues in a catchment can lead to substantial community conflict and lack of confidence in government, research and other relevant agencies.

- ***Recommendation 9*:**
  ICM needs to ensure Government agencies and other technical advisers or experts do not push highly speculative solutions that may create greater social conflict and loss of trust in policy processes. In particular, the resolution of sensitive issues requires clear local interpretation supported by appropriate and locally credible data.

The perceived level of openness and inclusiveness of the processes established for the management of the ICM organisation's representational structure (eg. election of office bearers, use of proxies, reviewing membership) will reflect on its credibility within the catchment community and government. In addition, ICM committee members are frequently active and committed community leaders who wear "too many hats" such that they may have difficulty in committing sufficient time to ICM activities.

- ***Recommendation 10*:**
  An ICM process needs to establish clear and agreed ground rules on how the ICM organisation will operate (ie. purpose, structure, composition, representative appointment process, decision-making rules, and roles and responsibilities). In particular, efficient use of proxies and turn over of representatives are essential for an inclusive, enthusiastic and actively influential ICM process.

Feelings of personal and community control are related to feelings of tractability of the NRM problem. The perceived impediments to effective ICM most commonly relate to feelings of personal or community control and include 'institutional failure' (eg. slow government responses and strategies, departmental conflicts, lack of government

commitment to a 'whole of government' approach) and economic issues (eg. high costs of solutions and lack of financial capacity in the community).

- ***Recommendation 11*:**
  The perceived impediments to managing land and water need to be addressed by speeding up government responses and strategies, promoting where possible low cost solutions to problems and ensuring regular communication with the community about what is happening. This will assist in improving relations with the community and heightening trust in government.

4.4 Creating Awareness of Issues and the ICM Process

ICM processes frequently are required to deal with intractable issues that are embedded in past land use decision making behaviour and land management practices. Successful ICM requires a high degree of community awareness that there are important environmental problems that require timely action. However, land and water management issues may not be uppermost in people's minds, first priorities frequently lie with 'life issues'. Awareness raising undertaken by an ICM initiative is likely to be more productive in relation to issues that are well understood scientifically and have local relevance rather than remaining fundamentally contentious.

- ***Recommendation 12*:**
  In facilitating an effective ICM process, ICM organisations and supporting government and industry agencies should place a priority on the collection of key natural resource use data to understand past and present resource use and management practices in the local catchment context. This information can inform the community debate on the nature and extent of both future resources use and the level of behavioural change required to meet these aspirations. The information can also be usefully presented as a catchment Atlas for broad distribution and use within the community. In addition, effective awareness raising requires a reasonable knowledge of the current level of awareness in the community on specific issues and on the sources of information most widely used by people in the catchment community. In particular, an ICM process can influence a community's awareness on natural resource issues and the ICM process itself through opportunistic use of high-profile political or controversial issues/events of local relevance.

4.5 Influencing and Precipitating Action

Although there may be good agreement among stakeholders on the key catchment resource management issues, for any particular issue individual stakeholder diagnosis of their causes and possible solutions may vary significantly. The success of ICM in precipitating action on catchment issues depends significantly on the choice of method of community engagement, which should be based on a clear understanding of the particular decision context of that issue.

- ***Recommendation 13*:**
  The success of ICM in precipitating action on catchment issues depends on the willingness of the participating individuals to build trust, deal sensitively with conflicts in the catchment community and work on maintaining productive interactions within the context of workable institutional arrangements. In particular, in choosing a method of

community engagement and a strategy for action for a particular catchment problem, clear understanding is required of the decision context relating to that problem, including the locally perceived mode of solution or level of technical complexity involved in resolving the problem and the nature and intensity of community conflict associated with the decision.

Raising awareness of issues amongst resource managers alone is not necessarily going to result in a change in management behaviour. Many long-term solutions to natural resource problems are frequently not in a landowners self-interest financially or social benefit to undertake. Specifically the costs of action are incurred by both individual landowners (eg. opportunity cost of land, restoration or remediation works, materials and construction costs, in-kind contributions of time and equipment) and the catchment community (eg. cost of reparation or remedial works, construction costs, wages and publicisation). Similarly the benefits will accrue to both landowners (eg. avoided costs of lost production, aesthetic attraction of improved habitat, reduced production costs, improved water supply) and the catchment community (eg. improved downstream water quality, retention and improvement of natural habitats, reduced social conflicts, reduced litigation and transaction costs, aesthetic benefits, avoided costs of resource degradation and damage to infrastructure). However, private property owners could incur considerable financial expense, but most benefits would accrue to the community in general.

- ***Recommendation 14*:**
  Many resource management issues require the political commitment and will of relevant local and state government agencies to effectively and consistently apply their relevant powers in land development decision-making and approval processes to ensure ICM principles are taken into account. However, effective and equitable cost-sharing and other incentive systems to encourage changes in land management behaviour need to be established to support these processes. In particular, an ICM process that relies on the voluntary cooperation of individual resource managers may need to offer financial incentives if a change in attitude is going to lead to a change in behaviour that will result in an improvement in sustainability of resource use.

Influencing resource managers and planning processes and precipitating on-ground action falls into the broad strategic direction set by the Catchment Management strategy. However, moving from identifying and prioritising issues and developing a catchment management strategy to precipitating action on those strategies is a major challenge for a community-based ICM process. In particular, due to the complexity of the problems being addressed and the limited resources available to ICM, the implementation is likely to be opportunistic and limited in terms of the locally available knowledge of the type of action or response required that is likely to be effective for catchment management. It may also be limited by the specific skills available to complete a desired action or response.

- ***Recommendation 15*:**
  The expertise of members of the ICM organisation is often critical in identifying opportunities for influencing resource managers and planning processes as well as precipitating action. Collaboration with other groups, agencies or individual experts with particular understanding of the issues involved is also often an expedient way of precipitating appropriate action. In addition, government agencies need to develop guidelines and advice

that identify practical on-ground options for a community to take action on specific types of issues. Government agencies also need to be aware of their own shortfalls in knowledge and respond to local knowledge where appropriate.

4.6 Gaining and Maintaining Commitment to the Process

One of the big challenges for ICM is keeping up the momentum in a process where tangible outcomes are slow to emerge and may well be attributed to others influenced by ICM rather than the ICM process itself. Representatives of ICM organisations are often community leaders who are often over-committed. Loss of motivation and burn out are therefore high potential risks amongst community participants.

- ***Recommendation 16*:**
  The management skills of key ICM personnel and office bearers are essential to a successful ICM process. In particular, an ICM initiative requires a credible and confident Catchment Coordinator who can "drive" the process and undertake essential and "burn-out" tasks. This requires a skilled person with experience and knowledge of NRM issues and agricultural systems, good communication skills, well developed interpersonal and conflict resolution skills for handling a diverse group of people, and who is sufficiently confident and prepared to stand up and be accounted for on catchment issues.

Although there may be community awareness and interest in catchment issues, the personal influence people feel they may have in addressing those issues may not be particularly high which can hinder community participation in ICM. A high personal sense of control in dealing with catchment issues, or a belief that individuals can help motivate the community to improve these problems will facilitate the promotion of ICM in the community and commitment to the process. In addition, government strategies are often not perceived to be highly useful to community members at the personal level and therefore not seen to be highly relevant at that scale.

- ***Recommendation 17*:**

  An ICM process needs to address the lack of influence felt by the community by showing that they have influence and demonstrating both the ways in which they can change land and water management and the relevance of catchment strategies at the farm or personal level.

4.7 Establishing an Influential Role

As a community-based process without statutory powers on natural resource use and management, an ICM initiative will rely largely on existing authorities and various programs and planning processes of state and local governments and private and non-government sectoral activities to implement its plans and achieve ICM objectives.

- ***Recommendation 18*:**
  As a multi-stakeholder mechanism for community participation in natural resource management, ICM should not be seen as a vehicle for radical shifts in power relations within the community, but rather a vehicle for influencing policy agendas and the system of planning processes on NRM within government (local, state and federal), industry and the broader catchment community.

Effective communication between groups and individuals is potentially an important means of influence in terms of changing outlook of others on ICM or environmental issues. In particular communication is effective in increasing awareness and gaining understanding and knowledge.

- ***Recommendation 19:***
  An effective overall system of communication on ICM across all stakeholder groups should be designed to facilitate significant outcomes including *mutual benefits* (such as information exchange, progress or ensuing action on the issue of communication, better understanding of issues), and *mutual influence* or changed outlook (including changed views, acknowledgment of problems, increased awareness of problems, sharing of ideas, increased acceptance and awareness of ICM). It should provide opportunities for both formal and informal exchanges between stakeholders.

A Catchment Management Strategy needs to be considered as a 'living document' that evolves as local community and technical understanding and relevant political imperatives change and develop over time. An endorsed catchment management strategy developed through a participatory process involving key stakeholders in the catchment provides the basis for developing both a shared vision of the catchment as well as leveraging funding support for the ICM organisation and related project activities. Generically, the general framework (ie. structure and content) of a Catchment Management Strategy however will be largely dictated by State level policy requirements.

- ***Recommendation 20*:**
  The local expertise of those stakeholders involved and consulted during the process of developing the strategy needs to be used to develop a strategy within the general framework required by government but that meets local needs. In addition, documented information and knowledge needs to be used to validate, 'reality check' and further develop the structures and issues generated by this participatory process. It is important also that the data and information that underpin the strategy document are maintained by the ICM organisation and that an on-going process of collection and integration of key information continues so that future versions of the strategy can reflect an increasing understanding of catchment management.

4.8 Communicating with the Community

Communication on NRM within a catchment community relies predominantly on existing social networks. However, local media can also provide a highly important source of information to the community.

- ***Recommendation 21:***
  Local media such as local newspapers can contribute to community discourse on natural resource management issues and can be exploited to bring attention to an ICM approach within a catchment community.

Community recognition of the importance, urgency and impacts of land and water issues can be exploited. Concentrating on solutions and actions can help to prevent a positively "doom and gloom" image sometimes perceived within a catchment community.

- ***Recommendation 22*:**
  When communicating with the catchment community, an ICM process should focus on those issues where there is low awareness and a desire to know more, including possible solutions for environmental problems and ensuring there is something provided that the community can start working with immediately. It may require systematic community investigation to identify those issues for all sectors.

4.9 Working with the Community

In working with the community, it is important to understand and acknowledge the historical issues that have been frustrating for the community in order to move forward, gaining support and involvement. In particular, an ICM process needs to acknowledge the importance of employment and financial issues.

- ***Recommendation 23*:**
  An ICM process needs to recognise money constraints and the limitations on people's time to become involved in local land and water management activities and promote solutions and activities for the broader community that can save them time or take very little extra time or effort. It also needs to assist in identifying and publicising employment opportunities in the solutions that are developed for land and water management.

ICM is promoted as a partnership approach between different levels of government (particularly local government), industry, landholders and the broader community. Implicit to this approach is a responsibility for landholders to do things on the ground, which is widely supported by the community.

- ***Recommendation 24*:**
  In a partnership approach to ICM, incentives for individual landholder efforts and resources for voluntary groups need to be provided by government rather than through regulation alone. An important way to implement this will be joint on-ground projects. This includes ensuring consistency of the information that is provided for the community from government to support these projects/activities. Giving the ICM group more autonomy will also act to increase motivation and a positive outlook.

4.10 Informing the ICM Implementation Process

The challenge to create policy processes, institutional arrangements and NRM practices that can contribute towards achieving sustainable and equitable resource use outcomes requires support from monitoring and evaluation of the progress and impact of the ICM policy initiative as part of the change process.

- ***Recommendation 25*:**
  Monitoring and evaluation of the progress and impact of an ICM policy initiative is fundamental to identifying change, supporting an adaptive approach that is flexible enough to meet the challenge of this change, and enabling learning at individual, community, institutional and policy levels. In particular, ICM initiatives need to be evaluated as a system that links the initiative's objectives and rationale to performance 'on the ground'.

Implementing an effective ICM program places a number of information needs on the ICM process. The specific information provisions required in order for ICM to contribute to the solution of problems are diverse from biophysical through socio-economic to procedural, variable with the stage of implementation of the ICM process, and in any specific instance, context specific. They are also likely to be unpredictable in response to changing circumstances and priorities in the catchment including political imperatives and opportunities, funding options and technical understanding.

- ***Recommendation 26*:**
  Major ICM based initiatives in the formal collection, collation and management of information relevant to the ICM process may be both inappropriate and unrealistic for a community-based ICM group to undertake. However it is imperative that effective communication of information is possible between relevant State agencies and other key stakeholder groups and members of the ICM organisation. Based on an adaptive and opportunistic approach, information needs for an ICM initiative can be usefully considered and managed in relation to four discrete tasks: developing a Catchment Management Strategy, raising awareness of ICM and the issues it is tackling, influencing and precipitating action and planning by others, and managing an effective ICM program.

Local corporate knowledge and expertise is likely to be a primary source of information applied within the ICM process. Accessibility and availability of the local knowledge and expertise on catchment issues can be provided through the diversity of catchment stakeholder groups/interests represented on the ICM organisation.

- ***Recommendation 27*:**
  An ICM organisation needs to provide not only for effective representation of key stakeholder groups but also as broad a base of expertise locally available as can be achieved. The Catchment Coordinator must have a key role to play in providing a stream of information to ICM members so that they can continue to expand their expertise in relation to ICM relevant issues.

A broad range of community, industry and government organisations with some level of responsibility or an interest in resource use management and planning function in catchments or at a regional level. The system of organisational structures and linkages is a critical mechanism for facilitating the exchange of information and supporting a coordinated and inclusive approach to catchment management decision-making.

- ***Recommendation 28*:**
  An assessment of the change in the system of organisational structures and formal and informal linkages on natural resource management can provide a key indicator of progress on ICM.

Landholder values, behaviours and attitudes toward land and water management in a catchment can provided an understanding of the social factors that influence the implementation of ICM initiative in a particular catchment.

- ***Recommendation 29*:**
  Attitudinal surveys of catchment residents extend social profiles beyond a demographic focus to perceptions. These include a better understanding of tractability, identifying how effective ICM is perceived to be, and defining priorities for investigation (ie. where to focus effort in regard to

specific issues, such as opportunities for use of the media). The analysis of newspaper coverage can also provide a useful and unobtrusive means of gauging community values about natural resource management issues.

The effectiveness of communications provides an important measure of whether coordination is happening, and also identifies where there are gaps in the system and the effectiveness of specific/different linkages on ICM.

- ***Recommendation 30*:**
  Measuring the effectiveness of communication networks should be a routine part of any ICM initiative, particularly in the early stages. As such it provides a mechanism for measuring an indicator of the transaction costs or communication "effort" required to keep a system such as ICM operating.

The assessment of local knowledge on NRM issues and processes provides an effective means of identifying key gaps in local understanding in relation to management options and in evaluating fundamental assumptions that underpin local management practice and may thereby provide an appropriate basis for prioritising research needs.

- ***Recommendation 31*:**
  Investigation of changes in local knowledge over time provide a powerful tool for evaluating some of the key impacts of an ICM process. In particular, an approach based on 'landscape literacy' can allow the characterisation of resource user perceptions and the determination of significant differences amongst stakeholders to the principles underpinning ICM.

Accountability of public expenditure is an increasingly important requirement of agencies that have been allocated public funding and/or have applied for public funding for the provision of a program or a public good. ICM organisations are developing into well-defined and well-organised community structures with financial resources for which they are required to be accountable.

- ***Recommendation 32*:**
  Cost benefit analysis (or similar) can provide valuable information for an ICM organisations that can guide the ICM implementation process regarding the efficiency of its investments as well as the distribution of the costs and benefits resulting from its activities. To facilitate such evaluations, indicators measuring the condition of natural resources need to be identified and monitored to enable substantiation of claims of natural resource improvement.

ACKNOWLEDGEMENTS

The authors wish to acknowledge the financial support of the Land and Water Resources Research and Development Corporation, which made this research possible.

The authors wish to express their extreme gratitude to all those people with have an interest or who are actively involved in the implementation of Integrated Catchment Management in Queensland and who gave time from their busy schedules to complete interviews or questionnaire survey forms that were fundamental to the success of many project activities. Of special note are the following people and agencies who willingly co-operated and provided valuable assistance to this five-year research project:

- The members of the Herbert River Catchment Coordinating Committee who actively participated and contributed their valuable time, views and knowledge.
- Dave Horsley, CSR Herbert River Mills, who was an invaluable source of information on natural resource management and related activities in the Herbert River catchment, provided substantial advice to the researchers and contributed actively to many of the research activities of this project.
- The Herbert River Catchment Coordinators, Rob Hunt and subsequently Andrew Petroeschevsky, who provided valuable comment and information as well as facilitating interactions with HRCCC members.
- Ray Quabba, Chair of the HRCCC, who gave his time, knowledge, invaluable assistance and encouragement to the researchers over the life of the project.
- Philip Rowland, Mike Merrin and Don Begbie, Department of Natural Resources, Queensland who have actively supported the project since its commencement and provided valuable assistance and access to information to the researchers involved.
- Luis Laredo, CSIRO Tropical Agriculture, Brisbane, who has provided valuable general computing assistance to the researchers involved and contributed actively to database development and management for some key research activities.
- Kathy Mitchell and Leesa Austin, CSIRO Tropical Agriculture Brisbane for invaluable assistance in the preparation of this publication.
- Katrina MacDonald and Suzanne MacLeod, Department of Geographical Sciences and Planning, University of Queensland, for their valuable assistance in the preparation of material for 'An Anthology of ICM in Queensland' (Chapter 4).

EXECUTIVE SUMMARY

This report describes the perceptions Chairmen and Coordinators 14 CCCs in Queensland, and members of the Herbert River Catchment Coordinating Committee towards the Queensland ICM program. It is based on the results of a mail questionnaire which was completed by all coordinators and 60% of chairs statewide and all but three members of the HRCCC.

The survey revealed many common attitudes but often a diversity between catchments and between Coordinators and Chairs in a given catchment. Key factors affecting this diversity included:

- the age of the CCC which conditions its maturity and opportunity to undertake planning, awareness raising and projects
- the environmental circumstance of the catchment - while many are costal rivers, there are also a number of inland rivers which have quite different resources and resource management issues
- the capabilities and effectiveness of the Coordinators and Chairs and the dynamics of the CCC

Some of the significant results include:

- disturbing low level of satisfaction amongst the respondents (especially their Coordinators)
- low and expected awareness in the general public about resources management issues
- widely held view that local governments, both politically and at officer level have not been involved effectively in the ICM process
- lack of support at the state political level
- ineffective involvement of some state agencies

On a positive note there was wide agreement about the supportive role of the media and of the essential role that the CCCs, its Chairs and Coordinators play in gaining support from the stakeholders. Respondents also believed that the DPI (now DNR) and rural producer groups were effectively involved in the process.

In terms of the general approach and institutional arrangements for ICM:

- diversity of views of members sometimes a significant problem with respect to the role of the CCC, its coordinator and whether it should for example be involved in giving advice to landholders, coordinate state government activities and have a regional development function.
- A significant obstacle for ICM is the resistance of many of the community and those in CCCs to state imposed programs which require community action without resources - a perception of force.

Significant findings from the HRCCC responses are:

The most important *resource management issues* were:

- rural drainage
- allocation of sugar caneland
- erosion
- urban flooding

The most important impacts of these resource management problems on the people of the catchment were:

- loss of confidence in government to manage resources effectively
- drinking water quality
- higher production costs
- higher taxes

These issues and impacts focus on government's role in resource management. The concern suggests that among other concerns, the HRCCC should consider how its activities will enhance present government performance.

HRCCC members perceived a strong level of support from the Queensland Department of Primary Industries, the Sugar Infrastructure Improvement Package (SIIP) program, and rural producers. Relatively less support was provided by Local Government, State Government Politicians, and the Department of Lands (now part of new Department of Natural Resources). The public was perceived to have:
(i) a low to moderate level of awareness about natural resource issues and associated impacts,
(ii) low to moderate level of support to solve natural resource issues; and
(iii) supported the local CCC program at a very low to moderate level.

These trends have implications for the extent and nature of partnerships which the HRCCC has developed.

Effective implementation of ICM in the Herbert River catchment is perceived to be aided primarily by:
- the role of the Chairman, Coordinator, and members,
- the representativeness of the membership of the wider catchment community, and
- the view that technical solutions can solve resource management problems in the catchment.

This finding has implications for the professional development and training of coordinators, chairs and members.

Effective implementation of ICM in the Herbert River Catchment is perceived to be hindered primarily by:
- poor understanding of problems
- lack of clear and immediate economic benefits
- high cost of solutions
- long timeframe to see benefits
- lack of trust in government sponsored programs
- public's lack of interest in community based activities
- lack of financial resources within the community
- large size of the Herbert River Catchment
- ICM lacks clear goals and objectives.

This finding has implications for:
- the feasibility of implementing community based initiatives like ICM,
- the need to raise the present level of community support for ICM,
- the need for cost sharing arrangements among governments, private industries, and
- individuals, and
- the need for visible commitment by state and local leaders to ICM.

PART 1 INTRODUCTION

This report describes the perception of Integrated Catchment Management (ICM) coordinators and chairs in Queensland, and the members of the Herbert River Catchment Coordinating Committee, to the following items:
(i) catchment issues,
(ii) resource management issues,
(iii) the level of support provided by other agencies and groups,
(iv) tractability of the issues,
(v) the institutional arrangements to deal with those issues, and
(vi) the process of ICM.
This introductory section provides background to the report, the focus, the approach taken, and the nature of the report itself.

1.1 Background

In 1994, the Division of Tropical Crops and Pastures of CSIRO received a five-year grant from LWRRDC (project CTC7) to assess the relative strengths and weaknesses of implementing Integrated Catchment Management (ICM) in the Herbert River Catchment. Specific research goals were to:

- develop a framework for evaluating the process of ICM implementation that was applicable to other catchment management programs in Australia;
- monitor and document the process of implementation of ICM in the Herbert River catchment and identify the social, economic and institutional factors that facilitated or hindered this process;
- evaluate the key impacts of the implementation process in terms of the attitude and behaviour changes in the community and changes in the severity or tractability of the resource use conflicts for the Herbert River catchment;
- assess the specific technical and related information needs that were relevant to an effective ICM implementation process in a wet tropical environment; and
- contribute to the development of more effective programs in Australia that implement production systems, conservation and land use planning programs based on the philosophy of ICM.

A number of activities have been associated with that research program. In the first year, the research team formulated an evaluation framework in order to organise the design, conduct and findings of subsequent activities (Bellamy *et al.*, 1995) (Figure 1). That framework focuses attention on four primary factors - the NRM context, the issue context, legislative aspects, and community processes.

This report is one aspect of the entire CSIRO DTCP research program, and been strongly influenced by the evaluation framework. The specific objectives of this report are, on both a state-wide basis and within the Herbert River Catchment Coordinating Committee:

- to identify the activities of Catchment Coordinating Committees, and how they are operating;
- to identify how well the CCCs are operating; and
- to identify economic, social and institutional factors which contribute and detract from effective implementation.

1.2 Research Framework

A range of technical, institutional, economic and social indices have been identified and incorporated as an integrated conceptual framework for observing change and evaluating the ICM implementation process. This framework combines aspects of the Mazmanian-Sabatier framework of policy implementation analysis described previously (Mazmanian and Sabatier 1991) with the criteria identified by the PRIME framework (Syme *et al.* 1994) from the social sciences, and environmental management and resource assessment techniques from the environmental sciences. The framework is illustrated in Figure 1.

1.3 Research Design and Approach

The study is based on a mail survey of two groups: (1) selected officials from all recognised ICM Committees and groups throughout the state; and (2) all members of the Herbert River Catchment Coordinating Committee (HRCCC). In addition to surveying these people, the study team interviewed the manager of the State ICM program on two occasions, reviewed all issues of *The Source*, other relevant publications on resource management initiatives in Queensland, and obtained some baseline data on the program from DNR files. This material was supplemented with a review of HRCCC meeting minutes and newspaper accounts, and interviews with selected HRCCC members, staff and local officials with other state and local government agencies.

The state-wide survey was limited to the coordinators and chairs of the 13 recognised CCCs and 1 Catchment Care Group operating in November 1995. The manager of the State ICM program provided the names of these individuals. Addresses for the HRCCC members were provided by the local coordinator.

The survey instruments were questionnaires designed to be readily completed by the respondents (Appendix 1 and 2). Conduct of the survey involved the following steps:

- the questionnaire was structured to follow the previously developed conceptual framework;
- pre-test of the questionnaire with the State ICM manager, the HRCCC Coordinator, and one other local ICM coordinator;
- a presentation at the November 1995 HRCCC meeting to outline the survey and request member support;
- mail out of the state-wide survey in November 1995, and the HRCCC survey in December 1995;
- mail our of reminder letters to non-respondents on December 15; and follow-up phone calls to non-respondents of the HRCCC survey in January 1996.

Formulation of the questionnaire considered both the evaluation framework (Figure 1) and pragmatic issues (*eg.*, ease of understanding). It contained a mixture of factual, scaled responses and open-ended questions on the following topics:

- biographical data on respondents: how long they had held current position, length of residency,
- the issues: what were the economic, social, and natural resource issues in the catchment; and what were specific resource management issues. and how tractable were they,
- attitudes to the support received from the public, government agencies, non-governmental organisations, and the clarity of their roles of ICM,
- overall strengths and difficulties,
- institutional arrangements and finance, and
- personal motivations for being a CCC member (on the HRCCC only).

PART 2 ICM IN QUEENSLAND: HISTORY AND INTENT

2.1 Integrated Catchment Management in Queensland

The quest for effective natural resource management has been the pursed by governments worldwide. Often, water has been a prime focus of attention because a catchment provides a natural system from which the interactions among people, water and related land resources can be considered, and the coordination of relevant public and private resource managers enhanced. To these ends, the State Government of Queensland, Australia released Integrated Catchment Management (ICM) in 1991 in order to:

> *integrate the management of land, water and related biological resources in order to achieve the sustainable and balanced use of these resources. It provides a framework for fostering cooperation and coordination between many landholders and other resource users, community groups and government agencies involved in the use and management of land and water resources* (Queensland, 1991, 1).

While it was recognised that other government initiatives such as the State Conservation Strategy, State-wide environmental programs (*eg.*, Landcare), and broad regional strategies such as the South East Queensland 2001 Growth Management Strategy and Coastal Protection Strategy would be important activities, ICM was perceived to be unique for two reasons. First, it was to involve all sectors of the community. Second, it was to be multiple, rather than single issue based.

ICM Principles

Five principles were to guide the ICM process. First, since land and water resources are basic and interactive parts of natural ecosystems, effective management was best achieved by using the catchment as the administrative unit. Second, since river catchments are continuously changing in response to natural processes and human activity, management strategies should anticipate, adapt, and respond to these changes. Third, decisions would be based on the best available information. Fourth, individual users and managers would be informed about water and land management issues and solutions. Fifth, ICM would provide for a "balance between economic development and conservation of land and water must be maintained" (Queensland, 1990, 1). By using these five principles to guide the formulation of catchment strategies, the following goals would achieved by promoting:

- community understanding, coordination and cooperation,
- common goals and community action, and
- economic and ecological sustainability.

Catchment Care Groups and Catchment Coordinating Committees were to be the driving forces behind ICM. Supported by QDPI which would provide information, education and training services about ICM, CCCs and CCCs were to provide the following functions:

- foster coordination between landholders, community action groups and government agencies in their land and water resource management activities;
- promote community understanding of the interactions between land, water and related biological resources and the value of a coordinated, catchment-wide approach for managing these resources;
- provide a forum for community and government discussions on catchment management issues for resolving conflicting demands on natural resources;
- identify and prioritise interrelated land and water resource issues in the catchment;
- develop catchment management strategies that address priority issues;
- promote and foster voluntary implementation of catchment management strategies by landholders and other resource users through community action groups and government agencies;
- provide advice and recommendations to landholders and other resource users, community action groups and government agencies on catchment management issues;

- monitor, review and report to Government and the community on progress and performance of catchment management strategies and activities [CCCs must report annually to Minister of DPI]; and
- recommend improvements in the administrative procedures and statutory requirements of government agencies to avoid duplication and conflicting requirements.

Implementation of ICM would foster a whole-of-government approach by providing a strategy which was consistent with policies and guidelines of all levels of government

ICM as a Process

ICM was to be a State-wide initiative. While the Queensland Department of Primary Industries (QDPI) would be the agency responsible for administering ICM, the important role of other agencies such as the Departments of Environment and Heritage (QDE), Lands (QDOL), and Housing and Local Government (QHLG) in supporting relevant aspects of ICM were recognised (Queensland, 1991). Collectively, State Government agencies would, within the scope of available resources, support and assist Catchment Care Groups (CCCs) and Catchment Coordinating Committees (CCCs). These two types of bodies would be formed in order to harness local and public agency involvement in order to formulate the catchment strategy document. CCCs would be less formal than CCCs and "link the activities of landholders, community action groups and government agencies" on relatively simple issues which involve a limited number of participants (Queensland, 1991, 2). Providing a forum for community discussion and fostering the cooperative development of solutions are the major roles of these groups. The initial intent was to form CCCs under legislation to address complex issues involving a large number of participants. In practice, legislation was never enacted because of a significant perception that ICM could result in another and unnecessary level of government. Instead, the level of support provided through QDPI has signalled the difference between CCGs and CCCs. The former has no catchment coordinator assigned to it and is ineligible for the $500.00 establishment grant. CCCs receive these types of support. Where a catchment was divided among several CCCs, Regional Catchment Coordinating Committees (RCCCs) could be formed to coordinate individual CCC activities. RCCCs are also eligible for the $500 establishment grant.

The State Government encouraged that CCGs and CCCs take a pragmatic approach which focused on "manageable and resolvable issues of high priority to the community rather than all issues" (Queensland, 1991, 20). When completed, the strategy would identify and describe major issues; describe relevant objectives, guidelines, policies and actions plans; identify mechanisms to achieve objectives; and provide appropriate monitoring and review mechanisms. Unless special legislation were passed, the requirements of the strategy would not be legally binding on any landowner or government agency.

ICM as a Product

The primary final product of the ICM process is a Catchment Strategy which prioritises catchment issues, and identifies appropriate implementation mechanisms. Three options for implementation were identified. The preferred choice would see the CCC seek the voluntary adoption of catchment management strategies by landholders and resource users, community action groups, and government agencies. Presumably, the strategy development process would educate resource managers about the need for of specified resource management activities. Where voluntary implementation was jeopardised, CCCs could request the appropriate state minister (*eg.*, QDPI, QDE, QDOL, QHLG) to have local and state agencies consider catchment management strategies in their routine operations. The final option would see the establishment of a catchment trust or similar statutory body for specified issues such as soil conservation, floodplain management, or river improvement. This issue was considered in the document 1994 document *The Sustainable Use and Management of Queensland's Natural Resources.*

The general intent of ICM may be summarised as follows. It is a voluntary approach which relies on local initiative to establish the need for the formation of a CCG or CCC. Both CCGs and CCCs and subsequent strategies lack legislative authority. Voluntary compliance by relevant private managers (landowners and corporate) and public agencies is the preferred method of implementation. Education of these managers through the exchange of information and the development of the Catchment Strategy is to facilitate the adoption of required actions. ICM Committees are to be composed of major stakeholders who have an interest or are influenced by significant resource management problems. Another dimension of this stakeholder approach, is the joint funding for relevant activities from both the State Government and relevant local participants. Catchment strategies are to focus on several important resource management issues operating on a catchment scale in order than an integrated consideration of problems and solutions is provided. While the state government has identified a number of requirements for all catchment strategies, local groups must seek their own approaches in the formulation of that document. Monitoring is to be an important element of all catchment strategies.

2.2 Forming and Operating a Catchment Coordinating Committee

The State Government identified ICM principles, processes and products. Local communities are to consider the need for ICM, and if appropriate, pursue the formation of catchment coordinating groups or committees. In this manner, ICM in Queensland should merge 'top down' and 'bottom-up' management. Both CCGs and CCCs are comprised of "representatives of the major sectors of the community and government which are involved in, or influenced by, the management of land and water resources in the catchment" (Queensland, 1991, 2). They are to work with state agencies and local groups in forming catchment strategies thus furthering the principle of partnership between state government and local government and groups.

CCGs and CCCs must encompass an administrative region of at least two local government areas and be catchment or sub-catchment based. The membership should "reflect the interests of the major sectors of the community" including local governments, key relevant primary industries, landholders in proportion to the range of land uses in the catchment, state government agencies, community groups and organisations, recreation and conservation interests, secondary interests, and major stakeholders outside the catchment (*eg.*, Great Barrier Reef Marine Park Authority, World Heritage Parks) (Queensland, 1995, 2). The membership should be determined by open election or through nomination by community groups, agencies, and the general public. Membership on RCCCs is drawn mainly from CCCs within the basin.

Once groups within a catchment have decided to form a CCC or CCG, they should apply for endorsement under the Queensland's ICM Strategy which provides them with access to operating and project funds, liability and accident insurance. Appropriate activities are funded from a number of sources. As the administering agency, QDPI provides seed funding for CCGs, CCCs and projects. A one-time $500 establishment grant is available to both CCCs and RCCCs. To cover the full costs of establishment, CCCs are to seek the financial and in-kind support from interested and member organisations. Operating grants are set at $2,000 per year for three years, and $1,000 afterwards. CCCs west of the Great Dividing Range and in the Fitzroy and Burdekin Districts are eligible for an increased level of grant up to $5,000 per year for three years, and $2,000 thereafter. Applications for additional project funding could also be submitted to funding agencies such as Landcare and LWRDCC, and other government and non-government agencies.

2.3 Review of State-wide ICM Activities (1991-1996)

By May 1993, 5 catchments - the Lockyer Valley, Johnstone River, Pioneer River, Mary River and Mitchell River - had been identified as pilot study areas. By October 1995, there were 13

CCCs and 1 CCG formed throughout the state, with most located along the eastern coastal catchments (Figure 1). There was initial concern that ICM and Land Care, which was launched in 1992 as a means of conserving natural resources and protecting the environment., would be seen as overlapping exercises. However, QDPI saw these initiatives as complementary.

> *ICM is about the 'big picture' or the condition of the whole catchment on a broad scale. Land Care deals mainly with localised issues on a property or small catchment scale...Both are flexible and can be moulded to suit the needs of the community* (*The Source*, April 1991, 8).

Several conferences such as the Downstream Effects of Agricultural Pollution (DEAP) have been held. The role of local government in ICM was highlighted in a 1994 study (QDPI *et al.*, 1994). A newsletter titled *The Source* provides information to all ICM members, coordinators, and interested participants. Between April 1992 and February 1996, 10 issues have been published.

The state government has also introduced a number of initiatives which influence the formulation and implementation of ICM strategies. These include the 1994 natural resource management discussion paper, environmental protection legislation, and reform and proposed reforms to the *Local Government (Environment and Protection) Act.*

As mentioned earlier, new legislation was initially considered as necessary to support ICM. In 1994, it became clear that this alternative would not be pursued. In a 1994 discussion paper titled *Sustainable Use and Management of Queenslands Natural Resources* the State Government identified its preference to amalgamate existing legislation within existing administrative arrangements, rather than create new agencies (QDPI, 1994). The overall objectives of the new framework are to "produce an integrated natural resource management (NRM) policy with non-regulatory strategies and a minimum of legislation," and to integrate the existing natural resource legislation administered by QDPI "to see an effective planning and management framework in place that provides for ecologically sustainable development for natural resources" (Queensland Department of Primary Industries, 1994).

Like implementation of ICM, the Queensland Government prefers voluntary compliance with its NRM requirements. However, if resource degradation was significant and effective community-based measures (*eg.*, ICM) were not forthcoming, QDPI could establish additional regulations and/or special statutory bodies under the NRM initiative. These would be in addition to and would probably supersede policies developed through the local planning and ICM process. If this situation is to be avoided, it is a community's interest to actively and effectively participate in the development and implementation of local plans, ICM strategies, and Codes of Practice. Non-involvement will detract from one's standing within the community, and contribute to the possible imposition of QDPI regulations and special statutory bodies. Local control would be reduced.

The need to reform existing legal arrangements within QDPI was also recognised in the discussion paper. Legislative options to overcome the "overly prescriptive", "highly variable" and "fragmented" nature of QDPI-administered Acts included: a single piece of legislation to replace the nine existing Acts and which incorporates Integrated Catchment Management (ICM); retention of the existing nine Acts with amendments, together with the preparation of an additional piece of legislation for ICM; preparation of umbrella legislation that sits across the existing Acts and that for ICM and; amalgamation of the existing Acts introduces three broad category Acts of Land, Forests and Water.

PART 3 STATE-WIDE FINDINGS

3.1 The Survey Respondents

Fourteen Coordinators (100%) and 11 (78%) Chairs responded to the questionnaire. All the responses were satisfactory, and most respondents provided significant additional written comments. In one case, Lake Baroon is a Catchment Coordinating Group and does not have a QDPI-supported coordinator. That respondent was treated as a chair for the purposes of data analysis.

All the ICM committees are quite young and most of the respondents were the initial appointees in their CCC although there has been some movement of coordinators.

Many of the coordinators were recent arrivals into the catchments as young professionals moving in to take up the newly created jobs although there are a couple of notable exceptions. Many of the Chairs are lifetime residents and most have lived in their catchments more than 15 years (60%). There are some relatively new arrivals amongst the Chairs (34%).

Table 1: The Survey Respondents

Catchment	*Respondents*	
Border Rivers Basin		Coordinator
Cardwell	Chair	Coordinator
Condamine		Coordinator
Dawson	Chair	Coordinator
Herbert River	Chair	Coordinator
Johnstone	Chair	Coordinator
Lake Baroon	Chair	not applicable
Lockyer		Coordinator
Maranoa-Balonne	Chair	Coordinator
Mary River	Chair	Coordinator
Mitchell River	Chair	Coordinator
Murray Darling	Chair	Coordinator
Pioneer		Coordinator
Russell-Mulgrave	Chair	Coordinator
Warrego-Paroo	Chair	Coordinator

3.2 The Activities and Progress of Catchment Groups

The major activities of the Queensland CCCs are summarised in Table 2 and in more detail in Table 3. There was a surprising difference in perception between coordinators and chairs as to whether the various activities above had been undertaken.

Table 2: Activities Undertaken by ICM groups in Queensland

Activity	*Yes*	*No*
Prepared a situation statement	5	9
Catchment strategy	11	3
Advice to Landholders	6	9
Conducted projects	9	5

Table 3: List of Activities Carried Out by ICM Groups in Queensland

General ICM Establishment Tasks	
Arranged meetings and presentations to Ministers.	Established a Catchment Centre and appointed a manager.
Landholders inventory.	Process of CCC formation is one of my major tasks at present
Community Education and Awareness	
Officer in place at the Catchment Centre.	Land management demonstration site Chillagoe.
Raise catchment and NRM awareness.	Roadside erosion control workshop.
Increase in awareness of committee members of the whole catchment	Arranged catchment seminar.
Carried out extensive consultation with the broad community.	Catchment seminar.
Fish breeding with school children, catchment care caravan.	Road signs, newspaper articles, newsletter, TV., radio
Cross section of communities viewpoints of necessary works.	Increased many people's level of awareness of "catchment"
Initiated a catchment-wide water watch program.	Involvement of local government
Land degradation workshop	Prepared education paper on catchment.
Produced 2 brochures	Public awareness of ICM
Planning	
A draft has been prepared for seven major issues	Catchment Strategy in draft form
Coordination of efforts across the basin.	Developing a Catchment Strategy
Draft only for catchment strategy/plan.	Developed a catchment strategy and implementation
Going back to the community with draft strategies and plans	Initiated appraisal planning study.
Land Use report (draft) - part of Water Quality project.	Ranked issues.
Series of position statements on key issues of community concern.	The catchment plan is almost ready for circulation
the Creek project is in draught	Working Groups (7) Issue based
Technical Work and Information Collection	
Commencing Flow Management Plan for basins.	Draft Strategy for Riverine Management issues
Fire Management Strategy.	Initiated water management planning project for basin
Principals and Guidelines for landuse	Existing Water Quality data collate/assess.
Water Quality Monitoring Program	Fertiliser Audit (draft) - part of Water Quality project,
Initiated study on soil type 1.	Nutrient Management Strategy due to commence (CMSS)
Pesticide Audit (draft) - part of Water Quality project,	Prepared paper on "Water Pricing Policy and Ownership",
Specific projects	
Assisted community groups and agencies to implement projects pertaining to catchment priorities.	Instigation of the DLP.
"river" Revival. Project	Voluntary Riverbank Restoration Grant Scheme.
	Prepared reports on status of stream banks, mangroves of area.

The wide range of activities reflects the age and maturity of the CCCs. Some have been in operation since 1988? whereas some are still in the process of being formed. The range of activities are all envisaged in the ICM Policy which now requires the preparation of catchment strategies before funding is provided for projects.

A progression of activities can be recognised from organisational activities - public awareness and involvement - issues generation - catchment planning - technical studies.

Table 4: Chairs and Coordinators' Level of Satisfaction with Progress in their ICM Program

Information supplied by	*Number of responses*	*Rating*					
		0	1*	2	3	4	5
Chair	11				4	6	1
Coordinator	13	1*		3	4	4	1

0 = no response, 1 = very unsatisfied, 2 = unsatisfied, 3 = neither satisfied nor unsatisfied, 4 = satisfied, 5 = very satisfied.

* One coordinator did not respond. No Coordinators or Chairs were very unsatisfied.

Less than half the coordinators were satisfied with progress in their CCC and three were unsatisfied, one to the point of resigning over it. The Chairs were generally more satisfied with progress, and while none was actually dissatisfied, almost half were ambivalent. The reasons for this disturbing low level of satisfaction are revealed in later discussion.

Table 5 shows the reasons given by Coordinators and Chairs for difficulty in implementing ICM in their catchment. The fundamental problem is that there are no apparent economic benefits for ICM in the short term. The time frame is long before benefits are seen. This in a context in which government agencies and landowners need to make changes to their practices to achieve coordination and to elevate resources management issues.

Table 5: The Reasons Implementing ICM is Difficult

Issues	*Coordinators ratings*					*Chairs ratings*				
	1	*2*	*3*	*4*	*5*	*1*	*2*	*3*	*4*	*5*
Resource management problems are not well understood		5	5	3			2		6	3
Technical solutions are not feasible	2	6	2	3		1	5	2	2	1
The impacts of mismanagement are long term and incremental	1	2		6	4		1	1	8	1
There is no single acute resource management issue within the catchment	2	4	2	1	4	2	2	1	5	1
The long time frame between implementing a solution and seeing the benefits		1	1	8	3		1		7	3
The high level of behavioural change required	1	1	2	7	2		3		6	2
The high cost of known solutions		2	1	6	4	1	2		5	3
The high level of change required from existing government agencies			4	5	4		1	1	5	4
The absence of clear and immediate economic benefits	1	1	1	7	3		1	1	5	4

1 = strongly disagree, 2 = disagree, 3 = neither, 4 = agree, 5 = strongly agree, 6 = NA/don't know

It is important to note that the reasons do not seem to be the lack of technical knowledge of solutions to address the problems. In all cases respondents believed that the problems were increasing in significance.

Coordinators made the following comments about current difficulties:

The decision of the Murray Darling Basin Ministerial Council to place an interim cap on all water diversions within the Murray Darling Basin required the CCC to be involved in negotiating Queensland's position re the "cap". The CCC initiated workshops to inform the catchment community about the Water Audit in the Basin and the Ministerial decision. The Goondiwindi Workshop provided a community response to Murray Darling Basin Mining. Council outlining this catchment's position and proposed action ie. development of a Flow Management Plan for the BR catchment (Qld and NSW). (2) Tree clearing guidelines. The CCC requested to be contact point in catchment. This was not to be the case. Community consultation on this issue has been nothing short of pathetic. Any decisions/actions etc. taken by CCC and other groups/departments etc. were overriding in this process.

The Council have introduced their Development Control Plan - many people are trying to come to terms with what it means for them - they tend to focus on Resource Management issues. Also the Sugar Industry Package is operating the area and it too focuses on Research Management issues - especially drainage

- Flooding incidences have decreased hence that issue is not as high on the agenda as it would normally be. Mahogany Glider habitat concerns have come to the forefront as they directly impact on cane expansion etc.

- Impacts of PEDA legislation. Impacts of EPA - Environment Protection Act. Impacts of infrastructure imposed by government with a disregard for Catchment Management Principals. Low ground water levels due to overuse and drought. Increasing urban sprawl and encroachment on agricultural land, sewage and waste disposal.

- The continuing drought has heightened awareness and involvement

Extractive industry review showed potential consumption sky marketing. CCC setup working group to formulate a policy approach. Followed this with setting up Reference Panel with DPI to review community responses on industry review. Council's management of rural subdivision spotlighted - CCC to lobby improved land capability studies, and amended DPI priorities for mapping. Riverbank erosion increased in importance as discussions and debate flourished on how to manage. CCC inserted Voluntary Riverbank Restoration Grant Scheme as a response.

· Change has occurred due to increased length of drought. CCC has responded by commissioning Water Management Project, but ultimately there are problems with over-allocation of water which the people who over allocated in the first place now need to redress. This, of course, requires admission that mistakes were made, and they are reluctant to do that. Also, that horrible word "compensation" keeps cropping up, acting as further impediment. Hence my non-answer to 11D.

· The placement of Government. Resource Management infrastructure has eg. ? have caused the committee to address a range of issues associated with the EIS process as well as evaluating the ICM works project

· Our CCC is fairly new. The beginning saw members who were in the main merely seat warmers, protecting sectional interests. I have drawn the members away from narrowly based interests to seeing themselves as the Catchment Management Authority. We believe that we have been managing this catchment from the beginning of recorded history and see no reason to change now! We know best! We will not accept government direction on how we run it, We will run it! We request government support for our (the community's) running of our own affairs. We don't want direction!

Changes are mainly introduced by external forces eg. Government - eg. tree clearing dispute, Murray Darling Basin Commission enforcing a moratorium on water licenses on our rivers. The CCC ensured general awareness of the problems and put forward position statements.

Chairs made these comments

The prolonged drought has focussed the catchment on water issues and alternative and effective water management strategies are being implemented. The threat to native state forests is now drawing attention to management of tree species. The structural unemployment is being exacerbated by the drought and means are being sought by us to address these three problems and wholistically.

· CCC still being formed

Change has occurred because of drought for past five years - has placed pressure on the resources particularly
water. Lately government actions concerns to tree clearing.

Councils like Mareeba Shire are having visionary exercises and starting to take a more holistic approach. (4d) Local consultation groups are being set up in the lower catchment by DPI production to help graziers tackle (?) some of their most immediate problems.

· NRM legislation - CCC involved in all resource management issues

· Some of the triggers for action are natural - especially drought. There is also a strong reaction from some respondents about the external direction and difficulties arising from the ICM initiative itself and from other proposed legislation such as PEDA, NRM.

3.3 The Issues

The issues seen as significant by the respondents naturally varied between regions. In all regions natural resource issues were approximately on par with social and economic issues. Most significantly both Chairs and coordinators believed that too much government regulation was the single most significant issue, exceeding all other issues. The most significant natural resource issue was water quantity, substantially higher than land degradation and water quality problems, although these too also were significant in most catchments.

Those issues rated highly and very highly by coordinators included economic sustainability, native and feral animal management and pests in national parks, creek bank erosion and siltation, groundwater salinity, land tenure and uncoordinated farm drainage and cross border coordination. Chairs rated only a few issues highly and very highly including rural residential development and storm water and native tree species management.

Table 6: The Significance of Social, Economic and Natural Resource Issues in Queensland Catchments

Issues	*Coordinators ratings*						*Chairs ratings*						
	1	2	3	4	5	6	0	1	2	3	4	5	6
Social Issues													
School	1	3	1	4	2	2			1	4	4	2	
Crime	2	6	4	1					5	5	1	1	
Unemployment		3	5	4	1				2	3	5	1	
Health care			7	3	1	2		1		4	5	1	
Economic Issues													
Land valuations		1	4	4	3	1			2	4	3	2	
High government spending		3	4	1	3	2		1	3	3	2	2	
High taxes		2	1	3	5	2	1		1	2	4	3	
Institutional Issues													
Too much Gov regulation		1	3	1	8				1	2	4	4	
Natural Resource Management Issues													
Agric land degradation problems			6	4	3				1	3	4	3	
Water quality problems		2	4	5	2				2	2	5	2	
Water quantity problems		2	2	1	8				1	3	3	4	
Nature conservation	1	2	4	3	3				1	6	3	1	

(0 = no response, 1 = very low, 2 = low, 3 = moderate, 4 = high, 5 = very high, 6 = NA/don't know.)

This question asked how the natural resource management issues were affecting the people in the catchment. These included loss of farm productivity and higher production costs. Chairs were particularly sensitive towards psychological impacts, emotional stress on individuals and a loss of confidence in government.

Some specific comments included: We fear abandonment of land to native claim and consequent bad management" and personal/family dislocation due to imposed infrastructure/compulsory acquisition" and concern about incapacity of government to make and carry out decisions"

Table 7: ICM Coordinators and Chairs Opinions on How Serious the Natural Resource Management Issues are in Queensland Catchments

Issue	*Coordinators ratings*							*Chairs ratings*

3.4 Attitudes and Support

Support from the Public

Table 9: Chairs and Coordinators' Opinion on the Level of Public Awareness about Natural Resource Issues and Impacts

Level	*Coordinators*	*Chairs*
Very high	0	0
High	4	1
Moderate	4	5
Low	5	5
Very low	0	1

Table 10: Chairs and Coordinators' Opinion on the Strength of Public Support to Solve Natural Resource Issues

Level	*Coordinators*	*Chairs*
Very high	2	0
High	2	1
Moderate	6	8
Low	3	2
Very low	0	0

A slight majority of all respondents believed that the public was moderately to highly aware of the resources management issues, including only 50% of Chairs who less sanguine overall than coordinators, a significant proportion of whom believe that the public had low to very low awareness. There is also significant diversity of views about the degree of public support (See table 11). Chairs are significantly less confident than coordinators in the degree of public support.

Table 11: Chairs and Coordinators' Views on the Degree of Public Support (pairs by catchment)

	Chairs					
	Level	Very low	Low	Moderate	High	Very high
Coordinators	Very high					
	High					
	Moderate					
	Low					
	Very low					

Coordinators generally believe that the most potent factors affecting the acceptance of ICM by the general public are the efforts of the CCC Chairs, members and the Coordinators themselves. Demonstration of positive outcomes and the support of industry and community groups were also seen to be important. Chairs share these views on the importance of the CCC itself but have a higher regard for the importance of state government activities. Support from local governments and from state politicians seemed to be unimportant for most coordinators and Chairs.

Table 12: The Significance of Various Items in Gaining Acceptance of ICM from the Public

	Coordinators ratings							*Chairs ratings*						
	0	1	2	3	4	5	6	0	1	2	3	4	5	6
The State's ICM policy statement		3	6	3	1				1	6	4			
Local government political support		1	6	2	3	1				5	1	2	3	
Local government agencies support		1	6	4	1	1				4	3	4		
State government political support		1	6	3	3					5	1	3	2	
State government agencies support			4	6	2	1					4	5	2	
Good financial resources of CCC		2	3	7	1				2		4	2	3	
Efforts of the CCC Chair				2	6	4	1				6	1	3	1
Efforts of the CCC Coordinator	1			3	4	3	2	1			2	5	3	
Positive outcomes....			4	2	4	3				2	3	3	3	
Support from industry and community			1	5	3	4				1	6	2	2	

(0 = no response, 1 = very low, 2 = low, 3 = moderate, 4 = high, 5 = very high, 6 = NA/don't know)

Comments made about the value of different activities include that the efforts of CCC members, (Rating 5), support from Landcare and production of plain English reports and statements, and that Quarries, industry, irrigators, were very low in supporting ICM work. One Chair argued that some Landcare groups lacked understanding of ICM.

Support from Government Agencies

Table 13: Coordinator and Chairs Opinion on How Effectively the Efforts of their CCC has been Accepted by other Government Agencies in the Catchment?

	Coordinators	*Chairs*
Very ineffectively	1	0
Ineffectively	2	0
Neutral	6	2
Effectively,	4	2
Very effectively,	1	4
NA/don't know)	0	1

Only 35% of Coordinators are satisfied with the acceptance of their CCCs by other government agencies. Chairs are more positive on this point.

Table 14: The Significance of Various Items been in Gaining Acceptance from other Government Agencies

Item	*Coordinators ratings*							*Chairs ratings*				
	1	2	3	4	5	6	1	2	3	4	5	6

Mining, Industry, Irrigators	1											

(0 = no response, 1 = very low, 2 = low, 3 = moderate, 4 = high, 5 = very high, 6 = NA/don't know)

Support from Local Industry and Community Organisations

Table 15: Coordinators and Chairs Opinion on How Effectively the Efforts of their CCC have been accepted by Local Industry and Community Organisations

	Coordinators	*Chairs*
Very ineffectively	1	0
Ineffectively	1	0
Neutral	5	3
Effectively,	5	5
Very effectively	1	1
NA/don't know)		1

Although 40% of respondents from the two groups are neutral as to the effectiveness of local industry and community organisations' support of the CCC, respondents are in general more satisfied with the acceptance of these groups and the difference between Coordinators' and Chairs' opinions are minor. Only one respondent believed it to be ineffective.

Table 16: The Significance of Various Items been in Gaining Acceptance from Industry and Community Organisations

Item	*Coordinators ratings*							*Chairs ratings*						
	0	1	2	3	4	5	6	0	1	2	3	4	5	6

Mining, industry, irrigators		1												

(0 = no response, 1 = very low, 2 = low, 3 = moderate, 4 = high, 5 = very high, 6 = NA/don't know)

A wide range of factors generate support from industry and community organisations, especially the efforts of the CCC Chairs. Again both groups of respondents were commonly unhappy with political support and of the acceptance of local government at both the agency and political levels. As in many other results of the survey there are regular exceptions to common patterns. Other organisations considered to be valuable for CCC groups included ACF, QCC, Regional Environmental Council, Ecological Society, Marine Cons. Soc. of Aust. (although there was ambivalence on this some being obstructionist). Other community groups rating as important include Landcare groups, Recreational fishing, Commercial Fisherman's Assoc Aboriginal. Council , Sugar Industry (Mills), Tourism. One group mentioned that graziers were not helpful.

Table 17: The Effectiveness of Involvement of Various Rural industry Groups

Rural Industry Group	*Rating of Involvement*
Canegrowers	5, 5,4,5,5,5,4
Cattlemen's Union, UGA	4
Cotton growers	3, 4,
CU	4,4,3,1,4
CWA	3
Farmers and irrigators	6
Landcare	5
Landholders	4
QCFO	5
QDO	5, 4, 4
QFVG	4
QGGA	3, 4, 4,3
QPUG,	5, 4
Timber Industry.	4
UGA	3, 4, 4, 3,4, 4, 4, 3,3,4,1,4

(0 = no response, 1 = very ineffective, 2 = ineffective, 3 = neither, 4 = effective, 5 = very effective, 6 = NA/don't know)

Support from the Media

All groups use local newspapers as the most frequent form of media outlet. Worthy papers such as the Border News, Argus, Border Post, Macintyre News, Cairns Post, Innisfail Advocate, Tablelander, Central Telegraph, Chinchilla News, Star, Chronicle, Gympie Times, Sunshine Coast Daily, Maryborough Chronicle, Cairns Post, Pyramid News, Tully Times, were mentioned. ABC rural programs were mentioned by many respondents and a slightly lesser number mentioned local commercial radio. A few CCCs were able to use TV, one even place subsidised advertisements on regional TV.

Only one respondent believed the media to be ineffective in supporting the CCC. Eighty percent of Coordinators believed the media to be effective. One said the media were The Key!" and two others found the MDBC videos very valuable.

Table 18: The Effectiveness of Media

Rating	*Coordinators*	*Chairs*
No response	0	1
Very ineffectively	0	0
Ineffectively	0	1
Neither	3	4
Effectively,	8	5
Very effectively	2	0
Don't know	0	0

An overall summary of the importance of support from different groups is provided in Table . Clearly and not surprisingly, the dominant effective partnership is between the CCCs, the DPI and the rural producer groups. There was less agreement between the Coordinators and Chairs on the effectiveness of the involvement of local government and even some ambivalence on the involvement of others such as the DE. Coordinators did not in general seem impressed with the involvement of Lands and Local Government.

Table 19: The Effectiveness of Involvement in the CCC by Various Groups

Group	*Coordinators ratings*							*Chairs ratings*						
	0	1	2	3	4	5	6	0	1	2	3	4	5	6
Rural producers				3	7	3		1			1	8	1

Drainage Board(s)		1		2	3		7		1		2	1	1	6
Media	5		1	4	2	1		2	1	2	2	3	1	

(0 = no response, 1 = very ineffective, 2 = ineffective, 3 = neither, 4 = effective, 5 = very effective, 6 = NA/don't know)

The views of the respondents about what could or should be done at state/local levels to improve the acceptance and involvement of relevant groups in your CCC process are summarised below:

Coordinators' comments

Advertise on a statewide basis on the Catchment concept and what local CCC groups are trying to achieve.

Locally we also need to advertise more our existence and the local issues we are trying to tackle.

Funding for implementing catchment strategies is vital. the community are more impressed with on-ground works than publication of reports, meetings etc.

A full scale ICM promotion program by State Government agencies.

Ministerial rockets required to ensure stronger commitment to ICM process from some State and Federal agencies, notably DEH and Wet Tropics Management Authority!

Better funding for Management Committee's expenses. If each Exec. member had access to a fax machine, for example, it makes it easier to share information/communicate.

A major state-wide promotion of ICM

Put a halt to new legislation. No more DRAFT POLICY OPTION PAPERS! Consultation Techniques of State Agencies to undergo major overhaul. Give the CCC more funding (subject to a catchment strategy).

Have Gov. commit itself to respond positively to CCC recommendations. Have Gov. Departments pay more than just lip service to ICM principles, and recognise CCCs.

We the CCC need to get runs on the board. To do that we need a more positive mind set amongst committee members, which needs to be encouraged at state/local levels.

The Government should change their attitude. It is believed that ICM is simply a taken gesture and not a serious consideration. The Gov. regularly undermines the community consultation process.

Chairs' comments

Some representation at state level. We have no say and no chance to answer unfair criticism.

More available funds, so that the community as a whole can see some useful work being completed instead of hearing of numerous studies being done with no effective follow-up work being obvious.

An ongoing programme of media releases and a public information programme highlighting the achievements and pointing out the benefits to individual stakeholder groups being involved, eg. be involved in forming the strategies and decisions before some bastard does it for you.

Support the process by allocation of funding (increasing it!) ICM won't solve all catchment management problems but it will help with many issues (eg. diffuse/ non-point pollutant loadings) not easily address

Involve ICM at the beginning of consultation and not at end as is the case at present and expect a rubber stamp.

Provide money for work on the ground.

Produce Catchment documentaries for TV presentation within catchments. We have to use the media of today and that is TV. I cannot stress this enough!

Little. Perhaps making public more aware of role and activities of CCC.

Apathy in this region is high. ICM is at a vulnerable stage within the community.

3.5 Institutional Arrangements and Finance

Table 20 provides results that probe more deeply into the difficulties within CCCs. Coordinators believe that some of the most important difficulties are due to the wide variety of beliefs amongst CCC members, a view not so strongly held by Chairs; a perception that the program has been forced on the catchment by the State in communities without finical resources to respond and a lack of trust in the public in government sponsored initiatives. The Coordinator do not agree in general that the CCCs do not have important groups represented. The Chairs hold similar views differing significantly as a group only in relation to the significance of the wide variety of beliefs and values of CCC members and to a lesser extent on the difficulties posed by the large size of catchments. There are some potentially fatal problems identified here, although many can be overcome as the ICM process matures and achieves ownership and clearer common perceptions.

Other reasons implementation is difficult and their ratings from **Coordinators** were:
- Very busy people on the Committee - there because they represent other groups
- Prodigious rainfall, short run-off, World Heritage, stupidity
- No single issue (problem) with NRM exists
- Perceived or real lack of Government. support

Table 20: The Reasons Implementation of ICM in CCCs is Difficult

Reason	*Coordinators ratings*						*Chairs ratings*					
	1	2	3	4	5	6	1	2	3	4	5	6
Large size of catchment or poor transportation links	1	5	2	4	1		1	3	1	1	4	1
Wide variety of values and beliefs among CCC members		2	1	8	2		1	4	2	2	2	
Media don't report resource issues accurately	1	6	6				1	5	4		1	
Important groups are not represented on the ICM committee	1	5	3	4			2	4	4	1		
Perception that ICM has been forced on the catchment by the state	1	4	3	3	2		2	5	1		3	
Lack of an effective level of interest by CCC members		3	5	5			1	4	2	2	1	
Public's lack of trust in state or local government sponsored initiatives		2	2	3	5	1		2	1	5	3	
Public's lack of interest in community type activities		3	1	8	1			3	1	6	1	
The lack of financial resources within the community	1		1	6	5			2	1	1	7	

(1 = strongly disagree, 2-disagree, 3 = neither, 4 = agree, 5 = strongly agree, 6 = NA/don't know)

Chairs comments

Lack of full coordination between government agencies

Lack of understanding of ICM in community

Table 21 reveals more detail on the operation of the CCCs themselves. Perhaps the most interesting feature of these results is the wide spread of opinions as to the purpose and operation of CCC among the various individuals and catchments in the State. Coordinators for example are not in clear agreement as to what they and their CCCs should do - some believe that Coordinators and CCCs should coordinate activities and give advice to landowners, other do not Chairs seem more consistent as a group in their beliefs about the role and purpose of CCCs and are in broad agreement with Coordinators on many issues. Significant differences in opinion exist as to whether the objectives of the local ICM programs are clear to all members and to the level of participation of their CCC members in meetings. They too do not always agree as to whether the CCC should give advice to landholders.

More NLP money is finding its way to on the ground activities. We have been very lucky with NLP funding in that we have received all the money we have applied for.

We have gained over $200,000 in funding from members and the Commonwealth Government.

Very little financial support from local or state government.

Successful applications for NLP and ICM works funding

The level of funding in my situation (Pumicestone Passage) is "unsecured". Initial NLP funding is only for 18 months until increased June 1996. it is difficult to interact with public when funding is precarious.

NLP funding made available for Catchment Centre Coordinator

MHW] (2) $140,000 Drought Landcare Program for Voluntary River Restoration Grant Scheme.

Increase in local government. input. Drought Landcare programme.

Drought Landcare Project started

DOL and DEH have increased support.
Lack of funds for new projects

Landcare is more active and the Wet Tropics Tree Planting Scheme has materially assisted our efforts.

Table 21: Coordinators and Chairs Opinions on the Role and Conduct of CCCs

Statements	*Coordinators*							*Chairs*						
	0	1	2	3	4	5	6	0	1	2	3	4	5	6
Purpose of ICM														
The objectives of the local ICM are very clear to all members	1		6	2	3	1				2	1	6	1	1
There is a strong consensus among CCC members concerning what the CCC should do	1		3	4	5					4	2	3	1	1
The CCC should coordinate state and local government resource management programs	2	1	3	1	3	3				3		4	3	1
The CCC should prioritise resource management problems in the catchment	1				6	6				1		5	4	1
The CCC should provide a forum for conflict resolution among resource users	1		1		6	5					3	4	3	1
The local ICM process has or will resolve resource conflicts in an open manner	1		1	1	6	4				1	2	2	3	3
The CCC should educate the public about the catchment's resource management problems and solutions	1				6	6					2	3	5	1
The CCC should provide a forum for information sharing within and between public and private resource managers	1				7	5					1	4	5	1
The CCC should prepare a strategic resource management plan	1			1	6	5					1	4	6	1
The CCC should facilitate the implementation of resource management initiatives noted in the strategic plan	1				6	6						5	5	1
The CCC should identify a common set of policies which will be implemented by relevant resource managers	1				6	6						5	5	1
The CCC should make private resource managers/owners more responsible for the impacts arising from their activities	1		3	4	1	3	1			1	3	4	2	1
The CCC should stimulate community or regional development	1		2	3	3	4				2	1	5	2	1
The CCC and its coordinator should provide advice to landholders	2	1	4		4	2		2	1	1	1	5		1
The local ICM process has or will resolve resource conflicts efficiently	1			7	4		1			1	2	5	1	2
Membership and Role														
The membership of the CCC effectively represents the interests of the catchment community	1			2	7	3						6	4	1
At CCC meetings, all CCC members participate actively	1	3	3	1	5							8	2	1
A CCC member's role is to provide their personal views on resource management issues at CCC meetings	1	3	3	1	5			2	2	2	1	2	1	1
A CCC member's role is to provide the views of their constituency group on resource management at CCC meetings	1	1		1	5	5		2		1		3	4	1
A CCC member's role is to provide a catchment wide perspective of natural resource management issues at CCC meetings	1		2	2	5	3		2			1	3	4	1
Performance														
The ICM process is very responsive to local needs	1		2	3	7					1	2	7		1
The CCC is solving the priority natural resource management problems in the catchment	1		4	3	4	1		1		2	3	3	1	

(1 = strongly disagree, 2-disagree, 3 = neither, 4 = agree, 5 = strongly agree, 6 = NA/don't know)

Changes that have occurred

Corporate support has decreased.

We never got any real support and only receive it when we go looking and asking for it!

We have no financial support from QDPI (except for NLP funding)

External project funds increased. Internal budget allocation decreased. Change in focus from planning to implementation and changed status of CCC. Funding for ongoing operations will

continue to decline (from DPI internal funds) while project funding from external sources expected to increase (hopefully) in the future.

Introduction of ICM grants

Table 22: Over the last 12 months, the level of financial and in kind support from QDPI has:

Catchment	*Rating*	*Changes that have occurred*
Border Rivers	Remained the same	
Cardwell	Remained the same	
Cardwell	Remained the same	
Condamine	Decreased	Corporate support has decreased
Dawson	Decreased	We never got any real support and only receive it when we go looking and asking for it!
Dawson	Decreased	We have no financial support from QDPI (except for NLP funding)
Herbert	Remained the same	
Herbert	Remained the same	
Johnstone	Increased	External project funds increased. Internal budget allocation decreased. Change in focus from planning to implementation and changed status of CCC. Funding for ongoing operations will continue to decline (from DPI internal funds) while project funding from external sources expected to increase (hopefully) in the future.
Johnstone	Increased	Introduction of ICM grants
Lake Baroon	Remained the same	
Lockyer	Remained the same	Not known, however, I am assuming it has basically remained the same.
Maranoa-Balonne	Remained the same	
Maranoa-Balonne	Remained the same	
Mary River	Decreased	Coordinators budget cut $50,000
Mitchell River	Increased	Resources through DPI for Salinity Project and through DME for Contain. minesite assessment. However, DME new say NAP funds are no longer available so what have they done with them! and are they fair dinkum about ICM.
Murray-Darling	Increased	Increased DPI commitment to Murray Darling NRMS programme
Murray-Darling	Increased	
Pioneer	Increased	ICM works funding $115,000
Russell-Mulgrave	Increased	We are starting to get serious and getting serious means spending more money - seed money! Now we need results money.
Russell-Mulgrave	Increased	Funding for coordinator to be employed three days a week instead of two.
Warrego-Paroo	Remained the same	
Warrego-Paroo	Increased	Funding for committee has increased.

Table 23: Changes in the level of financial and in kind in the past 12 months

3.6 Other Comments

Coordinator's comments

The Government, particularly DPI, provides considerable supportive rhetoric to ICM and CCCs, well in access of financial and acknowledgment support. The continued pressure on CCCs to progress ICM and develop management strategies to deal with the complex issues confronting them will take its toll on the volunteers. We need a champion in a position to fully support the community, with resources to back it and a willingness to adopt the ICM initiative throughout its structure, ie. the Government. Some of the committee members in the Qld section of the MURRAY DARLING BASIN feel they are being used (abused) to "rubber stamp" decisions of Government. to make those decisions more palatable to the tax payer. I personally feel that Government. (DPI) is trying to "push" the Committees "out there" to assist the Committees in creating their own identity. This is not what ICM is about. CCCs are a partnership. Government. should be open about its support and be seen to be functioning integrated with community. This is what ICM is about - providing avenues of communication between all stakeholders particularly Government/Community that existing communication networks do not allow. CCCs have not evolved sufficiently to operate 100% effectively or to understand where they sit in the big picture. Government. also needs to develop/evolve. Neither has a clear understanding of what each has to offer or is prepared to offer.

Substantially more funds are required to implement strategies. Implementation is what CCC members and coordinators work towards, however, there are no/limited funds available for on-ground works.

The concept of ICM is very good. As Scoot Sturgeons recently stated, the State Government is asking volunteers to do a huge job that requires super human feats. It appears to me that the government is asking private individuals to do all the work, then take all the credit and yet provide no financial support. ICM is a huge task. The money poured into the Johnstone River, a very small catchment, confirms these thoughts. How other catchments are meant to achieve these results with no support makes you really wonder!!

Could write a book about it. Just let me know what you want to know!

So far (as I have only been President for 3 months) I am concerned that the efforts of Sector Groups, particularly Landcare and Progress Associations, Industry Groups have major fears regarding the State and Federal Government's keened to overrule ICM principles with their own infrastructure agendas. This makes the whole process a bit of a joke. Examples are Eastlink Highway Bypasses, Railway access roads, other powerlines and roads. The Government is wasting its money putting it into ICM if it can be overruled/overshadowed by Government infrastructure. Infrastructure corridors should be put in place which respect the principles of ICM. I am sorry to have not provided this response sooner. If I have missed your deadline it is because I required some time to "settle into" my role as President in order to gauge my responses to the response form. Thank you for your attention to these matters.

I have left the job because of total lack of confidence in the process. ICM is being used as a smoke screen to pump up the agencies' need to be seen to be consulting the community. It is more like insulting the CCCs intelligence.

ICM in the Mary is plagued with apparent discontent in many parts of the community with existing LGA and State Agency response to issues. The CCC is seen as another potential source of help - this allows the CCC to be in touch with many issues but bogs it down and detracts from taking a strategic and catchment view of issues at times. There are many false expectations of the CCC, eg. it can make decisions and tell agencies what to do. When these expectations are not realised many people switch off and follow alternative methods to get what they want - this has implications for community support for the CCC (the no teeth! problem). Similarly, the empowering, facilitating, detailing, networking, influencing role is often seen as too slow to achieve the desired result in the time frames desired by some (yet some of the most enduring change in the last 3 years has come from this - its very subtle adherence [?] is often missed as an achievement.

I believe that the process as it currently stands will not survive. I think that the process would be more effectively served if Catchment Coordinators were appointed as Local Authority Natural. Res. liaison officers. That way they could act as conduits for info. flow between community groups and Local government. At the moment, we have CCCs deliberating on issues that many are unqualified or not interested in. The amount of skill and commitment available in catchments with large areas and small populations is also a worry. Last, but most importantly, many people in CCCs don't really believe that, when push comes to shove, Government. will really take notice of the CCCs, so they query their value. The action with the tree clearing guidelines confirmed their worst suspicions.

The lack of real State Government. commitment to the implementation of ICM strategies and funding and support of committees is holding back the implementation of ICM.

ICM in Western Queensland is still very new as compared to other catchments.

Chair's comments

The state government departments do not consult with us! Our correspondence and contacts go largely unanswered and our suggestions go unheeded. Our resources are used by QDPI without acknowledgment or payment despite repeated requests. I think we are one of the best structured and best managed ICM groups in Queensland (ask Neil McDonald at NLP) but the state government. don't want to know us!

The role of Catchment Coordinators is vital to developing an effective strategy and bringing the diverse stakeholder groups together. He/she should be a mature person with a wide knowledge and experience of the working of government and who has very good personal communication skills. If the best and most effective representatives are to be attracted to serve on CCCs, then need to be supported, resource wise, by a facility such as a Catchment Centre (for a group of catchments if necessary) to provide briefing, interpretations and back up support. An effective and ongoing media and public information programme is essential (using community media outlets with locally generated release) to effectively inform the Catchment Community on natural resource management

There appears to be a distinct lack of government policy about the direction ICM is to take in the community at this stage, with Departmental personnel at odds as to what they are prepared to accept from the committees and their role in the management of natural resources. Committees are feeling as though they are being used like pawns in a chess game. The amount of time and travel involved in the larger catchments is a burden on members as the amount of expenses reimbursed is not great from the limited funds available.

ICM should provide a framework for managing change throughout the State (NRM change). Current landholders cannot be expected to rectify the mistakes of generations without massive assistance from the general community. It is unrealistic to expect ICM, a voluntary group, to carrying the burden of enacting positive cultural change. Natural resource use changes must be sustainable. To be so they must also be profitable to landholders. More use must be made of practical landholders experience and observations instead of waiting for the results of expensive research. There needs to be an environmental cost charged into product prices so landholders can effect positive environmental procedures. Social and economic needs have to be kept to the fore in all NRM considerations.

ICM is a very worthy cause. However, I believe QDPI shoots itself in the foot with:

(1) Getting a coordinator to do more than one catchment

(2) Not funding coordinators on anything other than one year contracts making it difficult for them to get housing loans etc. --> low morale

(3) Getting coordinators to fill in holiday and leave for other departments in DPI and then not covering their job if they take leave

(4) Having non-sustainable policies such as irrigation water charges eg. Quota system - people should pay for what they use and if they use above sustainable level, penalty rates should apply.

(5) Having a wishy-washy relationship with local governments which tend to circumvent most legislation that deals with appropriate Natural Resource Management, ie. you cannot expect industries, groups and individuals to change their paradigms, when local councils ride roughshod over legislation to encourage development; eg. Eacham Shire Council forcing sewage on ratepayers after vote against because of financial hardship. Community consultation pah! and Mareeba Shires DCP fitting snugly around Mr Quaid's plans. Credibility for natural resource management is required and councils need to be made to come into line. Even with simple things like enforcing the requirement on landholders to remove noxious weeds. I suggest that, 2 or 3 Rural Councils are audited annually and if necessary held to account every year, until they get the picture.

3.7 Summary and Implications

The survey provided an insight into current attitudes of the two key groups the Coordinators and Chairs. These attitudes will surely change as a result of:

- changes in government policy and finance
- changes in the natural environment itself such as droughts
- most importantly in the CCCs themselves as they mature

The survey revealed some common attitudes but often a diversity between Coordinators and Chairs in a given catchment and between respondents from different catchments. Key factors affecting this diversity include:

- the age of the CCC which conditions its maturity and opportunity to undertake planning, awareness raising and projects
- the environmental circumstance of the catchment - while many are costal rivers, there are also a number of inland rivers which have quite different resources and resource management issues
- the capabilities and effectiveness of the Coordinators and Chairs and the dynamics of the CCC

Some of the significant results include:

- disturbing low level of satisfaction amongst the respondents (especially their Coordinators)
- low and expected awareness in the general public about resources management issues

- widely held view that local governments, both politically and at officer level have not been involved effectively in the ICM process
- lack of support at the state political level
- ineffective involvement of some state agencies

On a positive note there was wide agreement about the positive role of the media and of the essential role that the CCCs, its Chairs and Coordinators play in gaining support from the stakeholders. Respondents also believed that the DPI (now DNR) and rural producer groups were effectively involved in the process.

In terms of the general approach and institutional arrangements for ICM:

- diversity of views of members sometimes a significant problem with respect to the role of the CCC, its coordinator and whether it should for example be involved in giving advice to landholders, coordinate state government activities and have a regional development function.
- A significant obstacle for ICM is the resistance of many of the community and those in CCCs to state imposed programs which require community action without resources - a perception of force.

PART 4 THE HRCCC AND SURVEY RESULTS

4.1 Natural Resource Management Problem Definition

Evolution of HRCCC

Formed in March 1993, the HRCCC is the most recent attempt to address the resource management challenges of the Herbert River catchment. Previous studies include the:

1976 North Queensland Sugar Industry Drainage Study
1977 North Queensland Sugar Industry Flood Mitigation Study
1980 Herbert River Flood Management Study
1984 Herbert River Drainage Study
1993 Stream Management Plan Herbert River and District, and ongoing Sugar Infrastructure Improvement Package.

Continuing concerns for flooding and drainage prompted the need for the formation of the HRCCC. The 1991 flood caused a very significant reduction in sugar cane yield. Mining dams, some of which were abandoned in the late 1890s, pose a hazard to all downstream residents These and other resource issues provide for user conflicts, and impede economic and social development. Since the 1994 hiring of a full-time catchment coordinator, three types of activities characterise the HRCCC program.

The first concerns the formulation of the strategic plan. Given the numerous studies already conducted on the catchment and the 1993 completion of the Stream Management Plan, there was a belief that the HRCCC should implement its recommendations rather than develop a new strategy. While this is a legitimate view, the HRCCC should differ from previous studies in the following ways. First, it examines the entire catchment rather than the lower portion. Second, it addresses a broad range of resource issues, rather than specific concerns. Finally, it promotes ongoing dialogue among a range of interests from all parts of the catchment, rather than terminating at the completion of its strategic plan. These characteristics are very consistent with the general ICM principles noted in Section 2.

In developing the strategy, the HRCCC formed a number of subcommittees which drafted discussion papers on land, water, stream and habitat management. Items were clarified and incorporated into a single document (the Herbert River Catchment Management Strategy (Draft)) which will be circulated among relevant agencies, non-governmental organisations, and private interests for comment. Based on this input, the draft will be revised and finalised. The strategy should represent a significant departure from the sectoral approaches of the past to an integrated package required to deal effectively with the realities of the present.

Obtaining funding and implementing projects is the second type of activity. In August 1993 the HRCCC requested information from the Department of Minerals and Energy about the rehabilitation requirements which would be placed on new mine owners on mining bases in the Herberton Shire. This was followed by an inventory of dams in the Nanyetta Creek catchment. Other projects completed by October 1994 include: the rehabilitation of a 1 ha property adjoining Palm Creek (in cooperation with CSR Ltd.), the control of slumping on the lower Herbert (in cooperation with Herbert River Improvement Trust and James Cook University), and the control of water hyacinth along Palm Creek. The three schools in the Palm Creek planted the trees which had been purchased by the HRCCC. Funding was sought and received from the National Landcare Program (NLP). Most of these projects involved the participation of other groups which is very consistent with the community-oriented intent of ICM. These types of activities demonstrate the means and benefits of community-based activities, and enhance the HRCCC's public profile.

The third type of activity relates to the HRCCC's role as a referral agency. Hinchinbrook Shire and State agencies such as the former Department of Lands, and Primary Industries circulated subdivision, drainage and other relevant applications to the HRCCC for comment. It has been involved in the drainage planning in the Cattle Creek catchment, and the Sugar Infrastructure Improvement Package. The HRCCC has also provided some farm and drainage management advice to individual landowners on an *ad hoc* basis.

The Pomona case study illustrates some of the difficulties associated with dealing with resource conflicts. In 1995, cane assignment was granted in an area known as Pomona land holding. During land clearing, the area was found to be an important habitat for an endangered species, the Mahogany Glider (QDE, 1995)A conservation order was placed on the site, and later a draft conservation plan was prepared. There was a significant level of uncertainty and conflict among industry, government and non-government participants concerning this development. At present, a drainage permit under the *Water Resources Act 1989* has been applied for by the proponents, and is under review by the Queensland Department of Natural Resources (DNR)

The HRCCC held a site tour and issued a press release which noted the need for sustainable development on floodplains. It maintained that a Code of Practice should be developed. Until that code is completed, landowners were asked to plan their developments more effectively, and seek government advice.

Several HRCCC members reflected on this experience. While there is a consensus that the Pomona subdivision raised public awareness about environmental issues, the role of the HRCCC suggests significant differences of opinion. Some members suggested that it created friction between landowners and government agencies." The following comments were also offered:

- Pomona subdivision - HRCCC responded with inspections and some publicity. No further action taken and in hindsight was a lost opportunity.
- The HRCCC sat on fence and failed to comment (deliberately) on gross environmental vandalism in clearing creek beds and banks on Pomona Station. Even the council is now complaining about failure to observe 10m buffer on creek but still ICM holds the "must be polite" line.
- The HRCCC has made very broad comments condemning expansion in Pomona, the group could have been more forceful in their statements but have taken a "political approach."

There is a diversity opinion among HRCCC members concerning this and many other resource issues. This should be expected given its membership. It also suggests that early deliberations and successes may focus on process issues, such as establishing a basis for discussion, rather than tangible agreements on directions and priorities.

The Pomona case illustrates some of the difficulties in moving toward integrated approaches. Some of the drainage problems associated with that area have technical solutions. However, it is relatively more difficult to appropriately balance these solutions with sugar cane development with ensuring that biodiversity considerations, downstream landowner interests and water quality aspects. ICM in Queensland is to provide a more balanced approach which in the Herbert River should be facilitated by the HRCCC's strategic plan.

4.2 Context of ICM in the Herbert River Catchment

Recent Evolution of ICM in the Catchment

The importance of obtaining community involvement in the local program was mentioned frequently as the HRCCC's as noted in the following comments:

Cross Section of communities viewpoints of necessary works. Trying to coordinate natural resources activity in the Herbert Catchment.

The level of awareness of ICM to Canegrowers has been slow. Formation of the group went well. The formation of a strategic plan has been slow. The ICM group did become involved with issues as they arose, but had no policy at that stage. This is being addressed now.

Too early to tell.
People from significant backgrounds starting to talk and share ideas. This has proven to be a slow process.

Works on the mining sites in the upper catchment.

The only achievement I see is the controlling of the mining operations in the Herberton area. This has caused major siltation in the Herbert River. This siltation has caused very dirty water for the residents of the Hinchinbrook Shire. I feel there are too many meetings, too much talking - more positive decision making required.

Formulation of a management strategy. Formulation of Upper Catchment subcommittee.

Coordination of the mapping of total catchment and drawing up of catchment management plan.

Bringing together different group problems and trying to solve them.

The comments above focus on the HRCCC as a process. Progress has been tentative and hesitant, and members indicate a moderate level of satisfaction with progress to date (Table 4.1). This is not surprising given the absence of many tangible achievements at the time the survey was undertaken. The preceding comments also suggest that the process has been more difficult and slower than members anticipated. There is no single correct approach to doing ICM. When the transition is made from HRCCC as a process to HRCCC as a product, higher levels of satisfaction could be anticipated. The need for ICM is reflected by the perception that resource management issues have increased in importance over the last 12 months (Table 4.2).

The HRCCC offers both a need and opportunity to demonstrate one possible integrated approach to water and related resource management. This survey represents a benchmark against which the development of the HRCCC program can be measured.

Table 4.1: How satisfied are you with progress in the CCC.

	1	2	3	4	5
HRCCC	1	1	3	5	1

0 = no response, 1 = very unsatisfied, 2 = unsatisfied, 3 = neither satisfied nor unsatisfied, 4 = satisfied, 5 = very satisfied

Table 4.2: In the last 12 months, the importance of resource management issues has:

Catchment	Increased	Stayed the Same	Decreased	No response
Herbert	8	2	1	

General Issues in the Herbert River Catchment

The most important local issues were perceived to be (Table 4.3) too much government regulation, land valuation, unemployment, water quantity issues, nature conservation, agricultural land degradation, crime

There is reasonable parity among all issues - no single issue is perceived to dominate the region. Instead, there are multiple, yet interdependent issues. For instance, too much government regulation and land valuation can be considered as 'institutional or governance issues' which are likely long-term and chronic problems

However, it is unclear whether government is part of the problem rather than a symptom of other problems. If the HRCCC's forthcoming strategy is to effectively address this institutional issue, it must conduct socioeconomic and policy related studies to complement the biophysical inventories and analyses which tend to dominate resource planning activities. By understanding present management practices, the HRCCC can consider how government regulation can be reduced while maintaining or enhancing outcomes.

Table 4.3: In your opinion, what is the significance of the following issues in your catchment?

HERBERT	0	1	2	3	4	5	6
Social issues							
Schools			3	2	4	2	
Crime			1	2	5	2	1
Unemployment				2	7	1	1

Water quality problems			3	3	1	4	
Water quantity problems			1	4	2	4	
Nature conservation			1	3	4	3	

0 = no response, 1 = very low, 2 = low, 3 = moderate, 4 = high, 5 = very high, 6 = NA/don't know

4.3 Resource Management Issues in the Herbert River Catchment

The most important resource management issues in the catchment were perceived to be (Table 4.4) - rural drainage, allocation of sugar caneland, stream bed and bank erosion, urban flooding, land clearing

Table 4.4: In your opinion, what is the significance of the following issues in your catchment:

Affects the catchment	0	1	2	3	4	5	6
Agricultural and degradation problems							
Crop land degradation		2	3	3	2	1	
Grazing land degradation		1	1	4	3		2
Soil salinity		3	2	1	2		3
Weeds				4	7		
Insects and disease on crops			3	2	4	2	
Urban expansion onto farm lands		4		2	3	1	1
Allocation of caneland			2		5	4	
Land clearing			1	3	3	3	1
Water quality problems							
Surface water salinity		2	3		3	1	2
Wastewater management		4	1	2	3	1	
Surface water nutrient enrichment		2	3	1	3		2
Pesticides in waterways		3		5	1		2
Groundwater quality		1	1	4	3	1	1
Acid soils		2	3	4	1		1
Stream bed and bank erosion			1	1	7	2	
Water quantity problems							
Surface water availability		2	1	3	2	2	1
Groundwater availability		2		2	5	1	1
Rural flooding and water....		1	1	2	6	1	
Rural drainage				1	7	3	
Urban flooding		1			8	2	
Nature conservation							
State forests and National Parks		2		6	1	1	1
Instream and outstream water use conflicts		2	1	4		2	2
Dryland veg. habitat loss		2	3	3	3		
Freshwater habitat. loss....		2	2	2	3	1	1
Coastal wetland habitat. loss		2	2	1	4	1	1
Barriers to fish migration		2		3	4		2
Other/s							
Lack of water storage infrastructure				1			

0 = no response, 1 = very low, 2 = low, 3 = moderate, 4 = high, 5 = very high, 6 = NA/don't know

Rural drainage was perceived to be the most significant natural resource issue, and supports the view that water quantity problems were the most important general resource issue confronting people in the catchment. It was closely followed by the remaining issues. Rural drainage, flooding and erosion represent longstanding issues in the lower Herbert River catchment. Caneland allocation and land clearing reflect more recent concerns. Other emerging issues which were mentioned frequently during interviews with local and state government officials include acid sulphate soils. This item received a very modest ranking from members. Upstream water issues such as water availability were viewed as low to moderate in significance.

The previously mentioned socioeconomic and policy studies should likely focus on rural drainage and caneland allocation. When completed, the HRCCC can determine the role it and other relevant interests should play in improving current practice.

Impacts of Resource Management Problems

The four most important impacts of these resource management problems on the people of the catchment were perceived to be (Table 4.5) loss of confidence in government to manage resources effectively, drinking water quality, higher production costs, higher taxes

These issues and impacts focus on government s role in resource management. The concern suggests that among other concerns, the HRCCC should consider how effectively its forthcoming strategy and activities will enhance present government performance

Table 4.5: What is the significance of the impact of these natural resource issues on people in the catchment, the following rankings were presented:

HERBERT							
Catchment	0	1	2	3	4	5	6
Aesthetic and Recreational Impacts							
Access to recreation		1	2	1	3	3	1
Environmental amenities		1	1	2	4	3	
Loss of scenic values		1	6	2	1	1	
Environmental and Life Support Impacts							
Drinking water quality				3	4	4	
Human health		1	2	3	2	2	1
Fishery decline		1	1	3	5	1	
Functional Resource Impacts							
High cost of water		1	1	4	2	2	1
Loss of farm productivity		1	1	3	4	2	
Higher production costs			1	2	5	3	
Shortage of irrigation water		2	3		5	1	
Higher taxes			1	3	5	2	
Social-Psychological Impacts							
Loss of independence to make (farm) decisions		1	3	3	3	1	
Emotional stress on individuals			1	4	2	3	1
Conflicts with other resource users			2	6	2	1	
Loss of confidence in government's ability to manage natural resources			2	1	3	5	

0 = no response, 1 = very low, 2 = low, 3 = moderate, 4 = high, 5 = very high, 6 = NA/don't know.

Support from Constituent Groups

Since ICM is to foster coordination between landholders, community action groups and government agencies in their land and water resource management activities, a series a questions concerned the perceived level of support and how this support was earned (Tables 4.6-4.18).

HRCCC members perceived a strong level of support from the Queensland Department of Primary Industries, the Sugar Infrastructure Improvement Package (SIIP) program, and rural producers. Relatively less support was provided by Local Government, State Government Politicians, and the Department of Lands (now part of new Department of Natural Resources)The public was perceived to have: (i) a low to moderate level of awareness about natural resource issues and associated impacts, (ii) low to moderate level of support to solve natural resource issues; and (iii) supported the local CCC program at a very low to moderate level.

These trends have implications for the extent and nature of partnerships which the HRCCC has developed. Implementation of ICM is to foster whole-of-government approach to water and land management. Given that many important agencies are participating ineffectively in the HRCCC process, this goal may be difficult to achieve. The perceived level of public support suggests that promoting community understanding of integrated resource management could also impair effective implementation of ICM. However, the HRCCC is aware of these potential shortcomings and can be addressed during the catchment strategy information process.

4.4 Institutional Structure for ICM

Effective implementation of ICM in the Herbert River Catchment is perceived to be hindered primarily by (Tables 4.19-23), poor understanding of problems (Table 4.19), lack of clear and immediate economic benefits (Table 4.19), high cost of solutions (Table 4.19), long time frame to see benefits (Table 4.19), lack of trust in government-sponsored programs (Table 4.20), public s lack of interest in community-based activities (Table 4.20), lack of financial resources within the community (Table 4.20), large size of the Herbert River Catchment (Table 4.20), ICM lacks clear goals and objectives. (Table 4.21), lack of consensus by HRCCC on objectives (Table 4.21).

While members believed that technical solutions could solve many resource problems in the catchment, many factors detract from their feasibility (Table 4.19)In the absence of adequate funding arrangements among senior and local governments, private interests, NGOs and property owners, the adequacy of any technical solution must be questioned. The poor understanding of resource problems seems to contradict the confidence placed in technical solutions, and reflects the reality of uncertainty often associated with all approaches to resource management

If technical solutions are beyond the financial capacity of the catchment community, behavioural solutions might be sought. However, members questioned the public's willingness to adopt community-based initiatives (like ICM) and it lacked confidence in government-sponsored initiatives. The HRCCC should consider how effectively its public information program and forthcoming strategy address these catchment-based shortcomings. Behavioural change by all resource managers is likely required to effectively solve the catchment's priority problems. Part of this change can be fostered through a visible commitment by state and local leaders to ICM.

Factors Assisting the Effective Implementation of ICM

Effective implementation of ICM in the Herbert River catchment is perceived to be aided primarily by (Tables 4.19-4.23) the role of the Chairman, Coordinator, and members (Tables 4.9 and 4.14), the representativeness of the membership of the wider catchment community (Table 4.22), and the view that technical solutions can solve resource management problems in the catchment (Table 4.19).

Clearly, members generally value the contribution which they make, and in particular the efforts made by the Chair and Coordinator. This belief is very appropriate given the voluntary nature of ICM. However, given the significance of these people, it is unclear how the state has supported the professional development of any of these individuals. While the State Government has allowed catchment committees to utilise their own means to produce the catchment strategy, it has not demonstrated clear leadership in facilitating an effective exchange of information among groups and provided for skill development. These items deserve effective action in the immediate future.

While HRCCC members believe they effectively represent the catchment community, one member was concerned that it was speaking "too much behind closed doors and not informing the public." This raises issues concerning how HRCCC members provide feedback to their constituent groups. However, the relationship between representative and constituent group is tenuous because, according to one member, "too many of the members of the CCC, have affiliations to too many other organisations. Some have 6 to 8 organisation involvements."

4.5 Summary and Implications

Integrated Catchment Management is a resource policy initiative for redressing the fragmented responses of the past and solve some of the complex problems of the present. While it is still too early to determine the efficacy of the approach, there appears to be considerable merit. The HRCCC has sustained its multi-stakeholder membership for over two years and the forthcoming release of the catchment strategy provide many challenges.

The importance of local leadership, particularly from the Chair, coordinator and members are perceived as extremely important in establishing credibility among other private and public resource managers. However, there are few opportunities for these individuals to obtain the skills, and systematically exchange experiences with other CCCs.

Some obstacles to effective implementation are perceived to be outside the influence of the catchment. These include the lack of clear and immediate benefits, and the high cost of solutions. Issues which the HRCCC can influence concern the perceptions that: (i) there is a lack of trust in government initiatives; (ii) there is a lack of interest in community activities; and (iii) there is a lack of clear goals regarding ICM objectives. Changing general public and specific resource manager attitudes and behaviours is a considerable challenge, but one which must be met if effective implementation is to be realised. The consultations which will occur after the release of the HRCCC strategy will be critical in determining the ultimate success and failure of the program

If and when that strategy is adopted, it will be years before the benefits of any HRCCC initiatives are realised. Consequently, the ultimate performance should be monitored over a long time frame. That performance will ultimately be measured through the reduction in resource conflicts and the improved well being of residents within the catchment.

Table 4.6: What is the level of public awareness about these natural resource issues and associated impacts?

Catchment	No response	Very low	Low	Low to Mod.	Moderate	Mod. to High	High	Very High
Herbert River			5	1	4			1

Table 4.16: Over the last 12 months, the level of financial and in kind support from QDPI has:

Catchment	No response	Decreased	Decreased - Remained the Same	Remained the Same	Increased
Herbert	2			2	3
					4

Changes that have occurred:

Herbert

- Don't know if there has been any changes
- More DPI personnel available for advice; some increased special purpose funding; support for a student to work in the catchment.

Table 4.17: Over the last 12 months, the level of financial and in kind support from other state and local agencies, and other external funding organisations (eg. National Landcare Program) has:

Catchment	No response	Decreased	Remained the Same	Increased
Herbert	2		6	3

Changes that have occurred:

Herbert

- As above - I am not aware of the detailed breakdown of contributions.
- Approval of funding for a Landcare project.

Table 4.18: How effectively do you believe the news media presents your CCC's position on an issue?

Catchment	Very ineffectively	Ineffectively	Neither	Effectively	Very Effectively
Herbert	2	2	2	4	1

What could or should be done at state/local levels to improve the acceptance and involvement of relevant groups in the Herbert River CCC process?

Herbert River
More public news items. School promotions. Industry promotions at grower level.

More available funds, so that the community as a whole can see some useful work being completed instead of hearing of numerous studies being done with no effective follow-up work being obvious.

Continue to support with financial and technical back up

I think the CCC has to prove its credibility.

Greater public consultation and "listening" to public opinion

Increase public awareness of issues eg. organised articles in paper exploring issues to raise awareness. Can be difficult to manage when local "experts" get wound up.

Recognise the role of the CCC through legislation (The Chair believes the CCC is simply an advisory group).

The first thing that should be done is change the structure of the present CCC committee. There are members in it who do not have the confidence of the community at large. Their trust is gone and new faces and new ideas must be implemented. Many of the members have their fixed views which are not acceptable to the community. The next question has some clues.

Greater involvement of local council - information swapping and cooperation prior to action by council. Use of CCC as database and advisory agency - high level of local knowledge on varied topics in group.

Much more media publicity on CCC objectives and achievements. More funding for specific projects.

Increase the public's awareness of CCC.

Table 4.19: Tractability of the Issues: The implementation of ICM in your catchment is difficult because:

HERBERT	0	1	2	3	4	5	6
11a Resource management problems are not well understood			1		8	2	
11b Technical solutions are not feasible			7		1	1	2
11c The impacts of mismanagement are long term and incremental			1	1	7	2	
11d There is no single acute resource management issue within the catchment			5		5	1	
11e The high level of behavioural change required			1		6	4	
11f The long time frame between implementing a solution and seeing the benefits			2		5	4	
11g The high cost of known solutions			2		7	2	
11h The high level of change required from existing government agencies			1	1	6	3	
11i The absence of clear and immediate economic benefits					8	3	

Table 4.20: Institutional Arrangements and Finance. The implementation of ICM in your catchment is difficult because:

HERBERT	Strongly disagree (1)	Disagree (2)	Neither (3)	Agree (4)	Strongly Agree (5)	NA/don't know (6)
22a Large size of catchment (or poor transportation links between parts of catchment)			1	10		
22b Wide variety of values and beliefs among CCC members		3		5	3	
22c Media don't report resource issues accurately		4	1	4	2	
22d Some important constituency groups are not represented on the ICM committee		9	1		1	
22e Perception that ICM has been forced on the catchment by the state government	1	5	2	1	1	1
22f Lack of an effective level of interest by CCC members	1	4	3	2	1	
22g Public's lack of trust in state/local government-sponsored initiatives		2	1	5	3	
22h Public's lack of interest in community type activities		2	1	5	3	
22i The lack of financial resources within the community		2	1	5	3	

Other/s:

- Lacks specificity and "teeth" to solve public issues - Rating 4 (Agree)
- Ecology vs. development and expansion; downstream effects ignored by upstream development - Rating 5 (Strongly agree)

Table 4.21: HRCCC Process: Rate your level of agreement with the following statements concerning the operations of the CCC

HERBERT	1	2	3	4	5	6
23a The objectives of the local ICM are very clear to all members	1	5		4	1	
23b There is a strong consensus among CCC members concerning what the CCC should do	1	6		3	1	
23c The CCC should coordinate state and local government resource management programs			2	8	1	
23d The CCC should prioritise resource management problems in the catchment		1		7	3	
23e The CCC should provide a forum for conflict resolution among resource users		1	2	6	2	
23f The local ICM process has or will resolve resource conflicts in an open manner	1	1	4	4	1	
23g The CCC should educate the public about the catchment's resource management problems and solutions			1	6	4	
23h The CCC should provide a forum for information sharing within and between public and private resource managers			1	3	7	
23I The CCC should prepare a strategic resource management plan				5	6	
23j The CCC should facilitate the implementation of resource management initiatives noted in the strategic plan				7	4	
23k The CCC should identify a common set of policies which will be implemented by relevant resource managers within the catchment				7	4	
23l The CCC should make private resource managers/owners more responsible for the impacts arising from their activities		2	1	5	3	
23m The CCC should stimulate community or regional development		3	2	4	2	
23n The CCC should be providing individuals with technical advice on solutions to natural resource issues	1	1	1	4	4	
23o The activities of our CCC have been effectively coordinated with the activities of other state and local government agencies		3	1	6	1	
23p The membership of the CCC effectively represents the interests of the catchment community		1	1	8	1	
23q At CCC meetings, all CCC members participate actively		2	2	7		
23r The local ICM process has or will resolve resource conflicts effectively		3	5	3		
23s The local ICM process has or will resolve resource conflicts efficiently	1	2	5	3		
23t The ICM process is very responsive to local needs		1	2	8		
23u The CCC is solving the priority natural resource management problems in the catchment	1	1	2	6		1

1 = strongly disagree, 2 = disagree, 3 = neither, 4 = agree, 5 = strongly agree, 6 = NA/don't know

Personal Motivations

Table 4.22: Average hours per month devoted to ICM:

Catchment	Position	Hours/mth
Herbert	Chair	15
Herbert	Member	15
Herbert	Member	10
Herbert	Member	6
Herbert	Member	6
Herbert	Member	6
Herbert	Member	6
Herbert	Member	5
Herbert	Member	4
Herbert	Member	4
Herbert	Member	3

Table 4.23: Identify your level of agreement with the following statements:

HERBERT	Strongly disagree (1)	Disagree (2)	Neither (3)	Agree (4)	Strongly Agree (5)
28a The amount of time I devote to ICM significantly interferes with my own business/job requirements	1	4	2	4	
28b The amount of time I devote to ICM significantly interferes with my family commitments	1	6	1	3	
28c My involvement with the CCC causes significant out-of-pocket expenses	1	4	5	1	
28d I find being a member of the CCC personally rewarding because I can contribute to the community			3	7	1
28e I find being a member of the CCC personally rewarding because I care about natural resource management				8	3
28f I find being a member of the CCC personally rewarding because I can meet other members of the community who can influence resource management decision making				9	2
28g I find being a member of the CCC frustrating	1	3	2	3	2
28h I see my role in the CCC as a short-term commitment	1	6	1	3	
28i A CCC's member's role is to provide their personal views on resource management issues at CCC meetings		3	2	6	
28j A CCC member's role is to represent the resource management views of their constituency group at CCC meetings					8
28k A CCC member's role is to provide a catchment-wide perspective of natural resource management issues at CCC meetings.				3	6

Question 29 Further comments

A possible problem associated with ICM in the Herbert River District is that it is virtually a single industry catchment - this gives the sugar and allied industries a fair bit of punch. My personal opinion (possibly cynical) is that certain issues - expansion, drainage, wet land reclamation, river improvement???, use of pesticides and herbicides - may not be consistent with the ideal of ecologically sustainable development. To varying degrees, these practices can be detrimental to natural flora and fauna, also downstream users of the catchment and adjacent lands and waters.

If ICM is to succeed, I repeat that a new concept of information and advice must be found. The present views of "so called elected people" eg. Hinchinbrook Council, Canegrowers representatives, CSR and a few other organisations, must be got rid of. Unbiased people who will adopt common sense and reasoning and have a knowledge of all existing problems must be considered quickly. The above-named organisations do not know the trust of the community

and I fear that if the present scenario continues, ICM will fail. People want action not to be asked to go to meetings continually. There have been millions of dollars already wasted. Let's be constructive and not destructive

Comments on pages 2 and 3: We are being strangled by Bureaucrats who don't know the "grass roots" of problems. Over budgeting and serious lack of communication with the public.

The issues of Riparian Vegetation on existing cane land is a major issue with the potential of causing anxiety if not managed carefully. The issue of river management that is sand bars, instream vegetation and levies that can be rationalised has to be resolved. The level of meeting attendance is a problem and does effect continuity of the decision making process. The lack of a street frontage office I think effects our ICM public accessibility. There would be extra costs with it but it should be looked at.

Changes that have occurred:
Pomona subdivision - CCC responded with inspections and some publicity. No further action taken and in hindsight a lost opportunity. Erosion control works in Herbert River at Long Pocket region and was successful in funding. Cattle Creek drainage - to be dealt with in 1996. Trebonne Creek drainage - to be dealt with in 1996.

Mahogany glider conservation plan - response in progress

Main issue is Mahogany Glider habitat conservation is all out clearing for cane expansion. CCC sat on fence and failed to comment (deliberately) on gross environmental vandalism in clearing creek beds and banks on Pomona Station. Even the council is now complaining about failure to observe 10m buffer on creek but still ICM holds the "must be polite" line.

The CCC has made very broad comments condemning expansion in Pomona, the group could have been more forceful in their statements but have taken a "political approach."

It is my opinion that the CCC is speaking too much behind closed doors and not informing the public for support etc. Too many of the members of the CCC, have affiliations to too many other organisations. Some have 6 to 8 organisation involvements. The CCC chairman is a Shire Councillor and deputy chairman of the Hinchinbrook Shire, Chairman of Works, member of the Herbert River Improvement Trust, a member of the Rural Drainage Proposed Board and he is involved in several other committees. He and several others in the CCC should not be on the CCC Board. These people should be replaced because they cannot make a decision that is good for all the organisations they represent. Fingers in too many pies. I enclose a copy of the Herbert River Express dated December 5th which outlines my views on why I oppose the decision making capacity of the Trust member, Cr. Barnes. I and the organisation I represent have been asking for this work to be done for more than 15 years. When it could be done cheaply, now we see a very high cost involved. Too much talking and very little factual work has been performed.

Extensive land clearing due to caneland expansion. Mahogany Gliders Issue has possibly made some people more environmentally aware. Also created friction between landowners and government agencies.

An increasing awareness of the need for water storage for agriculture in the upper catchment. ICM will be coordinating and monitoring any moves in this direction.

Buffer zones on land clearing.

A loss of confidence on government's ability to manage resources was the most significant impact. A decline in drinking water quality, higher production costs, higher taxes, and emotional stress on individuals were also highly ranked.

PART 5 SUMMARY AND CONCLUSIONS

These conclusions are couched in terms of the evaluation model presented in S1.2.

5.1 Problem Definition

It is crucial to the evaluation of the ICM process to identify what is *the problem* and how it affects the policy implementation process. For this purpose, it is convenient to disaggregate resource management into technical and socio-economic dimensions (without losing sight of their close interdependencies). From a *technical* point of view resource management is finding effective mechanisms to address specific well defined biophysical problems such as soil erosion, flooding, nutrient enrichment, unreliable water supplies, loss of biodiversity. The solutions are defined in terms of land management practices, engineering structures, input usage and similar hard technological matters. From a *socio-economic* point of view, resources management is a matter of designing and implementing socially acceptable and effective solutions and preventative actions to these same problems through awareness raising and education, economic, administrative and legal measures

The survey revealed that there are clear enough technical solutions to many of the natural resources management problems in Queensland. These have been canvassed and promoted in some cases for decades and longer - eg floodplain management, soil erosion control, groundwater depletion and acidification. In the Herbert for example there have been three flood studies and three drainage studies over the past twenty years. The proposed technical solutions have been similar in each case, but the resources management problem still exists because of lack of implementation.

Other emergent problems, such as biodiversity conservation and nutrient enrichment of waterways are not so well defined in technical terms, and ICM groups where these are key issues have greater difficulty focusing their priorities and activities. They need research support to gain a greater understanding of the processes involved and to demonstrate the necessity and effectiveness of technological solutions.

In a very large State like Queensland, there is a wide diversity of issues. While it may be possible to "regionalise" resources management to gain some efficiencies, this diversity limits the degree of diffusion of technical solutions that can occur from catchment to catchment. This makes ICM much more difficult to implement than other more pervasive public policies such as health care, education and engineering construction standards for example.

All the respondents acknowledged the difficulty of promoting a program with relatively few immediate benefits but often with immediate cost imposition on land holders. This problem is intrinsic to ICM, and can only be alleviated by a change in ethics in the community as a whole. It would be assisted by technical and economic data that demonstrated the severity of the problems and reality of the long term benefits. Those catchments with more apparent and visible resource issues (such as water shortages or acute soil erosion) will have a better chance of focussing community attention.

The integrated approach emphasises that there is not a single issue but a multitude of interdependent issues that must be addressed. It is difficult for society to solve single environmental issues - extremely difficult to establish means to address interdependent issues.

The Queensland ICM program is part of the struggle to move from sectoral approaches to resources management to an integrated whole of landscape approach. The survey revealed that the biggest obstacle to ICM is the *process* within the community and within government to redress and prevent resource management problems - social processes to apply technological solutions. There is no well tested solution to this problem as a guide to action. Not surprisingly, this change of philosophy is accompanied by uncertainty and resistance especially when the way forward is not signposted.

The traditions of the past within government and the relationships between different groups in the community must change. Attitudes of land owners and managers, conservationists and government officials in sectoral agencies with a long record of sectoral thinking must also change. This is the major problem facing integrated resources management and ICM in particular.

The move towards an integrated approach to natural resources management has come at a time when community expectations about environment and resources issues have increased. In some cases these changes have been rapid and the shift in resource management and economic goals magnifies the extent of attitude and behaviour change required. For example, twenty years ago, farmers were encouraged to develop natural resources such as irrigation, tree clearing for grazing, clearing and drainage for agriculture. Recently, they have been asked to revise their practices substantially.

These changing requirements for resource management have to a considerable extent been isolated from the economic development decision making process although their are promising signs that the merger of resource and environmental issues with economic development issues is beginning to occur in rural areas of the State. For example decisions on water resources development, agricultural expansion, water control, use rights and land tenure, resources extraction are becoming the concern of ICM groups. In order to do this successfully, further and more pervasive behaviour change will be required by the major players in natural resources management. At present the ICM program is largely limited in scope to a relationship between farmers and the Department of Natural resources (formerly Primary Industries). Sustainable development requires a whole of government and a whole of community approach to decision about resources and economic issues.

5.2 Context for ICM

The Queensland ICM program has been active only since 1990. Consequently a major constraint to this evaluation is the relatively short period of time that CCCs have been in existence and the opportunities they have to bring about change. A progression of activities was recognised from organisational activities - public awareness and involvement - issues generation - catchment planning - technical studies - implementation. Judging from the diversity of responses, it requires approximately five years before a CCC will reach maturity along this spectrum. A considerable amount of time is taken establishing the CCC, creating some coherence amongst its members, learning the challenges and opportunities and having the platform for planning and implementation.

Perhaps for the reason that ICM requires a complex process of social learning there was a disturbing low level of satisfaction amongst the respondents at the state level (especially the Coordinators).

CCCs have to contend with low awareness in the general public about resources management issues and a general resistance to external intervention. A surprising, consistent and very significant result from the survey was respondents universal view that there is too much government regulation. People in rural Australia resent government controls on land use

whether they arise from World Heritage listing and conservation generally, tree clearing regulations, water and land management regulations, changes to land tenure and land rights laws. There is a clear message here that landholders in particular will resist any solution to ICM problems that involve state and Australian government regulations.

Respondents accepts the significance of NRM issues which were rated equally with major economic issues such as unemployment or social issues such as crime or health care in terms of importance.

DNR is the lead agency for ICM which was perceived to be a successful partnership between DNR and the rural land owner interests and not much more than that. There was a widely held view that local governments, both politically and at officer level have not been involved effectively in the ICM process.

Despite the need for ICM to integrate across government agencies there is a clear absence of a "whole of government" approach , commitment or involvement in ICM. State politicians seemed to ignore ICM and there was ineffective, even counter productive involvement of some state agencies. While there was no reported hostility from politicians, agency staff and community groups, it seems that CCCs must create these supporting links themselves with little support from outside. A program with such ambitious goals for integration must cope with the lack of interest and commitment from some essential stakeholders.

On a positive note there was wide agreement about the supportive role of the media and of the essential role that the CCCs, its Chairs and Coordinators play in gaining support from the stakeholders. Clearly, the ability of these people is critical to the success of individual ICM programs. The study could not assess these abilities and what skills are essential, personal or technical.

5.3 Institutional Structure

Queenslands ICM program has very broad, and from a community point of view somewhat nebulous goals. This might create scope for specification at the local level but it also provides relatively little guidance to newly formed CCCs. There is general agreement on the ultimate purpose of ICM, but also a wide spread of opinions as to the purpose and operation of CCC among the various individuals and catchments in the State. Perhaps this is not a deficiency of the program given that it is intended to be community based. It is also based on social-learning and the extent to which the goals were prescriptive from the top down, the program would limit local ownership.

Financial resources for a program with such ambitious goals has been erratic and low (about the same as the operating costs for the parliamentary refectory). A key source of funds has been the NLP, without which ICM would struggle to survive. CCCs are required to find funding on their own initiative rather than use established revenue sources as do most public programs. They have no revenue raising capacities. There is a lack of confidence in government funding for implementation which is of particular concern given that once CCCs have been established and created strategies, their requirement for funds for on-ground works will increase their financial requirements. Planning is inexpensive relative to action.

As discussed above, CCCs have not had effective involvement from local governments nor from key agencies with statutory resources management responsibilities. As coordinating focus for mainstream decisions affecting resources, ICM have not yet been successful. Examples of important resources management decisions which could have focussed on, or at least specifically include ICM include:

- approval of mining projects

- tree clearing guidelines
- Water Policy under the state Environmental Protection Act
- regional planning under the Local Government Planning and Environment Act
- wildlife conservation programs

None of the relevant statutes or policies incorporates ICM at this time.

CCCs are served by a cadre of competent and enthusiastic coordinators. There is no career path from them and apart from the State Coordinators Conference, no tailored professional development activities. Their network is however strong.

APPENDIX 1

QUEENSLAND ICM COORDINATOR'S SURVEY

Background

1. Which catchment do you represent?

2. How long have you lived in this catchment? _____ years

3. What year did you assume your present responsibilities?

4. When you assumed your present position, what did you expect the CCC to accomplish by this time?

5. Since assuming your current responsibilities, how well has the CCC met your expectations: (please tick):

_____ very well
_____ well
_____ moderately well
_____ not well
_____ not very well

Context of ICM with other issues

6. In your opinion, what is the significance of the following issues in your catchment? Rate using the following scale:

1 = very high
2 = high
3 = moderate
4 = low
5 = very low
6 = not applicable

_____ Provision of schools
_____ High crime rate
_____ High unemployment
_____ Public health care
_____ Ineffective land valuation for municipal tax purposes
_____ High level of spending by government
_____ High taxes
_____ Government inefficiency
_____ Too much government regulation
_____ Agricultural land problems (*e.g.* soil salinity, urban development)
_____ Water quality problems (*e.g.* nutrient enrichment, dirty drinking water)
_____ Water quantity problems (*e.g.* flooding, poor drainage)
_____ Degradation of natural environment (*e.g.* habitat loss)

7. In your opinion, what is the significance of the following natural resource management problems in your catchment? Rate using the following scale:

1 = very high
2 = high
3 = moderate
4 = low
5 = very low
6 = not applicable

_____ Erosion of crop land
_____ Productivity decline of crop land
_____ Erosion of grazing land
_____ Productivity decline of grazing land
_____ Soil salinity

_____ Weed problems
_____ Insects and disease on crops
_____ Urban expansion into agricultural lands
_____ Land clearing
_____ Surface water salinity
_____ Surface water nutrient enrichment (algae)
_____ Pesticides in waterways
_____ Degradation of freshwater/aquatic natural life
_____ Groundwater quality
_____ Acid soils
_____ Surface water availability
_____ Wastewater management
_____ Allocation of cane land
_____ Management of public land
_____ Groundwater availability
_____ Rural flooding
_____ Rural drainage
_____ Urban flooding
_____ Urban drainage
_____ Instream and offstream water use conflicts
_____ Stream bed and bank erosion
_____ Dryland vegetation habitat loss
_____ Freshwater habitat loss
_____ Coastal wetland habitat loss
_____ Barriers to fish migration
_____ Others (list)

8. In your opinion, what is the significance of the impacts associated with these natural resource problems on the people in the catchment? Rate using the following scale:

1 = very high
2 = high
3 = moderate
4 = low
5 = very low
6 = not applicable

_____ loss of scenic land values
_____ loss of other environmental amenities (e.g. wildlife habitat)
_____ higher cost of water supplies
_____ loss of on-farm productivity
_____ degraded drinking water quality
_____ personal health problems
_____ emotional stress for individuals
_____ significant conflicts with other resource users
_____ higher taxes
_____ decline in recreational and/or commercial fishery
_____ loss of access to other recreational activities
_____ loss of confidence in government's ability to manage resources effectively
_____ Other (specify)

9. Who do you believe is most responsible for solving these resource management problems? (Please tick)

_____ individuals (e.g. producers, landowners)
_____ local CCC
_____ Local Government
_____ Other local agencies/interests (e.g. Valley Trust, Drainage Board, CANEGROWERS, industry) (specify)
_____ State Government
_____ Commonwealth Government
_____ GBRMPA
_____ Others (specify)

10. In your opinion, what is the level of public awareness about these natural resource problems and associated impacts? Rate using the following scale:

1 = very high
2 = high
3 = moderate
4 = low
5 = very low
6 = not applicable

_____ Erosion of crop land
_____ Productivity decline of crop land
_____ Erosion of grazing land
_____ Productivity decline of grazing land
_____ Soil salinity
_____ Weed problems
_____ Insects and disease on crops
_____ Urban expansion into agricultural lands
_____ Land clearing
_____ Surface water salinity
_____ Surface water nutrient enrichment (algae)
_____ Pesticides in waterways
_____ Degradation of freshwater/aquatic natural life
_____ Groundwater quality
_____ Acid soils
_____ Surface water availability
_____ Wastewater management
_____ Allocation of cane land
_____ Management of public land
_____ Groundwater availability
_____ Rural flooding
_____ Rural drainage
_____ Urban flooding
_____ Urban drainage
_____ Instream and offstream water use conflicts
_____ Stream bed and bank erosion
_____ Dryland vegetation habitat loss
_____ Freshwater habitat loss
_____ Coastal wetland habitat loss
_____ Barriers to fish migration
_____ Others (list)

11. How strong is public support regarding the need for the ICM process to solve these natural resource problems in your catchment? (Please tick)

_____ very high
_____ high
_____ moderate
_____ low
_____ very low

12. Please rate your level of agreement with the following statements concerning how the nature of resource management problems in your catchment affects implementation of ICM according to the following scale:

1 = completely agree
2 = agree
3 = neither agree nor disagree
4 = disagree
5 = completely disagree

12a. _____ The lack of an appropriate technical solution to the natural resource management problems in this catchment seriously detracts from effective implementation.

12b. _____ Because resource management problems in the catchment are not well understood, effective implementation is very difficult.

12c. _____ The long-term and incremental nature of the impacts associated with resource management problems in the catchment seriously detracts from effective implementation.

12d. _____ The absence of a single acute resource management issue within the catchment significantly detracts from effective implementation.

12e. _____ The long time frame between implementing a solution and seeing the benefits seriously detracts from effective implementation.

12f. _____ The high level of behavioural change required by private landowners to effectively solve resource management problems seriously detracts from effective implementation.

12g. _____ The high level of behavioural change required by industry to effectively solve resource management problems seriously detracts from effective implementation.

12h. _____ The high level of administrative, legal and financial change required from existing government agencies to effectively solve resource management problems seriously detracts from effective implementation.

12i. _____ The absence of clear and immediate economic benefits seriously detracts from effective implementation

13. In the last 12 months, have resource management problems (circle one) increased/stayed the same/declined in importance within the catchment? If changes have occurred, please explain what has changed.

_____

Context for ICM

14. What level of public support do you believe your CCC has? (Please tick)

_____ very high level of support
_____ a high level of support
_____ moderate level of support
_____ low level of support
_____ very low level of support

15. How significant have the following items been in gaining acceptance from the public? Rate using the following scale:

1= very high
2= high
3= moderate
4= low
5= very low
6=not applicable

_____ ICM policy statement
_____ strong local government support (political level)
_____ strong state government support (political level)
_____ strong support from local government agencies (administrative level)
_____ strong support from state government agencies (administrative level)
_____ strong financial resources of CCC
_____ strong leadership of CCC Chair
_____ strong leadership of CCC coordinator
_____ positive outcomes associated with CCC activities
_____ strong support from relevant industry and community groups
_____ other (specify)

16. How effectively have the efforts of your CCC group been accepted by other government agencies within the catchment? (Please tick)

_____ very effectively
_____ effectively
_____ somewhat effectively
_____ ineffectively
_____ very ineffectively

17. How significant have the following items been in gaining acceptance from other government agencies? Rate using the following scale:

1 = very high
2 = high
3 = moderate
4 = low
5 = very low
6 = not applicable

_____ ICM policy statement
_____ strong local government support (political level)
_____ strong support from QDPI (political or administrative levels)
_____ strong public support
_____ strong financial resources of CCC
_____ strong leadership of CCC Chair
_____ strong leadership of CCC coordinator
_____ positive outcomes associated with CCC activities
_____ strong support from relevant industry and community groups
_____ other (specify)

18. How effectively have the efforts of your CCC been accepted by relevant local industry and community organisations? (please tick)

_____ very effectively
_____ effectively
_____ somewhat effectively
_____ ineffectively
_____ very ineffectively

19. How significant have the following items been in gaining acceptance from relevant industry and community organisations? Rate using the following scale:

1 = very high
2 = high
3 = moderate
4 = low
5 = very low
6 = not applicable

_____ ICM policy statement
_____ strong local government support (political level)
_____ strong support from QDPI (political or administrative levels)
_____ strong public support
_____ strong financial resources of CCC
_____ strong leadership of CCC Chair
_____ strong leadership of CCC coordinator
_____ positive outcomes associated with CCC activities
_____ other (specify)

20. What have been the main activities of your CCC in the last 12 months? Please list and rate their significance according to the following scale:

1 = very high
2 = high
3 = moderate
4 = low
5 = very low

RATING ACTIVITIES

_____
_____
_____
_____
_____
_____
_____
_____

21. How effective has the involvement of the following groups been to the CCC?

1 = very effective
2 = effective
3 = moderately effective
4 = ineffective
5 = very ineffective
6 = not applicable

_____ rural producers (specify)
_____ local government politicians
_____ local government administrators
_____ state government politicians
_____ state government agencies:
  _____ DPI
  _____ DEH
  _____ Housing, Local Government and Housing
  _____ Department of Lands
_____ Valley Trust
_____ Drainage Board(s)
_____ Sugar Industry Infrastructure Package Program
_____ rural industry organisations (specify)
_____ environmental organisations (specify)
_____ local urban community (specify)
_____ media

22. What news media do you regularly use to present your CCC's views of resource management issues? (Please tick)
_____ newspaper (specify)
_____ radio (specify)
_____ TV (specify)

23. How effectively do these media report your position on an issue?
_____ very effectively
_____ effectively
_____ somewhat effectively
_____ effectively
_____ very effectively

24. Over the last 12 months, has the level of acceptance of your ICM program among the public, government agencies, and relevant industry and environmental groups (circle one) increased/ stayed the same/ decreased? If changes have occurred, explain why.

25. Please identify your level of agreement with the following statements concerning the context of your CCC's activities according to the following scale:

1 = strongly agree
2 = agree
3 = moderately agree
4 = disagree
5 = strongly disagree

25a. _____ The large size of the catchment (or poor transportation links between parts of catchment) seriously detracts from an effective level of cooperation being developed among CCC membership.

25b. _____ The wide variety of values and beliefs among CCC members seriously detracts from an effective level of cooperation developing among them.

25c. _____ The media has played a very constructive role in developing a sense of cooperation among CCC members.

25d. _____ The media has played a very constructive role in developing a sense of cooperation between the CCC and the catchment community.

25e. _____ All the important constituency groups are effectively contributing through the CCC in developing an effective level of cooperation.

25f. _____ The perception that ICM has been forced on the catchment by the state government has seriously detracted from an effective level of cooperation developing among CCC members.

25g. _____ The lack of an effective level of interest by CCC members seriously detracts from an effective level of cooperation developing among CCC members.

25h. _____ The lack of trust in government-sponsored initiatives seriously detracts from effective implementation.

25i. _____ The lack of interest in community type activities seriously detracts from effective implementation.

25k. _____ The lack of financial resources within the community seriously detracts from effective implementation.

Institutional Aspects of ICM

26. Rate your level of agreement with the following statements concerning the operations of the CCC according to the following scale:

1 = strongly agree
2 = agree
3 = moderately agree
4 = disagree
5 = strongly disagree

26a. _____ The objectives of the local ICM are very clear to all members.

26b. _____ There is a strong consensus among CCC members concerning CCC functions.

26c. _____ A very important function of the CCC is to coordinate the implementation of state and local government resource management programs.

26d. _____ A very important function of the CCC is to prioritise resource management problems in the catchment.

26e. _____ A very important function of the CCC is to provide a forum for conflict resolution among resource users.

26f. _____ A very important function of the CCC is to educate the public about the catchment's resource management problems and solutions.

26g.. _____ A very important function of the CCC is to provide for information sharing within and between public and private resource managers.

26h. _____ A very important function of the CCC is to prepare a strategic resource plan.

26i. _____ A very important function of the CCC is to implement resource management initiatives noted in the strategic plan.

26j. A very important function of the CCC is to identify a common set of policies which will be implemented by relevant resource managers within the catchment.

26k.. _____ A very important function of the CCC is to make private resource managers/owners more responsible for the impacts arising from their activities.

26l. _____ The activities of our CCC have been effectively coordinated with the activities of other state and local government agencies.

26m. _____ The membership of the CCC effectively represents the interests of the catchment community.

26n.. _____ At CCC meetings, all CCC members participate actively.

26o. _____ The local ICM process allows for an effective resolution of resource conflicts.

26p. _____ The local ICM process is a very efficient for resolving resource management conflicts.

26q. _____ The local ICM process is an open approach for resolving resource management conflicts.

26r. _____ The ICM process is very accountable.

26s. _____ The ICM process is responsive to local needs.

26t. _____ A CCC member's role is to provide their personal views on resource management issues at CCC meetings.

26u. _____ A CCC member's role is to provide the resource management views of their constituency group at CCC meetings.

26v. _____ A CCC member's role is to provide a catchment-wide perspective of natural resource management issues at CCC meetings.

26w.._____ The CCC is solving the priority natural resource management problems in the catchment.

27. Over the last 12 months, the level of financial and in kind support from QDPI has (circle one): remained the same/declined/increased. Explain any changes.

28. Over the last 12 months, the level of financial and in kind support from other state and local agencies, and other external funding organisations (*e.g.* Landcare) has (circle one): remained the same/declined/increased. Explain any changes.

29. How effectively have your CCC initiatives been coordinated with the activities of the resource agencies? Rate using the following scale:

1 = very effective
2 = effective
3 = somewhat effective
4 = ineffective
5 = very ineffective
6 = not applicable

_____ QDPI
_____ QDEH
_____ Queensland Department of Lands
_____ Department of Housing, Local Government and Planning

_____ Wet Tropics Management Agency
_____ Great Barrier Reef Marine Park Authority
_____ River Improvement Trusts
_____ Drainage Boards
_____ Cane Assignment Committees
_____ Local Government
_____ Landcare
_____ Industry groups (specify)
_____ Environmental groups (specify)
_____ Others (specify)

30. How clear is the role(s) of the following groups in the local ICM process? Rate using the following scale:

1 = very clear
2 = clear
3 = neither clear nor unclear
4 = unclear
5 = very unclear
6 = not applicable

_____ QDPI
_____ QDEH
_____ Queensland Department of Lands
_____ Department of Housing, Local Government and Planning
_____ Wet Tropics Management Agency
_____ Great Barrier Reef Marine Park Authority
_____ River Improvement Trusts
_____ Drainage Boards
_____ Cane Assignment Committees
_____ Local Government
_____ Landcare
_____ Industry groups (specify)
_____ Environmental Groups (specify)
_____ Others (specify)

31. What has the level of attendance been at CCC and relevant sub-committee meetings from the following groups? Rate using the following scale:

1 = very high
2 = high
3 = moderate
4 = low
5 = very low
6 = not applicable

_____ QDPI
_____ QDEH
_____ Queensland Department of Lands
_____ Department of Housing, Local Government and Planning
_____ Wet Tropics Management Agency
_____ Great Barrier Reef Marine Park Authority
_____ River Improvement Trusts
_____ Drainage Boards
_____ Cane Assignment Committees
_____ Local Government
_____ Landcare
_____ Industry groups (specify)
_____ Environmental Groups (specify)
_____ Others (specify)
_____ Media

32. If there are any further comments you wish to make about ICM, please feel free to do so.

APPENDIX 2

QUEENSLAND ICM CHAIR'S SURVEY

Background

1. Which catchment do you represent?

2. How long have you lived in this catchment? _____ years

3. What year did you assume your present responsibilities?

4. When you assumed the Chair, what did you expect the CCC to accomplish by this time?

5. Since assuming your current responsibilities, how well has the CCC met your expectations: (please tick):

_____ very well
_____ well
_____ moderately well
_____ not well
_____ not very well

Context of ICM with other issues

6. In your opinion, what is the significance of the following issues in your catchment? Rate using the following scale:

1 = very high
2 = high
3 = moderate
4 = low
5 = very low
6 = not applicable

_____ Provision of schools
_____ High crime rate
_____ High unemployment
_____ Public health care
_____ Ineffective land valuation for municipal tax purposes
_____ High level of spending by government
_____ High taxes
_____ Government inefficiency
_____ Too much government regulation
_____ Agricultural land problems (*e.g.* soil salinity, urban development)
_____ Water quality problems (*e.g.* nutrient enrichment, dirty drinking water)
_____ Water quantity problems (*e.g.* flooding, poor drainage)
_____ Degradation of natural environment (*e.g.* habitat loss)

7. In your opinion, what is the significance of the following natural resource management problems in your catchment? Rate using the following scale:

1 = very high
2 = high
3 = moderate
4 = low
5 = very low
6 = not applicable

_____ Erosion of crop land
_____ Productivity decline of crop land
_____ Erosion of grazing land
_____ Productivity decline of grazing land
_____ Soil salinity
_____ Weed problems

_____ Insects and disease on crops
_____ Urban expansion into agricultural lands
_____ Land clearing
_____ Surface water salinity
_____ Surface water nutrient enrichment (algae)
_____ Pesticides in waterways
_____ Degradation of freshwater/aquatic natural life
_____ Groundwater quality
_____ Acid soils
_____ Surface water availability
_____ Wastewater management
_____ Allocation of cane land
_____ Management of public land
_____ Groundwater availability
_____ Rural flooding
_____ Rural drainage
_____ Urban flooding
_____ Urban drainage
_____ Instream and offstream water use conflicts
_____ Stream bed and bank erosion
_____ Dryland vegetation habitat loss
_____ Freshwater habitat loss
_____ Coastal wetland habitat loss
_____ Barriers to fish migration
_____ Others (list)

8. What is the significance of the impacts associated with these natural resource problems on the people in the catchment? Rate using the following scale:

1 = very high
2 = high
3 = moderate
4 = low
5 = very low
6 = not applicable

_____ loss of scenic land values
_____ loss of other environmental amenities
_____ higher cost of water supplies
_____ loss of on-farm productivity
_____ personal health problems
_____ emotional stress for individuals
_____ significant conflicts with other resource users
_____ higher taxes
_____ decline in recreational and/or commercial fishery
_____ loss of access to other recreational activities
_____ loss of confidence in government's ability to manage resources effectively
_____ Other (specify)

9. Who do you believe is most responsible for solving these resource management problems? (Please tick)

_____ individuals (e.g. producers, landowners)
_____ local CCC
_____ Local Government
_____ Other local agencies/interests (e.g. Valley Trust, Drainage Board, CANEGROWERS, industry) (specify)
_____ State Government
_____ Commonwealth Government
_____ GBRMPA
_____ Others (specify)

10. In your opinion, what is the level of public awareness about these natural resource problems and associated impacts? Rate using the following scale:

1 = very high
2 = high
3 = moderate
4 = low
5 = very low
6 = not applicable

_____ Erosion of crop land
_____ Productivity decline of crop land
_____ Erosion of grazing land
_____ Productivity decline of grazing land
_____ Soil salinity
_____ Weed problems
_____ Insects and disease on crops
_____ Urban expansion into agricultural lands
_____ Land clearing
_____ Surface water salinity
_____ Surface water nutrient enrichment (algae)
_____ Pesticides in waterways
_____ Degradation of freshwater/aquatic natural life
_____ Groundwater quality
_____ Acid soils
_____ Surface water availability
_____ Wastewater management
_____ Allocation of cane land
_____ Management of public land
_____ Groundwater availability
_____ Rural flooding
_____ Rural drainage
_____ Urban flooding
_____ Urban drainage
_____ Instream and offstream water use conflicts
_____ Stream bed and bank erosion
_____ Dryland vegetation habitat loss
_____ Freshwater habitat loss
_____ Coastal wetland habitat loss
_____ Barriers to fish migration
_____ Others (list)

11. In your opinion, how strong is public support regarding the need for the ICM process to solve these natural resource problems in your catchment? (Please tick)

_____ very high
_____ high
_____ moderate
_____ low
_____ very low

12. Please rate your level of agreement with the following statements concerning how the nature of resource management problems in your catchment affects implementation of ICM according to the following scale:

1 = completely agree
2 = agree
3 = neither agree nor disagree
4 = disagree
5 = completely disagree

12a. _____ The lack of an appropriate technical solution to the natural resource management problems in this catchment seriously detracts from effective implementation.

12b. _____ Because resource management problems in the catchment are not well understood, effective implementation is very difficult.

12c. _____ The long-term and incremental nature of the impacts associated with resource management problems in the catchment seriously detracts from effective implementation.

12d. _____ The absence of a single acute resource management issue within the catchment significantly detracts from effective implementation.

12e. _____ The long time frame between implementing a solution and seeing the benefits seriously detracts from effective implementation.

12f. _____ The high level of behavioural change required by private landowners to effectively solve resource management problems seriously detracts from effective implementation.

12g. _____ The high level of behavioural change required by industry to effectively solve resource management problems seriously detracts from effective implementation.

12h. _____ The high level of administrative, legal and financial change required from existing government agencies to effectively solve resource management problems seriously detracts from effective implementation.

12i. _____ The absence of clear and immediate economic benefits seriously detracts from effective implementation.

13. In the last 12 months, have resource management problems (circle one) increased/stayed the same/declined in importance within the catchment? If changes have occurred, please explain what has changed.

Context for ICM

14. What level of puyblic support do you believe your CCC has? (Please tick)

_____ very high level of support
_____ a high level of support
_____ moderate level of support
_____ low level of support
_____ very low level of support

15. How significant have the following items been in gaining acceptance from the public? Rate using the following scale:

1= very high
2= high
3= moderate
4= low
5= very low
6=not applicable

_____ ICM policy statement
_____ strong local government support (political level)
_____ strong state government support (political level)
_____ strong support from local government agencies (administrative level)
_____ strong support from state government agencies (administrative level)
_____ strong financial resources of CCC
_____ strong leadership of CCC Chair
_____ strong leadership of CCC coordinator
_____ positive outcomes associated with CCC activities
_____ strong support from relevant industry and community groups
_____ other (specify)

16. How effectively have the efforts of your CCC group been accepted by other government agencies within the catchment? (Please tick)

_____ very effectively
_____ effectively
_____ somewhat effectively

_____ ineffectively
_____ very ineffectively

17. How significant have the following items been in gaining acceptance from other government agencies? Rate using the following scale:

1 = very high
2 = high
3 = moderate
4 = low
5 = very low
6 = not applicable

_____ ICM policy statement
_____ strong local government support (political level)
_____ strong support from QDPI (political or administrative levels)
_____ strong public support
_____ strong financial resources of CCC
_____ strong leadership of CCC Chair
_____ strong leadership of CCC coordinator
_____ positive outcomes associated with CCC activities
_____ strong support from relevant industry and community groups
_____ other (specify)

18. How effectively have the efforts of your CCC been accepted by relevant local industry and community organisations? (please tick)

_____ very effectively
_____ effectively
_____ somewhat effectively
_____ ineffectively
_____ very ineffectively

19. How significant have the following items been in gaining acceptance from relevant industry and community organisations? Rate using the following scale:

1 = very high
2 = high
3 = moderate
4 = low
5 = very low
6 = not applicable

_____ ICM policy statement
_____ strong local government support (political level)
_____ strong support from QDPI (political or administrative levels)
_____ strong public support
_____ strong financial resources of CCC
_____ strong leadership of CCC Chair
_____ strong leadership of CCC coordinator
_____ positive outcomes associated with CCC activities
_____ other (specify)

20. What have been the main activities of your CCC in the last 12 months? Please list and rank their significance according to the following scale:

1 = very high
2 = high
3 = moderate
4 = low
5 = very low

RATING ACTIVITIES

  _____ Housing, Local Government and Housing
  _____ Department of Lands
_____ Valley Trust
_____ Drainage Board(s)
_____ Sugar Industry Infrastructure Package Program
_____ rural industry organisations (specify)
_____ environmental organisations (specify)
_____ media

22. How effectively do the news media present your CCC's views of resource management issues? (Please tick)

_____ very effectively
_____ effectively
_____ somewhat effectively
_____ ineffectively
_____ very ineffectively

23. Over the last 12 months, has the level of acceptance of your ICM program among the public, government agencies, and relevant industry and environmental groups (circle one) increased/ stayed the same/ decreased? If changes have occurred, explain why.

24. Please identify your level of agreement with the following statements concerning the context of your CCC's activities according to the following scale:

1 = strongly agree
2 = agree
3 = moderately agree
4 = disagree
5 = strongly disagree

24a. _____ The large size of the catchment (or poor transportation links between parts of catchment) seriously detracts from an effective level of cooperation being developed among CCC membership.

24b. _____ The wide variety of values and beliefs among CCC members seriously detracts from an effective level of cooperation developing among them.

24c. _____ The media has played a very constructive role in developing a sense of cooperation among CCC members.

24d. _____ The media has played a very constructive role in developing a sense of cooperation between the CCC and the catchment community.

24e. _____ All the important constituency groups are effectively contributing through the CCC in developing an effective level of cooperation.

24f. _____ The perception that ICM has been forced on the catchment by the state government has seriously detracted from an effective level of cooperation developing among CCC members.

24g. _____ The lack of an effective level of interest by CCC members seriously detracts from an effective level of cooperation developing among CCC members.

24h. _____ The lack of trust in government-sponsored initiatives seriously detracts from effective implementation.

24i. _____ The lack of interest in community type activities seriously detracts from effective implementation.

24j. _____ The lack of financial resources within the community seriously detracts from effective implementation.

Institutional Aspects of ICM

25. Rate your level of agreement with the following statements concerning the operations of the CCC according to the following scale:

1 = strongly agree
2 = agree
3 = moderately agree
4 = disagree
5 = strongly disagree

25a. _____ The objectives of the local ICM are very clear to all members.

25b. _____ There is a strong consensus among CCC members concerning CCC functions.

25c. _____ A very important function of the CCC is to coordinate the implementation of state and local government resource management programs.

25d. _____ A very important function of the CCC is to prioritise resource management problems in the catchment.

25e. _____ A very important function of the CCC is to provide a forum for conflict resolution among resource users.

25f. _____ A very important function of the CCC is to educate the public about the catchment's resource management problems and solutions.

25g. _____ A very important function of the CCC is to provide for information sharing within and between public and private resource managers.

25h. _____ A very important function of the CCC is to prepare a strategic resource plan.

25i. _____ A very important function of the CCC is to implement resource management initiatives noted in the strategic plan.

25j. _____ A very important function of the CCC is to identify a common set of policies which will be implemented by relevant resource managers within the catchment.

25k. _____ A very important function of the CCC is to make private resource managers/owners more responsible for the impacts arising from their activities.

25l. _____ The activities of our CCC have been effectively coordinated with the activities of other state and local government agencies.

25m. _____ The membership of the CCC effectively represents the interests of the catchment community.

25n. _____ At CCC meetings, all CCC members participate actively.

25o. _____ The local ICM process allows for an effective resolution of resource conflicts.

25p. _____ The local ICM process is a very efficient for resolving resource management conflicts.

25q. _____ The local ICM process is an open approach for resolving resource management conflicts.

25r. _____ The ICM process is very accountable.

25s. _____ The ICM process is responsive to local needs.

25t. _____ The CCC is solving the priority natural resource management problems in the catchment.

25u. _____ Over the last 12 months, QDPI has provided an adequate level of funding and in kind support to our CCC.

25v. _____ Over the last 12 months, our CCC has received an adequate level of financial assistance and in kind support from other state government agencies.

26. Over the last 12 months, the level of financial and in kind support from QDPI has (circle one): remained the same/declined/increased. Explain any changes.

27. Over the last 12 months, the level of financial and in kind support from other state and local agencies, and other external funding organisations (*e.g.* Landcare) has (circle one): remained the same/declined/increased. Explain any changes.

28. How effectively have your CCC initiatives been coordinated with the activities of the resource agencies? Rate using the following scale:

1 = very effective
2 = effective
3 = somewhat effective
4 = ineffective
5 = very ineffective
6 = not applicable

_____ QDPI
_____ QDEH
_____ Queensland Department of Lands
_____ Department of Housing, Local Government and Planning
_____ Wet Tropics Management Agency
_____ Great Barrier Reef Marine Park Authority
_____ River Improvement Trusts
_____ Drainage Boards
_____ Cane Assignment Committees
_____ Local Government
_____ Landcare
_____ Industry groups (specify)
_____ Environmental groups (specify)
_____ Others (specify)

29. How clear is the role(s) of the following groups in the local ICM process? Rank using the following scale:

1 = very clear
2 = clear
3 = neither clear nor unclear
4 = unclear

5 = very unclear
6 = not applicable

_____ QDPI
_____ QDEH
_____ Queensland Department of Lands
_____ Department of Housing, Local Government and Planning
_____ Wet Tropics Management Agency
_____ Great Barrier Reef Marine Park Authority
_____ River Improvement Trusts
_____ Drainage Boards
_____ Cane Assignment Committees
_____ Local Government
_____ Landcare
_____ Industry groups (specify)
_____ Environmental Groups (specify)
_____ Others (specify)

30. What has the level of attendance been at CCC meetings from the following groups? Rank using the following scale:

1 = very high
2 = high
3 = moderate
4 = low
5 = very low
6 = not applicable

_____ QDPI
_____ QDEH
_____ Queensland Department of Lands
_____ Department of Housing, Local Government and Planning
_____ Wet Tropics Management Agency
_____ Great Barrier Reef Marine Park Authority
_____ River Improvement Trusts
_____ Drainage Boards
_____ Cane Assignment Committees
_____ Local Government
_____ Landcare
_____ Industry groups (specify)
_____ Environmental Groups (specify)
_____ Others (specify)
_____ Media

Personal Demands and Motivations

31. On average, how many hours per month do you devote to ICM? _____ hours/month

32. Identify your level of agreement with the following statements according to the following scale:

1 = completely agree
2 = agree
3 = moderately agree
4 = disagree
5 = completely disagree
6 = not applicable

32a. _____ The amount of time I devote to ICM significantly interferes with my own business/job requirements.

32b. _____ The amount of time I devote to ICM significantly interferes with my family commitments.

32c. _____ My involvement with the CCC causes significant out-of-pocket expenses.

32d. _____ I find being a member of the CCC personally rewarding because I can contribute to the community.

32e. _____ I find being a member of the CCC personally rewarding because I care about natural resource management.

32f. _____ I find being a member of the CCC rewarding because I can meet other members of the community who can influence resource management decision making.

32g. _____ A CCC's member's role is to provide their personal views on resource management issues at CCC meetings.

32h. _____ A CCC member's role is to represent the resource management views of their constituency group at CCC meetings.

32i. _____ A CCC member's role is to provide a catchment-wide perspective of natural resource management issues at CCC meetings.

33. If there are any further comments you wish to make about ICM, please feel free to do so.

Chapter 2

What They Told us:
The Views of Queensland Catchment Committee Chairs and Coordinators on ICM

Geoff McDonald[1] and Dan Shrubsole[2]

[1]Department of Geographical Sciences and Planning, University of Queensland. Qld 4072
[2]Department of Geography, University of Western Ontario, London. Ontario Canada

Originally Published as:
McDonald, G. T. and Shrubsole, D. 1996. What they told us - Queensland ICM in focus. *Australian Journal of Soil and Water Conservation*, 9 (4), 10-15.

Summary This paper reports on a survey of Queensland Catchment Committee Chairs and Coordinators. The mail survey sought to find their views on how they thought the ICM process was going in the state and what were the issues that made it successful or were obstacles. Apart from some preliminary analysis by the authors in the discussion at the end of the paper, this summary is limited to "what they told us". Opinions are presented on the major issues for catchment management, levels of support from various quarters and suggestions on how to make the process work better.

THE SURVEY AND RESPONDENTS

This report is a summary of the responses of the Chairs and Coordinators of the 14 Catchment Coordinating Committees (CCCs) that operated in Queensland in late 1995 to a survey of their opinions about the Queensland ICM program. Individuals responded to the survey on the understanding that their views would be confidential and used only in providing summary information. The survey sought their responses to a number of questions concerning:

- the activities of their own catchment committee,
- important catchment management issues,
- the level of support provided by the community, other agencies and NGO groups,
- the difficulty of resolving catchment management issues,
- the institutional and financial arrangements for ICM and the general process adopted in Queensland.

This is only a small fraction of the information supplied by the respondents and a complete tabulation of the results is available from the authors. The Mazmanian-Sabatier model of policy implementation provided the theoretical framework for this survey but theoretical perspectives are kept in the background in this discussion.

The state-wide survey was limited to the Chairs and Coordinators of the 13 recognised CCCs and one Catchment Care Group operating in November 1995. It was very pleasing for the quality of the survey that fourteen Coordinators (100%) and 11 Chairs (78%) responded to the questionnaire. All the responses were satisfactory, and most respondents provided significant additional written comments. All the ICM committees are quite young and most of the respondents were the initial appointees in their CCC. Many of the Coordinators were recent arrivals into the catchments as young professionals moving in to take up the newly created jobs with a few notable exceptions. Most of the Chairs are lifetime residents and have lived in their catchments more than 15 years (60%), although there are some relatively new arrivals amongst the Chairs (34%).

The Activities and Progress of Catchment Groups

The major activities of the Queensland CCCs are summarised in Table 1.

Table 1: Activities Undertaken by ICM groups in Queensland

Activity	*Yes*	*No*
Awareness and education programs	14	0
Prepared a situation statement	5	9
Catchment strategy	11	3
Advice to Landholders	6	9
Conducted on-ground projects	9	5

Respondents reported a wide range of activities reflecting largely the age and maturity of the CCCs. Some have been in operation effectively since 1988, whereas some are still in the process of being formed. A progression of activities can be recognised from organisational activities - public awareness and involvement - issues generation - catchment planning - technical studies. The range of activities are all envisaged in the Queensland ICM Policy which now requires the preparation of catchment strategies before funding is provided for projects (Queensland

Department of Primary Industries, 1992)

Table 2: Level of Satisfaction with Progress in their ICM Program

	Chairs	Coordinators
Very unsatisfied	0	0
Unsatisfied	0	3
Neither satisfied nor unsatisfied	4	4
Satisfied	6	4
Very satisfied	1	1
No response	0	1

Less than half the coordinators were satisfied with progress in their CCC and three were unsatisfied, one to the point of resigning over it. The Chairs were generally more satisfied with progress, and while none was actually dissatisfied, almost half were ambivalent.

Local Issues

The issues seen as significant by the respondents naturally varied between regions. In all regions natural resource issues were approximately on par with social and economic issues. Most significantly both Chairs and Coordinators believed that too much government regulation was the single most significant issue, exceeding all other issues. The most significant natural resource issue was water quantity, substantially higher than land degradation and water quality problems, although these too also were significant in most catchments.

Those issues rated highly and very highly by coordinators included economic sustainability, native and feral animal management and pests in national parks, creek bank erosion and siltation, groundwater salinity, land tenure and uncoordinated farm drainage and cross border coordination. Chairs rated only a few issues highly and very highly including rural residential development and storm water and native tree species management.

Table 3: The Significance of Social, Economic and Natural Resource Issues

Issue	*Coordinators ratings*						*Chairs ratings*						
	1	2	3	4	5	6	0	1	2	3	4	5	6
Social Issues													
Crime	2	6	4	1					5	5	1	1	
Unemployment		3	5	4	1				2	3	5	1	
Economic and Institutional Issues													
Land valuations		1	4	4	3	1			2	4	3	2	
High taxes		2	1	3	5	2	1		1	2	4	3	
Too much Government regulation		1	3	1	8				1	2	4	4	
Natural Resource Management Issues													
Agricultural land degradation problems			6	4	3				1	3	4	3	
Water quality problems		2	4	5	2				2	2	5	2	
Water quantity problems		2	2	1	8				1	3	3	4	
Nature conservation	1	2	4	3	3				1	6	3	1	

(0 = no response, 1 = very low, 2 = low, 3 = moderate, 4 = high, 5 = very high, 6 = NA/don't know.)

Attitudes and Support

Most respondents believed that support from the general public was low due largely to the public's low level of awareness about natural resource management issues. (Table 5)

Table 4: Level of Public Awareness about Natural Resource Issues and Impacts

Level	*Coordinators*	*Chairs*
Very high	0	0
High	4	1
Moderate	4	5
Low	5	5
Very low	0	1

Only 35% of Coordinators are satisfied with the acceptance of their CCCs by other government agencies. Chairs are more positive on this point.

A wide range of factors generate support from industry and community organisations, especially the efforts of the CCC Chairs. Again both groups of respondents were commonly unhappy with political support and of the acceptance of local government at both the agency and political levels. As in many other results of the survey there are regular exceptions to common patterns. Other community groups rating as important include Landcare groups, Recreational fishing, Commercial Fisherman's Association, Aboriginal. Council, Sugar Industry (Mills), Tourism. Environmental organisations considered to be valuable for CCC groups included ACF, QCC, Regional Environmental Council, Marine Conservation Society (although there was ambivalence on this, some respondents believed that these groups were obstructionist).

All groups use local newspapers as the most frequent form of media outlet.. ABC rural programs were mentioned by many respondents and a slightly lesser number mentioned local commercial radio. A few CCCs were able to use TV, one even place subsidised advertisements on regional TV. Only one respondent believed the media to be ineffective in supporting the CCC. Eighty percent of Coordinators believed the media to be effective. One said the media were "The Key!" and two others found the MDBC videos very valuable.

An overall summary of the importance of support from different groups is provided in Table 5. Clearly and not surprisingly, the dominant effective partnership is between the CCCs, the DPI (now DNR) and rural producer groups. There was less agreement between the Chairs and Coordinators on the effectiveness of the involvement of local government and even some ambivalence on the involvement of others such as the Department of the Environment. Coordinators did not in general seem impressed with the involvement of Lands and Local Government.

Table 5: The Effectiveness of Involvement in the CCC by Various Groups

Group	*Coordinators ratings*							*Chairs ratings*						
	0	1	2	3	4	5	6	0	1	2	3	4	5	6

(0 = no response, 1 = very ineffective, 2 = ineffective, 3 = neither, 4 = effective, 5 = very effective, 6 = NA/don't know)

Institutional Arrangements and Finance

Table 6 provides results that probe into the difficulties within CCCs. Coordinators believe that some of the most significant difficulties are due to the wide variety of beliefs amongst CCC members, a view not so strongly held by Chairs; a perception that the program has been forced on the catchment by the State Government in communities without finical resources to respond, and a lack of trust in the public in government sponsored initiatives. The Chairs hold similar views differing significantly as a group only in relation to the significance of the wide variety of beliefs and values of CCC members and to a lesser extent on the difficulties posed by the large size of catchments. Both groups believe that the CCCs have the important groups represented. There are some potentially fatal problems identified here, although many can be overcome in time as the ICM process matures and achieves ownership and clearer common perceptions.

Table 6: The Reasons Implementation of ICM in CCCs is Difficult

Reason	*Coordinators ratings*						*Chairs ratings*					
	1	2	3	4	5	6	1	2	3	4	5	6
Large size of catchment or poor transportation links	1	5	2	4	1		1	3	1	1	4	1
Wide variety of values and beliefs among CCC members		2	1	8	2		1	4	2	2	2	
Media don't report resource issues accurately	1	6	6				1	5	4		1	
Important groups are not represented on the ICM committee	1	5	3	4			2	4	4	1		
Perception that ICM has been forced on the catchment by the state	1	4	3	3	2		2	5	1		3	
Lack of an effective level of interest by CCC members		3	5	5			1	4	2	2	1	
Public's lack of trust in state or local government sponsored initiatives		2	2	3	5	1		2	1	5	3	
Public's lack of interest in community type activities		3	1	8	1			3	1	6	1	
The lack of financial resources within the community	1		1	6	5			2	1	1	7	

(1 = strongly disagree, 2-disagree, 3 = neither, 4 = agree, 5 = strongly agree, 6 = NA/don't know)

Table 7 reveals more detail on the operation of the CCCs themselves. Perhaps the most interesting feature of these results is the wide spread of opinions as to the purpose and operation of CCC among the various individuals and catchments in the State. Coordinators for example are not in clear agreement as to what they and their CCCs should do - some believe that Coordinators and CCCs should coordinate activities and give advice to landowners, others do not. Significant differences in opinion exist as to whether the objectives of the local ICM programs are clear to all members and to the level of participation of their CCC members in meetings. They too do not always agree as to whether the CCC should give advice to landholders.

Table 7: Chairs and Coordinators Opinions on the Role and Conduct of CCCs

DISCUSSION

Problem Definition

It is crucial to the evaluation of the ICM process to identify what is *the problem* and how it affects the implementation process. From a *technical* point of view resource management is finding effective mechanisms to address specific well defined problems such as soil erosion, flooding, nutrient enrichment, unreliable water supplies, loss of biodiversity. The solutions are defined in terms of land management practices, engineering structures, input usage and similar hard technological matters. From a *socio-economic* point of view, resources management is a matter of designing and implementing socially acceptable and effective solutions and preventative actions to these same problems through awareness raising and education, economic, administrative and legal measures

The survey revealed that there are clear enough technical solutions to many of the natural resources management problems in Queensland. These have been canvassed and promoted in some cases for decades and longer - eg floodplain management, soil erosion control, groundwater depletion and acidification. In the Herbert for example there have been three flood studies and three drainage studies over the past twenty years. The proposed technical

solutions have been similar in each case, but the resources management problem still exists. Other emergent problems, such as biodiversity conservation and nutrient enrichment of waterways are not so well defined in technical terms, and ICM groups where these are key issues have greater difficulty focusing their priorities and activities. They need research information to gain a greater understanding of the processes involved and to demonstrate the necessity and effectiveness of technological solutions.

All the respondents acknowledged the difficulty of promoting a program with relatively few immediate benefits but often with immediate cost implications for land holders. This problem is intrinsic to ICM, and can only be alleviated by a change in ethics in the community as a whole. It would be assisted by technical and economic data that demonstrated the severity of the problems and reality of the long term benefits. Those catchments with more apparent and visible resource issues (such as water shortages or acute soil erosion) will have a better chance of focussing community attention.

The Queensland ICM program is part of the struggle to move from sectoral approaches to resources management to an integrated whole of landscape approach. The survey revealed that the biggest obstacle to ICM is the *process* within the community and within government to redress and prevent resource management problems - political and social processes to apply technological solutions. Not surprisingly, this change of philosophy is accompanied by uncertainty and resistance especially when the way forward is not signposted. As yet there is no well tested solution to this problem as a guide to action.

The move towards an integrated approach to natural resources management has come at a time when community expectations about environment and resources issues have increased. In some cases these changes have been rapid and the shift in resource management and economic goals magnifies the extent of attitude and behaviour change required. For example, twenty years ago, farmers were encouraged to develop natural resources such as irrigation, tree clearing for grazing, clearing and drainage for agriculture. Recently, they have been asked to revise their practices substantially. These changing requirements for resource management have been isolated to a considerable extent from the economic development decision making process although there are promising signs that the merger of resource and environmental issues with economic development issues is beginning to occur in rural areas of the State. For example decisions on water resources development, agricultural expansion, water control, use rights and land tenure, resources extraction are becoming the concern of ICM groups. In order to do this successfully, further changes will be required by the major players in natural resources management. At present the ICM program is largely limited in scope to a relationship between farmers and the Department of Natural resources (formerly Primary Industries). Sustainable development requires a whole of government and a whole of community approach to decision about resources and economic issues.

Context for ICM

The Queensland ICM program has been active only since 1990. Consequently a major constraint to any evaluation is the relatively short period of time that CCCs have been in existence and the limited opportunities they have to bring about change. A progression of activities was recognised from organisational activities - public awareness and involvement - issues generation - catchment planning - technical studies - implementation. Judging from the diversity of responses, it requires approximately five years before a CCC will reach maturity along this spectrum. A considerable amount of time is taken establishing the CCC, creating some coherence amongst its members, learning the challenges and opportunities and having the platform for planning and implementation.

Perhaps for the reason that ICM requires a complex process of learning, there was a disturbing low level of satisfaction amongst the respondents at the state level (especially the Coordinators).

CCCs have to contend with low awareness in the general public about resources management issues and a general resistance to external intervention. A surprising, consistent and very significant result from the survey was respondents universal view that there is too much government regulation. People in rural Australia resent government controls on land use whether they arise from World Heritage listing and conservation generally, tree clearing regulations, water and land management regulations, changes to land tenure and land rights laws. There is a clear message here that landholders in particular will resist any solution to ICM problems that involve state and national government regulations.

DNR is the lead agency for ICM which was perceived to be a successful partnership between DNR and the rural land owner interests and not much more than that. There was a widely held view that local governments, both politically and at officer level have not been involved effectively in the ICM process.

Despite the need for ICM to integrate across government agencies there is a clear absence of a "whole of government" approach , commitment or involvement in ICM. State politicians seemed to ignore ICM and there was ineffective, even counter productive involvement of some state agencies. While there was no reported hostility from politicians, agency staff and community groups, it seems that CCCs must create these supporting links themselves with little support from outside.

On a positive note there was wide agreement about the supportive role of the media and of the essential role that the CCCs, its Chairs and Coordinators play in gaining support from the stakeholders. Clearly, the ability of these people is critical to the success of individual ICM programs. The study could not assess these abilities and what skills are essential, personal or technical.

Institutional Structure

Queenslands ICM program has very broad, and from a community point of view, somewhat nebulous goals. There is general agreement on the ultimate purpose of ICM, but also a wide spread of opinions as to the purpose and operation of CCC among the various individuals and catchments in the State. Perhaps this is not a deficiency of the program given that it is intended to be community based.

Financial resources for a program with such ambitious goals has been erratic and low. A key source of funds has been the NLP, without which ICM would struggle to survive. CCCs are required to find funding on their own initiative rather than use established revenue sources as do most public programs. At present they have no revenue raising capacities and there is a lack of confidence in government funding for implementation, which is of particular concern given that once CCCs have been established and created strategies, their requirement for funds for on-ground works will increase their financial requirements. Planning is inexpensive relative to action.

As discussed above, CCCs have not so far had effective involvement from local governments nor from key agencies with statutory resources management responsibilities but the problem is understood and action being taken (DNR, 1996). As coordinating focus for mainstream decisions affecting resources, ICM have not yet been universally successful but then we are talking about a long term process.

Questionnaire 101

PART I INTRODUCTION

1. Survey Objectives

The primary objective of the survey reported here is to provide a benchmark against which the activities and achievements of the Herbert River Catchment Coordinating Committee (HRCCC) can be prepared. The results of the survey together with results of monitoring the institutional arrangements and performance of integrated catchment management in the state and indeed nationally and internationally provide a fundamental context and yardstick for the evaluation of the HRCCC.

This survey is the second statewide survey of all ICM groups in the Queensland, the first being conducted in 1995.

Other papers and reports of this research program define the conceptual framework for observing change and evaluating the ICM implementation process. The framework combines aspects of the Mazmanian-Sabatier framework of policy implementation analysis with the criteria identified by Syme's PRIME framework to provide overall direction to the program and to define dimensions of implementation to be included in the survey reported here.

2. Research Design and Implementation

The study is based on a mail survey of the Chairs and Coordinators of all recognised ICM Committees and groups throughout the state. The manager of the State ICM program provided the names of these individuals.

The survey used a self-administered questionnaires designed to be readily completed by the respondents (Appendix 1).

Conduct of the survey involved the following steps:

- the questionnaire was structured to follow the conceptual framework; further detail on this is available in the 1995 report
- the questionnaire was an adaptation of the one used largely successfully in 1995. Some questions were deleted or reworded as a result of the 1995 experience to make the questionnaire shorter and clearer
- mail out of the state-wide survey in October 1997,
- mail our of reminder letters to non-respondents in late November 1997
- the survey was 'closed' in December 1997

3. ICM Groups in Queensland

There are four categories of ICM groups recognised in Queensland based primarily on their functional role:

(a) *Catchment Coordinating Committees* (CCCs): these are the most common type of catchment group whose key roles are to provide a forum for community input and discussion, to foster community awareness and understanding of the interactions between natural resources and the value of a coordinated catchment-wide approach for managing these resources, and to prepare and oversee voluntary implementation of catchment management strategies. Membership is broadly based involving representatives of significant stakeholder groups and interests in the catchment, with a majority of non-government members. These groups are usually assisted by a full or part time catchment coordinator, technical support from state and local government agencies and other

tertiary institutions, cash and inkind support from organisations in the catchment and state government establishment and basic operational grants.

(b) *Regional Catchment Coordinating Committees* (RCCCs): these catchment groups have the role of overseeing the preparation of a regional strategy, coordination of subcatchment planning and implementation, and linking with other regional activities. Membership is broadly based involving representatives of significant stakeholder groups and interests with a majority of non-government members. These groups are usually assisted by a full or part time catchment coordinator, technical support from state and local government agencies and other tertiary institutions, in kind support from working groups, cash and inkind support from organisations in the catchment and state government establishment and basic operational grants

(c) *Steering Groups* (SGs): these are catchment groups in a formative phase whose terms of reference are to work on setting up a CCC. There role, membership and support provided is similar to that of CCCs -some have formal coords and some not..

(d) *Catchment Care Groups* (CCGs): from a policy point of view, CCGs no longer exist, although there is one remaining formally established group. Their principal role is to provide a forum for public discussions on catchment management issues identified by community action groups, agencies or members of the public to foster community awareness and cooperative solutions to local catchment issues. This role is therefore more akin to that of a Landcare group within the context of a whole catchment. Membership involves interested individuals, and no specific support mechanisms are provided.

	1995	**1997**
CCCs (include Fitzroy)	14	22
RCCC	1	2
Steering Groups	6	9
Catchment Care Groups	1	1
Total	**22**	**34**

Table 2. Classification of Queensland Catchment Groups in 1997

1. Catchment Coordinating Committees

Central

Lower Fitzroy Catchment Care Group Inc
Fitzroy Catchment Coordinating Group Inc.
Pioneer Integrated Catchment Management Assoc Inc
Dawson Valley Development Association Inc.

North

Johnstone River Catchment
Douglas Shire Catchment Coordinating Committee
Management Association Inc.
Mitchell River Watershed Management Association Inc.
Russell-Mulgrave Catchment Coordinating Committee
Herbert River Catchment Coordinating Committee
Cardwell Shire Catchment Coordinating Committee
Barron River ICM
Weipa Catchment Coordinating Committee

South East

Bremer River Catchment Coordinating Association Inc.
Burnett Catchment Care Incorporated
Maroochy Mooloolah Catchmentcare Committee
Mary River Catchment Coordination Assn. Inc.
Noosa River Catchment Management Committee
Pumicestone Region Catchment Coordinating Committee
Norman Creek Catchment Coordinting Committee
North and South Pine Rivers Integrated Catchment Assn Inc
Lockyer Resource Management Group Inc.

South

Border Rivers Catchment Coordinating Committee
Murray-Darling Basin Regional Coordinating Committee
Balonne-Maranoa Catchment Coordinating Committee
Condamine Catchment Coordinating Committee

West
Warrego-Paroo Catchment Coordinating Committee

2. Steering Groups
Southern Gulf Catchments Coordinating Committee Steering Group
Annan River Catchment Management Group
Sarina Steering Committee
Baffle Creek Catchment Management Interim Committee
Catchment Management Lake Eyre Basin Steering Group
Endeavour Catchment Group
Whitsunday Steering Committee

3. Catchment Care Groups
Lake Baroon Catchment Care Group Inc.

4. Survey Response

Surveys were distributed to Chairs and Coordinators of all Catchment Groups in Queensland. Two groups currently have Coordinators only (Weipa and Norman Creek), while five groups have a Chair only (Annan River, Endeavour, Sarina, Whitsunday, Baffle Creek). The responses received are shown in Table 3.

Table 3: Number of ICM Groups of all Types and Survey Response

	Total Groups	Total Chairs	Total Coordinators	Responses from Chairs No. (%)	Responses from Coordinators No. (%)
CCC	22	21	22	11 (52)	15 (68)
RCCC	2	2	2	1 (50)	0 (0)
SG	9	8	4	3 (38)	2 (50)
CCG	1	1	1	0 (0)	1 (100)
Total	34	31	29	15 (52)	18 (62)

Of the Steering Groups, 4 groups (Lake Eyre Basin, Southern Gulf, Barron, Weipa) have formal Catchment Coordinators appointed and have developed to a stage that they effectively have a role and function of a CCC. Therefore for the purpose of the analysis of ICM Chairs and Coordinators opinions in Queensland, responses from these four catchment groups will be included with CCCs and RCCCs and analysed as follows:

Table 4: Number of Catchment Coordinating Committees and Responses

	Total Groups	Total Chairs	Total Coordinators	Responses from Chairs No. (%)	Responses from Coordinators No. (%)
CCC groups	29	26	28	13 (50)	17 (61)
Other	5	5	1	2 (40)	1 (100)
Total	34	31	29	15 (52)	18 (62)

Note There were 8 CCCs for which both the Catchment Coordinator and the Chair responded: Douglas Shire, Russell-Mulgrave, Herbert, Bremer, Burnett, Mary, Condamine, Balonne-Maranoa

Given that there were 29 CCC groups at the time of the survey and that both Chairs and Coordinators replied from eight of them, the survey received a response from either Chairs and/or Coordinators from 22 of the 29 groups. Another way of looking at the response rate is that there is a response from 75% of the catchments. Pairwise comparisons would have been very valuable to chart progress. Regrettably the numbers are too small to provide meaningful statistical analysis while protecting confidentiality. There were only five groups for which we received responses from chairs in both surveys (and only two with the same chair!) and six groups common to both surveys where coordinators responded and only three with the same coordinator two years later.

PART II SURVEY RESULTS

1. ICM Activities and Achievements (Q1-8)

Question 2 How long have you lived in this catchment (years) ?

	< 2	2 - 5	6 - 10	11 - 20	21 - 30	31 - 40	> 40	N/a	Total
Coordinators	6	8	0	1	0	1	0	2	18
Chairs	0	1	1	2	1	2	6	0	13

Note: Excluding blank responses but including values of zero.

While occasionally a new resident becomes a CCC Chair, most are lifetime residents. This contrasts markedly with Coordinators, most of whom moved to the catchment to take up their position. It is quite significant that most of the coordinators have lived less than five years in their catchments and many less than two.

Question 4 What year did you assume your present responsibilities with the catchment group?

	1992	1993	1994	1995	1996	1997	N/A	Total
Coordinators	1	0	2	4	8	2	1	18
Chairs	0	4	0	4	2	1	2	13

Recency of appointment is no surprise given that many of the CCCs are new, almost half being created between 1995 and 1997. There are a few long serving members of the older CCCs, but even in them there is considerable turnover.

Question 5 Since assuming your current responsibilities, how satisfied are you with progress in the CCC?

	Very Satisfied	Satisfied	Neither	Unsatisfied	Very Unsatisfied	No Response	Total
Coordinators	2	13	1	1	0	1	18
Chairs	2	8	3	0	0	0	13

Several Chairs and one Coordinator are ambivalent about their successes but the majority of both Chairs and Coordinators are satisfied, two it is pleasing to see, are very satisfied. While a few are non-committal, only one coordinator claimed to be unsatisfied.

Question 6 How much money did your CCC spend last year (approximately) on.

	Projects	Administration	Consultancies	Other
No Funding	11	9	17	12
Less than $50,000	1	8	1	5
$50,001 to $100,000	3	1	0	0
$100,001 to $150,000	1	0	0	0
$150,001 or more	2	0	0	1

Note: This table uses the Coordinators' responses. A value of zero may represent 'No Funding' or 'No Response' at this stage

CCCs are in general financially poor. While several CCCs had significant project funding. The majority are able only to fund essential committee costs, mostly the salaries of Coordinators. Almost all the longer running CCCs gain their core funding from two sources – either Queensland Department of Natural Resources operating grant together with either operating or project funds from the Natural Heritage Trust and its components the NLP, Bushcare, Rivercare and Coastcare and Waterwatch. Several CCCs indicated receiving

financial support from local councils and in-kind support from councils and local industry sources. Only one mentioned significant funding from private corporations (mining companies).

Question 7 What have been the major achievements of your CCC?

	Coordinators (18)		Chairs (13)	
	Yes	No	Yes	No
Prepared situation statement on the catchment	7	11	3	10
Prepared a catchment strategy or plan	14	4	12	1
Offered advice to landowners	7	11	6	7
Conducted projects	9	9	5	8
Other	3	15	1	12

Note: For details on what 'Other' represents, refer to the Notes on Question 7

Question 7 List of Other Activities of CCC Groups

Artificial wet land in cane field drainage system	Augmentation of mangroves and fisheries ponds
Bore drain replacement – Greta Artesian Basin	Catchment wide Dairy Effluent Project
Cleaning-up Acid Mine Drainage	Community monitoring of urban water quality
Construction of wetlands	Coordinated water quality monitoring program
Creek Floodgate	Developing localised "action" plans
Implementing sub catchment action plans	Integrated Information Management System for Catchment Managers
Integrated pest management	Landholders inventory
Major river mgt projects	Model Sub Catchment
National Riparian Project	Nutrient Management Planning
Owl nesting box program	Principles and guidelines for land use planning
Property development planning	Resolve inventory project
Resource atlas	River bank stabilisation using landowners IDCAS/ownership
Riverbank Restoration	Soil conservation works $200 000
State of Rivers - Anderson method.	Streambank Revegetation
Teachers professional training day.	Total grazing pressure. Safe carrying capacity
Vetiver Grass Trials	Voluntary riverbank restoration program
Waterwatch	

Most of the longer running CCCs have now prepared catchment strategies, the newer ones being preoccupied with group formation or in the early stages of strategy formation. Many of these strategies have been endorsed by the Queensland Catchment and Landcare Council. (See Map 1) There have also been other related strategic activities in committees, such as Identification of issues and development of options, development of natural resources & environmental management plan. Despite rumours that abound that CCCs only prepare catchment strategies to qualify for project funding, most respondents state that their plans were prepared for the "right" reasons and that they have assisted their committees focus on priority issues and to identify the way forward. These views are best reflected in the comments made by chairs and coordinators in response to Question 8.

Question 8 Responses Given to About the Purpose and Usefulness of Catchment Plans

Prepared strategy or catchment plan?	For what purpose?	Useful?	Why?
CHAIRS			
Yes	Identify areas of concern in relation to catchment management	Yes	It gives direction and works towards goals in prioritised order
Yes	To identify where investment and effort will achieve the greatest positive impact on resource management	Yes	Forced people to put personal agenda's aside. Finalised the development of a genuine community government partnership

Prepared strategy or catchment plan?	For what purpose?	Useful?	Why?
No	Have completed second discussion paper.	N/A	
In Progress	To assist with coordination of actions by community & agencies	N/A	Still developing
Yes	Set goals for catchment management. Sustainable Natural Resource Management	Yes	Enlightening experience for the ICM Committee. Makes us aware of the inter dependence and fragility of all sections of the catchment's
In Progress	Present situation statement & future	N/A	Will be
Yes	Addressing issues of concern in catchment and seeing their implementation continually updating	N/A	Only ready for printing.
Yes	For the communities use and advice and to address priority issues	Yes	Helped to develop the regional plan and assist with funding applications
Yes	We believe that a strategy is the focal point for our assn. This will support any funding applications & also give us local credibility on issues	In Progress	Our strategy is still being developed - stage one is complete, stage two currently being developed - will be submitted to the state body in the new year
Yes	Even though the strategy is broad. It does give land u se managers guidelines on how to manage their land use so as to minimise overall negative affect on the general environment	Yes	The plan will soon be adopted but it has already focused land users decision makers on all aspeccts of the development
Yes	The sustainable management of natural resources of our district	Yes	As a basis for dealing with issues in a coordinated way
COORDINATORS			
Yes	For the better management of all the natural resources of the catchment	Yes	Provides focus to citizenry and govt agencies
In Progress	To provide direction for how we will manage our natural resources by developing strategies and action plans by encouraging/promoting a change in community attitudes, behaviour and the adoption of self regulation practices	N/A	
Yes	Identify issues, agree on them, Id options & best approaches, rank Id responsible stakeholders for implementation. Involve stakeholders	Yes	Stakeholders are agreeing on some of the issues - leading to dev & rehab plan
Yes	To set direction & priorities. To give equal priority to soil, water & vegetation & fauna issues	Yes	Shapes priorities for projects in the catchment eg. NHT funding, private enterprise sponsored projects
Yes	Prioritise issues, strategies & actions to minimise duplication, maximise benefit on ground & to encourage partnerships between government, industry & community	Yes	Greater appreciation of issues. High involvement of all stakeholders. Provide direction for activities. Established better links between stakeholders
Yes	We have affirmed the BCC's Norman Ck Catchment Management Plan (1996). From this NCMP we have reprioritised certain action plans and related them to broader social objectives of the N4C. The above NCMP had its limitations but as the N4C matures and educates itself the inherent deficiencies will I hope be overcome by our community social	Yes	Yes. It has been the culmination of four years of hard work by RAGE to influence the BCC to develop the plan. It was the catalyst of forming the N4C. However its ongoing effectiveness cannot be evaluated at this point in time until runs are on the bd
Yes	Draft strategy to propose a way forward	Yes	Has been useful in moving the process forward and generating debate
Yes	Provide direction, set priorities, promote a joint community/government partnership using a shared vision	Yes	Provided direction. For localised action plans. Set priorities within the catchment & region. Helped to identify projects required to meet catchment objectives. Negotiating point with other stakeholders in catchment
Yes	To provide a focus and priority to the catchment community (including L.G. and State agencies) for catchment action over the	Yes	Developing a shared perspective on issues. Engendering a deeper understanding of causes behind issues

Prepared strategy or catchment plan?	For what purpose?	Useful?	Why?
	next 10-20		(through the debating and discussing side of preparing the Strategy). Useful in keeping the CCC focussed rather than running off up every blind gully
No	Process of doing so. To promote ICM/INRM and Sustainable Development. To guide NHT investment in CQ	N/A	
No	In the process of: for long term planning & coordination of resources. Seeking financial support	N/A	Developing stages.
Yes	ID priority action/needs/responsibilities. Aid in funding applications	N/A	Draft form - final by May 98
Yes	Basis to prepare acceptance implementation of action plans for sustainable management	Yes	Just starting to test it through local government plans river improvement trust and rural industry
Yes	To guide the councils agencies & landholders in a coordinated way to develop sustainable resource management	Yes	Completed one week ago, the process has involved community education & a genuine ownership of the issues & the plan

2. Problem Characterisation and Role of the Group (Q9)

Question 9 Please rank your level of agreement with the following statements about the role your CCC has played in the catchment. The local CCC has:

	Strongly Agree	Agree	Neither	Disagree	Strongly Disagree	N/a
Coordinators (18)						
9a. Helped negotiation among resource stakeholders to accommodate a wide range of resource uses	2	10	3	2	1	0
9b. Helped stakeholders in defining the source of resource problems and solutions to them	1	11	4	2	3	0
9c. Helped stakeholders in ensuring their resource management practices are effective, efficient, equitable, accountable	1	5	9	2	1	0
9d. Encouraged research and data gathering and analysis in order that solutions to resource problems can be better understood	2	11	4	1	0	0
9e. The ICM program in Queensland is well-suited to address complex resource issues within this catchment?	3	7	3	2	3	0
Chairs (13)						
9a. Helped negotiation among resource stakeholders to accommodate a wide range of resource uses	0	7	3	0	1	2
9b. Helped stakeholders in defining the source of resource problems and solutions to them	1	10	0	0	1	1
9c. Helped stakeholders in ensuring their resource management practices are effective, efficient, equitable, accountable	0	5	4	1	1	2
9d. Encouraged research and data gathering and analysis in order that solutions to resource problems can be better understood	3	8	1	0	0	1
9e. The ICM program in Queensland is well-suited to address complex resource issues within this catchment?	2	5	3	0	1	2

There is wide agreement that CCCs helped negotiation amongst resource users and other stakeholders in defining problems and solutions. Most encouraged research and data gathering also. There was less uniformity, indeed one might say ambivalence, especially amongst coordinators that the Queensland ICM program was suited to addressing the problems of catchments. The differences between coordinators and chairs on this question are significant – coordinators being less certain that the Queensland ICM model is well-suited to address the problems. Two-thirds of respondents did not believe that they had directly helped stakeholders in resolving their own resource management practices.

3. Information Use (Q10)

Question 10. Information relevant to ICM and CCCs and their activities may be available in a number of forms (eg., databases, reports, pamphlets, maps). How useful has information or data about the following topics been to you and your CCC

	None Available	Very Useful	Useful	Neither	Not Useful	N/A
Coordinators (18)						
10a.Catchment natural resources ?	2	8	8	0	0	0
10b.Population and land use in your catchment?	2	9	6	1	0	0
10c.Local organisations, industry and community groups in your catchment?	4	6	6	2	0	0
10d.Government institutional arrangements for ICM, Landcare, natural resources, and related issues?	0	5	10	1	2	0
10e.Government policies and regulations on natural resources and related issues?	1	5	4	2	5	1
10f.Options for funding of ICM and other community activities?	5	3	8	2	0	0
10g.Group management and administration?	5	7	2	3	1	0
Chairs (13)						
10a.Catchment natural resources ?	1	4	6	2	0	0
10b.Population and land use in your catchment?	1	5	6	1	0	0
10c.Local organisations, industry and community groups in your catchment?	0	5	7	0	0	1
10d.Government institutional arrangements for ICM, Landcare, natural resources, and related issues?	1	4	5	2	1	0
10e.Government policies and regulations on natural resources and related issues?	1	1	7	4	0	0
10f.Options for funding of ICM and other community activities?	0	3	8	1	0	1
10g.Group management and administration?	0	6	3	2	1	1

Coordinators and Chairs from most catchments found that information on catchment natural resources, population and land use, local organisations, industry and community groups, options for funding for ICM, and group management and administration was most useful to the CCC. A small but significant number believed that information on government policies and regulations on natural resources either not useful or neither useful nor unuseful. Nearly 30% of Coordinators identifed information relating to both options for funding ICM activities and group management and administration was not available to the CCC.

4. Public Attitudes, Support and Recent Developments (Q11-18)

Question 11 In your opinion, what is the level of public awareness about natural resource issues in your catchment?

	Very High	High	Moderate	Low	Very Low
Coordinators (18)	1	4	8	4	1
Chairs (13)	0	2	8	3	0

Coordinators and Chairs from most catchments believed that the level of public awareness about resource management issues in most catchments was moderate to low. There is a small but significant number of catchments however where this is not the case.

Question 12 What level of public support do you believe your CCC has?

	Very High	High	Moderate	Low	Very Low
Coordinators (18)	0	3	13	2	(
Chairs (13)	0	1	8	4	(

The level of public support for CCCs remains moderate to low but many of the coordinators and chairs make positive statements about the trends and about activities and events that have had a positive influence on public support and awareness.

Question 12 Comments on Changes in Public Awareness

Chairs

Treated with suspicion Cannot understand why.

Not much

Become aware of the complexity and number of issues that need to be dealt with

Outside catchment committees little change. We have involved a local government which potentially means greater understanding

Several issue have arisen (eg) acid sulphate soils, clearing of water holes on streams. These issues were well publicised. The owl nesting box story lifted public perception. Issue of catchment Atlas & later CD of the Atlas

Public awareness probably hasn't changed much in 12 months if anything it's improved a little

Considerably, our activities have highlighted certain issues and the controversy over the Kurrerava Cotton Project has created interest

People expect things to change overnight. Catchment Management is slowly catching on in areas of NRM. What has been bad practice in the past take a while to rectify and achieve good results

The promotion of the strategic plan

Coordinators

The drought has increased competition for access to water so people especially water users, have been forced to look at the sustainability of bath surface & ground water use through at the Condamine

There has been a shift of emphasis from weed/land management concern to a prioritisation of water management (especially allocation and access)

Mining. Live cattle exporting.

Through Waterwatch, WAMP & increasing demands for water

Public consultation with strategy document. Tourism industry active lobbying eg sewage & effect on GBR

Through a clarification of groups roles & responsibilities within the area.

Release & presentation of Bremer Catchment Strategy. Release of draft Brisbane R Management Plan. Release of discussion paper on Water Quality. Wide ranging programs with Ipswich Enviroplan.

I'd say it's increased due to our projects & media coverage of issues

More awareness as Burnett Catchment Care Association becomes involved in more community activities

Increased especially during & as a result of the catchment planning process

There has been 2 discernible change but its hard to quantity. The perception of public awareness change relates move to intuitive 2nd subjective feelings related to how the CCC's going. At the moment its positive and optimistic

More people are aware of ICM especially the "ICM process" of negotiation and partnerships

Very slightly. A marketing campaign is needed & will be looked at in the near future

Has been a turn around in how to deal with riverine problems. Awareness in key areas (such as the Mayors) has increased greatly. General positive "vibes" coming from field days, night meetings etc with community groups, farmer groups regarding

the approach of the CCC & the catchment concept.
I think we have done a lot of work on raising the issues - whether or not people's understanding at the issues has improved is another thing
It hasn't. People nurtured our womb-to-tomb welfare are robbed of initiative. Most know little of what is outside their own yards and care less
Don't know (still waiting on NHT funding to get our education & awareness program up & running)

Question 12 A Selection of Opinions as to Whether Public Support for CCCs is Rising or Not

Chairs
Public support is rising as the displays and education programs through the schools and to the general public take effect.
More inquiries to CCC for advice
Increased with local government. Is increasing as we become more professional & accountable
We have promoted awareness and offered solutions. Our committee is not a negative group - most of us would prefer to educate by example & find outcomes as part of the public awareness campaign
There is confusion on the role of ICM & Landcare and some other major projects which are in process.
Moral support is moderate but when it comes to the bulk of the public doing things - apathy takes over
Because of the direction of our research we have not really considered this. I would suggest there has been increased support but only from certain community sectors
Younger people are becoming more supportive and my overall view would be yes
An awareness that strategic planning is this further direction

Coordinators
Possibly increased slightly due to a recent turnover in members (only every 3 yrs) & establishment of an independent office out of DNR. Generally public support is low - people are generally unaware of our goals
Many sectors of the community would be more aware of the existence of our CCC. Some sectors are more supporting now that our group is more active, but many people are still suspicious of our group, our role
Now have a core membership of 13 stakeholder groups
Very little: The same people have been involved, although local governmentt has shown increasing interest.
Increase in membership - currently 100
Unsure - many still see ICM as arty farty that is green and doesn't really help them on the ground
In urban catchment its move a case of establishing a profile 2nd this for the N4C has been slow & steady. Enquires are building up 2nd network development is becoming more established - in short, yes!
The CCC in this catchment is going through a transition phase and the process has generated more involvement
There has been a slight increase in support - although generally the "public" do not have an adequate understanding of CCC & how they may be able to help
2,3 but increasing. More people making suggestions to improve actions (as opposed to not accepting the actions in the strategy). More landholders joining in the CCC's projects. More dollars coming from Local Govt.
Increased participation at meetings we have opened a catchment information centre and are getting more drop ins
It will improve when the above planning and proposed projects are carried out. The public realises that the NRCCC is a sound natural resource body & has definite long term benefits for the broader community

Question 13 How effective has the involvement of the following groups been to the CCC?

	Very Effective	Effective	Neither	Ineffective	Very Ineffective	Not Applicable
Coordinators (18)						
13a.Rural producers	3	9	2	1	1	2
13b.Rural industry organisations	1	6	4	3	2	2
13c.Local government politicians	2	6	4	3	3	0
13d.Local government administrators	3	3	5	5	1	1
13e.State government politicians	0	4	5	6	1	2
13f. State government agencies DPI/DNR	2	12	1	1	0	2
13g.Forestry	2	2	9	1	1	3
13h.Land Management	0	8	3	3	2	2
13i.Lands Administration	0	3	7	3	2	3
13j.Department of Environment	0	8	7	2	0	1
13k.Local Government and Planning	1	6	7	3	0	1
13l.River Improvement Trust	1	5	5	1	1	5
13m.Drainage Board(s)	0	2	6	1	0	9
13n.Environmental Organisations	3	7	6	0	0	2
13o.The Media	1	11	2	1	1	2
13p.Landcare Groups	5	10	1	0	1	1

	Very Effective	Effective	Neither	Ineffective	Very Ineffective	Not Applicable
Chairs (13)						
13a.Rural producers	1	11	1	0	0	0
13b.Rural industry organisations	2	6	2	2	0	1
13c.Local government politicians	2	6	3	1	0	1
13d.Local government administrators	2	6	4	1	0	0
13e.State government politicians	0	2	5	3	0	3
13f. State government agencies DPI/DNR	2	4	5	1	0	1
13g.Forestry	5	2	3	1	1	1
13h.Land Management	2	5	3	0	1	2
13i.Lands Administration	2	1	5	1	2	2
13j.Department of Environment	1	6	4	2	0	0
13k.Local Government and Planning	1	6	4	1	1	0
13l.River Improvement Trust	2	2	1	1	1	6
13m.Drainage Board(s)	0	1	2	0	0	10
13n.Environmental Organisations	1	3	4	0	3	2
13o.The Media	1	5	2	3	1	1
13p.Landcare Groups	2	9	2	0	0	0

As expected, the respondents believed that rural producers and their counterparts in DNR were the most effectively involved in the ICM process. Community groups such as Landcare groups and environmental groups are also effectively involved. The media too played an important role. In about half the CCCs, producer organisations were not effectively involved – although coordinators and Chairs differed significantly on this issue.

Those stakeholders that should be involved, but were not effectively involved in a number of CCCs, included local government administrators and politicians and in particular state government politicians. It remains a very apparent weakness of the ICM process that local and state government politicians do not engage themselves with the ICM process.

An interesting feature of the respondents' views is that Chairs had, on average and for the same catchment, a more positive opinion on the level of involvement of most groups compared with coordinators who were more restrained in their assessment of effectiveness.

Question 14 Selected Opinions on What Can be Done to Gain Greater Involvement of Community and Other Stakeholder Groups

Chairs

Sponsor seminars and promotions state wide about ICM and Landcare presence in each community

More understanding of ICM process

Stop the self interest & use of position for own benefits.

More publicity, find ways to involve public more

Regional press releases/brochures regular briefing by dept managers, more advice/info on dept field officer activites in our area

Formal structure ie trust or board. Competitive appointments of members groups better resourced. Better alignment of agency programs with strategies. Separation of RAP's & Regional Strat Groups - transparency

Govt Agencies must make the effort to advise what they are doing in the catchment.

Grass roots contact and full identification of issues. Change in attitude by all bodies who at present appraoch the programmes with a parochial attitude. This includes State Govt as well as Local Govt

Coordinators in catchments working with community and industry offering advice on how to address situations. Education in schools from an early age

More communication with public, more involvement by gov agencies

Promotion of ICM for all state depts to facilitate whole of government approach

DNR ICM staff should visit the regions more often and ask us what our needs are, rather than tell us e.g. communications unit. Improve links with Local Governments. Disband River Improvement Trust & Development. Giving

Coordinators

State advertising

State wide or regional media campaign, insist councils become involved

Help with PR to include positive linkage with CCCs. CCC stability within district through support for permanent

coordinators. More formal linkage/contact with govt dept officers. More stability in funding support system.
Awareness campaign - relevance to different areas to do things like this we need assistance - time & resources. It would be better for the locals to be involved in this but the time & cost is to great - they need some financial support
State: More generic promotional material. State: Info on legislative requirements. State: Info on jurisdictions.
Govt should get serious about strategies for r Mgt issues, population & sustainability
Closer ties with local government. CCC's should be used by LG as a resource to comment on land use & planning issues
Remove the immediate association of the general community that it is another part of government & is government owned
Greater resourcing of CCC activities. Greater coordination of state & local govt so that in kind assistance is more focused at the grass-roots level 2nd available to CCC's etc. A major priority of CCC's is to have 2 public shop front to enable them to be a focal point for ICM activities. This is where state/local govt has a role to play.
Local govt project is proceeding perhaps followed by some implementation funds for LGS that identifies issues with CCC & develops partnerships
Marketing campaigns to gain more. Community ownership
State - get rid of that dickhead advising Hobbs - less insertion of extra layers of bureaucracy through regional CCC especially their projects
Full cooperation from government agencies. Make CCC's Strategy authorities with power to enforce change. Up here is Comalco land people feel abandoned by the govt altogether - we can't ever get a local government authority so approaches (SEQ anyway). Direct budgetting to ICM Committees! Local groups should promote themselves better - public participation is poor. Resolve the deadlock is negotiations with aboriginal communities
1. Adequate funding. 2. Concerted media and public awareness campaign. Professionally organized and run at state level 3. An acceptance by Cairns City Council that it is responsible for the old Mulgrave Shire as well since the previou slabor govt forced amalgamation - too much spirit in Cairns
An education & awareness campaign on radio & television outlining the community benefits of the ICM process

Question 15 What types of involvement or linkages has your CCC had with Local Governments in your catchment?

	Coordinators (18)		Chairs (13)	
	Yes	No	Yes	No
None	0	18	0	13
Joint projects or activities	12	6	6	7
CCC has a referral agency on natural resource issues/projects for local government	6	12	6	7
Local Government as a source of information/advise for the CCC	11	7	8	5
CCC strategy development	13	5	10	3
Local Government planning schemes/strategy development	9	9	7	6
Other	13	5	4	9

The links between CCCs and local government are increasing markedly in Queensland ICM. As shown on the Table, many local governments are involved in joint activities and assist CCCs in strategy development. Conversely, CCCs are increasingly involved in local government planning schemes and as a source of advice.

Question 17 The implementation of ICM in this catchment is difficult because:

	Strongly Agree	Agree	Neither	Disagree	Strongly Disagree	N/A
Coordinators (18)						
17a. The large size of the catchment (or poor transporation links between parts of catchment	4	6	2	2	4	0
17b. The wide variety of values and beliefs among CCC members seriously detracts from an effective level of cooperation developing among them	0	4	4	5	5	0
17c. Some important constituency groups are not represented in the ICM process	2	8	2	3	3	0
17d. The perception that ICM has been forced on the catchment by the state government	1	5	7	3	2	0
17e. The lack of an effective level of interest by CCC members	1	4	2	9	2	0
17f. The public's lack of trust in state/local government-sponsored initiatives	4	7	6	1	0	0
17g. The public's lack of interest in community type activities	1	6	3	5	3	0

17h. The lack of financial resources within the community	4	10	3	1	0	0
17i. The lack of agreement among CCC members concerning its objectives	0	1	4	9	4	0
Chairs (12)						
17a. The large size of the catchment (or poor transporation links between parts of catchment	5	2	1	4	0	0
17b. The wide variety of values and beliefs among CCC members seriously detracts from an effective level of cooperation developing among them	0	3	2	7	0	0
17c. Some important constituency groups are not represented in the ICM process	0	2	0	8	2	0
17d. The perception that ICM has been forced on the catchment by the state government	0	2	3	6	1	0
17e. The lack of an effective level of interest by CCC members	0	3	3	4	2	0
17f. The public's lack of trust in state/local government-sponsored initiatives	2	6	2	2	0	0
17g. The public's lack of interest in community type activities	3	5	1	3	0	0
17h. The lack of financial resources within the community	5	3	3	1	0	0
17i. The lack of agreement among CCC members concerning its objectives	1	0	2	7	2	0
17j. The lack of agreement on feasible solutions	1	1	3	5	2	0
17j. The lack of agreement on feasible solutions	0	2	7	7	2	0

Obstacles to ICM include the size of some catchments, or poor transport links, and perceived financial constraints. A majority of Coordinators agree that there are important missing constituency groups, a view not largely shared by Chairs. There is agreement between Coordinators and Chairs that the public lack trust in government sponsored initiatives. It is interesting to note that a majority of Chairs believe the community's lack of interest in community affairs is an obstacle – a view not so strongly held by Coordinators.

Question 18 Rate your level of agreement with the following statements

	Strongly Agree	Agree	Neither	Disagree	Strongly Disagree	N/A
Coordinators (18)						
18a. There is a strong consensus among CCC members concerning CCC functions	2	10	1	4	1	0
18b. At CCC meetings, all CCC members participate actively	0	9	0	7	2	0
18c. The local ICM process effectively resolves resource conflicts	0	5	7	6	0	0
18d. The ICM process is responsive to local needs	1	9	6	1	1	0
18e. The CCC is solving the priority natural resource management problems in the catchment	0	11	6	0	1	1
Chairs (13)						
18a. There is a strong consensus among CCC members concerning CCC functions	1	7	3	1	1	0
18b. At CCC meetings, all CCC members participate actively	3	8	1	1	0	0
18c. The local ICM process effectively resolves resource conflicts	0	4	5	3	0	1
18d. The ICM process is responsive to local needs	1	9	3	1	0	1
18e. The CCC is solving the priority natural resource management problems in the catchment	0	6	3	1	0	3

Question 18 addressed issues relating to the performance of Committees. In some CCCs respondents were not sure that the CCC members had consensus about their functions, although 75% were. In common with most meetings, not all members participate actively, a situation that 80% of Chairs and 50% of Coordinators noted.

Perhaps the most telling finding here is that only 28% of Coordinators and 30% of Chairs agreed that the local ICM process effectively resolves local resource conflicts. Much higher proportions of respondents at least believe that the process is responsive to local needs and is addressing priority problems.

5. Personal Demands and Motivations (Q19-20)

Question 19 On average, how many hours per month do you devote to ICM?(hours / month)

	Range		
		Median	Average
Coordinators	40-255	180	186.76
Chairs	8-60	25	25.92

Question 20 The implementation of ICM in this catchment is difficult because:

	Completely Agree	Agree	Moderately Agree	Disagree	Completely Disagree	N/A
Coordinators (18)						
20a.The amount of time I devote to ICM significantly interferes with my own business/job requirements	2	3	1	1	2	9
20b.The amount of time I devote to ICM significantly interferes with my family commitments	4	6	1	2	0	5
20c.My involvement with the CCC causes significant out-of-pocket expenses	2	1	1	6	1	7
20d.I find being a member of the CCC personally rewarding because I can contribute to the community	6	8	0	0	0	4
20e.I find being a member of the CCC rewarding because I care about natural resource management	8	7	0	0	0	3
20f.I find being a member of the CCC rewarding because I can meet other members of the community who can influence resource management decision making	5	9	0	1	0	3
20g.A CCC's member's role is to provide their personal views on resource management issues at CCC meetings	2	2	5	4	3	2
20h.A CCC member's role is to represent the resource management views of their constituency group at CCC meetings	7	7	2	1	0	1
20i.A CCC member's role is to provide a catchment-wide perspective of natural resource management issues at CCC meetings	6	7	1	2	0	2

Chairs (13)						
20a.The amount of time I devote to ICM significantly interferes with my own business/job requirements	5	1	4	3	0	0
20b.The amount of time I devote to ICM significantly interferes with my family commitments	2	4	2	5	0	0
20c.My involvement with the CCC causes significant out-of-pocket expenses	4	2	3	3	1	0
20d.I find being a member of the CCC personally rewarding because I can contribute to the community	4	9	0	0	0	0
20e.I find being a member of the CCC rewarding because I care about natural resource management	7	6	0	0	0	0
20f.I find being a member of the CCC rewarding because I can meet other members of the community who can influence resource management decision making	4	7	1	1	0	0
20g.A CCC's member's role is to provide their personal views on resource management issues at CCC meetings	2	5	4	2	0	0
20h.A CCC member's role is to represent the resource management views of their constituency group at CCC meetings	5	6	1	1	0	0
20i.A CCC member's role is to provide a catchment-wide perspective of natural resource management issues at CCC meetings	5	6	2	0	0	0

For chairs, ICM interferes to some extent with business and family interests, but all agree that they have personal rewards from contributing to the community.

In terms of the role of CCC members, chairs mostly agree that members' role is to present their own and constituency views at meetings, many coordinators do not agree that it is appropriate for members to present personal views.

PART III DISCUSSION

1. Overall Discussion of 1998 Results

The number of ICM groups has expanded continuously in Queensland. Now there are 32. A consequence is that they are mostly new and many of the older ones have been executive turnovers.

Many respondents are satisfied with progress but would like to move faster.

CCCs are in general financially poor. Most have funding from DNR and/or NHT for their coordinators and some project funds from the same sources. There is no doubt that the NHT has been a major driving force in the Qld ICM process, but the core support remains in DNR.

Most of the CCCs have prepared plans which they believe have assisted substantially in focussing people on priorities. This was the major achievement of the majority of CCCs.

Public awareness and support to CCCs is still only moderate to low in most cases but showing signs of increasing due to various CCC activity.

A notable feature was increasing interaction with local government.

Only about 30% of respondents believed ICM was effectively resolving local resource management issues.

2. Comparative Analysis 1995-1998

Since assuming your current responsibilities, how satisfied are you with progress in the CCC?

		Very Satisfied	Satisfied	Neither	Unsatisfied	Very Unsatisfied	No Response
1995	Coordinators (13)	1	4	4	3		1
	Chairs (11)	1	6	4			
1997	Coordinators (18)	2	13	1	1	0	1
	Chairs	2	8	3	0	0	0

Levels of satisfaction increased significantly between 1995 and 1997, despite the fact that many new committees were formed that may not have consolidated sufficiently to have major achievements.

What have been the major achievements of your CCC? (Coordinators responses)

	1995		1997	
	Yes	No	Yes	No
Prepared situation statement on the catchment	5	9	7	11
Prepared a catchment strategy or plan	11	3	14	4
Offered advice to landowners	6	9	7	11
Conducted projects	9	5	9	9

Note: For details on what 'Other' represents, refer to the Notes on Question 7

What level of public support do you believe your CCC has?

		Very High	High	Moderate	Low	Very Low
1995	Coordinators	2	2	6	3	0
	Chairs	0	1	8	2	0
1997	Coordinators (18)	0	3	13	2	0
	Chairs (13)	0	1	8	4	0

Public support has not changed noticeably over the period.

How effective has the involvement of the following groups been to the CCC? (Coordinators responses)

		Very Effective	Effective	Neither	Ineffective	Very Ineffective	Not Applicable
Rural producers	1997		9	2	1	1	2
	1995		7	3			
Local government politicians	1997	2	6	4	3	3	0
	1995	2	3	4	3		
State government politicians	1997	0	4	5	6	1	2
	1995	1	2	4	5		

State government agencies						
DPI/DNR 1997	2	12	1	1	0	2
1995	6	6	0	1		
Lands Administration 1997	0	3	7	3	2	3
1995	2	2	5	2	2	
Department of Environment 1997	0	8	7	2	0	1
1995	4	1	5	1	2	

Sources of support and involvement vary significantly between catchments, depending on relevance of particular issues and state department priorities. The involvement of state politicians has not improved in most catchments and that of local politicians varies considerably from catchment to catchment. Some coordinators remain unhappy about the effectiveness of Lands Administration and Department of Environment involvement.

Perhaps most importantly, coordinators in most catchments regard the involvement of rural producers as effective and remaining so.

ICM Queensland - Statewide Surveys of Chairs and Coordinators in 1995 and 1997

ICM Groups in 1995

	Total
CCCs (include. Fitzroy)	14
RCCC	1
Steering Groups	6
Catchment Care Groups	1
Total	22

ICM Groups in 1997

	Total Groups
CCC	22
Regional CCC	2
Steering Groups	9
Catchment Care Groups	1
Total	34

Of the Steering Groups, 4 groups (Lake Eyre Basin, Southern Gulf, Barron, Weipa) have formal Catchment Coordinators appointed and have developed to a stage that they effectively have a role and function of a CCC.

APPENDIX

ICM IN QUEENSLAND
ICM COORDINATOR'S AND CHAIR'S OPINIONS

BACKGROUND

1. Which catchment are you involved in? ……

2. How long have you lived in this catchment? …….Years

3. What is your occupation? ……

4a. What year did you assume your present responsibilities with the catchment group? ……..

4b. What are your responsibilities?

☐ CCC Chair

☐ Catchment Coordinator

5. Since assuming your current responsibilities, how satisfied are you with progress in the CCC? (please tick)

☐ very satisfied

☐ satisfied

☐ neither satisfied nor unsatisfied

☐ unsatisfied

☐ very unsatisfied

6. How much money did your CCC spend last year (approximately) on:

Projects	$……
Administration	$……
Consultancies	$……
Other (Please Specify)	
……	$……
……	$……
……	$……..

Please list the principal sources of the CCC's income:

……

……

……

……

7. What have been the major achievements of your CCC? (please tick)

- ☐ prepared situation statement on the catchment
- ☐ prepared a catchment strategy or plan
- ☐ offered advice to landowners
- ☐ conducted projects
- ☐ other (Please specify)

……

……

……

……

Please list some of the most significant projects:

……

……

……

……

8a. Has your Committee prepared a catchment strategy/plan? (Yes/No)

For what purpose?

……

……

……

……

8b. Has the catchment strategy/plan been useful? (Yes/No)

Why?

……

……

……

……

9. Please rank your level of agreement with the following statements about the role your CCC has played in your catchment.

	Strongly agree	Agree	Neither agree nor disagree	Disagree	Strongly disagree	Don't know
The local CCC has:						
Helped negotiation among resource stakeholders to accommodate a wide range of resource uses.	☐	☐	☐	☐	☐	☐
Helped stakeholders in defining the source of resource problems and solutions to them	☐	☐	☐	☐	☐	☐
Helped stakeholders in ensuring their resource management practices are effective, efficient, equitable, accountable.	☐	☐	☐	☐	☐	☐
Encouraged research and data gathering and analysis in order that solutions to resource problems can be better understood .	☐	☐	☐	☐	☐	☐
The ICM program in Queensland is well-suited to address complex resource issues within this catchment?....	☐	☐	☐	☐	☐	☐

10. Information relevant to ICM and CCCs and their activities may be available in a number of forms (eg., databases, reports, pamphlets, maps).

	None available	Very Useful	Useful	Neither	Not useful
How useful has information or data about the following Topics been to you and your CCC					
Catchment natural resources?.....	☐	☐	☐	☐	☐
Population and land use in your catchment?.....	☐	☐	☐	☐	☐
Local organisations, industry and community groups in your catchment?.....	☐	☐	☐	☐	☐

	None available	Very Useful	Useful	Neither	Not useful
Government institutional arrangements for ICM, Landcare, natural resources, and related issues?.....	☐	☐	☐	☐	☐
Government policies and regulations on natural resources and related issues?.....	☐	☐	☐	☐	☐
Options for funding of ICM and other community activities?	☐	☐	☐	☐	☐
Group management and administration?	☐	☐	☐	☐	☐
Other - please specify:					
....	☐	☐	☐	☐	☐
....	☐	☐	☐	☐	☐

Please list some of the most significant reasons why information has been useful/lacking?:

……

……

……

……

……

PUBLIC ATTITUDES AND RECENT DEVELOPMENTS

11. In your opinion, what is the level of public awareness about natural resource issues in your catchment? (please tick)

☐ very high
☐ high
☐ moderate
☐ low
☐ very low
☐ don't know

How has public awareness changed over the last year?

……

……

……

……

12. What level of public support do you believe your CCC has? (please tick)

- ☐ very high
- ☐ high
- ☐ moderate
- ☐ low
- ☐ very low
- ☐ don't know

How has public support for the CCC changed over the past year?

……

……

……

……

13. How effective has the involvement of the following groups been to the CCC?

	Very effective	Effective	Neither	Ineffective	Very ineffective	Not applicable
Rural producers (specify)	☐	☐	☐	☐	☐	☐
Rural industry organisations (specify)	☐	☐	☐	☐	☐	☐
Local government politicians	☐	☐	☐	☐	☐	☐
Local government administrators	☐	☐	☐	☐	☐	☐
State government politicians	☐	☐	☐	☐	☐	☐
State government agencies:						
DPI	☐	☐	☐	☐	☐	☐
DNR						
.....Forestry.....	☐	☐	☐	☐	☐	☐
.....Land Management	☐	☐	☐	☐	☐	☐
.....Lands Administration.....	☐	☐	☐	☐	☐	☐
Dept of Environment.....	☐	☐	☐	☐	☐	☐
Local Government and Planning.....	☐	☐	☐	☐	☐	☐
River Improvement Trust.	☐	☐	☐	☐	☐	☐
Drainage Board(s).....	☐	☐	☐	☐	☐	☐
Environmental organisations (specify)	☐	☐	☐	☐	☐	☐
The Media……	☐	☐	☐	☐	☐	☐
Landcare Groups.....	☐	☐	☐	☐	☐	☐

Other (please specify):

..... ☐ ☐ ☐ ☐ ☐ ☐

..... ☐ ☐ ☐ ☐ ☐ ☐

..... ☐ ☐ ☐ ☐ ☐ ☐

14. What could or should be done at state/local levels to improve the acceptance and involvement of relevant groups and the general public in your CCC process?

……
……
……
……
……
……
……

☐ **What types of involvement or linkages has your CCC had with Local Governments in your catchment? Pleas tick.**

☐ None

☐ Jint projects or activities

☐ CCC as a referral agency on natural resource issues/projects for local government.

☐ Local Government as a source of information/advise for the CCC

☐ CCC strategy development

☐ Local government planning schemes/strategy development

☐ Other (please specify).

……
……
……
……
……
……
……

Please list some of the significant reasons for and benefits/disbenefits of this involvement?

……
……
……
……
……
……

16. What have been some of the recent major changes (political, financial, economic, or environmental issues at local, regional or national scales) that have significantly influenced the CCC's efforts?

……
……
……
……
……
……
……

17. The implementation of ICM in this catchment is difficult because:

		Strongly agree	Agree	Neither	Disagree	Strongly disagree	Don't know
17a	The large size of the catchment (or poor transporation links between parts of catchment)	☐	☐	☐	☐	☐	☐
17b	The wide variety of values and beliefs among CCC members seriously detracts from an effective level of cooperation developing among them	☐	☐	☐	☐	☐	☐
17c	Some important constituency groups are not represented in the ICM process	☐	☐	☐	☐	☐	☐
17d	The perception that ICM has been forced on the catchment by the state government	☐	☐	☐	☐	☐	☐
17e	The lack of an effective level of interest by CCC members	☐	☐	☐	☐	☐	☐
17f	The public's lack of trust in state/local government-sponsored initiatives	☐	☐	☐	☐	☐	☐
17g	The public's lack of interest in community type activities	☐	☐	☐	☐	☐	☐
17h	The lack of financial resources within the community	☐	☐	☐	☐	☐	☐
17i	The lack of agreement among CCC members concerning its objectives	☐	☐	☐	☐	☐	☐
17j	The lack of agreement on feasible solutions	☐	☐	☐	☐	☐	☐

18. Rate your level of agreement with the following statements:

18a	There is a strong consensus among CCC members concerning CCC functions.....	☐	☐	☐	☐	☐	☐
18b	At CCC meetings, all CCC members participate actively.....	☐	☐	☐	☐	☐	☐
18c	The local ICM process effectively resolves resource conflicts.....	☐	☐	☐	☐	☐	☐
18d	The ICM process is responsive to local needs	☐	☐	☐	☐	☐	☐
18e	The CCC is solving the priority natural resource management problems in the catchment.....	☐	☐	☐	☐	☐	☐

PERSONAL DEMANDS AND MOTIVATIONS

19. On average, how many hours per month do you devote to ICM? **……Hours/months**

20. Identify your level of agreement with the following statements according to the following scale:

		Completely agree	Agree	Moderately agree	Disagree	Completely disagree	Not applicable
20a	The amount of time I devote to ICM significantly interferes with my own business/job requirements.....	☐	☐	☐	☐	☐	☐
20b	The amount of time I devote to ICM significantly interferes with my family commitments.....	☐	☐	☐	☐	☐	☐
20c	My involvement with the CCC causes significant out-of-pocket expenses	☐	☐	☐	☐	☐	☐
20d	I find being a member of the CCC personally rewarding because I can contribute to the community.....	☐	☐	☐	☐	☐	☐
20e	I find being a member of the CCC rewarding because I care about natural resource management.....	☐	☐	☐	☐	☐	☐
20f	I find being a member of the CCC rewarding because I can meet other members of the community who can influence resource management decision making	☐	☐	☐	☐	☐	☐

20g	A CCC's member's role is to provide their personal views on resource management issues at CCC meetings	☐	☐	☐	☐	☐	☐
20h	A CCC member's role is to represent the resource management views of their constituency group at CCC meetings.....	☐	☐	☐	☐	☐	☐
20i	A CCC member's role is to provide a catchment-wide perspective of natural resource management issues at CCC meetings.....	☐	☐	☐	☐	☐	☐

Chapter 4

ICM in Queensland 1990-1999: An Anthology

G.T. McDonald[1], J.A.Bellamy[2], K.J. McDonald[1] and S. MacLeod[1]

[1]Department of Geographical Sciences and Planning, The University of Queensland Q 4072
[2]CSIRO Tropical Agriculture, 306 Carmody Road, St Lucia Q 4067

Note: This publication is based on data and documentation provided with the permission of the Department of Natural Resources, Queensland (current as at 12/99).

Contents

1. Introduction and Explanatory Notes **115**

2. Integrated Catchment Management in a National Context **117**
2.1 National Whole Catchment Management – A Review and Analysis of Processes (S. Syme, J. Butterworth, B. Nancarrow) - extracts 119
2.2 The Way Forward: Barriers and Bridges to Progress in Integrated Catchment Management in Australia (G. McDonald) 139

3. Origins of ICM in Queensland **150**
3.1 Integrated Catchment Management: A Strategy for Achieving the Sustainable and Balanced Use of Land, Water and Related Biological Resources (Queensland Government) - Summary 152

4. Development of ICM in Queensland **158**
4.1 Integrated Catchment Management in Queensland - an overview and review (P. Rowland and D. Begbie) 160
4.2 Framework, Arrangements and Policy 169
4.2.1 Arrangements, Policy and Legislation 169
4.2.2 Funding 172
4.2.3 Related Land and Water Management Programs 177
4.2.4 Natural Heritage Trust – Operational Arrangements in Queensland. (Queensland Government) 183
4.2.5 A Strategic Analysis of Landcare and Rivercare Funding in Queensland 191
4.2.6 Catchment Management Strategies Guidelines 1995 202
4.2.7 Catchment Management Strategies Guidelines 1999 204
4.3 Progress
4.3.1 Catchment Coordinating Committees 215
4.3.2 What are the goals of a Catchment Coordinating Committee and What does a Catchment Coordinating Committee do? 215 216
4.3.3 Guidelines for obtaining endorsement and support funding for Catchment Coordinating Committees 216
4.3.4 ICM Groups in Queensland July 1999 217

5. Reviews of ICM in Queensland **221**
5.1 Review of Catchment Management Component of ICM Initiative(DPI 1993) 221
5.2 ICM Coordinators and Chairpersons Reviews 235
5.2.1 CCC – Mini Forum Maleny 235
5.2.2 CCC Forum Rockhampton 237
5.2.3 Inaugural Landcare and Integrated Catchment Management Annual Conference – Cairns 241
5.3 Enhancing the Effectiveness of Catchment Management Planning – Queensland. (AACM) 249
5.4 What You Told Us – A Survey of the Views or Queensland ICM Chairs and Coordinators and Herbert River Catchment Coordinating Committee Member – Part 2 ICM in Queensland: History and Intent " (G. McDonald and D. Shrubsole) 254
5.5 Summary and Synthesis 257

6. Landcare and ICM **259**
6.1 Landcare & ICM: Report and Recommendations Paper. Review of ICM and Landcare Arrangements. (Queensland Department of Natural Resources) 260
6.2 Interim Business and Operational Plan. January 1998-June 1998. (Landcare and Catchment Management Council) 271
6.3 Strategic Plan 1998 – 2001. (Landcare and Catchment Management Council) 277

7. Regionalisation **283**
7.1 Extracts from"Interim Guidelines for the Development of Natural Resources and Biodiversity Conservation Regional Strategies"(Queensland Department of Natural Resources) 284

8. Local Government **289**
8.1 Executive Summary from "The Local Government and Integrated Catchment Management Communication Plan" (Department of Natural Resources) 290
8.2 Integrated Catchment Management & Local Government Information Bulletin of the ICM and Local Government Planning Schemes Project (No.3 January 1999)"(Queensland Department of Communication and Information, Local Government and Planning) 292

9. Bibliography **296**

1. INTRODUCTION AND EXPLANATORY NOTES

This report is an anthology of papers on the origins and development of Integrated Catchment in Queensland over the period 1990 to 1999. The report consists largely of papers and extracts from documents that track the progress of this policy initiative and its implementation. There is relatively little new interpretative or critical evaluation provided by the authors here, although a number of extracts and papers included do provide critical evaluations.

Resource management in general and ICM in particular is a constantly changing policy area in government. Knowing what the current state of policies and programs in any region or state at any given time is a challenge. Legislation changes frequently as governments come and go, funding sources and levels of support vary from year to year (eg the NHT) and administrative arrangements are constantly restructuring. It is difficult to name another area of public policy subject to such variability over time.

The purpose of this report is to provide researchers, students and managers with a convenient source book of key reports and data to enable them to understand the historical evolution of ICM in Queensland. Many of the extracts included are from government policy papers, program publicity and evaluation studies that are not easily found now. Some of the papers here are from conference proceedings and other fugitive sources. It is important to note the essential historical nature of many of the documents included which describe policies or issues at a given time and may now be obsolete.

The anthology begins with a brief overview of the *national context* to show how the ICM program in Queensland (at least in 1997) compares with other states. At the time of writing a Commonwealth parliamentary inquiry into ICM was underway. The report and findings of this inquiry will provide essential reading when they become available.

Section 2 of the report contains a brief explanation of the *origins of ICM* in Queensland together with key elements of most of the policy paper released in 1991 that created the program.

Section 3 of the report contains documents and data that track the *development of ICM since 1991*. It includes an important progress report by Rowland and Begbie, two key agency staff involved in managing the ICM program almost since its inception. There is information on funding for ICM and reviews of related legislation and programs including the recently very important Natural Heritage Trust. Catchment Committee staff and members have met on a number of occasions to review progress and recommend improvements – summaries from their meetings are included here also.

Section 4 reproduces a significant part of the recently published Guide to Catchment Management in Queensland. It details the current *progress in the formation of catchment groups*, the key issues they deal with and their progress in catchment planning.

Section 5 specifically addresses the relationship between *ICM and Landcare,* based on a policy review paper on the topic and explanation of the structure and role of the Landcare and Catchment Management Council.

The final two sections focus on emerging directions of the ICM program – the development of regional strategies as frameworks for catchment planning and the adoption of catchment management by local governments.

ICM as practised in Queensland is a community based "bottom-up" process. It has bi-partisan support in state government but still has a fragile funding base. It has been a real time

experiment in locally based resource management and is in constant change. This report hopefully captures some of the key documents that show that process through time and can help provide a baseline for further informed development.

2. INTEGRATED CATCHMENT MANAGEMENT IN A NATIONAL CONTEXT

A river catchment is a naturally-defined natural resources ecosystem, characterised by a clearly-definable physical boundary, the watershed, determined by its hydrological and geomorphological history and established a natural barrier for many of the biological and physical processes at work within it (Burton, 1988: 43). Misuse of soils and water in a catchment will be clearly revealed in the waterways - the natural integral of land management – and human use must be managed to provide desired ends in water quantity and quality for other human uses and for the needs of in-stream natural life.

ICM has become a rallying point for renewed efforts in land conservation in Australia in recent years. Integrated Catchment Management is the integration of water and land management activities and the contributions of government agencies involved in these activities, within a catchment in a cooperative manner. For the purposes of this review we define ICM to be **formal** government policies, programs and laws for the management of land and water resources on a catchment basis. Of course many land use activities can be designed for better catchment outcomes without being defined as ICM.

In Australia, land use planning and natural resources management are State Government functions, undertaken by a range of conventional and essentially single-purpose agencies. All of the Australian States have adopted programs of integrated catchment management under a variety of names and using a variety of policy and legislative frameworks. In some states ICM is called Total Catchment Management (TCM) or Integrated Catchment Management. At present the application of ICM varies widely throughout Australia, with some states such as NSW having established legislation, whilst others such as WA and Qld have no specific legislative powers. In effect there have been six experiments running in parallel but as yet no dominant model has emerged.

There is a considerable literature on the principles and practice of ICM in Australia, most of starting with the NSW efforts to create Total Catchment Management in the mid-1980s. Key sources for tracking this development of ICM are the two National Workshops, the initial formative one held in 1988 and the other later in 1997 which provided a comparative reflection on structures, processes and performance. Other key references include Laut and Taplin (1988), Mitchell and Hollick (1993) and AACM (1995)

In this section, two papers of the study team authors are included, Symes, Butterworth and Nancarrow's 1993 review of ICM nationally and McDonald's keynote paper at the second national workshop on ICM held in 1997.

2.1 NATIONAL WHOLE CATCHMENT MANAGEMENT A REVIEW & ANALYSIS OF PROCESSES

S. Syme, J. Butterworth and B. Nancarrow

(Source: Extracts from Syme, S., Butterworth, J., Nancarrow, B. 1993. *National Whole Catchment Management. A Review and Analysis of Processes.* CSIRO Australia, Division of Water Resources, Australian Research Centre for Water in Society)

1.0 INTRODUCTION

The Land and Water Resources Research and Development Corporation (LWRRDC) in partnership with the Murray-Darling Basin Commission and the National Landcare Program established a national program on dryland salinity research, development and extension. The program seeks to develop a national response to dryland salinity that optimises the use and sustainability of natural resources.

To fully integrate and coordinate the program's activities, one focus catchment has been selected in each of the five mainland States. Outcomes and experiences gained in these catchments will be extrapolated to other regions.

The five focus catchments comprise the Loddon-Campaspe (Victoria), Liverpool Plains (New South Wales), Upper South East (South Australia), Upper Burdekin (Queensland) and Kent River (Western Australia).

In acknowledging that the management of salinity has to be considered within the broader context of whole catchment planning and management, a principal aim of the program is to foster the development and implementation of catchment management plans which are closely linked to State salinity and/or whole catchment planning strategies. The program intends to support activities related to the priorities and recommendations outlined in catchment management plans which have been developed at the community level with appropriate State agency assistance. Each of the five catchments are currently at different stages in developing such plans, with some not yet under way.

Related to these different stages of development are factors such as social history, environmental differences, socio-economic differences, variations in community cohesion and structure and differences in policy and institutional approaches between the States. One striking similarity throughout the country, however, is that the concept of Whole Catchment Management (or the equivalent concepts of "Integrated Catchment Management and "Total Catchment Management") is at a fledgling and relatively untried stage of development. Thus, as with any novel policy or approach, Whole Catchment Management is destined to undergo various teething problems and frequent processes of refinement and reassessment. Action at the grass roots level will be the major testing ground. Therefore, it is necessary to examine current approaches and the various institutional linkages from farmers to Government Ministers.

As part of the program, a framework which can assist the development of whole catchment plans is required. Of equal importance within this framework are mechanisms that can facilitate and provide continuity to the implementation, monitoring and evaluation of such plans. This report aims to outline such a framework.

Specifically, a study was undertaken in accordance with the following terms of reference.

(1) Assess different approaches taken nationally to prepare whole catchment plans, drawing conclusions as to the procedural requirements for each approach. Derive and compare common similarities and differences.
(2) Where relevant, consider how salinity issues relate to broader catchment management issues in these approaches and how they are dealt with.
(3) Consider what the role of the community has been in the process of preparing whole catchment management plans, how their participation has been fostered and what lessons are to be learnt.
(4) Develop a framework for the preparation of whole catchment management plans and make recommendations as to how the process of planning should be managed and what the roles and responsibilities of relevant stakeholders and agencies should be in the development, implementation, monitoring and evaluation of catchment management plans.
(5) Make recommendations as to how catchment management plans can be integrated into State-wide salinity strategies.

These terms of reference are addressed in the following sections of the report.

Terms of reference:

(1) and (2) in section 6.0;
(3) in section 7.0;
(4) in sections 8.0 and 9.0;
(5) in section 10.0.

No attempt has been made to compare the strengths and weaknesses of the different State approaches, as it was considered that this would be unproductive and meaningless. Therefore, in being predominantly concerned with the necessary processes rather than specific structures for whole catchment management, the recommendations, guidelines, roles and responsibilities in this report are tailored in such a way as to traverse the States' various structural arrangements. Consequently, any recommendations as to national structural requirements are along generic and needs-based lines.

Examination of case studies in each state are used to derive a number of general guidelines or "overarching principles". They are proposed as a means to streamline Whole Catchment Management from the farmer to Federal Government. Procedural and role criteria are identified for determining if the guidelines have been met and to form the basis for assessing progress from a national perspective. While recognising the differing needs and issues of catchments across the country, the guidelines are at a level of generality that is applicable in all contexts.

2.0 Methodology

The following investigative methodology was adopted.

2.1 Literature Review

A review of all available, relevant literature was undertaken. This involved an examination of documentation regarding the five focus catchments, as well as other areas nationally where the processes of catchment management are under way and would provide a range of both techniques used and progress made in relation to dryland salinity and whole catchment management. The review included:

- consultancy reports which have lead to the development of the National Dryland Salinity Program; draft and completed catchment management plans;
- any relevant government agency or research institution research/consultancy reports, or policy documents;
- any possible community initiated research/consultancy reports;
- any documentation of previous public involvement exercises or processes in each catchment and in other areas;
- literature on participatory environmental management;
- other sources, such as newsletters, brochures and booklets.

2.2 Telephone Discussions

Preliminary discussions were conducted with government personnel and community "leaders" to obtain an initial impression of catchment and dryland salinity management issues in each State and, more specifically, in the five focus catchments and other selected areas. When required, follow-up discussions were conducted to clarify issues raised.

2.3 Site Visits

The focus catchments (with the exception of the Upper Burdekin- see below) were visited to obtain a first hand impression of community/government relationships and interactions and community perceptions of the effectiveness of present dryland salinity and catchment management processes. Other areas in each state where the processes of catchment management are under way and considered relatively progressive were also visited. Catchments were also selected to provide a wide range of management approaches and on the basis of the issues being addressed, from the single issue of salinity management to multiple issues involving "whole-community" efforts.

Catchments were chosen in accordance with these criteria. Based also on time and budgetary constraints and from advice from people familiar with and active in the Upper Burdekin catchment, it was decided to omit the Burdekin from the intended visits. However, two catchment areas and the central office of the Department of Primary Industries were visited in Queensland to ensure that relevant issues were illustrated.

Where possible, each site visit comprised interviews on a group or individual basis with key government agency personnel and members of local or regional groups with a resource management focus. A number of field trips to demonstration sites and other areas of interest were also made to gain further appreciation of specific, catchment-based issues.

2.4 Previous Experience

Insights gained by the study team from past studies on catchment and land management were used to assist in the interpretation of comments from the interviews and phone discussions.

3.0 SCOPING WHOLE CATCHMENT MANAGEMENT

Integrated Catchment Management (ICM) and Total Catchment Management (TCM) are coordinated, community involved, whole of government approaches to natural resource management on a catchment-wide basis. The key components are public involvement, inter-government cooperation and policy and program coordination among state agencies such that the community and government work together to achieve sustainable, natural resource management. Importantly, effective catchment management needs to be considered as a long-term exercise, since it is necessary not only to address immediate problems but also to change organisational cultures, individual and community perceptions and attitudes and some traditional modes of operation (Mitchell, 1991).

As noted by Martin and colleagues (1992) ICM, TCM and associated activities such as Landcare, dryland salinity management and property or whole farm management planning are viewed throughout Australia under a "myriad of different names and perspectives". However, despite these differences, "the central thrust has been an appreciation of the need for a more integrated - and coordinated - approach" to natural resource management (p. 187).

Coordinated planning and action at all levels - including the Commonwealth, State, regional, local and individual land manager - is considered paramount chiefly because land degradation problems often transcend property boundaries. The actions in one part of a catchment can affect other areas in the catchment. Consequently, farms and other land holdings can no longer be managed as closed systems.

For the purposes of simplicity, when discussed in general terms in this document, ICM and TCM will be referred to as Whole Catchment Management (WCM).

In recent years, there have been many advances in the understanding of and action towards amelioration of land degradation by both farmers and State and Federal Government agencies. However, as a general summary, the need for WCM emerged, among other things, from concern about:

- continuing and increasing degradation of land, water and related resources;
- conflicting government policies;
- different agencies with statutory responsibilities leading to programs not always being complementary;

increasing public expectations for involvement in decision-making.

As the unifying theme for action, WCM is presented as a:

* **philosophy** - WCM needs to foster an organisational culture and associated attitudes which view cooperation and collaboration as essential. For example, authorities and groups need to be encouraged to work toward common objectives by consultation, responsibility sharing and joint financing.
* **process** - if WCM is to be effective, there needs to be a well understood planning and implementation process through which it is delivered. This should reflect the philosophy of WCM.
* **product** - the resultant plan or set of implementation guidelines will vary from place to place, depending on conditions and needs. Any guidelines should, however, incorporate environmental, economic and social considerations and should clearly relate to specific resource management outcomes.

Without guidelines and objectives, it is difficult to set directions, establish roles relevant to other programs and activities and monitor progress. However, in some quarters, the relatively late attention to defining what the product of WCM should be has contributed to a lack of understanding about WCM and a loss of enthusiasm.

Therefore, while WCM is regarded by many as a philosophical and overarching planning framework, in the long-term, an appreciable association of WCM with a product needs to be established. Essentially, the product of WCM needs to be the planning and implementation of sustainable agricultural practices, whether via Landcare or other means. In this way, landholders can contribute to WCM by initiating and maintaining action on the ground. Additionally, procedures outlining the means to achieve these desired ends, including detail as to how effective

participation may be achieved in practice must be articulated in accessible terms. Otherwise, landholders may fail to comprehend how WCM is translated into real and practical terms and, consequently, WCM will attain little validity within catchments.

The building blocks on which WCM is based must be made explicit and need to emphasise that WCM has philosophical, procedural and product components. Ultimately these building blocks need to become part of the culture of agencies and groups. These are as outlined by Hollick and Mitchell (1991):

(1) **A systems and integrated** (rather than comprehensive) **approach** in which attention is directed to the key issues (rather than all issues) and to the linkages among the key issues.

(2) **A stakeholder approach.** All stakeholders have to be acknowledged and given input into WCM on an equitable basis. For WCM to be successful, representatives of all stakeholder interests have to be brought to at least a minimum common level of understanding of issues, such as land use, degradation problems and constraints to adoption. Thus, there is a need to define standards for use of information (Webb, 1993).

(3) **A partnership approach.** This will require the search for and achievement of, common objectives in an efficient and equitable manner and decisions about the relative roles and power of stakeholders.

(4) **A balanced approach**. This will, for example, require the achievement of a balance between economic development, protecting natural ecosystems and satisfying social norms and values.

3.1 Relationship of WCM toTo other Policies and Strategies

WCM policy needs to be considered in the broader policy context. Parallel policy hierarchies do exist between Federal and State in relation to land, water and the environment. At the national level, for example, the National Conservation Strategy, the Agricultural and Resource Management Council of Australia and New Zealand (ARMCANZ), the National Soil Conservation Program strategy (NSCP) and Australian Environment Council (AEC) policies on land and water care provide broad, top-level statements of principle. Other major statements, such as the National Decade of Landcare Plan (NDLP), can be seen as derivatives, or frameworks for the implementation, of these principles. While there is no formal Federal WCM policy, the Government is pursuing this approach via its funding programs.

3.2 The National Landcare Program

The Commonwealth Government has a significant role in providing leadership and overall direction for WCM. For example, Commonwealth policies, legislation and strategies impact on State priorities and community attitudes and behaviour. In particular, as a coordinating and facilitating mechanism, Commonwealth funding programs (aimed at sustainable resource management, conservation and long-term productive capacity) have a motivating role in focusing community and State Government action.

At the national level, the Commonwealth Government has used the NDLP and the Commonwealth funding program, the National Landcare Program (NLP), as a vehicle to influence the policy environment, help control land degradation and promote sustainable land use. The NDLP emphasises the need for an integrated approach to resource management and collaboration of all levels of government, industry groups, community groups and individuals. This undertaking encourages groups of people to work together in their local area and emphasises that "land" includes a whole ecosystem. Notably, many Landcare groups form around a single issue, but often move towards a more comprehensive outlook as they develop. This is also a practical progression as Commonwealth funding is more likely for overall strategies than for individual projects or single resource solutions.

Ultimately, the actions of Landcare groups and individual farmers will make the biggest difference to rural land. Groups, however, have differing strengths and varying needs. Group needs may also change over time as groups progress through different developmental stages. Options to help establish and maintain groups includes direct support such as technical advice and assistance, while others include encouraging the establishment of networks of Landcare groups. Funding also facilitates work that would otherwise be beyond the scope of many groups (NSW Interim Decade of Landcare Plan, 1992).

Also at the national level, opportunities exist for providing coordination and skills transfer. These include, the development of procedures for social and economic assessment of salinity (and other resource) management options, the development of decision support systems and a general framework for communication across groups (Webb, 1993). In addition, Mitchell (1991) recommends that regular exchange among WCM State representatives could help to avoid problems or become aware of other approaches to resolving problems.

3.3 The Development of WCM

Development and implementation of the WCM concept has encountered mixed fortunes and some basic problems continue to obstruct general progress at the government and institutional level. Two main concerns are:

- resistance by government agencies to a truly integrated approach;
- lack of adequate resources to finance the development and implementation of WCM strategies.

On the first point, Hollick and Mitchell (1991) highlight a strong sentiment within the agricultural industry that WCM should essentially be community-based and locally managed rather than a top-heavy structure. However, some government agencies and staff may still possess ambivalence toward public involvement, being unconvinced of its value and often seeing it more as an encumbrance. It is also important at this time to remember that (often for good historical reasons) local communities may hold suspicion and cynicism about the motives and objectives of government agencies, making it difficult to develop solid working relationships. One of the reasons for this is the long history of expert-layperson interaction that has dominated extension services and general government programs in Australia.

According to Martin and colleagues (1992), the quality of interaction between rural people and bureaucracy at the local level varies considerably and involves a number of complex factors. This may depend on the attitudes of local extension officers, the commitment of regional bureaucracy to Landcare and WCM, local perceptions of the State and the motivations of people for forming or joining groups. However, "the historical technocentric and scientistic orientation of the government agencies involved in resource management impose significant barriers to the recognition of rural people as competent partners in resource management. Whatever reasons ultimately lie behind the adoption of TCM and Landcare, unless government agencies are sensitive to the logic of the participatory process, the results of their overall actions... may not yield the desired outcomes " (p. 190).

On the second point, Synnott (1991, p.42) argues that a basic impediment to the progress of WCM in Australia has been "lack of adequate resources to finance the development and implementation of WCM strategies". Hence, it is essential to consider what resources are needed to facilitate the implementation of WCM objectives as it is pointless and counterproductive on many occasions to develop plans which cannot be implemented in the foreseeable future. This question, however, cannot be addressed until WCM priorities are clearly defined.

Hollick and Mitchell (1991) suggest to determine financial and other resource needs at the State level, it would be advantageous to conduct analyses of the needs in priority catchments. This has been the approach in several States and now nationally. Included should be consideration of the need for and costs of providing:

- incentives for landholders to adopt conservation measures;
- administrative support to catchment-based community groups;
- compensation to individuals to cover costs of participation. The analysis could, for example, consider opportunities for joint Commonwealth-State initiatives in areas such as taxation (Hollick and Mitchell, 1991).

With particular reference to dryland salinity management in Australia and from his review of the five focus catchments in the National Dryland Salinity Program, Webb (1993) highlights a number of pressing problems with current initiatives. These are:

- much of the technical expertise required is already heavily committed;
- limited resources;
- fragmentation of research;
- lack of continuing involvement from agencies, groups and individuals;
- the lack of development of R&D outputs into practices which can be integrated into production systems;
- the general perception existing in all states that the likely success of salinity management depends on the extent to which it is based on economically attractive production systems.

Difficulties also remain in comparing individual programs and discriminating good WCM from bad WCM. On this point, financial viability and adequate resourcing have been proposed as possible tests of successful WCM and at least provide some indication of political and community support. However, by itself, availability of resources is an inadequate measure of WCM success because it raises the issue of "how much is enough" (Synnott, 1991).

Despite the attention to resources paid by the above authors, a social response (rather than an economic or government intervention) model, which seeks to shape public attitudes through persuasion rather than prescriptive direction, currently dominates WCM in Australia. The dominance of this model may explain the proliferation (but hardly coordinated) range of individual programs. These include national programs for soil conservation, salinity management, water management and afforestation. As vehicles for directing the response of different interest

groups, this distribution of programs makes sense. While the diversity ensures that there is something for everyone, a more focused approach to WCM might create greater coherence in the use of public resources and, thus, encourage more even progress in a holistic sense.

In summary, there is a widespread conviction that the management of specific issues such as dryland salinity should not be viewed in isolation, but undertaken within an integrated planning framework on a catchment scale. Such an endeavour should acknowledge the complexity of dryland salinity management and include comprehensive environmental, economic and social assessment. To this end, the Dryland Salinity Management Working Group (1993) recommended that dryland salinity management be projected as an integral subset of WCM and as being related to other resource-use and degradation issues.

As an aid to distinguishing WCM, Landcare and dryland salinity management, all three components can be presented within the general model shown in Table 1.

In conclusion, WCM, which has central aims of maximising stakeholder involvement and fostering community empowerment, is presently considered the most effective means of coordinating and overseeing initiatives such as dryland salinity management and Landcare. However, its apparent strengths notwithstanding, WCM appears to have had limited application as a means for the complex management of natural resources. To date, it has mainly been used as a vehicle for community awareness programs. For instance, all planning and policy documentation which has been produced endorses participation, but provides little detail as to how it may actually be achieved in practice (beyond structural changes that allow rural people more say in decision-making). Across Australia, in both WCM and Landcare, the challenge still remains of reconciling "top-down" provision of funds and services, with a "bottom-up" direction of work on the ground.

Ultimately, the success of WCM depends on committed support, solid leadership and major changes in established social and bureaucratic actions in resource management. Most importantly, to maximise the adoption of sound remedial measures, the facilitation of maximum (and sustained) community awareness, acceptance and ownership of WCM objectives should be the underlying principle in the plans and implementation strategies for each catchment.

Table 1
Distinguishing WCM, Landcare and Dryland Salinity Management

COMPONENT	POSITION
WCM	*Catchment focus/ecology centred:* - An "overall umbrella", systems approach to planning.
WCM Charter	- To encourage plans from local to State levels to be developed according to WCM guidelines.
WCM Program	- To encourage processes and implementation of sustainable agricultural practices according to WCM philosophy.
Landcare	*Sub-catchment focus/people centred*: - the landcare ethos is about caring and "close management" of the land through encouraging the formation of groups of people who share a common natural resource problem and who live in the same catchment; - Landcare is the vehicle for implementing whole catchment plans.
Dryland Salinity Management	*Problem focused and centred*: - Salinity is often the most pressing and manifest problem to focus on; - In many instances, often for expediency, a focus on salinity has acted as the impetus for group formation, fund raising, planning and action. In many of these areas, structures and processes are now in place to relate to and deal with broader issues. Additionally, while a focus on salinity may be framed singularly, environmental issues are interrelated and the operational issues and benefits of salinity management broaden out to encompass other concerns.

4.0 CATCHMENT DEFINITION

As experience in a number of the areas visited during the study has shown, the definition of catchments purely in geographical terms may act to the detriment of achieving WCM. Indeed, if the majority of landholders do not recognise or perceive the existence of a "catchment-based community" or "regional" community, coordinators, group leaders and the like will be hard pressed to achieve the collaboration and support that is required for WCM to be effective.

Essentially, it is important for people to organise themselves in ways they consider to be comfortable or acceptable. Group organisation will be less than optimal (and possibly non-existent) if this is not the case. For example, in Section 9.0, the local context is characterised at a sub-catchment or catchment level in which the local community can be easily defined by common interest or a clear environmental variable such as soil type. Without these clear similarities, allowance will need to be given for a time-lag between the initial stages of developing awareness of the catchment-based nature of WCM and its application. To instigate programs, it may therefore be more advantageous to define catchments according to social as well as physical parameters and to examine the interplay between the two. In this respect, the "measurement of community" (defining the natural, existing boundaries of communities, based on variables including common interest and the local acceptability of any suggested community boundaries) has merit in determining the likely response to WCM as a feasible concept within each catchment.

The complexity of achieving a national response to dryland salinity management through a whole catchment management framework is also highlighted by noting that different communities will react differently to policy initiatives (Branch, 1984) and that some communities will deal with change better than others (Ayres & Potter, 1989). The assertion that different approaches are needed for different areas also indicates that general recipes for community participation are unrealistic (Wilkinson & Barr, 1993) and that there is a need to better account for cultural, economic and regional differences between and within communities.

The clear messages here, therefore, are that:

- Communities are not static nor passive recipients of policy initiatives;
- In many, if not most, instances, communities are not formed and do not function according to prescribed catchment lines. Landholders and other stakeholders can at best be ambivalent toward the concept of whole catchment management if they are largely unaware of the catchment they live in. Additionally, many farmers still regard Landcare as "green", so how, during a rural downturn, will they react to the more ambiguous or sketchy concept of Whole Catchment Management?;
- To assist the development of Whole Catchment Management as an ethic and a component of farm management, catchments need to be defined in social terms. Accordingly, at this early stage in the evolution of resource management on a whole catchment basis, it may be more productive for stakeholders to work with naturally formed communities and groups rather than groupings of people based on geographical criteria;
- In line with the above points and complex environmental realities, Whole Catchment Management must be viewed as a long-term exercise. Expectations and goals need to be couched in realistic short to medium terms so that progress towards WCM can be measured and appreciated by stakeholders.

Looking ahead, community development will need to be integrated if resource management within catchments is to be integrated (Chamala & Mortiss, 1990). As a general classification, the development needs facing catchment-based communities or groups can be seen as two interdependent but distinct problems.

- To gain access to resources outside the catchment, such as government programs, sources of financing and technical information.
- To develop the capacity of persons within the catchment to work together to pursue common goals. In part, this will entail developing structural and organisational capacities to effectively access outside resources. Moreover, it will involve increasing the capacity of those within the defined community and area to develop their own potentials (O'Brien, Hassinger, Brown & Pinkerton, 1991).

In summary, the social dynamics operating within rural communities may act to facilitate or impede efforts to achieve sustainable approaches to resource management. As a logical extension of physical planning research, research of a community nature can enrich the information and knowledge about communities, including existing constraints to change and factors that may facilitate change (Nowak, 1992). In short, catchment planners, coordinators, agency personnel and others need to give attention to defining catchments in social as well as environmental terms.

5.0 THE STAKEHOLDERS

Achieving WCM is dependent on the coordinated activity of a variety of groups with particular values and interests. It is essential therefore that these interests are defined and incorporated in the principles and procedures of WCM.

Laut (1992) stated that "the key to successful catchment management lies in the development of suitable political/administrative structures to allow catchment communities and state agency personnel to collaborate in the development of regional catchment management policies and their implementation". Many authors have also emphasised the importance of a coordinated approach to community analysis to achieve WCM (eg. Martin et al, 1992; Syme, 1992). Community cohesion will best be created through planning mechanisms which enhance the aspirations of stakeholders as much as is possible.

It must be emphasised, however, that the labelling of the stakeholders presented here is little more than stereotypical. There are, for example, substantial differences in the attitudes, values and modes of operation of differing Landcare groups or Local Governments, as will be shown in the review of current procedures. There are also many people who have multiple roles, especially in rural communities. Nevertheless, the categorisation does provide an aide in considering the human resources available. For example, many tend to assume that WCM is primarily the concern of the farming community and the government alone. To do so is to ignore the potential contribution of Local Government, urban dwellers, conservation groups and others. **Whole Catchment Management is a Whole Community Issue**.

However, it is important to state that, since the landholder has primary immediate responsibility for sustainable land management, there is a necessity for WCM programs to assume that the public good is well served by making it as easy as possible for the landholder to achieve this. In this sense, the landholder may be considered as a *central client* for the WCM process.

The following are the stakeholders who need to be considered in the derivation of a WCM approach. There has been no attempt to ascribe values to each group, but their desirable roles are examined in relation to specific procedures in later sections.

a) The Community

- Individual Landholders
- Local Landcare Groups
- Catchment Groups
- Local Government
- Urban Dwellers
- Conservation Groups
- Community Interest Groups (eg. Farm Improvement Groups, Service Clubs)
- Industry (including industry associations)

b) Institutions

- Schools
- Universities/TAFE/Agricultural Colleges
- Research Institutions (eg. CSIRO)

c) State Government

- Local/Regional Public Servants
- Head Office Public Servants

d) Federal Government

- Relevant Federal Government Departments' Public Servants

e) Politicians

- State and Federal Government Politicians

A note should be made here about the classification of Local Government. Although it can be logically categorised as a third level of government, its significance, in WCM terms, is that it can, and often does, provide a local focus and catalyst for catchment issues. It also has the potential to act as a coordinator of available resources and is a natural body for any local revenue raising, should it be deemed necessary. Already, therefore, Local Government is a highly significant stakeholder. As its role is widened, as is currently the trend, more Local Government influence and involvement may be expected and encouraged. This widening of the role has been to bring Local Government closer to the community.

6.0 THE STATE APPROACHES

6.1 Victoria

WCM appears largely to be lead by salinity management in Victoria, although activities associated with salinity management have come to address wider environmental issues. In fact, salinity management in Victoria is the most organised and advanced in Australia (Webb, 1993) and, after WA, Victoria has had the longest experience in dealing with salinity issues. In addition, due to the early onset and recognition of dryland salinity and the progressiveness of its salinity program, many aspects of the Victorian experience are widely drawn upon by other States.

Resolve to tackle problems in a comprehensive manner stemmed from community criticism of earlier salinity management approaches in Victoria and the realisation that imposition of technical solutions through Government action had been inadequate. This led to the release in 1987 of the Conservation Strategy for Victoria, the creation in 1988 of the Victorian Government Salinity Control Program and a detailed Salinity Control Strategy (known as "Salt Action: Joint Action") in which the community has a major role in developing salinity management plans for the State's catchments and irrigation districts. The philosophy behind the program is that salinity management cannot succeed without active, local community involvement and support, with the latter being considered likely to come from community input to plan development.

The three key agencies in the Salinity Program are the Department of Conservation and Natural Resources (DCNR), the Department of Agriculture and the Rural Water Corporation. While not the "lead" agency, DCNR has acted as the coordinating agency in dryland areas. The concept of integrating land and water management has a fairly precise meaning in Victoria following the formation of the DCNR in August 1990. The department includes environmental planning, water resource management and fisheries and forestry management. Ultimately, the Salinity Sub-Committee of Cabinet has responsibility for salinity management. The Landcare program is currently being held within by the Ministers for Naturl Resources, and Conservation and Environment, although efforts are being made to broaden this out to include Agriculture through the Salinity Sub-Committee (or equivalent).

The Salinity Bureau (situated within the Department of Premier and Cabinet) has an overall role in the ongoing coordination and implementation of the Salinity Control Strategy (SCS). The rationale for this institutional development was to locate a body within a "neutral" department (separate from the 3 key agencies), with direct links to the Premier and Cabinet and with some prominence within the structure of government. This includes an "independent" and guaranteed budget. While its positioning has often been contentious, the Bureau has maintained a central role in setting budgets and provide an independent source of information for the rural community. The Salinity Bureau has, however, been criticised by some for having insufficient authority and staffing to adequately undertake the monitoring role envisaged by the SCS and ensure that Strategy objectives are met (Special Report No. 19: Salinity, 1993).

As part of the SCS, the State has been divided into nine "salinity regions" and eight sub-regions in dryland areas, within which land management units have been identified and used as the basis for planning. In this way, the SCS provides the basis for simplifying salinity management and for preparing salinity management plans at the sub-regional, regional and State level. As outlined in the Strategy's framework, these plans are developed by community-based working groups, such as the Salinity Program Advisory Committee (SPAC), which receive technical input from relevant agencies. During the planning phase these working groups have been fully funded by the State. As a gauge of community influence in the SCS, SPACs, or their equivalents, have been required to review and determine the R&D program for their regions.

The basis of the planning process involves a comparative economic, environmental and social evaluation between a "no intervention" option and a series of options including planning horizons and costs and benefits. In addition, the dryland planning process typically identifies and maps areas with similar geological and hydrogeological features and salinity characteristics, termed "Land Management Units" (LMUs). Common groupings of salinity control options are developed for the same LMU classification.

Developed for each region and sub-region of the State, each plan involves a thorough process extending over two or more years. After the relevant plan is endorsed by Government, the implementation phase is expected to extend conceivably over a period of between 10 and 50 years, highlighting the long-term nature of the Program (Special Report No. 19: Salinity, 1993).

It is important to note that dryland salinity in Victoria, Western Australia and South Australia has tended to be treated as a separate entity, whereas in Queensland and New South Wales salinity is regarded as one of several forms of land degradation. There do appear to be some benefits from this more general approach of Queensland and New South Wales, including more correspondence with initiatives of the Decade of Landcare (Dryland Salinity R&D, 1992).

In Victoria, management linkages between salinity and other forms of land degradation has not been overly clear and until the NDLP initiative in 1989 (and subsequent release of the Victorian Decade of Landcare Plan), salinity, in particular irrigation salinity, was the primary focus of concern. Processes of integration between salinity management and other Landcare concerns (and thus, a movement or `evolution' towards an ICM approach) are presently under way, with the Victorian Landcare Plan aiming to build on the SCS, with salinity management becoming a subset of Landcare. In this way, the Victorian Landcare Program is seen as the focus for all resource management program activities.

As a consequence, a State-wide coordinating body - the State Landcare Committee - has been established. Further, it is required that Regional Landcare Plans be developed for each (salinity) region in the State. Presently at, or nearing the completion stage, plans have been developed collaboratively between participating agencies and non-government regional communities, with the DCNR acting as lead agency. The intention has been to build on and incorporate existing information, such as the regional salinity management plans, as a means to formulate an overall (and more integrated) strategy for land and water management at the regional level. At the same time, salinity management approaches can use the Landcare plans to address and include other issues where relevant. Among other things, the Regional Landcare Plans provide consideration of:

- catchment processes;
- implementation targets and responsibilities;
- recommendations for ongoing coordination and review/upgrade;
- possible community advisory structures;
- the need to encourage greater community participation and stronger community networks;
- the roles and responsibilities of agencies ;
- the need to encourage greater sharing of resources between agencies;
- priorities for resource allocation;
- regional Landcare boundaries;
- interface issues with adjacent regions.

The Landcare plans provide a more general overview than the salinity management plans and were developed over a shorter period. As noted in the Goulburn Regional Landcare Plan (1993) the aims are "to set future directions for Landcare activities, to set the scene for on-going community involvement and the future allocation of resources... and to advise the Government on appropriate administrative and community consultation arrangements". Accordingly, the Avoca-Loddon-Campaspe plan aims to "propose how the community's values and desires can be determined and acted on by government departments". In addition, "the plan brings together the excellent work prepared by salinity community groups and suggests a natural progression to the community's management of all Landcare programs for the catchment".

These Plans also outline the establishment of a Goulburn-Broken ICM Council and Avoca-Loddon-Campaspe Regional Landcare Council, with both having the responsibility for ongoing community consultation, coordination and plan implementation. The Councils would be responsible to the State Landcare Committee and comprise a community-majority representation. It has also been recommended that the Councils undertake some roles previously held at the State level.

To summarise the complementary linkages between Landcare and dryland salinity management, the new Regional Landcare Plans recommend that all existing plans will retain their integrity and will not be affected. In effect, the Regional Landcare Plans will provide a framework within which other plans can operate. Provision may also be made for the role of salinity working groups to appropriately be extended to incorporate a regional Landcare support role. For example, in the Goulburn region, the new Dryland Program Group is seen to replace the SPAC Dryland sub-committee, while the overall SPAC maintains a focus for the development and implementation of programs.

In addition to these developments, "Catchment and Land Protection" legislation has been proposed (a discussion paper has been released for public comment and a draft Bill will be presented to the spring session of Parliament) that seeks to integrate the Soil Conservation Act (1958) with the Vermin and Noxious Weeds Act (1958). Such a proposal has occurred through the acknowledgment of the role of the community in natural resource management

and is seen as a means to review and update legislation and to achieve a catchment-based, "whole systems" approach across the State.

Highlighting the continuing coordination of policy and the movement toward catchment-based responses to salinity and other resource management concerns, it is noteworthy that the current Victorian Water Policy advocates an integrated catchment perspective and approach to water and salinity management. Additionally, the Water Act (1989) compels the water authorities to consult with "Catchment Coordinating Groups". (Special Report No. 19: Salinity, 1993).

A number of concerns, however, have been raised about the increase in the number of different initiatives operating at the State level. For example, it has been suggested that an ICM legislative framework is unwarranted and unwise at this time and, at best, is catch-up legislation to a strong community-led approach. In the words of one interviewee, "it's a process looking for a reason and will remove power from the community-based advisory approach". The existing approach is seen to be evolving naturally from an initial single-issue focus to a more comprehensive and integrated form. Thus, achieving ICM is essentially a developmental and long-term process, rather than a prescriptive one.

Secondly, there is widespread opinion that if legislation is considered appropriate, it should only outline the means to formally endorse a coordinating structure and ensure stakeholder representation. Thus, ICM should not require an exacting organisational form but be presented more as a principle or philosophy. In addition, ICM legislation may not provide the panacea for resolving all problems and there may still be a number of procedures to undergo in order to spell out some of the issues, such as the degree of legislation being proposed, more thoroughly.

6.2 New South Wales

Endorsed as a NSW Government policy in 1987, Total Catchment Management (TCM) acts as the umbrella administrative framework for natural resource management in the State. In 1989, a Catchment Management Act was passed in NSW, providing a formal structure and statutory basis for the coordination of TCM. The Act defines TCM as the coordinated and sustainable use and management of land, water, vegetation and other natural resources on a catchment basis so as to balance resource utilisation and conservation. The lead agency for TCM is the Department of Conservation and Land Management (CaLM). CaLM and the Department of Water Resources (DWR) share responsibility for the management of dryland salinity. Responsibility for administering the Catchment Management Act lies with the Minister for Land and Water Conservation.

Like ICM, the two broad objectives of TCM are to ensure that natural resources are managed by coordinating policies, programs and activities and to achieve active community participation. Similarly, the underlying emphasis of the TCM process is to foster a solid working relationship between community and government. Under the Act and with input from the NLP, provision has been made for three components or levels of coordination. These comprise:

(a) Local Action
Local (usually Landcare) groups address "common" natural resource management issues. Such groups currently number over 400 in NSW.

(b) Regional Action
Regional Catchment Management Committees (CMCs), Catchment Management Trusts and Landcare coordinators and facilitators (funded by NLP) provide oversight and coordination of TCM policies and programs at a regional, or entire river valley level. As mentioned in the Interim Decade of Landcare Plan for NSW (1992), there is some cooperation and informal links between Landcare groups and CMCs (open discussion and communication are encouraged by CMCs), but CMCs have no direct control over the actions of Landcare groups, which are considered as independent (farmer based and farmer controlled) bodies. However, a primary objective of the Interim Plan is that the establishment of CMCs will greatly assist the planning and coordination of Landcare initiatives within regions.

Regional strategies prepared by CMCs form blueprints for action at the regional level. CMCs also coordinate the preparation of programs for funding; facilitate related research; assess funding requests from Landcare groups and monitor, evaluate and report on the progress of TCM plans and strategies. All agencies' roles continue but are coordinated by the CMCs.

CMC membership and participation is voluntary. The CMCs (and Trusts) are made up of community and government members who live and work in the region for which they are established. They consist of a majority representation of landholders (TCM Annual Report, 1991-92).

Catchment Management Trusts are established by the State Government when natural resource degradation within a particular region is deemed to be adversely affecting local communities. As corporations, Trusts are required to prepare a corporate plan containing a written scheme of the strategies and programs they intend to implement. To fund these initiatives, they also have the authority to levy rates on all land within a Trust area declared to be a "catchment contribution area".

(c) State Action

A State Catchment Management Coordinating Committee (SCMCC) provides the central coordinating mechanism for the implementation of TCM throughout NSW. In endeavouring to bring a State perspective on regional issues, the committee coordinates the establishment and operation of the CMCs and liases with the Catchment Management Trusts. Its structure, comprising community, CMC, industry, environmental, Local Government and State agency representatives, is intended to be flexible and needs-based. The SCMCC is responsible directly to the Minister for Land and Water Conservation regarding rural issues and to the Minister for the Environment for urban issues.

A number of subcommittees, including the Salt Action Task Force, the Natural Resources Programs Coordinating Subcommittee (NRPCC) and the Landcare Working Group assist the SCMCC. For example, "Salt Action", the NSW Salinity Control Strategy (a 5 year program released in 1989 and a component of the TCM Program) provides coordination at a State level, operates (through CaLM) on a regional basis and promotes community involvement in salinity management. The Salt Action task force comprises representatives from NSW Agriculture, DWR and the Environmental Protection Authority. This State initiative has been supplemented by funding programs such as Natural Resources Management Strategy for the Murray-Darling Basin (NRMS) and the National Soil Conservation Program (NSCP).

Additionally, while there is no formal or direct link between Landcare and TCM, the Landcare Working Group has the roles of planning for the Decade of Landcare and developing and monitoring Landcare policy and activity respectively. A State Landcare Coordinator and a Decade of Landcare Coordinator assist in this regard.

The NLP operates within the TCM framework and provides input into TCM by acting as the central funding mechanism for components of the NRMS, the Save the Bush Program and the One Billion Trees Program. Under the NLP, local community and agency applications for funding are reviewed and prioritised by the relevant CMCs and the NRPCC. Final assessment and recommendation for funding is made annually by a State Assessment Panel which is made up of all CMC Chairs and all members of the NRPCC. In addition, the SCMCC is currently in the process of developing a draft State Strategy for Natural Resources Management. This is intended to assist the coordination of TCM efforts and enable funding priorities and project selection criteria to be set under the NLP.

Another important aspect of TCM is the role of Local Government in the implementation of TCM. The need for Local Government representation in formal TCM processes is highlighted when noting that Shires are responsible for development control in their area. They prepare local environmental plans and allocate land for particular purposes. They are also responsible for the construction of roads, drainage systems and amenities and must ensure that land degradation and pollution are avoided.

However, a number of critical problems with TCM, many based around under-resourcing, have become manifest. Notably, there appears to be a thin spread of technical support at the local level. Additionally, the SCMCC has shown concern about the resourcing of TCM and the proliferation of CMCs pursuing statutory status. Martin and colleagues (1992) also highlight the criticism that, unlike Landcare, the development of TCM policy has been limited mainly to NSW Government initiatives. TCM and Landcare have also lacked integration at the centralised policy level. As a result, the TCM concept is often viewed with suspicion and/or confusion by many rural people. As noted, "at the interface of government agencies and the community within TCM and Landcare there emerges the contradictory nature of bureaucratic practice within a policy of participatory environmental management" (Martin et al., 1992, p. 190).

The economic rationalisation policies of the Liberal-National Government in NSW are also considered problematic by some for TCM at the regional level. For example, CMCs -where the major policy initiative is placed - receive a meagre allocation of resources for coordinating natural resource management. As argued, "the State Government wishes to shift responsibility for environmental management towards rural people at the regional level but seems unwilling to supply the resources needed" (Martin et al., 1992, p. 203).

6.3 South Australia

The lead agency with the major operational responsibilities for dryland salinity management in South Australia is the Department of Primary Industries (SADPI). Other contributing agencies include the Engineering and Water Supply Department (EWS), the Department of Mines and Energy and the Woods and Forests Department. The SADPI also has the responsibility for the NDLP, with the State Landcare Plan (1992) being coordinated by its Soil and Water Conservation Branch. Dryland salinity is considered a component of the Landcare Plan and it is coordinated with other agencies through the State Dryland Salinity Committee (DSC).

The DSC was established in 1989 as the main coordinating body for dryland salinity management in the State. Following on from the development of the South Australian Salinity Program by the SADPI, a Technical Strategy formulated and released in 1990 by the DSC forms the basis for the dryland salinity component of the State Landcare Plan. The Strategy is funded by the relevant agencies and through additional sources including NRMS, NSCP and LWRRDC.

Both the DSC and the Technical Strategy have accelerated the implementation of the Salinity Program, given limited resources (PDP Australia, 1992). The committee is chaired by the SADPI and comprises representatives from the relevant agencies, CSIRO Divisions of Soil and Water Resources and the University of Adelaide. Included in its terms of reference is to:

- develop and oversee the implementation of a strategy aimed at minimising the impacts of dryland salinity on the State's soil, water and vegetation resources.
- ensure efficient resource allocation by maintaining a coordinating mechanism between relevant government bodies.
- provide a coordinating role for organisations and agencies and a priority-setting role for funding proposals.
- promote discussion on planning and technical issues.
- ensure effective community collaboration and education.

As outlined in the State Soil Conservation and Landcare Act (1989), planning and management of natural resources in South Australia is founded primarily on a regional basis, with the emphasis on "district" planning within Soil Conservation Districts. Covering the entire area of the State and aligned along Local Government boundaries, each district is under the jurisdiction of Soil Conservation Boards (SCB), comprised of representatives from Local Government, State agencies, industry and the community. Links may also exist between SCBs and (more localised) Landcare groups.

In having the responsibility for soil degradation issues in their district, each SCB is required to prepare a soil and/or water conservation plan for their district within five years of becoming listed as a Board. This involves providing an outline of the key land-use issues and, finally, recommending `best-bet' work programs for managing dryland salinity and/or other problems such as water erosion and wind erosion. At the level of government, the Soil Conservation Council (comprising community and government representation) oversee the formation of Boards, review draft conservation plans and advise the Minister for Primary Industries. The Natural Resources Council (NRC) is the peak body (one under cabinet) and comprises CEOs of all land-use agencies and chairpersons of the land-use councils; the Soil Conservation Council, Water Resources Council and Native Vegetation Council. Notably, the NRC has acted as the proponent of the management plan developed for the Upper South East region.

There is presently no formalised structure or recognised process for WCM in South Australia (no natural resource management plans have specifically been termed "WCM" plans). In fact, it appears that only catchments in the Adelaide Hills area are considering resource management issues on a catchment basis. At this time, the future development of an WCM model for the State depends largely on the outcomes from this area.

Currently, the potential for WCM lies with largely uncoordinated systems and structures, such as government agencies (eg., the Department of Environment and Natural Resources, SADPI and EWS), SCBs, Drainage Boards, Water Resources Committees, Local Government and the community. In particular, to achieve a uniform response to whole catchment management issues State-wide, a more unified government view and commitment is required. Agricultural, water and environmental interests in government need to be integrated and coordinated. It has been argued that, on their own, technical solutions to salinity and other catchment problems will falter without this broad vision.

In summary, in assessing the potential for South Australia to develop a whole catchment management framework, a number of issues have been identified. These are as follows.

- Implementation of plans largely depends on organisation and funding. It has been suggested that funding arrangements are geared to integrate the three levels of funding (Commonwealth, State and Local). In particular, State commitment is essential, especially in initiating the beginning stages of implementation.
- While possessing some legislative authority, Soil Conservation Boards are hindered in their actions by under-resourcing. Consequently, local community representatives seem to be overwhelmed by the tasks set them to the extent that the boards are not functioning anywhere near full potential.
- As a means to further develop a regional and more comprehensive focus for natural resources management, there appears to be advocacy for the establishment of Regional "Natural Resources" Boards. This would provide a means of pooling expertise and integrating a number of (seemingly unrelated) regional planning strategies.
- As is occurring in other states, recent widespread and ongoing changes in State Government and bureaucratic structures are creating a good deal of concern. For example, the amalgamation of State agencies (reduced from 30 to 12) appears to many to be based more on economies of scale than a philosophy of agency coordination. Major staff cutbacks and difficulties with defining the functions and operations of new departments are also occurring. Apart from issues surrounding centralisation and job security, the question has arisen as to how these moves will act in the interests of developing resource management approaches based on responsiveness, long-term commitment and adequate resourcing.

6.4 Queensland

Responding to community interest and building on the foundation created by the NDLP, the Queensland Government launched an ICM Program in 1990 as part of the Natural Resources Management Program. In 1991, a State Steering Committee (comprising representatives of rural industry organisations, community and conservation groups, Landcare groups, River Improvement Trusts, universities, local authorities and government agencies) was formed to develop a Program and Strategy for ICM, which were released in October 1991. Although foreshadowed in the Strategy (and currently being reviewed), there is as yet no new or specific legislation for ICM, with all activities operating through existing legislation. Because there is no statutory basis for ICM and as ICM cuts across established and traditional agency mandates, administrative commitment and bipartisan political support are regarded as having critical importance.

Most of the State functions relating to ICM and Landcare have been amalgamated into an enlarged Department of Primary Industries (QDPI). Dryland salinity issues are also dealt with virtually exclusively by the QDPI. Additionally, management and operational aspects of the QDPI have recently been regionalised into five areas State-wide. Each region has a regional director and four or five regional managers representing different sections of the QDPI.

The ICM Program seeks to integrate the management of land, water, vegetation and other biological resources in order to achieve sustainable and balanced use of these resources (QDPI, 1991; 1993) The Program is founded on notions of common understanding of issues between stakeholders (from individual landholders to government), individual responsibility, voluntary changes in the use of natural resources and the provision of opportunities for individuals to contribute through participation in representative community groups (QDPI, 1991). Goals also include community cooperation and coordination (on a local level, regional level and with government) and economic sustainability.

To illustrate, the formal structure of the ICM Program includes provisions for the community and government to work together in developing and implementing ICM strategies through catchment and State-wide coordinating committees (QDPI, 1993). The initiative is also built on the Landcare Program and aims to incorporate the network of Landcare groups established throughout the State. The Queensland Program also states specifically that ICM is the means to provide catchment-wide objectives and strategies and Landcare is the means to foster the local action required to achieve sustainable and balanced resource use.

As an initial step to State-wide adoption, the ICM Program has initiated Pilot Studies focusing on five key river catchment areas, with studies intended for completion by 1996. Each study area involves the establishment of a Catchment Coordinating Committee (CCC) supported by a Catchment Coordinator from the QDPI. The committees comprise representatives from key government agencies, industry and community groups. They provide a forum for input and debate on catchment issues, are responsible for identifying and prioritising important issues and develop and promote the implementation of ICM strategies (QDPI, 1993). In addition, the ICM approach is also being adopted by conservation groups, Landcare groups, local authorities and government agencies in at least ten other catchments in the State.

For example, while most activity in ICM has been centred on coastal rivers separate from the Darling River system, an ICM project has commenced in the Queensland part of the Murray-Darling Basin (after Queensland joined the Murray-Darling Basin agreement in July 1992). A proposed structure was determined, four key catchments areas were identified and a CCC was formed in each catchment. To coordinate activities across the Basin, a regional CCC comprising representatives of the four committees has also been established. A management strategy for the Basin was released in April 1993.

A Catchment Management Coordinating Committee (CMCC) has been established to oversee the development and implementation of the ICM Strategy (developed in 1991) at the State level. This body comprises representatives of government, industry and community. Priorities include: fostering coordination among agencies, industry and community organisations; creating public awareness of ICM; recommending State priorities for ICM; monitoring and reviewing the ICM Program; and, providing advice to CCCs on the means to gain technical and financial support and how to prepare and implement catchment management strategies. An ICM unit within the QDPI assists the CMCC in achieving these priorities. The CMCC is responsible to the Minister for Primary Industries.

CMCC subcommittees have also been formed to consider and report on specific aspects of the CMCC's responsibilities (QDPI, 1993). These have various directives including examining the integration of ICM with other land use initiatives, supporting catchment-based initiatives and meeting community expectations by seeking to minimise the impacts of agricultural practices on downstream ecosystems.

In contrast to the other states, Queensland does not have its own dryland salinity strategy per se and tends to place a lower priority on this form of land degradation than others (PDP, Australia, 1992). However, through the Strategy for Natural Resource Management (developed by the Natural Resource Management Unit of the QDPI), dryland salinity is being addressed on a statewide basis as one of several resource management considerations rather than a separate problem. This overall approach indicates that dryland salinity is a relatively minor and, at this point in time, manageable problem in the State.

Current QDPI priorities for salinity management are not clear but are reported to be responding to community (Landcare) requests. However, while it is considered that solutions need to be farmer-driven, the Queensland Government has received criticism for setting many salinity management priorities at the State level with little input from community groups.

The Queensland approach, however, does emphasise that involvement of Local Government is integral to the success of ICM. The evolution of ICM in each area is seen to necessitate input from key players in local authorities who have the capacity to keep priorities and objectives on track. This is viewed as a means of providing a local focus for ICM, heightening local ownership, enabling resources to be accessed more locally and increasing the potential for securing external sources of funding. The potential to feed Local Government strategic plans into the catchment plan of each CCC is also regarded as possible and desirable.

6.5 Western Australia

The two main agencies that deal with land degradation, dryland salinity management and agricultural environmental issues in Western Australia are the Department of Agriculture (WADA) and the Water Authority of Western Australia (WAWA), with WADA acting as the lead agency. The multi-agency Steering Committee for Research on Land and Stream Salinity and the Soil and Land Conservation Council (SLCC) act as coordinating bodies for R, D & E. The Decade of Landcare Plan is managed by WADA and the SLCC and includes salinity management as an integral component.

Amendments to the Soil and Land Conservation Act, 1982, provided for the establishment of Soil Conservation Districts to address land degradation problems. The subsequently renamed Land Conservation Districts (LCDs) and "self-directing" LCD Committees (LCDCs) have received strong support from the local communities, with nearly all of the pastoral and agricultural areas now contained within 139 LCDs. This is seen as a significant event that has raised the awareness, enthusiasm and involvement of local communities in salinity and other land management concerns (PDP Australia, 1992).

The Soil and Land Conservation Act provides for an LCD to be established where a group of landholders determine the boundaries of a District and make a request to the Minister of Agriculture. Subsequently, the LCDC is appointed, with membership and representation being determined by the community involved. Relevant government agencies (most commonly WADA) are usually represented on the Committees. Local Government

representation is seen as essential. The WADA representative acts as a general advisor by convention and, therefore, can place the problem in a total land use scenario and identify necessary technical input (Robertson, 1989).

In areas dominated by agriculture, the Landcare activities of the LCDCs incorporate some of the basic ideas of ICM, particularly consideration of the linkages between land and water degradation. In addition, the committees are often considered the logical departure point for more localised, catchment, or sub-catchment management initiatives. In general, LCDCs assume more of an "executive" role and catchment groups more of a "doing" role. Catchment groups now number over 250 within the agricultural LCDs.

In areas not dominated by agriculture, however, other interests (such as industry, forestry, nature conservation and tourism) may need to be incorporated into planning and management. As a result, conflicts of interest are inevitable in ICM. Thus if ICM is to succeed, there is a recognition that processes of interest-based negotiation and conflict resolution need to be emphasised.

The WA State Government initially sought the development of ICM in 1987 and released a policy on ICM in 1989. The Government considered that WA had adequate legislative powers in place to undertake ICM. Hollick and Mitchell (1991), however, make the point that if administrative commitment and bipartisan support are not forthcoming, then legislation may need to be considered to provide credibility for ICM.

The intended coordinating mechanisms and their roles and objectives for ICM in WA are described below. However, it must be noted that many mechanisms are not yet fully developed and often only partially applied. There is concern by some that verticle integration of ICM from Local to State levels is some way from being effective. Nevertheless, the description of the intended structure is of assistance in considering general principles for WCM.

(a) Local action

As the ICM process has evolved, the decision was taken to create Community Catchment Groups (CCGs) in different catchments with representatives from community-based groups. It is envisaged that this could become a main mechanism for providing public involvement in defining problems and developing strategies. At this stage, the CCG concept is in its early phase of development. However, care should be taken to avoid uncertainty in the future in regard to the relative roles of CCGs, LCDCs, State agencies and Local Governments. Partly to this end, Mitchell (1991) recommends that at least several members of CCGs be representatives of Local Governments.

(b) Catchment-wide action

The CCGs act within their jurisdictions and influence the overall direction of ICM, which is coordinated by a regional **Catchment Coordinating Group**. This group provides the focus for facilitating community involvement in a catchment, coordinating community and government actions and providing the main link between Local and State Government policies and activities. As noted, in catchments dominated by agriculture, LCDCs may assume this role.

The Catchment Coordinating Group represents the relevant interests in the community, ideally has links with the Government Officers Technical Advisory Group (GOTAG - see below) and the Integrated Catchment Management Coordinating Group (ICMCG - see below) and reports to relevant Ministers. Typical membership includes representatives from groups involved in local action, (non-voting) State agency personnel and one representative from GOTAG.

The Catchment Coordinating Group is envisaged to oversees the development of an ICM "Plan", representing the collective activities of the broad community, local authorities and State agencies. By drawing together all relevant information as a guiding basis for future decisions in a catchment, the plan provides an overall view of management objectives for the catchment. The plan also needs to include mechanisms and processes that provide a streamlined framework for people to gain access to relevant information and allow constant revision.

GOTAG ideally provides technical advice to and works in parallel with Catchment Coordinating Groups. Membership varies between catchments, but usually includes officers from WAWA, Waterways Commission, WADA, the Environmental Protection Agency (EPA), the Department of Planning and Urban Development (DPUD) and the chairperson of the Catchment Coordinating Group. Other agencies such as the Department of Conservation and Land Management (CALM) are represented when appropriate.

(c) *State action*

The ICMCG is a State-level inter-departmental committee formed to address the inter-agency implications of resource and environmental policies, provide collaboration among agencies and to coordinate inter-agency policy,

objectives and actions required to implement ICM plans. The ICMCG is responsible directly to the Minister for the Environment.

Related priorities include:
(i) developing guidelines for joint, long-term financing of multi-agency initiatives;
(ii) developing recommendations on how the Government should provide funding for ICM activities;
(iii) reviewing the capability of existing legislation and agencies to implement ICM;
(iv) considering appropriate forms of power-sharing among stakeholders;
(v) determining research needs;
(vi) developing performance indicators at catchment and State levels.

Only government members are represented on the ICMCG, the argument being that such an arrangement is more likely to result in agencies seriously considering possible trade-offs (Hollick and Mitchell, 1991). However, as noted by Mitchell (1991), ICMCG does not "own" ICM but is considered solely as the appropriate forum to determine agency and partnership roles and priorities.

The Office of Catchment Management (OCM) is a small independent secretariat created to support the ICMCG, focus full-time on ICM and serve as a facilitator and catalyst in the implementation of ICM. In this regard, the OCM undertakes its own initiatives and hence assumes a proactive role relative to ICM.

The WA Water Resources Council (WAWRC) and the SLCC provide policy advice to the Minister for Water Resources and the Minister for Agriculture respectively. Hollick and Mitchell (1991) consider it appropriate for WAWRC and SLCC to continue to exist alongside the ICMCG despite some overlapping functions (eg., in determining the effectiveness of operational programs). However, unlike the ICMCG, both Councils include community representation and report to Ministers other than the Minister for the Environment. Notably, responsible Ministers will vary from catchment to catchment depending on the circumstances. However, the Minister for the Environment is always involved.

Mitchell (1991) recommends that since ICM is relatively recent in WA, there should be no radical changes to its implementation at this time. Instead, efforts should be made to make current arrangements work more effectively. In this regard, there are deemed to be adequate powers in existing legislation which only require coordination. This has the advantages of enabling substantial progress to be made without the disruption and delays that would be brought about by radical change; allowing the present system the opportunity to prove its worth and highlighting any weaknesses before any further structural adjustments are considered. Thus, an evolutionary rather than a revolutionary approach is advocated.

Hollick and Mitchell (1991) also state that cooperation between agencies in WA appears to be better than in some other states (although many public servants still carry a "territorial imperative"), thereby reducing the need for ICM legislation and increasing the prospects for successful implementation through non-statutory mechanisms. By comparison, the structure of governance in WA is also considered relatively simple.

However, in WA, it is still necessary to clarify roles for and relationships among all stakeholders. It must be noted, for example, that many pivotal issues and terms of reference regarding the composition, roles, powers and resources of Catchment Coordinating Groups vis a vis State agencies, local authorities and other community groups are yet to be resolved and defined. This highlights an important point that unless care is taken to determine the basis on which local or catchment-wide structures are to be established, unrealistic community expectations, frustration and loss of confidence in ICM may result (Hollick and Mitchell, 1991).

2.2 The Way Forward: Barriers and Bridges to Progress in Integrated Catchment Management in Australia.

G. T. McDonald, The University of Queensland

(Source: McDonald, G.T. 1997. *The Way Forward: Barriers and Bridges to Progress in Integrated Catchment Management in Australia.* Keynote Address 2nd National Workshop on Catchment Management. Canberra)

Summary: There are seven markedly different institutional models for ICM in the Australian states. This paper briefly reviews progress to date in catchment management in Australia and identifies emerging trends and promising developments.

The main source of data is a questionnaire survey of the leading practitioners of ICM to gauge their views on the barriers and bridges to the better implementation of ICM in Australia. The main conclusion is that most people in the business of ICM have their own clear prescription as to what should be done, but there is no dominant or commonly accepted way forward.

Progress to date fits the four-phase adaptive model applied so effectively in Gunderson, Holling and Light's *Barriers and Bridges to Renewal of Ecosystems and Institutions*. In Australia we are still in the alpha phase, looking for a new paradigm of integrated resources management to replace the undeniably inadequate old exploitive and compartmentalised one.

Introduction

The Second National Workshop on Catchment Management heard from some of the best speakers in Australia and indeed internationally on what should be done to increase the effectiveness of ICM programs in Australia. Furthermore the participants had hours of workshops and discussions on this matter as reported elsewhere on what needs to be done. What could be possibly left to say?

The purpose of this paper is to tie some of this together - to stand back and see the larger picture. I will take several approaches to this. The first and obvious point to note in this regard is that there is no compelling and clear cut direction to take that the workshop participants or any other large group of people would necessarily agree on. Individual participants at the workshop had strong views on what they believe was the best way forward, but collectively no single path emerges. Mapping the way forward at this time will have to consider a potentially distracting complexity of possible paths.

The rise of ICM resulted from the failure of all levels of government to have the right policies and programs for natural resources management, and the recognition of this by industry and community groups. Regrettably, governments responded slowly and failed to be the main source of warning and action about these problems.

Recent synthesis of natural resources management by Gunderson, Holling and Light's is helpful in this regard (Gunderson et al, 1996). The commonality between Australia's search for better resources management and those that other countries have experienced is remarkable.

This commonality is briefly canvassed to reveal some barriers and bridges. In Australia we are still in the alpha phase, looking for a new paradigm of integrated resources management to replace the undeniably inadequate old exploitive and compartmentalised one.

This paper also presents the results of a survey taken during the workshop. It reviews the opinions of this group of committed ICM professionals and participants. The participants were government agency staff involved in NRM, Catchment Committee members, researchers and landholders.

Terminology and scope is a problem in discussing ICM. The focus in this paper is on the formal government programs for ICM - the specific legislation, policies, administrative arrangements and finance provided for the integrated management of land and water on a catchment basis. ICM is a subset of natural resources management, which in a general sense also needs an integrated approach - leading to integrated (natural) resource management. Of course integrated management can occur without new and specific programs. The combined effect of enlightened management by separate land and water management agencies certainly can be directed at better and holistic catchment management.

Where are we now?

Notable features of the 2nd National Workshop were the breadth and depth of activities in ICM in Australia and, as shown in workshops and open forums, just how committed people are to ICM. Australia clearly has made great progress in identifying the needs for better resources management and in doing something about it. Diversity between state activities is one of the major features, as the summaries in Table 1 reveal.

Table 1 Summary of ICM Activities by States in Australia.

State	ICM Structure	ICM Processes and Outcomes
New South Wales	Total Catchment Management Act (1989) provides a legislative basis for the Catchment Management Coordinating Committee and the Catchment Management Committees (CMCs) and Trusts operating at the regional level that cover much of the state managed by DLWC.	CMCC consist of senior state department officials and representatives of land user groups, environmental and the CMCs; providing advice to ministers, policy programs and setting of state priorities CMCs, which have representatives of local government, business, land users, regional departmental officers and environmental interests, prepare regional strategies and programs
Victoria	Established Catchment Management Authorities (9) on 1 July, 1997. Combines roles of previous Catchment and Land Protection Boards, river management authorities, salinity implementation groups, and others	Prepare Regional Catchment Strategies Advising government on priorities and negotiating with DENR for services delivery
Queensland	ICM continues under the ICM Policy of 1991. Over 30 Catchment Coordinating Committees have been formed with funding and support from DNR. New NRM Legislation is being drafted	Role is advisory. It is voluntary and structures are not prescribed. CCCs prepare catchment strategies and seek the cooperation of local and state government agencies to implement them.
South Australia	Created a Natural resources Council in 1992 Water Resources Act 1997 subsumed earlier Catchment Water Management Act 1995 is establishing catchment boards (Patawalonga and Torrens, Murray River) Managed by DENR Soil Conservation and Landcare Act operational since 1988 established Soil Boards which still exist	Catchment Boards prepare catchment water management plans using prescribed consultation process advice to the minister promote community awareness
Western Australia	Adopted as government policy in 1987 but not legislative. A range of community based and specific cases have emerged. Supported also by the Soil and Land Conservation Act with district and catchment committees. Also the Salinity Action Plan and Focus Catchments	Environmental Protection Policies and State Planning Policies have been used for priority areas such as the Peel Harvey and the Swan.
Tasmania	No specific ICM programs or legislation Implemented through State Resource Management and Planning System	Development of ICM principles is underway
NT	No single legislation but implemented through the enabling provisions of the Water Act which enables a whole of catchment approach	Not statutory or formal but advisory Examples include the Mary River and Ludmilla Catchments which have Committees formed under the Water Act

Sources: Reports on the current position around Australia - this volume.

It is tempting to say that the diversity is just the old railway gauge problem all over again. Perhaps more positively, it should be concluded that the states are at different points along the evolutionary path and are doing it their own way. This could be viewed as seven different experiments and as Cullen noted there may be a benefit in having some diversity at this stage in development of ICM (Cullen, 1997). What is clear from the state of the states papers in this volume is that many states have made significant changes to their programs for ICM in recent years (SA and Vic) and others (Qld and NSW) are planning reviews. The key differences are whether or not ICM is supported by specific legislation. The administrative structures of resource and environmental agencies also varies markedly between the states, the main differences being in the varying relationship between production agencies, resource management, land management and administration and environmental programs. These relationships also change from time to time in most of the states. There is a search going on for better ICM practice. We are now in the phase of looking for the best policy to adopt - to move to a new paradigm.

Moving Forward - The Options

The essential purpose of ICM is to improve and maintain the long term condition of land and water resources. Given that under completely natural conditions this problem would not emerge, the solution to ICM relies totally and exclusively on changing people's behaviour - to have those people, land managers and others whose activities impinge on land and water resource outcomes, to behave in a way consistent with the goals of ICM. In a physical sense this means affecting the behaviour of the people actually using and changing the natural environment in various ways - cultivating, clearing, extracting water, disposing wastes. In a policy and community sense it means affecting the circumstances of the on-ground managers' behaviour through a range of government policies and community actions. These actions range from relatively un-intrusive and passive activities such as information gathering and research, aimed at influencing the land managers' understanding of resource condition and issues through to quite intrusive activities such as laws and regulations proscribing/prescribing activities. (See Figure 1) It is probably desirable to use the least intrusive and restrictive interference possible consistent with achieving ICM

objectives. For example, restrictive resource controls although seemingly effective in a superficial sense may be politically difficult to establish and enforce; whereas economic incentives, built into pricing policies for inputs and reflected in licensing charges for the use of environmental services, such as water, are more politically attractive and feasible.

Figure 1. Options for Achieving Better Resource Management - focus on land managers' behaviour

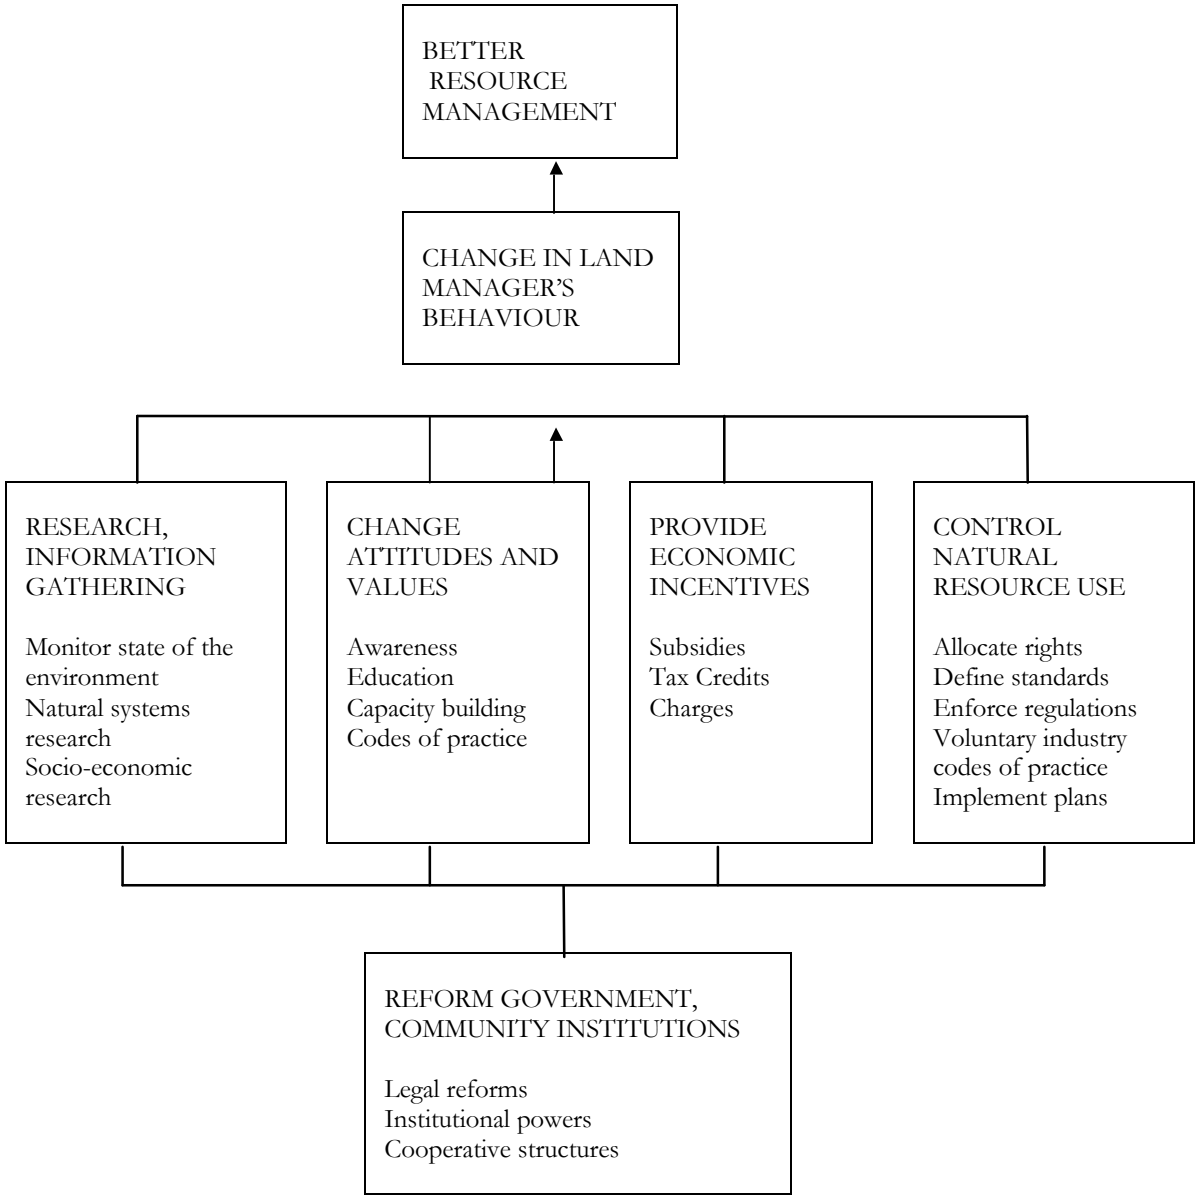

Figure 1 shows the relationships between these policy options and resource management outcomes. It shows the primacy of government and community institutions in selecting the right policy mix to deal with what are intrinsically "common property" problems. Critical in this regard is the feedback loop between information and awareness raising programs and the reform of institutions. Without pertinent and accessible information, community support and government responses for resource management will be retarded. This is a critical loop that many of the workshop participants emphasised. Table 2 shows how these generic policy options can be translated into specific actions that might be taken for moving ICM forward. This framework was used for the design of the questionnaire used in the workshop and reported in the next section of this paper.

Opinions of the Workshop Participants on Priority Actions

The Survey

A large number of ICM committee members, professionals in government agencies and private industry and from the research community attended the Second National Workshop which provided an excellent population to survey about progress to date and the way forward. These people expressed their views in many forums and workshops which are summarised elsewhere in the workshop proceedings.

In addition each participant received a two page (one sheet) written survey giving them a chance to express their views and to bring together the findings across the broad spectrum of the activities shown on Table 2. Three hundred people registered for the Workshop although only approximately 250 were regular and full-time attendees - full participants. Responses were received from 128, just over 50% of these people.

The responses are a mine of information on the opinion of the core group of people engaged in ICM. Clearly, this was a biased group, consisting of those directly involved in ICM.

Table 2 Some Specific Actions that Can be Taken to Advance ICM in Australia

I Information Gathering and Research	**IV Resource Use Controls**
Design of more integrated local solutions	Define resource rights
More socio-economic research	Defining water rights and allocations
More scientific research into resources management	Give ICM plans statutory force
Research on decision making by resource users	Planning
Research on the economics of options	Reduce area under irrigated pasture
Monitoring project/program effectiveness	Stronger resource use regulations
Monitoring resource condition	Restrictions on feed lot production
More funds for CRCs	Set strong standards at the national level
II Change Attitudes and Values	**V Institutional Reforms**
Awareness raising amongst politicians	Better representation on ICM committees
Capacity building in local communities	Create new autonomous regional institutions
Communication of knowledge to decision makers	Create elected catchment groups
More multi-disciplinary trained experts	Formalise and legislate the duty of care principle
	Give catchment groups financial powers
	Strengthen institutional arrangements
III Economic Incentives and Finance	Commonwealth government NRM structures
Invest in capital works	State gov't NRM structures
Levy landholders who cause off-site problems	Catchment management organisations
Reimburse (tax, rates) landholders who carry out prescribed conservation works	Local governments
	Landcare
Reform resource pricing systems	Reform Local government boundaries
Funds to local Landcare/ICM groups	Privatise water authorities
Increase funds for on-ground projects (works)	Use local governments as the prime instruments for implementing ICM

Representation of "client" groups, the landholders and the community were notably absent, except to the extent they were members of these other groups - hardly a representative sample nevertheless. Three groups dominated the Workshop - ICM committee members, government officials involved in natural resource management and researchers from tertiary institutions and research agencies such as the CSIRO. (See Tables 3, 4, 5)

Landholder/farmer	29
Catchment Committee member	8
Other	

Information Gathering and Research Priorities

The outstanding feature of this set is the almost universal view that the highest priority is to provide better access to information (Tables 6 and 7). This result was consistent across all groups and States. There was only medium support for the need for more scientific research into the resources themselves. Some typical comments were:

"More research which has been identified by community groups - NOT academics in isolation of the community working"

"Collate all existing and proposed research data and present it all to the lowest common denominator -'those doing the on ground action'. It is essential that available knowledge is owned by those working at the 'coal-face' of ICM."

"Results of (hands on - ie - understandable) research delivered in an understandable way to the "masses". Understanding the "Nature of the Place", then relating that understanding to catchment repair via a process of Strategic Thinking (not Planning) and step wise actions"

Table 6 Information Gathering and Research Priorities - Frequencies

	V.High 6	High 5	Med 4	Low 3	Nil 2	U 1	Mean
Research into best/good practice	24	54	35	12	0	0	4.7
More socio-economic research	25	35	45	16	0	1	4.5

	Research into Good Practice	Socio-econ research	Scientific research	Access to Information	Economic research	Project Monitoring	Resource Monitoring
Researchers	4.9	4.6	4.4	5.5	4.7	5.1	4.8
Administrators	4.6	4.3	4.2	5.4	4.7	5.1	5.1
Landholders	4.8	4.9	4.6	5.7	4.4	5.2	5.4
Catchment Group	4.6	4.7	4.5	5.4	4.7	5.0	5.1
Others	5.1	4.0	4.4	5.9	5.0	4.7	5.3

Priorities for Changing Awareness and Attitudes

Awareness raising, so important to generate support for ICM, particularly the need to raise the awareness of the community, politicians and decision-makers, had general strong support from respondents. (Tables 8 and 9) There was believed to be less need for awareness raising in government agencies or for the training of multi-disciplinary staff for ICM. Typical comments were:

"Awareness raising of politicians. They have a moral responsibility to focus on terms longer than three years or their term in office"

"Attitudes and values change as a result of prescription and legislation. If we wait for education/peer pressure to take effect there'll be nothing left"

"Aiming to make local communities interested in having effective input into management of local catchments"

"This whole area has a very high priority. Without an understanding and acceptance at the NRM imperatives in the whole community ICM will find it very difficult to make any significant impact"

Table 8 Priorities for Changing Awareness and Attitudes - Frequencies

	V.High 6	High 5	Med 4	Low 3	Nil 2	U 1	Mean
Awareness raising in local communities	65	39	19	4	0	0	5.3
Awareness raising amongst government agencies	37	50	28	8	3	0	4.9
Awareness raising of politicians	60	37	22	4	2	1	5.2
Capacity building in local communities	49	46	16	3	2	0	5.2
Communication of knowledge to decision makers	62	42	18	2	1	0	5.3
Training of more multi-disciplinary trained staff	27	47	36	12	1	1	4.7

Table 9. Priorities for Changing Awareness and Attitudes - Means for Groups

	Local Awareness Raising	Govt agency awareness raising	Politician Awareness raising	Capacity building in local communities	Communication to decision makers	Training more staff
Researchers	5.0	4.8	5.2	5.1	5.3	4.9
Administrators	5.1	4.6	5.1	5.3	5.2	4.5
Landholders	5.7	5.3	5.6	5.3	5.2	4.6
Catchment Group	5.5	5.1	5.3	5.1	5.6	4.8
Others	5.6	5.0	4.8	5.2	5.1	4.6

Priorities for Economic Incentives and Finance

There was surprisingly low priority given to the need for economic incentives as a means of implementing ICM programs. Only one-third of the respondents believed that using either positive or negative incentives for landholders were important or that resource pricing reform was a high priority. Providing increasing funds to ICM programs was also relatively low priority and investing in capital works for resource management very low. Respondents clearly understood the role of these policy tools but did not rate them highly compared with other policy options.

Some comments:

"To allow for "externalities", to have more accurate pricing of environmental resources (but being sensitive to equity). A role for ICM is to progress this debate"

"People will do the work if shown that it will "work" for them ($$, practical, outcomes). Priority is to develop incentive system integrated with adoption process, not more funding"

"Restructuring tax and rebates on rural landholders to provide financial incentives for ESD and SAD. At the same time tie government grants to local government to ESD and SAD planning and approvals criteria"

Priorities for Resource Use Controls

There was moderate support for the need for greater controls over land and water use. There was very low support for the setting of strong standards at the national level. In particular respondents expressed a view that more action oriented catchment plans were needed.

"Use national standards to create regional standards and workable regional systems. Then use regulations etc. to "enforce" adoption of standards"

"The ICM statutory body based on regional or catchment jurisdiction needs power to raise revenue and enforce its regulations within the context of a catchment plan that is available to all people affected for their information"

"Unsure of whether ICM should have statutory force, rather a change of thinking that will allow content of plans to be recognised and implemented in other plans"

Table 10. Priorities for Economic Incentives and Finance - Frequencies

	V.High 6	High 5	Med 4	Low 3	Nil 2	U 1	Mean
Invest in capital works	6	21	56	27	4	1	4.0

NT	5.0	3.0	5.0	3.0	3.0
ACT	5.1	4.6	4.7	4.6	4.1

Priorities for Institutional Reform

There was more diversity amongst the responses about institutional reforms than for other questions. There was low support for the creation of new or autonomous regional catchment groups, or for strengthening Commonwealth structures for dealing with catchments. Improvement in catchment organisations themselves and strengthening the links with local government were the highest priorities for institutional reform.

> "Co-ordination of local government, state government agency and catchment boundaries. Most catchment problems could be at least partially addressed by improved local government planning"
>
> "Better access of the community and other sectors for decision making on resource management issues - at individual, local and state levels"
>
> "Improve coordination between stakeholders, agencies and governments and ensure "land users" groups in general form coordinated comprehensive strategy. Tie in with each other and programs/processes ALREADY on line, eg. National Forest Policy, Montreal Process, Biodiversity Strategy etc."

"Proper representation from community. In Victoria Catchment boards are chosen by the Minister and often not representative at all. "

"Better representation in ICM committees' - In whose opinion? The community in general and those who are going to have change forced upon them in particular must be confident their views are represented"

"Give catchment groups statutory financial powers and reform local government boundaries

"Integration and coordination urgently needed in WA. Must include community who can be empowered to lead, scrutinise, etc."

"Formalise the status of catchment strategies as a guide/consideration in existing natural resource management structures such as land use planning"

Table 15 shows the opinions about institutional reforms by State, revealing some significant variations arising out of differing state experiences. While all the states' respondents supported the need for catchment committee organisational reforms and the need to forge better links with local governments and their planning processes:

- Victorian respondents were more concerned about committee representation than other states,
- Queensland respondents held substantially stronger beliefs in the needs to involve local governments,
- Western Australian respondents were particularly concerned about the financial powers of ICM groups and,
- South Australians were more concerned about their state's arrangements for ICM.

Discussion

Those priorities rating highest (means over 5 for all respondents) were:

1 Providing better access to existing information

2 Awareness raising in local communities
3 Communication of knowledge to decision makers
4 Awareness raising of politicians
5 Monitoring resource conditions
6 Prepare more action oriented catchment plans

There is an overall pattern in these results. All actions are important priorities in the minds of at least a significant minority of the respondents - some more than others, with the exception of increasing capital works programs which very few want. Better access to information and the greater awareness of local communities and politicians were the clear highest priorities. Presumably respondents believed that ignorance and apathy were limiting involvement and adoption of ICM principles by resource managers and their elected representatives. Only with higher awareness of the importance of ICM can the commitment, including commitment of funds and changing behaviours necessary to achieve better resource management, occur.
There were needs for institutional changes in most areas, but particularly in the character and performance of ICM groups themselves. This was a view of all groups from all states, but particularly those working in the catchment groups.

The most outstanding feature of the collective results of this survey are the high levels of significance the respondents placed on almost all the possible actions posed in the survey. Everything seems important and urgent to many people and almost all the actions to be critical to at least a minority of ICM participants. Very few of the potential solutions were classed as undesirable.

The Transition from Exploitation to Conservation

What does all this mean? Gunderson and Holling and Light recently published a book that provides valuable insights on this situation. (Gunderson, Holling and Light, 1996) *Barriers and Bridges to the Renewal of Ecosystems and Institutions* attempts to explain the process of institutional change in ecosystem management and explored the processes of managing complex regional systems. They and their contributors were particularly concerned with situations such as the Columbia River and the Everglades where management problems were acute and substantial change in the management paradigm was required. The new synthesis can be traced directly to Holling's 1986 paper in which he reviewed a large number of managed ecosystems in search of more general explanations. (Holling, 1986)

> "One of the puzzles mentioned in an introductory chapter was the apparently inevitable emergence of a pathology of regional development, at least in its early phases, as the consequence of initially successful exploitation and management of natural resources and the environment of a region. In the case studies we examined in the early 1970s, the ecosystem and environment became more vulnerable to surprise and crisis as resilience decreased, the management institutions became more rigid and less responsive both to the resource dynamic and to the public, and the citizenry became more dependent and with fewer options for self-reliance." (Gunderson, Holling and Light, 1996, 508)

The synthesis finds similarities between social and ecological adaptation theories. These contrast gradualist life cycle models with revolutionary ones - where long periods of slow change are punctuated by periods of rapid transformation. These theories outline the deep structures that result in gradual and only incremental changes in "equilibrium" periods, followed by brief periods of revolutionary change when the deep structure itself changes. (See also Kuhn (1970) who describes this as a paradigm shift). The process of change is described in a four-phase process as follows:

Table 13 Priorities for Institutional Reform - Frequencies

	V.High 6	High 5	Med 4	Low 3	Nil 2	U 1	Mean
Better representation on ICM committees	22	38	39	13	1	0	4.6
Create new autonomous regional institutions	13	14	26	33	18	12	3.4
Create elected catchment groups	8	20	36	24	16	12	3.5
Formalise and legislate the duty of care principle	32	39	28	16	1	1	4.7
Give catchment groups statutory financial powers	29	35	33	15	3	2	4.6
Strengthen Commonwealth NRM structures	17	38	32	20	4	0	4.4

1. Ω phase:-
   crises inevitably occur as systems (ecological, economic or social) mature, producing an increasing brittleness or susceptibility to crisis. Crises in this context is revealed as the "undeniable inadequacy" of policy. In the case of ICM evidence of this is the acute and chronic health of our rivers, land degradation and community conflict over scarce resources - something went wrong and we need to fix it.

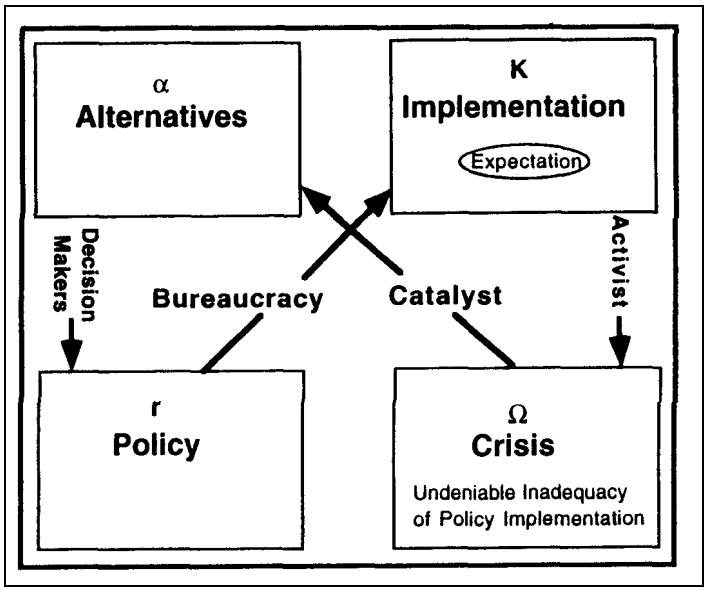
2. α phase:-
   in institutions following the crises, informal collaboration develops among groups of people outside the institutions to develop an integrated and shared understanding from which a variety of options for solving the crisis can emerge. There must be a search for solutions - how do we solve these new problems that previously existing

   institutions have not. The second phase requires activities that can launch the adaptive process. Their task is to find new solutions that overcome the problems of the past.

3. r phase:-
   specific but transient processes result in a reorganisation of the management institutions and society, with new goals, policies and organisational processes in place. This leads to a revision of policy and the subsequent continuation on a new path of better management

4. K phase:-
   implementation of the new "paradigm" and so the cycle continues until new crises occur. Of course the whole purpose of adaptive behaviour by ecological or social systems is to avoid the crises in the first place - to adapt continually to the condition of the resources and social demands on them.

Figure 2 Gunderson, Holling and Light's four-phase model of institutional change



(Gunderson, Holling and Light, 1996, 499)

The role of different groups in this process are:

i. *Bureaucrats:* concentrate on increasing efficiency in their implementation task and often focus on Are we doing this right? Rather than Are we doing the right things? They are often insular and surprised when the inevitable crisis occurs. Sometimes this is explained by the limited range of professional expertise.
ii. *Activists:* are essential to the move to the crisis stage. "The activists tenacious focus on narrowly defined goals and their need to identify enemies challenges whatever current goals are in practice guiding the institutions." p 501. While bureaucrats may ignore the activists, but when the public interest is aroused, the period of crisis ensues which exposes the weakness in policy and its implementation. This begins Holling Ω phase, the adaptive change in policy. Activists want something done now, and invoke conflict and trouble in order to achieve it.
iii. *Catalysts:* In the disruption of normal policy/implementation, a temporary "shadowy" group emerges of technical people who "functioned informally outside traditional institutions but drew on contacts within them" p 503. For these people the normal constraints of policy involvement are relaxed. Gunderson and his colleagues see three types of people in this group, visionaries, respected integrators and loyal heretics. These people are geared towards "unlearning" to forget/ignore old rules and to find new solutions. The outside visionary can transform "myths" amongst those intimately involved; the wise and respected "integrator" is respected by those inside and outside the system and can call on a veil of honesty to overcome countervailing obstacles; the loyal heretic (or bureaucrat) can also play a critical role because of the respect they hold inside and outside the system.

How can we interpret the current state of ICM programs in the light of this international experience? At what stage is ICM in and where might we hope or expect it to move next?

There is no doubt that Australia has experienced an "undeniable crisis in policy" in natural resources management which became evident in the 1970s and 1980s and lead to a search for a better way. A range of activists and catalysts emerged to help, especially from the community sector, people like John Burton, Watershed Jackson and others. Change did occur and ICM programs were created.

At present it could not be concluded that a mature, generally supported model for ICM exists in Australia. There are seven different state models which is not a pattern found in other policy areas such as health, education or law enforcement for example. Furthermore, some of these models are clearly not working well despite the loyal and well-intentioned actions (and statements) of those involved. Several states have indicated that they will review their programs in the near future.

In a conclusion acutely relevant for ICM, the Gunderson et al study concludes that "the traditional planning-led change process is rarely successful because it is imbedded in bureaucracies whose participants for all intents and purposes ignore change" p 505. Also planning is not a way to learn because it is dominated by (conservative) bureaucracies (Michael, 1973).

The diversity of views on priorities also suggests that ICM in Australia is neither well-structured nor meeting its objectives. There is considerable disagreement on the best way forward.

I would conclude that ICM is still in the omega phase - the activists are still searching for the best new alternative for policy - the new paradigm.

Conclusions

The summary of the state programs and the survey of a significant proportion of people involved in ICM in Australia confirm that there is no clear path present but that there are multiple paths that must be taken. Australia is not yet converging on a new paradigm for ICM although there are many valuable experiments going on that are beginning to show the shape of the paradigm. Perhaps the state of Victoria has progressed furthest in this respect. They have created the links between natural resources management in a hierarchy from Landcare to regional catchment strategies to state policy on natural resources management. They are well-advanced in exploring the links with local planning and the role of local government as a key implementer of ICM.

My own view is that ICM is as yet still a fringe activity to the core business of government - the economic (including infrastructure programs), resource management, development planning, and approval processes. These need to be incorporated. Whether or not there is a role for ICM as formal programs or whether ICM as practiced can be subsumed within the integrated management of development remains to be seen. This would be the New Zealand solution.

It is not at all clear to me that community empowerment, so central to the Landcare program can be translated easily up the scale to ICM. Landcare deals with voluntary small catchment works, tree planting and water controls whereas ICM deals with resources allocation at the river basin scale. ICM must deal with issues of resource rights and regulations not at all part of the Landcare ethic. ICM has more of a government role and thereby needs statutory foundations. It could even be envisaged as a regional form of government whether by delegation or independent elected and participatory form is a moot point. On the other hand, why create new agencies? Why not reform the existing agencies at each level to do a better job? To simply add another functional group - the ICM is perhaps to lead to further splitting of responsibilities rather than integration as its title suggests.

Is it now the right time to prepare a **"National Blueprint for Catchment Management"**? Such a model, similar to conservation, regional development and other policies, would set out the ideal catchment management model on the basis of experience by all the states, for adoption by the states with substantial assistance from the Commonwealth. It might include consideration of:

- what are the structures - legislation, regionalisation, boards (committees)
- what are the processes
- what should be the links with associated resources management and policies at all levels. Many of the key note speakers at the Workshop commented on this.

Bridges to the achievement of improved ICM through a national blueprint include increasing the considerable interaction and information sharing that already occurs. The NHT with its requirement that there be a regional approach to resource management projects, is certainly providing some convergence in this aspect at least.

Barriers to the agreement on the contents of such a structure would be states rights issues. The perennial problem of states rights (and the idiosyncratic bureaucratic structures) of states would certainly mitigate against a national model. Providing the model was not too prescriptive, there may well be agreement for variation in application within broad principles. A further barrier may be the belief that the issues are so fundamentally different between states. In particular there is a often discussed view that the southern states, and especially the Murray darling Basin have a different set of management problems than other parts of Australia. Certainly the issues are different but the blueprint need not be prescriptive about technical solutions.

In Gunderson, Holling and Light's terms how else can we move out of the alpha phase?

3. ORIGINS OF ICM IN QUEENSLAND

Integrated Catchment Management began in Queensland in 1991 as a State Government initiative supported by the Minister of Primary Industries at that time, Mr Ed Casey. The ICM initiative was a response to a community interest in dealing with and managing issues such as water quality, land degradation and river and stream management using a catchment-wide approach. The former Department of Primary Industries (DPI) had the lead administering role and important roles of other agencies, including the Departments of Environment and Heritage, Lands, and Housing and Local Government were recognised. (Rowland and Begbie, 1997: 1).

ICM in Queensland is defined as:

> *"Integrating the management of land, water, vegetation and other biological resources on a catchment basis in order to achieve the sustainable and balanced use of these resources." (DPI Queensland, 1993: 1)*

Queensland has no specific legislation for ICM and catchment coordinating committees (CCCs) were created under the DPI 1991 Guidelines. CCCs are formally appointed groups with members who have interests in catchment issues, including primary producers, environmental conservation, land use planning, river engineering and other aspects of natural resource management. The community and government work together in developing and implementing strategies for improving river catchment management. ICM encourages voluntary changes in the way people use and manage their natural resources. (DPI Queensland, 1993: 1).

The Catchment Management Coordinating Committee (CMCC) coordinated ICM programs at a State wide level. CMCC was comprised of representatives from peak industry, government and community sectors who have an interest in the management and use natural resources. The CMCC aimed to inform industry, and other sectors of the community interested in natural resources, of its activities. (DPI Queensland, 1993: 2)

The roles of the CMCC were to:

- recommend State priorities for the long-term implementation of the ICM program and the annual allocation of resources available for the program;
- provide advice on the provision of technical and financial support for catchment coordinating committees and the preparation and implementation of catchment management strategies;
- provide advice on new ICM legislation, monitor its effectiveness and recommend any amendments required to ICM an related statutory and administrative procedures;
- recommend State-wide ICM policies and identify the need for, and participate in the preparation of related policies;
- foster coordination between government agencies, industry, and professional and community organisation in their land, water and related biological resource management programs;
- foster the implementation of a State-wide ICM public awareness campaign and the distribution of catchment management information;
- maintain a register of catchment management strategies in Queensland, and
- monitor the implementation and progress of the ICM Strategy, and review its performance every three years." (DPI Queensland, 1993: 2).

The initial stage of the ICM program focused on five Pilot Study Areas: Johnstone River, Lockyer Valley, Pioneer River, Mitchell River and the Mary River. Catchment coordinating committees were established for each study area and were comprised of representatives from key interests groups from government, industry and the community. The committees role is to hold forums on catchment issues for community comments, identify and prioritise issues of concern in the catchment and develop and promote the implementation of catchment management strategies. The ICM approach has now been adopted in over 30 other catchments throughout

Queensland by local authorities, conservation groups, landcare groups and other state departments (DPI Queensland, 1993: 1)

This section contains extracts from the original strategy document.

3.1 Queensland Integrated Catchment Strategy – Summary

Department of Primary Industries

(Source: Extracts from Queensland Government Department of Primary Industries (DPI). 1991. *Integrated Catchment Management – A Strategy for Achieving the Sustainable and Balanced Use of Land, Water and Related Biological Resources*. Department of Primary Industries, Brisbane)

Purpose:
The purpose of the Strategy is to integrate the management of land, water and related biological resources in order to achieve the sustainable and balanced use of these resources.

Goals:

Community understanding, coordination and cooperation	• To have the community and government better understanding the interactions between land and water resources and related components of the ecosystem and the need to manage these resources on a catchment basis. • To have effective coordination within government, between government and the community, and within the community, of activities and policies relating to the management of Queensland's land and water resources. • To have effective cooperation between relevant government agencies, authorities, companies, industry and community groups, landholders and individuals involved in the management of Queensland's land and water resources.
Common goals and priority action	• To have all sectors of the community and government share common or agreed goals for land and water management. • To have all users or managers of land and water resources take account of the effects of their actions on these and other related natural resources. • To address interrelated land and water issues on a priority basis within catchments.
Economic and ecological sustainability	• To maintain economically viable industries within an ecologically sustainable framework. • To maintain, and where feasible, restore and improve the quality and productivity of land, water and related biological resources. • To maintain essential ecological processes, ecosystems and biodiversity. • To minimise detrimental environmental effects due to the development of land, water and related biological resources, within and beyond catchment boundaries. • To protect the wild, scenic and natural characteristics of rivers, lakes and the landscape.

Why Integrated Catchment Management?

Integrated Catchment Management (ICM) is a coordinated approach to the management of natural resources in Queensland. Its overall purpose is to integrate the management of land, water and related biological resources in order to achieve their sustainable and balanced use.

The ability of our land and water resources to meet our needs in the future is being threatened by continuing degradation and increasing demands on these resources for a range of uses. As a result, we are faced with problems such as soil erosion, salinity, siltation of creeks and rivers, flooding, water logging, polluted water supplies and damage to terrestrial and aquatic ecosystems.

Many of the problems affecting our land and water resources are interrelated and cannot be effectively solved individually. A cooperative and coordinated approach is needed to resolve these issues. ICM draws together those involved in primary production, environmental conservation, land use planning, river engineering and other aspects of natural resource management. It fosters joint action to address priority issues within river catchments.

The ICM Strategy

The Integrated Catchment Strategy

- **provides** a framework for fostering cooperation and coordination between the many landholders and other resource users, community groups and government agencies involved in the use and management of land and water resources;
- **is dependent** on landholders, the community and government having a sound understanding of the interactions between land and water and the need for a coordinated catchment-wide approach for addressing issues affecting them;
- **encourages** the community and government to promote an understanding of the value of an ICM approach and its underlying principles; and
- **recognises** that there will be many situations where existing groups and organisations can address important environmental problems. Land Care groups, local authorities, river improvement trusts and community groups play key roles in promoting the sound management of our land and water resources.

Issues

This strategy is designed to address interrelated land and water resource issues such as:

- The impact of land use on water quality
- Soil erosion and sedimentation of watercourses
- Stability of bed and banks of watercourses
- Salinity induced through clearing of vegetation
- Loss of habitat on land, in rivers and streams
- Flood mitigation and floodplain management
- The impact of land and water use on coastal and marine environments
- Productivity decline due to the degradation of land and water resources
- Spread of weeds by water
- Competition for land and water resources

Principles

The principles on which the ICM Strategy is based are:

Land and water resources are basic and interactive components of natural ecosystems
These interactions mean that changes in any one component of any ecosystem will frequently have an effect on other components. Because of this, no one component can be managed in isolation. People who use and manage natural resources must therefore understand the natural of the interactions in order to ensure that their decisions and actions do not adversely impact on another part of the ecosystem.

Management of land and water resources should be based on geographic units which account for the interactions between these resources.
River catchments often provide the most suitable unit for the management of land and water resources. A river catchment is characterised by a clearly definable physical boundary, which has been determined by natural history and establishes a natural barrier or interface for many of the physical, chemical and biological processes at work within and outside the catchment. It provides natural resource products and amenities of direct and indirect value to all life.

River catchments are continuously changing in response to natural processes.
Human activity will alter the rates and the way in which these changes occur. Such changes can be slow, like the siltation of water storages, or very rapid and obvious, like large-scale tree clearing or the effects of a flood. The management of river catchments much recognise and take account of the changes that are occurring due to natural and human causes.

Management of land and water resources must be coordinated.
Many people, community and industry groups, government agencies and authorities are involved in the use and management of land and water resources. Individually they tend to focus their attention on specific issues, such as forest management, water supply and conservation, in specific areas like floodplains, national parks and individual landholdings or within artificial administrative boundaries such as local authority areas.

Sound land and water resource management often requires coordinated action across whole river catchments by many of these individuals and groups. For example, successful flood mitigation and management require not just watercourse management (which may be the responsibility of State Government agencies, a local authority or a river improvement trust), but erosion control and careful land use planning throughout the river catchment (the responsibility of landholders, government agencies and local authorities).

Land and water resource management decisions must be based on the best available information.
Information on land and water resources, particularly on the interactions between these resources, is often deficient or not readily accessible. While additional information is often desired, management decisions will need to be made using available data to avoid unacceptable delays.

In a democratic society sound land and water management is best achieved through the informed action of the individual users and managers of these resources.

Mechanisms for community participation and education are necessary to encourage informed action, leaving enforcement of statutory controls as a 'last resort'.

A balance between economic development and conservation of land and water resources must be maintained.
The future economic viability and lifestyles of rural and urban communities depend on the sound use of land and water resources. An economically viable landholder, industry or resource user is better able to implement sound resource management practices than one who is not.

Land and water use practices which enhance and sustain economic performance in the long term, while maintaining and improving land and water resources, will benefit landholders, industries and the community.

Elements of the Strategy

The Strategy provides a framework for integrating the management of land, water and related biological resources by fostering the adoption of sound resource management practices and the coordination of government and community planning and action. The Strategy is designed to apply to both rural and urban areas of river catchments.

The key elements are:
- Awareness
- Community Action
- Government Action and Support

Awareness
The sustainable and balanced use of land and water resources depends on landholders and other resource users, the community in general, and government agencies and authorities having a sound understanding of the interactions between land and water, and of the need for a coordinated catchment-wide approach for addressing issues affecting these resources. A good understanding of these principles will enable all people and organisations involved to identify the need to change existing practices and adopt practices best suited to their own situation, without damaging other parts of the ecosystem.

Community Action
Long-term action to address land and water management issues in a catchment will only occur when landholders and other resource users and managers seek resolution of these issues. The Strategy encourages informed action by individual users and managers in their own activities and provides opportunities for them to contribute to the resolution of catchment management issues.

Government Action and Support
The planning and implementation of catchment management strategies will require the support and coordinated action of all levels of government – local, State and Commonwealth.

Individual Action
Individuals have a responsibility to ensure that their actions do not have adverse impacts on others or the environment. The Strategy encourages all people who use or manage land and water resources to use practices which maintain, restore or improve the quality and productivity of these resources. It also provides opportunities for individuals to contribute to the resolution of catchment wide issues through participation in community action groups.

Implementing the Strategy
Everyone has a role in adopting a whole catchment approach to the use and management of land, water and related biological resources. To achieve the sustainable and balanced use of these resources, it is important that the community and government accept the following roles.

Roles of Individuals include:

On the land

Adopting a whole property and whole catchment approach to property management, such that the effects of managing one component or part on another component or part in the same or other areas are understood and accounted for. For example: clearing land in accordance with sound land use and environmental protection guidelines, not constructing unauthorised levee banks or other works which may interfere with the flow of flood water.

In the office

Considering the full range of benefits and costs of proposed works and management plans. For example: designing transport corridors that minimise impacts on natural drainage systems; considering in-stream water requirements when allocating water for off-stream use; considering environmental and hydraulic aspects when proposing to develop swamps or wetlands.

During construction

Using machinery and carrying out work in a manner that does not cause erosion of land and watercourses, or pollute and block watercourses.

At leisure and play

Using only designated areas for boating, hiking, driving and other activities and in a manner that does not cause erosion, stream pollution, fires or other unwanted effects.

At home

Using water wisely, disposing of waste thoughtfully, recycling materials whenever possible and conserving energy.

Role of the community include:

- Establishing and supporting Catchment Groups or Committees as needed to address land and water issues
- Identifying interrelated land and water issues that should be addressed, and contributing to the development of solutions
- Participating in the development of catchment management strategies
- Influencing the community and individuals through local action groups to achieve results on the ground
- Promoting within the local community the concepts and principles of sustainable and balanced use of land and water resources
- Contributing funds to develop and implement catchment management strategies

Roles of local government include:

- Fostering community awareness and the formation of Catchment Care Groups
- Contributing technical and financial support to Catchment Groups and Committees, on a voluntary basis and as resources permit
- Participating in the development of catchment management strategies
- Contributing voluntarily to the implementation of catchment management strategies by considering incorporating relevant parts of these strategies in local authority plans, by-laws and administrative procedures and in their own field activities

Roles of the State Government include:

- Fostering community awareness and the provision of educational material and services
- Participating in the development of catchment management strategies
- Contributing technical and financial support to Catchment Coordinating Committees as resources permit
- Establishing policies, institutional arrangements and necessary legislation to facilitate the implementation of integrated catchment management
- Contributing to the implementation of catchment management strategies by considering the incorporation of relevant parts of these strategies in appropriate legislation, regulations and administrative procedures, and in the management of public land and water resources and the provision of infrastructure and services
- Developing State-side catchment management strategies and programs and monitoring their progress
- Ensuring interdepartmental coordination of land and water resource programs.

Roles of the Commonwealth Government include:

- Participating in the development of catchment management strategies
- Adopting catchment management strategies on land used or managed by the Commonwealth Government or its agencies
- Providing financial support to priority catchment projects where national interests apply
- Providing taxation and other financial incentives for expenditure on land and water conservation

Catchment Coordinating Committees

Catchment Coordinating Committees are established to address complex catchment management issues that involve many community groups and government agencies.

Catchment Coordinating Committees comprise representatives of the major sectors of the community and government which are involved in, or influenced by, the management of land and water resources in the catchment.

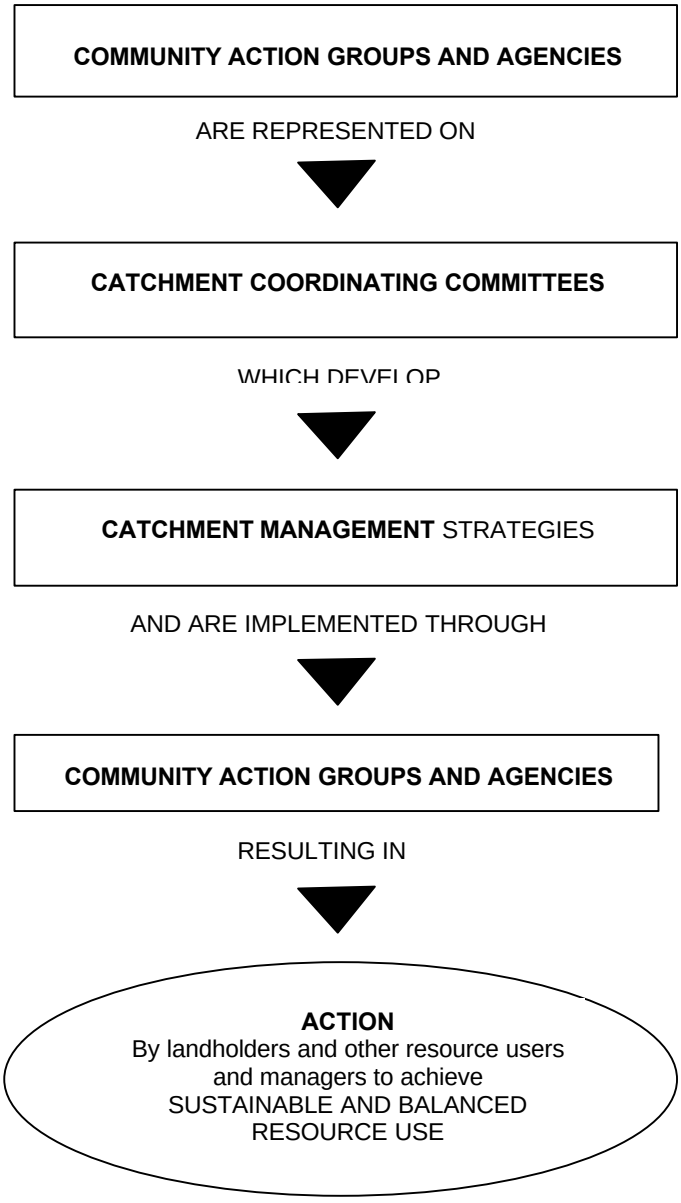
Their major roles are to provide a forum for community input and discussion, to prioritise the issues and to develop and promote the adoption of catchment management strategies.

Catchment Management Strategies

Catchment management strategies provide a broad assessment of the priority land and water issues in the catchment and contain recommended actions to address particular issues.

Catchment Coordinating Committees foster the voluntary implementation of catchment management strategies through existing government and community organisations. While catchment management strategies are not legally binding, they provide guidelines and recommended policies and action plans which all people who use and manage natural resources are encouraged to adopt.

How the ICM Strategy Works in a Catchment



Strategy Results

This strategy will help to achieve:

- **An understanding** and accounting by all users and managers of land, water and related biological resources and of the effects of their decisions and actions on these resources;
- **Cooperation** and coordination between the community and government in their land and water resource management activities;
- **Economically** viable industries within an ecologically sustainable framework; and
- Clean water, fertile soil and ecologically diverse and productive ecosystems.

Outcomes of the Strategy

The adoption of the ICM philosophy and processes will result in:

- All users and managers of land and water resources under-standing and accounting for the interrelationships between these natural resources in their management decisions and activities
- All sectors of the community and government accepting their individual responsibilities for the sound management of land, water and related biological resources
- Integrated policies and programs for the management of land, water and relation biological resources
- Common goals, strategies and coordinated action by the community and government in addressing priority land and water management issues
- The sustainable use of land and water resources while providing for the material, residential, industrial, recreational and environmental needs of current and future generations
- The maintenance of essential ecological processes, ecosystems and biological diversity.

4. DEVELOPMENT OF ICM IN QUEENSLAND

The Queensland ICM model is not a legislative approach but one based on cooperation between statutory agencies together with a substantial dependence on local initiative, ownership and drive. This section traces the development of ICM in Queensland following its initiation in 1991. It incorporates an overview by Rowland and Begbie, two DNR staff intimately involved in ICM since its inception.

The ICM program has been surprisingly robust – its philosophy and implementation have remained relatively constant. Many changes have occurred in the policy and institutional context however, and these are summarised.

Critical to the survival and success of any program is the level of commitment through funding and staffing. ICM has survived using a mixture of state program and core funds and, most importantly through the National Landcare Program and its successor, the Natural Heritage Trust. We trace these programs here. It is difficult to define accurately just what resources have been available for the ICM program and the Catchment Committees. Most significantly, the host Department, DPI then DNR (from 1995), provide in-kind support centrally and in the regions in the form of staff time and operational expenses. No one has estimated this accurately, because catchment related research, planning and implementation support are closely interconnected with many programs. Disentangling specific ICM related expenditures (eg river improvement, water allocation) is difficult and conceptually dangerous. There is therefore an in-built bias in the financial tables below towards underestimating whole-of-public-sector commitment to ICM.

The ICM program in Queensland has been experimental, evolutionary and incremental. The early pilot studies informed the expansion and maturing process to the point that over 35 catchments are now formally included in the program. Catchment Coordinating Committees are formally endorsed by the (now) Landcare and Catchment Management Council. Until 'committees' gain this recognition they are termed 'groups'.

This developmental process depended on improved understanding of community-based processes, acceptance and adoption of the need for strategies to guide catchment action, and more recently scaling up to the regional level in the form of regional NRM strategies. We include here the guidelines for these planning processes.

The adoption of a strategic approach was encouraged by strong incentives – no strategy, no funding. Section 3.4 tabulates the progress of ICM groups towards having LCMC endorsed strategies. Several papers in this chapter outline the process and there have been reviews by DPI (1993) and since 1995 regular fora of the ICM Coordinators and chairs.

4.1 INTEGRATED CATCHMENT MANAGEMENT IN QUEENSLAND - AN OVERVIEW AND REVIEW

Philip Rowland, Department of Natural Resources, Brisbane Queensland
Don Begbie, Department of Natural Resources, Brisbane, Queensland.

Integrated Catchment Management has been operational in Queensland on a state wide scale since 1991. Since then over thirty catchment coordinating committees have formed covering 77% of the state. The formation and participation of committees is voluntary, there not being a legislative framework. Committees undertake planning and coordination roles and to date, nine have produced catchment management strategies. Considerable community and government support has been generated for ICM and much of the planning work is now being translated into action. Significant issues facing ICM in Queensland include the need to clarify linkages with other planning and resource management structures and processes (for example regional planning initiatives for growth management), the lack of major funds for implementation, possible legislation needs to underpin implementation and the maintenance of a significant organisational structure built primarily on volunteers.

1 INTRODUCTION

This report is based on a number of sources of information including statewide workshops held in 1994 and 1996, reviews of ICM in the Lockyer Valley and Mitchell River, a survey of catchment committee chairs and coordinators and various academic reports on aspects of ICM in Queensland. The paper was reviewed by Mr Ken Stallman.

Integrated Catchment Management in Queensland was a State Government initiative. The lead administering role was given to the then Department of Primary Industries and the important roles of other agencies, including the Departments of Environment and Heritage, Lands, and Housing and Local Government were recognised. Initially the program had three key elements:

1. A Strategy for ICM in Queensland was published in 1991. This document outlined the broad policy and structural arrangements.
2. Five 'case studies' were initiated with Departmental support. Selected catchments were the Johnstone and Mitchell Rivers in north Queensland, the Pioneer River in central Queensland, and the Mary River and Lockyer Creek in south east Queensland
3. A special allocation of funding was secured by the Department for the ICM program which also included significant Treecare and Research (Downstream Effects of Agricultural Practices) components.

In developing the Queensland Strategy for ICM, models of similar programs or initiatives already operational in other states were reviewed, and aspects considered appropriate for Queensland, were incorporated. The resultant strategy was a mix of the approach being taken in Western Australia (strongly based on the Mitchell and Hollick proposals) and NSW as interpreted by John Burton. In summary, the significant elements of the approach promoted in Queensland were:

- Voluntary program. Participation in ICM was to be voluntary for both community and government.
- Community based, meaning that all structures were to have a majority of community members. Formation of catchment coordinating committees (CCCs) was dependent on interest from the community and other sectors.
- Partnership between the levels of government, industry and the community. All sectors and key stakeholders are to be involved. As the CCCs do not have statutory "teeth", implementation of strategies relies on negotiated and voluntary action by responsible agencies and individuals.
- Processes used by the committees in coordinating and integrating management of the catchment are to be participative and consultative.
- ICM is about taking a strategic and planned approach to tackling important issues. This should be a feature of the actions of all catchment management groups.

The five pilot studies provided an opportunity to learn about the processes needed for the formation of catchment committees and to develop an understanding of the nature of the interactions between the groups and individuals involved. Deliberately, all the pilot study catchments were different in the way they formed their catchment committees and tackled the issues in the catchment. However, the approaches used were consistent with the overall framework for ICM as set out in the State Strategy. Reviews of the pilot studies and other catchments (particularly the Mitchell, Lockyer Creek and Herbert) have confirmed the framework but a number of aspects of the program have been identified as needing attention. They are described later in the paper.

ICM Framework

Structural components of the program comprised catchment coordinating committees and catchment care groups organised in catchments across the state and the Catchment Management Coordinating Committee (CMCC) to provide state-wide policy. A support unit for ICM and landcare was established within the Department of Primary Industries. By 1993 it became apparent that there was a degree of confusion between the roles of catchment care groups and landcare groups. This was resolved by CMCC deciding not to encourage formation of catchment care groups, but that local groups interested in catchment management come under the landcare banner.

Features of the various structures are summarised in Table 1.

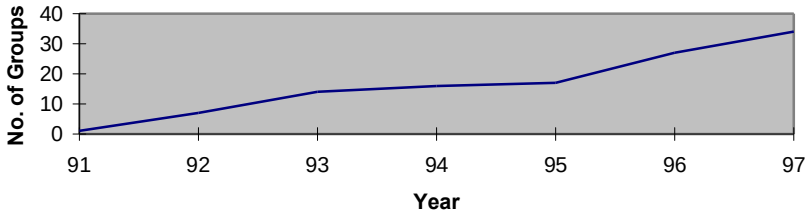
Apart from the pilot studies, the CMCC sought to encourage the formation of catchment committees in priority areas. This was prompted by the preparation of a brief document outlining priority areas for ICM action. Priorities of the Department of Primary Industries and other state departments, and Regional Assessment Panels were the targets of the document.

Using the experience gained in the pilot studies and other catchments, guidelines for the formation of catchment committees were produced. It became apparent that the formation of groups was a two phase process. First a steering group was formed to scope the issues needing attention and to prepare and oversee a plan for establishment of a formal catchment committee to address these issues. Second, a CCC was formed and endorsed by the Minister for the then Department of Primary Industries, now the Department of Natural Resources (DNR).

Catchment groups were initiated by local governments (there are 132 in Queensland), local interest groups, landcare groups, water boards and river improvement trusts. DNR provides facilitation support through Regional Extension Officers (ICM and landcare) and technical advice. Initially establishment and operating grants were somewhat nominal, but now up to $10,000 is paid per annum to some committees for operational support. Attendance fees are not paid but most committees meet at least the out-of-pocket expenses of members.

Most interest in catchment management was initially focused on the coast with groups in the wet tropics, and south east coastal areas where rapid development was increasing concerns about the condition of the catchment and adjacent coastal areas. Progress in the formation of catchment groups is shown in Figure 1.

Fig 1 Formation of catchment groups in Queensland



In 1992, Queensland joined the Murray Darling Basin Agreement. There were some conditions attached to Queensland's involvement including limiting involvement in pooling arrangements for infrastructure maintenance and exclusion of some decisions of the Ministerial Council prior to joining. Using an extensive process of community consultation, a preferred structure for Murray Darling Basin in Queensland was determined. It involved the formation of four CCCs and a regional CCC based around the four major catchments in the basin.

While there have been few changes to the CMCC since its formation in 1992, a recent review of the CMCC and the Queensland Landcare Council has resulted in a decision to merge these bodies into one called the Landcare and Catchment Management Council (LCMC). This new body has yet to meet. A significant sub-committee of the CMCC, entitled Downstream Effects of Agricultural Practices (although it deals with all land use impacts on water resources), meets three times a year and coordinates and leads research and development as well as monitoring of catchment condition and catchment processes. Considerable interest exists in understanding the impact of land based and river activities on estuarine and marine habitats, particularly the Great Barrier Reef.

Funding

State government support for the program was initially provided through a $5M new initiative grant from Queensland Treasury. This funding was only available for three years but at the end of that time it was added to base allocation for the Department, ensuring ongoing funding to ICM activities.

As well as establishment and operating grants, the state government provides over $250,000 per year in project grants to catchment committees and other bodies for conduct of projects leading to the development of a catchment

management strategy. Since 1995, a further $750,000 has been provided per year as grants for the implementation of catchment strategies. These grants have been administered in conjunction with the NLP/NHT assessment process and a number of projects have attracted commonwealth funding.

2. CURRENT SITUATION

Catchment Coordinating Committees

From three catchment coordinating committees in 1992, there are now 32, including two regional coordinating committees. A list of groups is provided in the Appendix. While not recognised under legislation, all committees are encouraged to be incorporated. Most are.

Over 77% of the state is covered by catchment committees, the major areas not currently involved in ICM are the upper Burdekin catchment area, areas in Cape York, and some areas on the coastal south east.

The Catchment Management Lake Eyre Basin Steering Group is not formally a catchment group under ICM. The current charter of the group is to assess the need for, and role of a catchment group should one be formed. A meeting scheduled for late 1997 will decide these issues.

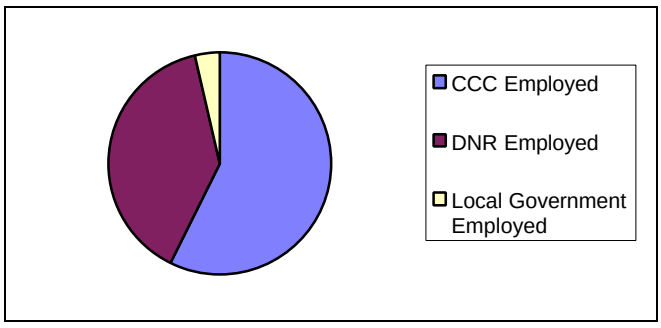
While the majority of catchment groups are formally recognised under the State Government's ICM initiative, there are a number of other groups practising ICM that do not come under this umbrella. These include the Brisbane River Management Group and the Logan Catchment Resource Management Group.

Reflecting the partnership approach, membership of all recoginsed CCCs is diverse. However, they have at least an officer from the DNR as a member, and most committees have other government departments as active members also.

All catchment steering groups and endorsed groups have access to establishment and operating grants although not all utilise these sources of funds. A number of local governments provide limited support in cash, while all catchment groups have members representing local government (either elected members or staff). Local governments and some producer organisations (for example CANEGROWERS) provide in kind support in the form of office accommodation and administration.

All catchment groups have a part-time or full-time coordinator/project officer/administrator. Initially these positions were provided by the state government, but increasingly committees have employed their own staff. A breakdown of the employment status of coordinator/project officer/administrator is shown in Figure 2.

Figure 2 Current employment status of coordinators/project officers/administrators



Catchment Management Strategies

CCCs have produced nine endorsed catchment management strategies including one regional strategy. Another seven are in an advanced draft condition.

Policy Framework

There have not been any significant changes to the state policy on ICM since its preparation in 1991. The only significant change has been encouraging groups that may have been called catchment care committees to come under the banner of Landcare.

Policy and guideline development has focused on operating grant support to groups and the preparation, endorsement and implementation of catchment management strategies.

The key role of local government has been recognised as important to ICM in Queensland. An ICM and Local Government Communication Plan was developed in 1995 to guide the linkages needed between catchment management and local government. A number of the strategies in the plan are in the process of being implemented, including a project to prepare guidelines to assist local government planners implement catchment management principles and practices in planning schemes.

New legislation for Natural Resource Management is being drafted. It will provide for the formation of statutory bodies or trusts to manage catchments. Several catchment groups are looking into forming statutory bodies, particularly to oversee the implementation of strategies and action plans.

Institutional Arrangements

Project grants are available (approximately $1M in 1997/98) through state grants for the preparation and implementation of strategies. Groups also avail themselves of over $4M in grants directly through the Natural Heritage Trust.

A network of Landcare and ICM extension officers (at least one in each of the five DNR regions) provide process support to CCCs.

The new Landcare and Catchment Management Council has yet to meet. The DEAP sub-committee will report to this body.

3 VISION/STRATEGIC DIRECTIONS

For ICM to progress in Queensland, a number of strategic directions and actions are needed. From consultation with catchment groups and others, these key areas have been identified.

1. A significant task of the new LCMC will be the preparation of a strategic and business plan to guide the direction of ICM. It will need to address many of the points listed below.
2. Confirmation of political support within State Government is needed to ensure the considerable investment by government and community will be able to continue long enough to fulfill its charter. Changes in government and policy positions has a destabilising effect on continued community commitment.
3. Local Government has been identified as a crucial player in advancing integrated resource management due to its pivotal role in land use planning and development control. Enhanced involvement by local government in CCC activities and the implementation of catchment management principles and practices is required. Improved awareness and communication with local government, as outlined in the ICM and Local Government Communication Plan will enhance this process.
4. Better integration and broad government support will assist catchment groups in preparing and implementing their strategies.
5. As a number of catchment groups are moving from the planning phase to implementation, new structures may be needed to achieve implementation. The use of Trusts or other statutory structures may be needed in some situations.
6. As implementation resources are limited, catchment management groups need to focus their efforts and target those significant issues which can have most impact. This applies at all levels in the structure - state, regional or catchment.
7. Flexibility in the nature and operation of catchment groups will ensure they are tailored to and meet community needs and expectations.
8. Additional catchment groups are required, particularly in priority areas like the upper Burdekin and Gold Coast.
9. The support base for catchment groups should be widened so that it is not seen as only a DNR initiative, but one very much involving the community with whole-of-government support.
10. Training and skills development for CCC members and project officers has been identified as a high priority need.
11. Linkages between CCCs, regional planning bodies (local government based) and planning process for NHT need to be clarified.

4 SUMMARY AND RECOMMENDATIONS

Before making recommendations an analysis of the ICM approach, as practised in Queensland, is presented. This analysis is not exhaustive and forms a start for thought and discussion of the issues. It is presented in the SWOT format which does result in some repetition of comments between categories.

Analysis

Strengths

- Broad and somewhat nebulous goals provide opportunities for a variety of ways of doing ICM and for tailoring the approach to suit the situation.
- Network of CCCs has been established and a mass of people have been exposed to, and had the opportunity for, some involvement in ICM.
- ICM has become institutionalised within DNR, and there is considerable support (at least at a policy level) for ICM in other government departments and local government
- Both levels of government, the community and industry have responded to the philosophy of catchment management in a variety of ways. The broad goals of ICM provide for a range of interests to be involved and contribute to achieving these goals.
- The participative approach has been well received by most sectors of the community. It has assisted in making catchment plans and management activities consistent with local needs and goals.
- Most CCCs have used a representative model for membership of the management committee. This has resulted in a broad diversity of interests coming together on the committees - often for the first time - with generally very positive results.

Weaknesses

- Breadth of the program has resulted in the need for individuals and groups to gain an understanding of what is trying to be achieved and how to apply it. This is a costly and time consuming process (for example it takes up to five years for catchment groups to be become fully operational)
- Financial resources to achieve these broad but ambitious goals have been erratic and low.
- CCCs have no statutory powers or revenue raising capability.
- Participants are concerned that the linear planning then implementation approach to ICM has resulted in questions being asked about the availability of resources to implement once all the planning is completed.
- Complex planning process are required with no single process being used. Each catchment group has needed to invent its own.
- Absence of a 'whole of government' approach, commitment or involvement.
- Emerging problems like biodiversity conservation and nutrient enrichment of waterways (particularly in the estuarine and marine areas) are not well defined technically, and ICM groups have found it difficult to focus their priorities and activities where these are key issues.
- Implementation mechanisms for catchment strategies are non existent or unclear.
- Funding guidelines and arrangements keep on changing making the targeting of these resources difficult.
- The public generally has a low level of awareness of natural resource management issues.
- Only a small percentage of the public are active participants in catchment management activities.
- Lack of monitoring and feedback mechanisms to provide data on the impacts of ICM and the effectiveness of the approach.
- Representative model used to form management committees is not always effective in getting the right individuals involved. It leads to assumptions about the quality of communication between the group and the constituent member organisations. There is a need for all members to take a whole-of-catchment view of issues - not protect sectarian interests.
- Differences in perceptions between the chairs and coordinators of progress in achieving the aims and objectives of catchment groups.

Opportunities

- Clear technical solutions exist for many of the natural resource management problems in Queensland.
- A critical mass of people has been established with an understanding of ICM and skills in its application.
- ICM has challenged people to understand causes and respond to them through targeted action to get real changes (for example much of the riparian zone management and rehabilitation activities).
- Local government is being increasingly involved in catchment management in a variety of ways (from stormwater management to rural residential design). Interest by local government continues to grow.
- Among those involved in, or at the fringes of groups doing ICM, there is a much greater acceptance of the need for a planned and strategic approach than seven years ago. The challenge is in translating this interest into practical action.
- The planning that has already occurred provides those groups with opportunities to tap into funding resources that require strategic and integrated solutions to problems (for example the NHT regional component).

Threats

- High expectations of what ICM can deliver by the community and government.
- Over reliance on voluntary contributions by community and industry without commensurate rewards, particularly in the short term.
- The level and breadth of skills needed to actually implement the complex catchment management plans produced.
- Identification and establishment of the right implementation arrangements (structures, policy and resources) for it to go ahead.
- On going resourcing of what are very large, voluntary based organisations.
- Ongoing commitment to technical and administrative support by government agencies, local government, industry organisations and tertiary institutions is required for the partnership between these bodies and the community to work. Voluntary community people involved in catchment groups require this support.

5 CONCLUSION

While it has had its teething problems ICM is alive and well in Queensland. This is reflected not only in the proliferation of community based groups practicing and promoting catchment management, but also the increasing number of agencies and organisation who see ICM as a 'way of doing business'.

Some of the broader coordination issues like that between landcare and ICM is being tackled in catchments and more recently at a state level through the formation of the Landcare and Catchment Management Council. DNR has also recently re-formed a landcare and catchment management group to coordinate, steer and support both initiatives.

Structures and mechanisms to achieve coordination between regional landcare, catchment management, regional planning and natural heritage trust arrangements are being developed and should result in better outcomes delivered more efficiently.

In the short term, a review of pilot studies is planned for 1997/98 to better identify weaknesses in the current arrangement and to assist in planning the changes needed. Training needs of CCC members is also a priority task for this year.

In the longer term, key areas requiring attention include:

- How to do more with less. The budgets of most public organisations are shrinking - what ways can we assist CCCs and others do what needs to be done without needing to find vast additional resources?
- The needs of accountability and performance are increasing. It will be a challenge to find ways to identify and monitor the tangible benefits that accrue from ICM.

Table 1 General features of catchment management structures in Queensland 1991 to 1997

Structure	Role	Membership	Operation	Support
Catchment Coordinating Committees	• Foster community awareness and understanding • Prepare and oversee implementation of catchment management strategies	• Broadly based with a majority of non-government members. Needs to include all significant stakeholder groups and interests. • Representational membership from key organisations.	Monthly/bimonthly	• Cash and inkind from organisations in the catchment • Establishment and Operating grants from DNR • Technical support from state government agencies, local government and tertiary institutions • DNR provided public liability and personal accident insurance cover
Regional Catchment Coordinating Committees	• Oversee preparation of Regional Strategy • Coordination of subcatchment planning and implementation • Link with other regional planning activities.	• Broadly based with a majority of non-government members. Includes all significant stakeholder groups and interests. • Representational membership from key organisations and CCCs in subcatchments	2 or more times per year	• Inkind support through working groups • Cash and inkind from organisations in the catchment • Establishment and Operating grants from DNR • Technical support from state government agencies, local government and tertiary institutions • DNR provided public liability and personal accident insurance cover
Catchment Management Coordinating Committee	• Policy/advisory at State level • Recommend priorities and allocation of resources • monitor implementation and progress • foster coordination between key organisations and agencies	• Peak industry and community bodies and state government departments • Appointed by Minister	3 times per year	• Executive support • Inkind support through sub-committees • DNR provided public liability and personal accident insurance cover
Catchment Care Groups	• Education/awareness	• Interested individuals	As needed	• No specific support mechanisms. • DNR provided public liability and personal accident insurance cover

4.2 Framework, Arrangements and Policy

4.2.1 Arrangements, Policy and Legislation

Initial Stage

1. Strategy for ICM (DPI 1991)
2. Five Pilot Studies – provided opportunities about the processes needs for the formation of CCCs
3. Special Allocation of funding secured by the Department for ICM – program included – Treecare and DEAP
   - focused on five pilot study areas (each involving the establishment of a CCC)
   - local authorities, conservation groups, Landcare groups and other State departments and agencies are also adopting the ICM approach in up to a dozen other catchments

ICM Framework

"Structural components of the program comprised catchment coordinating committees and catchment care groups organised in catchments across the state and the Catchment Management Coordinating Committee (CMCC) to provide state-wide policy. A support unit for ICM and Landcare was established within the Department of Primary Industries. By 1993 it became apparent that there was a degree of confusion between the roles of catchment care groups and Landcare groups. This was resolved by CMCC deciding not to encourage formation of catchment care groups, but that local groups interested in catchment management come under the Landcare banner.

Apart from the pilot studies, the CMCC sought to encourage the formation of catchment committees in priority areas. This was prompted by the preparation of a brief document outlining priority areas for ICM action. Priorities of the Department of Primary Industries and other state departments, and Regional Assessment Panels were the targets of the document.

Using the experience gained in the pilot studies and other catchments, guidelines for the formation of catchment committees were produced. It became apparent that the formation of groups was a two-phase process. First a steering group was formed to scope the issues needing attention and to prepare and oversee a plan for establishment of a formal catchment committee to address these issues. Second, a CCC was formed and endorsed by the Minister for the then Department of Primary Industries, now the Department of Natural Resources (DNR).

Catchment groups were initiated by local governments (there are 132 in Queensland), local interest groups, water boards and river improvement trusts. DNR provides facilitation support through Regional Extension Officers (ICM and Landcare) and technical advice. Initially establishment and operating grants were somewhat nominal, but now up to $10 000 is paid per annum to some committees meet at least the out-of pocket expenses of members.

Most interest in catchment management was initially focused on the coast with groups in the wet tropics, and south east coastal areas where rapid development was increasing concerns about the condition of the catchment and adjacent coastal areas.

In 1992, Queensland joined the Murray Darling Basin Agreement. There were some conditions attached to Queensland's involvement including limiting involvement in pooling arrangements for infrastructure maintenance and exclusion of some decisions of the Ministerial Council prior to joining. Using an extensive process of community consultation, a preferred structure for Murray Darling Basin in Queensland was determined. It involved the formation of four CCCs and a regional CCC based around the four major catchments in the basin.

While there have been few changes to the CMCC since its formation in 1992, a recent review of the CMCC and the Queensland Landcare Council has resulted in a decision to merge these bodies into one called the Landcare and Catchment Management Council (LCMC). A significant subcommittee of the CMCC, entitled Downstream Effects of Agricultural Practices (although it deals with all land use impacts on water resources), meets three times a year and coordinates and leads research and development as well as monitoring of catchment condition and catchment processes. Considerable interest exists in understanding the impact of land based and river activities on estuarine and marine habitats, particularly the Great Barrier Reef." (Rowland and Begbie, 1997: 2)

Policy Framework

"There have not been any significant changes to the state policy on ICM since its preparation in 1991. The only significant change has been encouraging groups that may have been called catchment care committees to come under the banner of Landcare.

Policy and guideline development has focused on operating grant support to groups and the preparation, endorsement and implementation of catchment management strategies.

The key role of local government has been recognised as important to ICM in Queensland. An ICM and Local Government Communication Plan was developed in 1995 to guide the linkages needed between catchment management and local government. A number of the strategies in the plan are in the process of being implemented, including a project to prepare guidelines to assist local government planner implement catchment management principles and practices in planning schemes." (Rowland and Begbie, 1997: 3)

Relevant Agencies; Their Role and Legislation

"During the beginnings of ICM the program was managed by the Department of Primary Industries (DPI) but was coordinated by a Catchment Coordinating Committee which included input from the Departments of Lands (DOL); Housing, Local Government and Planning (DHLGP); and Environment and Heritage (DEH). Currently, ICM is managed by the Department of Natural Resources (DNR) but coordinated by the Landcare and Catchment Management Council (LCMC) with inputs from the Department of Primary Industries (DPI), Department of Environment and Heritage (DEH), the Department of Local Government and Planning (DLGP), the Queensland Conservation Council, Greening Australia, The Queensland Farmers' Federation, the fishing industry, the water industry, the Local Government Association of Queensland and community members."

Department of Natural Resources (DNR)

"The DNR was formed in 1996 and combines the former Lands Department functions with the Water Resources and Resource Management units previously resident in the Department of Primary Industries. The DNRs aim is to address present and future management issues in the areas of land administration, water and resource management through an innovative and coordinated approach. The DNR is the lead agency responsible for facilitating ICM in Queensland. The DNR is responsible for managing the land, water and vegetation within the state of Queensland. The main programs provided by the DNR are: Land Services; Resource Management; Regional Infrastructure Development; Resource Science and Knowledge; Commercial Water Services; Land Court and Tribunals and Corporate Management. ICM is a sub-program of the Resource Management program. With regard to community participation programs such as ICM, the DNR aims to provide 'a sound and productive working partnership with the community and clients in both the public and private sectors, across the whole range of departmental activities - particularly in relation to provision of services, infrastructure and value-adding information and other assets of the department."

Department of Primary Industries (DPI)

"The DPI had responsibility for natural resource management for primary production and was the state agency responsible for the national landcare, save-the bush, and one billion trees programs. DPI administered 11 separate pieces of legislation which dealt with natural resource policy. These include the:

- *Soil Conservation Act* (Qld., 1986);
- *Water Resources Act* (Qld., 1989);
- *River Improvement Trust Act* (Qld., 1940);
- *Forestry Act* (Qld., 1959);and
- *Recreation Areas Management Act* (Qld., 1988).

The DPI initiated the Queensland ICM program and remained its prime mover until 1996 when the DNR was formed. The then Minister for Primary Industries, Mr Ed Casey showed strong support for the ICM program during his term in office. Interagency communication on ICM was initially limited, and started at the state Catchment Management Coordinating Committee (CMCC), which included members from DOL, DEH, the Local government Association and DHLGP.

The Government of Queensland adopted a whole of government (WOG) approach to natural resource management, with many planning and resource management issues being widely distributed within the government for consideration. DPI used the WOG approach to promote ICM at a state level. The (CMCC) has now been replaced by the (LCMC). The next institutions after the (LCMC) are Catchment Coordinating Committees (CCCs). These committees combine local industry leaders, local authority representatives, and selected staff from DNR, DPI, DEH and DLGP. The inclusion of community members and government is intentional - it develops co-management partnerships for natural resource management."

Department of Environment and Heritage (DEH)

"The Department of Environment and Heritage includes the National Parks and Wildlife Service, and various environmental agencies responsible for environmental impact assessment, environmental aspects of planning, and codes of practice for activities which impact on the environment. DEH administers a number of legislative instruments including the:

- *Nature Conservation Act* (Qld., 1992);

- *Environmental Protection Act* (Qld., 1994); and
- *Contaminated Lands Act* (Qld., 1991).

Codes of Practice for Agriculture have been developed under the Environmental Protection Act which have the potential to act as a framework for implementation of ICM activities relevant to agriculture.

There is no formal process for integrating the activities of DEH and DPI and DNR or DoE in catchments or on properties. However, the Codes of Practice offer an opportunity for close collaboration between DEH, DPI and DNR during the development, promotion, implementation, and monitoring of the Codes. This has already happened in some catchments - for example the Johnstone - where Best Management Guidelines have been developed for each agricultural industry as a means of compliance with the Codes of Practice for Agriculture."

Department of Local Government and Planning
"THE DEPARTMENT OF LOCAL GOVERNMENT AND PLANNING (DLGP) OVERSEES THE ACTIVITIES OF LOCAL AUTHORITIES AND STATE PLANNING REGULATIONS. THE DEPARTMENT ADMINISTERS THE:

- *Local Government (Planning and Environment) Act* (Qld., 1990); and
- *Local Government Act* (Qld., 1993).
- *Integrated Planning Act 1997*

DLGP has responsibility for regional development strategies, such as SEQ2001 and FNQ2010, and works with DNR, DPI and DEH on these."

Local Government
"Local Government, and their regional associations, play an integral role in catchment management in Queensland. In addition to having significant control of planning and development activities, local authorities have responsibilities for the delivery of water and sewage services to urban areas. This combination ensures that local authorities have a vested interest in water quality at the delivery and discharge ends of the reticulation system. Local authorities have widely supported landcare groups in many areas of Queensland. DPI and other departments work with Town Planners and City Engineers in a collaborative but informal relationship. There are 12 Shires in the Mary River Catchment, and a single regional association of local authorities. There are 2 Shires in the Johnstone River Catchment." (AACM & CWPR. April 1995: 34-38).

ICM Legislation

"Integrated Catchment Management is not currently covered by any special legislation. However, a range of existing legislative mechanisms can be used to achieve its aims. Catchment coordinating committees operate through existing legislation administered by government departments, local governments and statutory agencies. The table below shows the relationships between various government Acts and natural resource management issues.

Statute	**Governing areas**
Local Government (Planning and Environment) Act	Local government planning schemes; landuse zoning; State planning policies; strategic planning
Soil Conservation Act*; Soil Survey Act*	Coordinated runoff; erosion control
River Improvement Trust Act*; Resources Act*; City of Brisbane (Flood Mitigation Works Approval) Act*	Water Streambank erosion; clearing in watercourses; watercourse alteration; water storage; levee banks; water allocation and licensing; materials extraction in watercourses
Forestry Act* Sawmill Licensing Act*	State Forest management; forest products on Granting of sawmill licenses
Fisheries Act Fishing Industry Organisation and Marketing Act	Fish habitats; fisheries management Quality assurance, marketing, price
Mineral Resources Act	Water quality downstream from mines; rehabilitation; environmental standards on mine sites
Rural Lands Protection Act; Land Act (Queensland)	Clearing vegetation on leasehold land; property reconstruction; management of leasehold land; control of weeds and pest animals
Contaminated Lands Acts	Management of contaminated lands
Environmental Protection Bill Nature Conservation Act	Standards for water and air quality; environmental protection policies Protected areas; critical habitats; endangered species; nature conservation plans
Coastal Protection Bill Great Barrier Reef Marine Parks Act	Coastal protection areas; management plans Zoning and management of marine waters

Native Title Act; Native Title (Queensland) Act	Recognition and protection of native title; mechanisms for determining title claims
Community Services Act	Support and assistance to Aboriginal and Torres Strait communities
Recreation Areas Management Act	Activities and conduct in recreational areas
Brisbane Forest Park Act	Protecting Forest Park, by zoning, land use criteria
Wet Tropics World Heritage Protection Management Act	Protection of fragile areas, tourism management

These Acts are part of the Natural Resource Management legislation."
Queensland Government Department of Primary Industries. *Integrated Catchment Management, Bringing People Together.* Queensland Government, Department of Primary Industries, Brisbane.

Queensland Government Integrated Planning Act 1997.
The Act provides a framework to integrate planning and development assessment so that development and its affects are managed in a way that is ecologically sustainable and for related purposes.

The purpose of the Act is to seek to achieve ecological sustainability by -
a. coordinating and integrating planning at the local, regional and State levels; and
b. managing the process by which development occurs; and
c. managing the effects of development on the environment including managing the use of premises.

4.2.2 Funding

"In the 1990 State Budget, the Queensland Government provided a special allocation of $3.5m for an Integrated Catchment Management (ICM) initiative. This involved a coordinated land, water, forest and wetland management program based on key river catchments and designed to boost management of the resource base so fundamental to the long-term future of rural industries (1990 Budget Paper No. 8).

The ICM initiative was to be built on the highly successful Landcare program, and to incorporate the valuable network of community groups which had been established throughout Queensland. Its overall aim was to achieve long-term sustainability of the State's primary production by focussing on the natural systems in the landscape and utilising the expertise available in forest, land and water management in the restructured Department of Primary Industries.

The ICM initiative was continued during the 1991/92 and 1992/93 financial years, with special allocations of $3.5m each year, and was reviewed in May 1993 to evaluate its achievements and to determine its future direction and funding requirements. In 1999 the ICM is still operating in Australia. (DPI, 1993: 1-2)

4.2.3 Related Land and Water Management Programs

There are a number of land and water management programs that are closely linked to ICM. They include, State of the Rivers, WAMP, Waterwatch, Waterwise, National Heritage Trust Activities.

Waterwise

Waterwise Queensland' is an outcome of the Commission study 'Water Supply Sources of South-east Queensland.' Following this study, Cabinet directed that new water supply storages be investigated and existing supplies be conserved through better urban water demand management. By creating a change in attitude towards use, consumption levels can be reduced, existing resources will meet community needs for longer and capital expenditure on new resources can be deferred.

Some local authorities have already instigated their own water conservation strategies. These have generally been costly exercises. The Commission project team has assembled a statewide public education campaign which can be customised to suit individual local authorities in Queensland. This will avoid duplication and other saving in literature and other communication costs through economies of scale.
(The Source - Integrated Catchment Management News and Views. April 1992. 1: 6).

State of the Rivers

"The State of the Rivers project originated from a clear need for comprehensive information on the physical and environmental condition of the rivers and streams of Queensland, especially in terms of in-stream habitats, values and condition. DPI has already established programs for monitoring water quality and stream flows on a statewide basis. Assessment of the condition of some river sections has been undertaken by other agencies but is restricted in scope. There was a need for a catchment by catchment assessment of the ecology and physical condition of all the States' watercourses using a consistent and objective methodology. The data

collected can be related to other databases and will establish a baseline for use in the long-term monitoring of watercourse condition.

Dr John Anderson of AquaEco Services, East Lismore was commissioned to develop the methodology. The methodology is focused on taking a 'snap shot' of the condition of streams now, that is, at the time of survey. It does not aim to establish trends or the dynamics of changes in stream condition. But it is possible to establish trends or the dynamics of changes in stream condition. But it is possible to establish current condition in terms of a perceived extent or deterioration compared with the original pristine condition, using local undisturbed sites as a standard against which change can be measured.

Actions are coordinated with ICM groups and DNR and DPI staff to undertake surveys of priority streams. *(The Source - Integrated Catchment Management News and Views.* May 1993. 3: 8).

Waterwatch

"At a local level, Waterwatch programs are hosted by Landcare and ICM committees, environmental groups, local governments and other community organisations. Some of these groups were involved in water quality issues before the Waterwatch network was launched in 1993. Other programs have been established only recently.

Limited resources mean that groups in the network depend on sponsorship so they can continue to carry out their work. Various local community organisations and industries provide financial assistance, in-king support or people to do Waterwatch legwork. Waterwatch Queensland is also supported by the three levels of government. As well, local governments in Brisbane, Logan, the Gold Coast, Redland and Caboolture directly fund their own Waterwatch programs. Pine Rivers and Ipswich councils have also initiated Waterwatch activities.

The groups have similar themes, promoting:

- the need for an environment which will sustain diverse communities of indigenous species as well as human populations.
- the ecologically sustainable use of our natural resources.
- community empowerment, so that ordinary people can make a real contribution to managing and protecting their environment.

TWO CORE WATERWATCH ACTIVITIES ADDRESS THESE THEMES: Education and water quality testing. Most groups provide a valuable educational role by raising community awareness of water quality and catchment management issues. Given the interrelationship between human activity, catchment health and biodiversity (which requires a range of healthy habitats), this is an important aspect of the Waterwatch program.

As well, many make use of their catchment management links to assist in the provision of water quality data to help support local decision making. Groups which are collecting data for this purpose are moving to ensure that it is collected in a scientifically rigorous way.

There are two main reasons why this is important. First, communities want their data to be a useful tool for monitoring the condition and trend of the natural environment. Second, to be able to convince sceptics of the need to look after natural environments in more sustainable ways, they need evidence to back them up.

The groups use some or all of a variety of established tests which measure various chemical balances and habitat values. The chemical tests include turbidity (ie. how much particle matter is suspended in the water), pH (ie. how acid or alkaline the water is), salinity, temperature, flow rate, and levels of nitrates and phosphates (commonly used in fertilisers) and dissolved oxygen. The biological tests include surveys of waterbugs and assessments of vegetation, macrophytes, faecal coliforms and algae. (The State of Queensland, Department of Natural Resources. 1998. *Waterwatch Queensland Reflections 1996-97.* The State of Queensland, Department of Natural Resources, Brisbane: *pp* iv-v)

WAMP

Water: A Precious Resource

Water is the essential ingredient in almost everything we do. We use it in and around our homes, at work, and in many of our recreational activities. Our industries, such as agriculture and manufacturing, are dependent on it for their success. However, water is not in endless supply. We need to use our water resources wisely to ensure everyone receives a fair share.

To cater for the many competing uses of water, Queensland must manage its water resources in such a way that everyone's interests are considered. It also has to plan for the future, so that this generation as well as the next will have access to quality water resources.

The quality of our water resources is dependent on how well we look after our river systems and groundwater supplies. Dams and weirs are useful in providing access to reliable supplies of water. However, such activities interrupt the natural flow of our river systems. If these interruptions are too severe, or prolonged, the health of the river will deteriorate, affecting ecosystems and, in some cases, water quality.

The water needs of instream ecosystems must be catered for in order to keep our river systems healthy, and to maintain the quality of water. The link between healthy ecosystems and water quality has been recognised by governments and the community. Therefore, the Queensland Government is looking at the way we manage our water resources, and is making changes so that our use of water will be ecologically sustainable.

These changes will be challenging and will take some time to make. They may also require us to reconsider the ways we use water. Despite these challenges, this is a very exciting time for the people of Queensland. If we all work together, it's a chance for Queensland to get it right, so that our precious water resources will be used for the maximum benefit now and in the future.

Most importantly, it's a chance for everyone to have a say and be involved in decisions about the way we manage our water.

Existing Framework

In order to understand why changes to the water industry are necessary, we need to look at the way our water resources are presently managed:

- In Queensland, all water resources in declared groundwater areas and in watercourses, lakes and springs – are controlled by the State.
- Water entitlements of users are established through a system of licenses issued by the Department Natural Resources, on behalf of the State. Licenses may be issued to users on regulated or unregulated watercourses and in declared groundwater areas. Applications for a license to obtain water are considered in relation to the availability of supply. Essentially, however, applications for new water entitlements are considered on a 'first come – first served' basis.
- When an entitlement is made under license, the entitlement is attached to a specific property description or parcel of land. A license entitlement (in whole or in part) is not transferable (on a permanent basis) to other persons or parts of the catchment.
- Riparian landholders have an 'as of right' stock and domestic entitlements to provide water for stock and basic human needs.
- Some individuals do not have a specific water entitlement, but rely on beneficial flooding. For example, some graziers rely on beneficial flooding. For example, some graziers rely on beneficial flooding to maintain pastures and floodplain waterholes for stock. Many floodplain ecosystems also rely on this flooding.
- The current allocation framework does not have specific provisions for the supply of water for the environment.
- Decisions about granting of licenses are made by the State with opportunity for community input. A right of appeal to prescribed categories of landholders exists in many cases.

Reasons for change

As competition for scarce water resources increases, and the water needs of the environment are recognised, problems with the existing allocation framework are emerging. Some of the concerns are:

- The 'first come –first served' approach to dealing with applications for new entitlements can lead to diminishing security of existing entitlements. License holders are seeking more security in their entitlements, so that they may plan for the future with more certainty.
- The attachment of an entitlement to a property description blocks the opportunity to transfer water to other parts of the basin for perhaps more beneficial uses.
- The lack of means to protect those who rely on beneficial flooding may result in such individuals being adversely affected.
- The lack of means to allocate water to satisfy the environment has, in some areas, resulted in the degradation of natural resources and deteriorating river health.
- The cost of administering the existing licensing system is likely to escalate as demand for water increases, and legal challenges to water licensing decisions are made.
- Limited opportunities exist for water users and the community in general to become involved in decisions about licensing the use of water and the effect this has on the State's water resources.

The planning process

To address the concerns with the existing system the Queensland Government is introducing two new planning processes. These are:

- **W**ater **M**anagement **P**lanning processes; and
- **W**ater **A**llocation and **M**anagement **P**lanning processes.

Both these processes will result in the development of a plan.

A **WAMP** plan is a more detailed and rigorous process based on the best available social and economic data, and involves detailed environmental and hydrological analyses. A WAMP is intended to provide the framework for establishing in the plan area, property rights in water and resources management conditions under which 'trading in water' can occur, separate from land.

A statutory **WMP** process was provided in amendments to the Water Resources Act, 1989, assented in December 1996. A WMP is intended to provide the policy and principles for dealing with license applications in 'sensitive' areas of the State. The WMP process doe not involve the same complexity and detail of hydrologic-modelling and environmental studies as a WAMP and will not result in any changes to the way existing entitlements are made.

This information booklet explains the details of the **WAMP** process. If you would like additional information on the **WMP** process, the Department of Natural Resources has also produced a booklet on that process.

The WAMP process aims to provide the guidelines which will encourage fairer, more efficient, and ecologically sustainable use of water.

The development of a WAMP will be based on the best available ecological, social, and economic data, and involves extensive hydrologic analysis of a catchment. Essentially, the WAMP process will progress through the following steps:

- the total water resources within a catchment will be defined;
- all existing entitlements within the catchment will be identified;
- environmental flow provisions will be determined;
- additional priority water requirements (for example, town water supplies) will be reserved;
- water resources (if any) for further allocation will be defined;
- existing entitlements will be defined under the hydrologic model and, where appropriate, will become tradeable within sections of the catchment; and
- the rules for further allocation and management of water will be described and documented in a Water Allocation and Management Plan.

Local communities will play a valuable advisory role throughout the steps of the WAMP process.

Benefits of the WAMP process

The establishment of Water Allocation and Management Plans will result in benefits to water users and the broader community. Specifically, a WAMP will result in:

- improved planning confidence for primary and secondary industries;
- increased community involvement in the way water will be used in the future, particularly when negotiating an acceptable balance between competing uses;
- healthier river systems and instream habitats through the inclusion of environmental flow provisions; and
- the introduction of tradeable "property rights" in water. Property rights will lead to the separation f licenses from land. They will become personal assets which can be, where appropriate, traded to others within the catchment.

Improved planning confidence

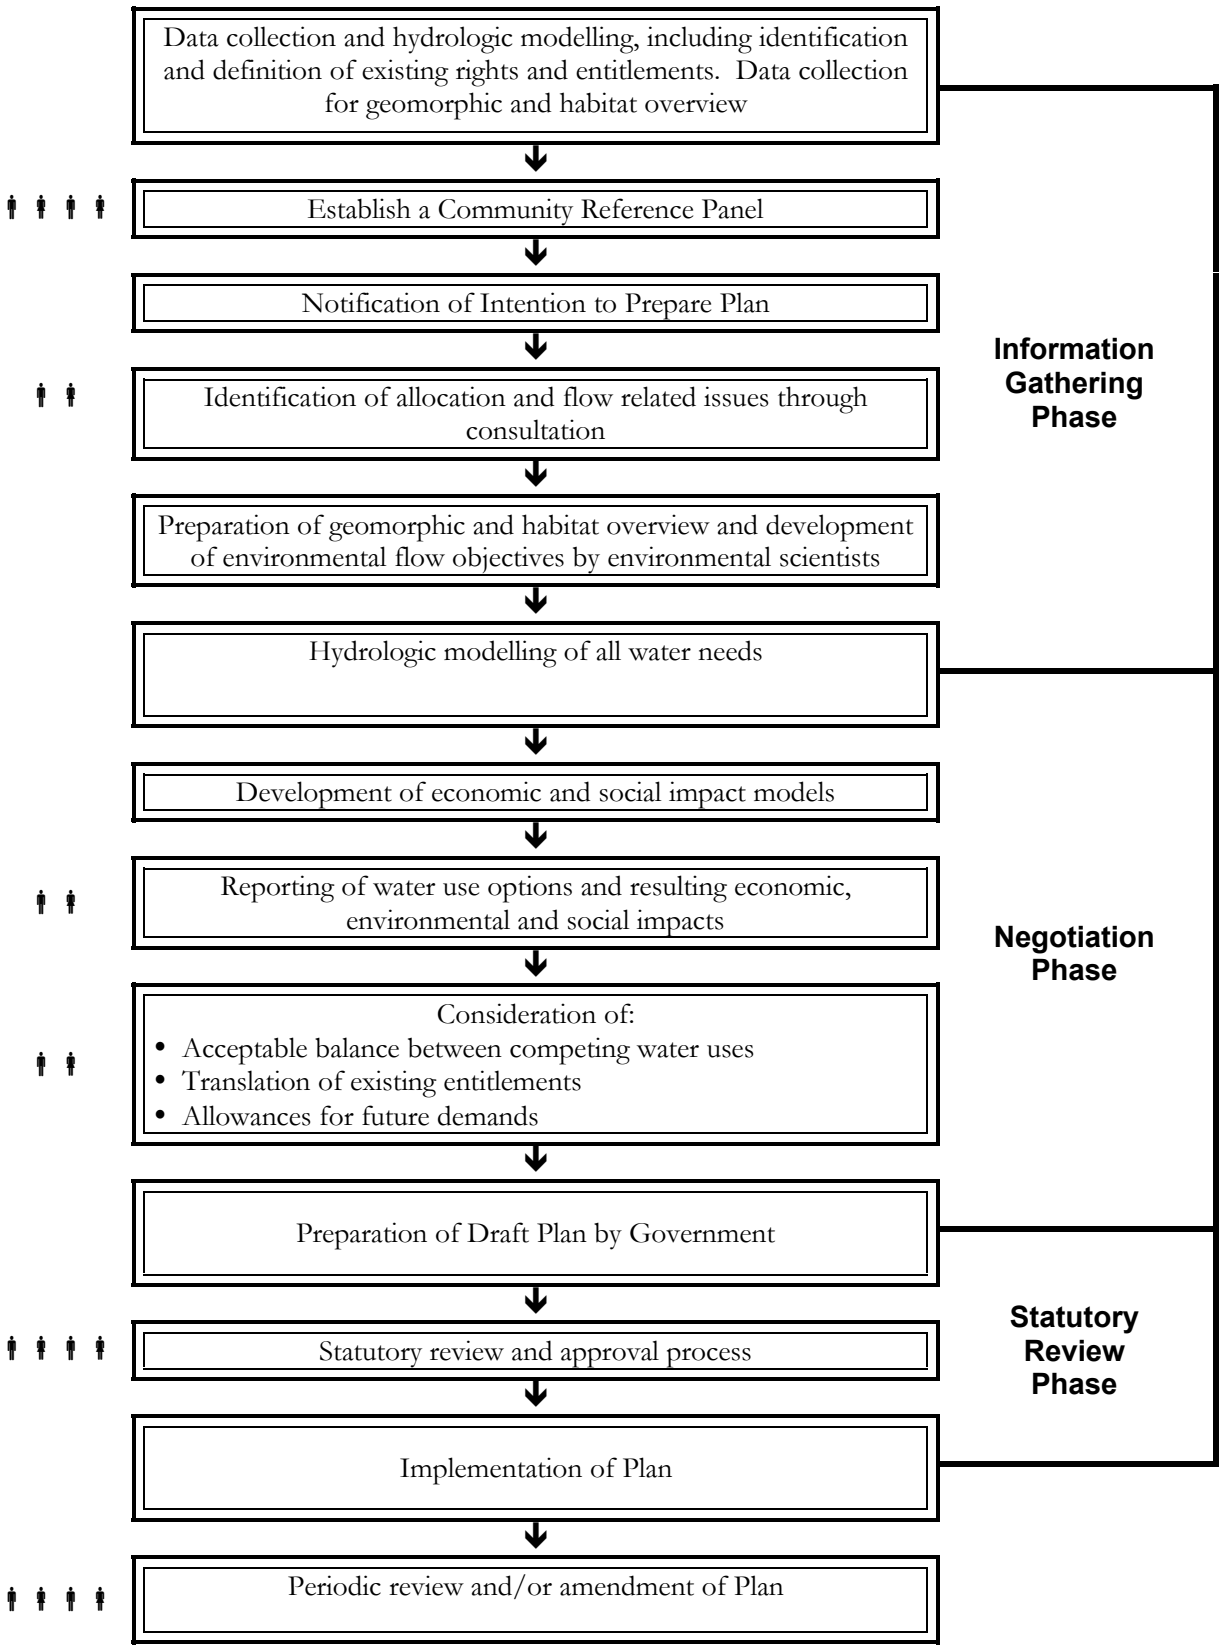
The WAMP process will result in improved planning confidence for users, as entitlements (existing and new) will be based on **basin-wide** hydrologic models. These models will include existing streamflow, licensing and storage data, as well as the amount of water available (if any) for future demand.

The additional knowledge and understanding of our river systems obtained from these hydrologic models will promote more informed decision making, and therefore ensure greater certainty of supply. The hydrologic models will be used as a planning tool to assess the impact of proposed developments on the environment, and the security of existing water entitlements.

Community input

The involvement of communities in decisions about the present and future use of water is a key feature in the WAMP process. Individuals and groups will be able to put forward their ideas and concerns through a community reference panel (CRP). A CRP will be made up of a broad mix of people to ensure everyone's interests are protected.

Water Allocation and Management Planning



Indicates stages in the process where Community Reference panel input is required

Indicates stages in the process where the general community will provide input

Throughout the WAMP process, the community will be kept informed and the Community Reference Panel will provide an observational role.

A CRP will be formed at the beginning of each WAMP process and will consist of representatives from key groups in the community, such as:

- Primary and Secondary industries
- Business and commerce groups
- Conservation groups
- Indigenous Australians
- Fishing industries
- Tourism industries
- Recreational groups
- Local governments
- Community groups

The CRP will meet during various stages of the WAMP process to provide advice and input and present community concerns. It is intended that members of the CRP will then report back tot he groups they represent to keep them informed of the progress of the WAMP process.

A regional WAMP coordinator, employed by the Department of Natural Resources, will liaise with CRP members and the broader community to provide information and support.

Protecting the environment

A key objective of the WAMP process is the maintenance and, where necessary/possible, improvement of instream ecosystems. This will be achieved by defining the water needs of these ecosystems (environmental flows).

A panel of environmental scientists will be appointed to identify particular environmental requirements of aquatic and riparian habitats. The panel will consist of experts from a range of scientific fields. For example, it may include a fish biologist, a river morphologist, and a riparian botanist. Defining how much water ecosystems need (and when it is needed) is a complex process, and it takes time and expertise.

Environmental flow requirements will be determined by the panel of environmental scientists after considering the needs of all ecosystems within the basin. Options for environmental flows will be developed.

All of the options will then be analysed for their impacts on water availability for other users. Each option will be considered in terms of its effectiveness in meeting environmental needs, as well as the resulting economic, social and indigenous impacts and opportunities.

A panel of experts, including resource economists and sociologists, will assess the economic and social impacts and opportunities. An indigenous input group will assess the impacts and opportunities with regard to the indigenous communities.

After careful consideration, the Department of Natural Resources (with advice from the CRP) will introduce the option with the best and fairest "mix" of water uses, taking into consideration the needs of all users in the basin.

Once environmental flows have been determined, they will be given formal recognition under the WAMP, much the same as other entitlements are protected. That is, the environment will have a legal right to water allocation.

Protecting the rights of existing water users

The WAMP process will include a basin audit to identify all existing entitlements. Existing and any new entitlements authorised within a WAMP will be described in a manner consistent with the hydrologic model for the basin.

The community will play a part in developing a "draft WAMP". Individuals will be able to view the draft plan to see how entitlements will be specified, and will be able to make submissions in response to the draft. All submissions will be reviewed, and some changes may be made to the draft. After approval of a WAMP, it will become the basis for allocation and management decisions.

It is expected that most licensees will retain their existing entitlements, but with a more comprehensive and secure definition, and that the terms of the license will not change significantly. However, if there are exceptions where entitlements are diminished, the license holder will be able to claim compensation. Principles for compensation are being developed as part of the proposed Natural Resource Management Legislation.

Interim arrangements

Existing license arrangements will continue to apply until a WAMP is fully developed. This means that, in some basins, existing arrangements will continue for several years. However, in basins where the allocation of water is already high, it may be necessary to restrict the issue of further licenses. This is to prevent over-allocation and to ensure that the hydrologic model, on which a WAMP is bases, is still accurate at the introduction of the plan.

When completed, a WAMP will become a statutory plan under the proposed Natural Resource Management Legislation. However, until this legislation is enacted, WAMPs will be developed as interim policies rather than statutory plans.

Water reforms
The Queensland Government, like other States and Territories, is a member of COAG (Council of Australian Governments). COAG consists of the Prime Minister, the State Premiers, the Territory Chief Ministers and the President of the Australian Local Government Association. By agreement among all governments, COAG develops major policies for the future of Australia.

At its meeting in February 1994, the members of COAG, including Queensland, agreed that action was needed to stop widespread degradation of our natural resources and to ensure the sustainable use of water.

The Queensland Government's Rural Water Pricing and Management document details the current approaches to a number of water reform matters in Queensland.

The WAMP process provides Queensland with a means of implementing reforms in regard to water resource allocations and entitlements that have been recommended by COAG.

When and where will WAMPs be undertaken
The WAMP process is very complex. To be sure everyone's interests are protected, the best mix of competing uses is achieved, and that everyone has had a chance to have a say. It may take about 2 years to develop a Water Allocation and Management Plan.

The WAMP process is currently under way (at various stages of development) in the following basins:
- Fitzroy
- Condamine-Balonne
- Border Rivers (jointly with NSW)
- Logan
- Barron

The WAMP processes are also planned to commence in 1997/98 in the following basins:
- Pioneer
- Burnett
- Burdekin

Additional information
For more information about the WAMP process in the above basins, please contact the relevant Department of Natural Resources office. These offices are listed in the back of this booklet.

4.2.4 Natural Heritage Trust – Operational Arrangements in Queensland

Purpose of this document

> This document has been prepared to inform industry, community and government – at local, regional and State levels – of the operational arrangements for the implementation of the Natural Heritage Trust (NHT) in Queensland. These arrangements have been endorsed by the Queensland Government and key stakeholders.

The Natural Heritage Trust: scope and components
The Natural Heritage Trust is about action. It represents the biggest financial commitment to the environment by any government in Australia's history - $1.25 billion Australia-wide. These funds will be available over fiver years for a range of integrated nature conservation, environmental protection, natural resource management and sustainable agriculture programs. The NHT recognises the fundamental link between these programs in achieving ecologically sustainable development (ESD)

The NHT covers five broad areas:
- vegetation (Bushcare: the National Vegetation Initiative, Farm Forestry Program)
- biodiversity (National Reserve System Program, Endangered Species Program, World Heritage Area Management)
- land (National Landcare Program, National Weeds Program, National Feral Animal Control Program, Advanced Property Management Planning)
- rivers (National Rivercare Program, Fisheries Action Program, Murray-Darling 2001, National Wetlands Program)

- coasts and marine (Coasts and Clean Seas Program including Marine Species Protection Program, Coastcare, Coastal and Marine Planning Program, and other programs)

Some NHT programs, such as the National Land and Water Resources Audit and those addressing clean air and waste management are managed by the Commonwealth Government on a national basis.

The Coasts and Clean Seas Program is currently administered under its own memorandum of understanding and has its own arrangements. The Department of Environment is the lead agent in Queensland for the delivery of all elements in the Coasts and Clean Seas Program.

NHT funding in Queensland is provided on three levels for:
- local community group projects
- regional projects (designed to implement priorities identified in regional strategies)
- projects that address State-wide issues

The bulk of NHT funding for Queensland is channelled through the State Government to regional areas, for implementing regional strategies and action plans through local and regional projects. The Queensland Government has entered into a partnership agreement with the Commonwealth Government. This agreement incorporates mechanisms at State and regional levels that target investment, account for expenditure and evaluate outcomes.

The Commonwealth has provided up to $40 million from NHT to protect the conservation and cultural values of Cape York. A Cape York NHT Plan has been prepared as an integrated regional initiative and will be administered under separate arrangements.

In recognition of the key role local government plays in the delivery of NHT program outcomes in Queensland, the State Government has prepared a memorandum of understanding with local government through the Local Government Association of Queensland.

Guiding principles of the NHT in Queensland
Commonwealth and State guidelines have been developed to ensure that the integrated package of NHT programs and related initiatives are delivered efficiently and effectively. The guidelines emphasise the importance of integrated delivery and the achievement of maximum on-ground outcomes, as well as partnerships between the community, industry and all levels of government. Queensland's process for NHT implementation is consistent with national guidelines.

There are 11 guiding principles for the NHT in Queensland:

1.Community groups (such as Landcare, catchment committees and conservation bodies), industry organisations and local government will be actively involved at local, regional and State levels in developing strategies, setting priorities, assessing funding proposals and evaluating results.

2.Bodies that develop and implement regional strategies will be separate from those that assess funding applications. However, these bodies will be linked through a common policy framework to ensure the integration of regional priorities with the assessment process.

3. Decision making will be devolved to the lowest level commensurate with efficient and effective application of available funds, and ensuring that national and State objectives, priorities and outcomes are met.

4.Bodies established to develop regional strategies and others established to assess funding applications will have an appropriate balance of interests in nature conservation, natural resource management and sustainable agriculture to reflect the range, breadth and expertise need to deliver NHT outcomes.

5. The regional management processes for the NHT will be sufficiently flexible to accommodate issues and communities that extend beyond any one region, eg. bioregional issues.

6. The encouragement and support of further regional strategic planning will enhance the integration of environment, natural resource management and sustainable agriculture programs. Priority will be given to ensuring all regions have the opportunity to develop a strategic approach to their issues.

7. Regional strategies will facilitate an integrated approach to investment that targets priority environmental, nature conservation, natural resource management and sustainable agriculture issues. While emphasising a strategic approach, opportunities still exist to support good local initiatives.

8. Regional organisations must have access to existing environmental data held by State agencies, in order to inform the preparation of regional strategies. The State must take the lead in coordinating access to data.

9. Every effort will be made to draw upon existing national, State, local government and catchment strategic plans. However, these plans must be amended to reflect the national and State objectives, priorities and outcomes of the NHT. No single regional strategic planning process for the NHT will be applicable across Queensland.

10. In allocating funds, priority will be given to
- implementing regional and catchment strategies and action plans
- targeting priority biodiversity and resource degradation issues across the State
- maximising social and economic benefits
- stimulating ongoing investment in ESD
- achieving on-ground change

11. Monitoring and evaluation of the development and implementation of the NHT in Queensland is critical, to ensure that funds are being allocated appropriately and that national and State outcomes are being achieved.

Queensland Management Arrangements
The NHT in Queensland is managed and implemented as a community-led process in partnership with government through a series of community and agency organisations (see Figure 1). These organisations include the Department of Natural Resources (DNR) which is the led agency for the NHT in the State. The Natural Heritage Committee of Ministers (NHCM), the Landcare and Catchment Management Council (LCMC) and regional strategy groups (RSGs) provide strategic direction for the NHT programs. The State Assessment Panel (SAP) and regional assessment panels (RAPs) ensure projects submitted for funding are technically sound and address priorities.

The Natural Heritage Committee of Ministers
The NHCM consists of the Minister for Natural Resources (as chairperson), the Minister for Environment, the Minister for Primary Industries, and the Minister for Local Government and Planning. The NHCM (with input from the Commonwealth) appoints the SAP and RAP chairpersons and members, and submits the State funding bid to the Commonwealth NHT Board.

The Landcare and Catchment Management Council
In recognition of the wide range of issues and interests the NHT addresses, the Queensland Government has appointed the LCMC to provide advice and strategic direction for the operation, management, administration, monitoring and evaluation of the NHT. The LCMC ensures that the NHT process is transparent and integrated and is responsible for reviewing the management arrangements. The LCMC also provides strategic advice to the Minister for Natural Resources on Landcare and catchment management in Queensland and provides a link between the community and government.

DNR provides executive support to the LCMC.

Membership structure of the LCMC
The LCMC has an independent Chairperson and Deputy Chairperson, appointed by the Minister for Natural Resources, and 18 members as follows:
- two members nominated by the Queensland Conservation Council – one with expertise in, and the ability to represent the interest of, in-stream freshwater or marine habitat conservation
- one member nominated by Greening Australia – Queensland
- three members nominated by the Queensland Farmers' Federation to represent extensive agriculture, intensive agriculture and grazing industries
- one member nominated by fishing interests
- one member nominated by water industries
- one member nominated by the Local Government Association of Queensland
- four government department representatives – one each from DNR, DPI, DoE and DLGP
- five community members to represent the five State regions.

Responsibilities of the LCMC
The responsibility of the LCMC come under the areas of planning and advice to government, community leadership and monitoring. They are as follows:

Planning and advice to government
- to develop the framework and provide strategic direction for the operation, management and administration of the NHT in Queensland
- to advise the Minister for Natural Resources on Landcare, catchment management and NHT issues

- to provide advice on State-wide priorities, policies, strategies and guidelines for the implementation of natural resource management, biodiversity conservation and sustainable production

Community leadership
- to develop guidelines for the membership and endorsement of RSGs, RAPs and the SAP
- to develop guidelines to ensure open and accountable assessment of project applications by RAPs and the SAP
- to provide guidelines for the preparation and endorsement of regional and/or catchment resource management strategies
- to endorse regional and/or catchment strategies and regional boundaries for the efficient management of regional strategy development and project assessment
- to foster support for land-holders and community groups in carrying out Landcare and catchment coordination activities
- to coordinate the implementation of State-wide public awareness and education campaigns
- to foster coordination and integration between government agencies and industry, professional and community organisations

Monitoring
- to develop a framework for monitoring, reviewing and evaluating the effectiveness of NHT programs in Queensland

State agency Coordination
DNR is the lead agency for the operation and management of the NHT in Queensland. The responsibility for NHT programs are shared by DNR, the Department of Environment (DoE) and the Department of Primary Industries (DPI). DNR is responsible for NHT policy, external funds management, Landcare, Murray-Darling 2001, Rivercare (including Waterwatch), Weeds and Feral Animal Control. DoE is responsible for Bushcare, National Reserves System, Endangered Species, Wetlands and World Heritage. DPI is responsible for Property Management Planning, Fisheries Action, and Farm Forestry.

The Department of Local Government and Planning (DLGP) also plays a key role in the delivery of NHT programs.

The administration of the NHT process is handled by a secretariat within NHR.

Major departmental policy and operational issues relating to NHT implementation that might arise will be dealt with by a committee of chief executive officers (CEOs) from the relevant government agencies. This committee is the CEO Committee of Natural Resources, Environment and Planning. Support for the CEO committee is provided by the NHT Interdepartmental Working Group, comprising representatives from each of the key agencies. This process will facilitate the adoption of a whole-of-government approach in support of the NHCM and the LCMC.

Management Structure of the NHT process in Queensland

Features of the NHT process (see Figure 1) include:
- The LCMC manages the implementation of Landcare and catchment management and develops the strategic framework for the operation of the NHT in Queensland
- Other councils, such as the Rural Lands Protection Board, Environment Protection Council and the Futureprofit Advisory Council, may provide technical input to the LCMC for each of the NHT program areas
- The LCMC provides guidance and direction to RSGs, RAPs and the SAP
- RSGs develop regional resource management, biodiversity conservation and sustainable production strategies
- The independent SAP appointed by the NHCM, with input from the Commonwealth, assesses State-wide projects and prepares the State bid for recommendation to the NHCM for funding.
- The NHCM recommends the State bid to the Commonwealth NHT Board

Queensland Priorities for NHT investment
Queensland's objectives, strategies and priorities have been incorporated into the partnership agreement between the State and the Commonwealth. They form an essential component of the NHT process to guide strategic plans, action plans and projects and are closely linked to the Commonwealth priorities.

The Queensland priorities will provide the benchmarks by which NHT projects will be ranked for funding allocation. These priorities will be reviewed annually to ensure that they are serving as the best guide to future planning.

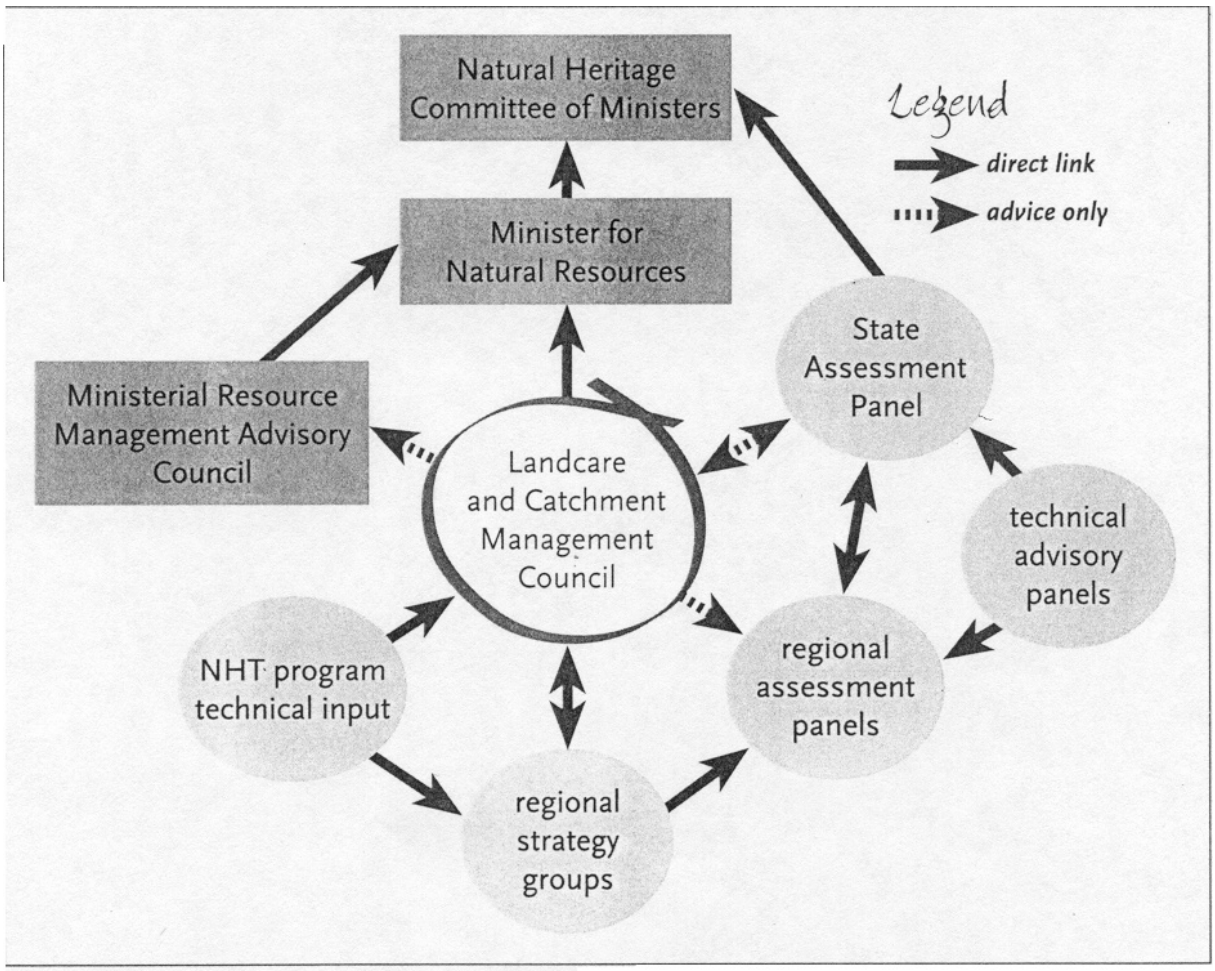


Figure 1 The NHT management process in Queensland

Regional strategy development

Queensland has 13 NHT regions (as shown in Figure 2) based on a combination of Landcare, catchment and bio-geographic boundaries. However, the boundaries should not be adopted rigidly. Some issues in a biogeographical region will often be relevant across a number of catchments or river basins and will therefore need to be dealt with in a number of regional strategies.

An RSG will be formed in each NHT region to prepare a regional resource management/biodiversity conservation strategy in accordance with guidelines prepared by the LCMC. The following criteria need to be met in the development of a regional strategy:

- Regional strategies should cover the range and breadth of environmental, nature conservation, natural resource management and sustainable agriculture issues, as well as NHT component objectives relevant to each region
- Regional strategies are to be developed primarily to facilitate an integrated approach to investment which targets priority issues within a region.
- Regional strategies should be consistent with State and national strategies and priorities, but should address the unique features, needs and priorities of each region
- The development of regional strategies should take up only a small proportion of the overall effort and resource put into addressing environmental, nature conservation, natural resource management and sustainable agriculture issues.
- Regional strategies should be regarded as dynamic documents which will need to be reviewed regularly to ensure they remain relevant after issues are addressed and new challenges emerge.

Regional Strategy Groups

Membership structure of RSGs

LCMC has prepared guidelines for the formation and endorsement of RSGs. Each RSG should be chaired by a community representative and encompass a broad membership. The membership is to include skills and experience covering environmental protection (including biodiversity conservation), sustainable agriculture and natural resource management.

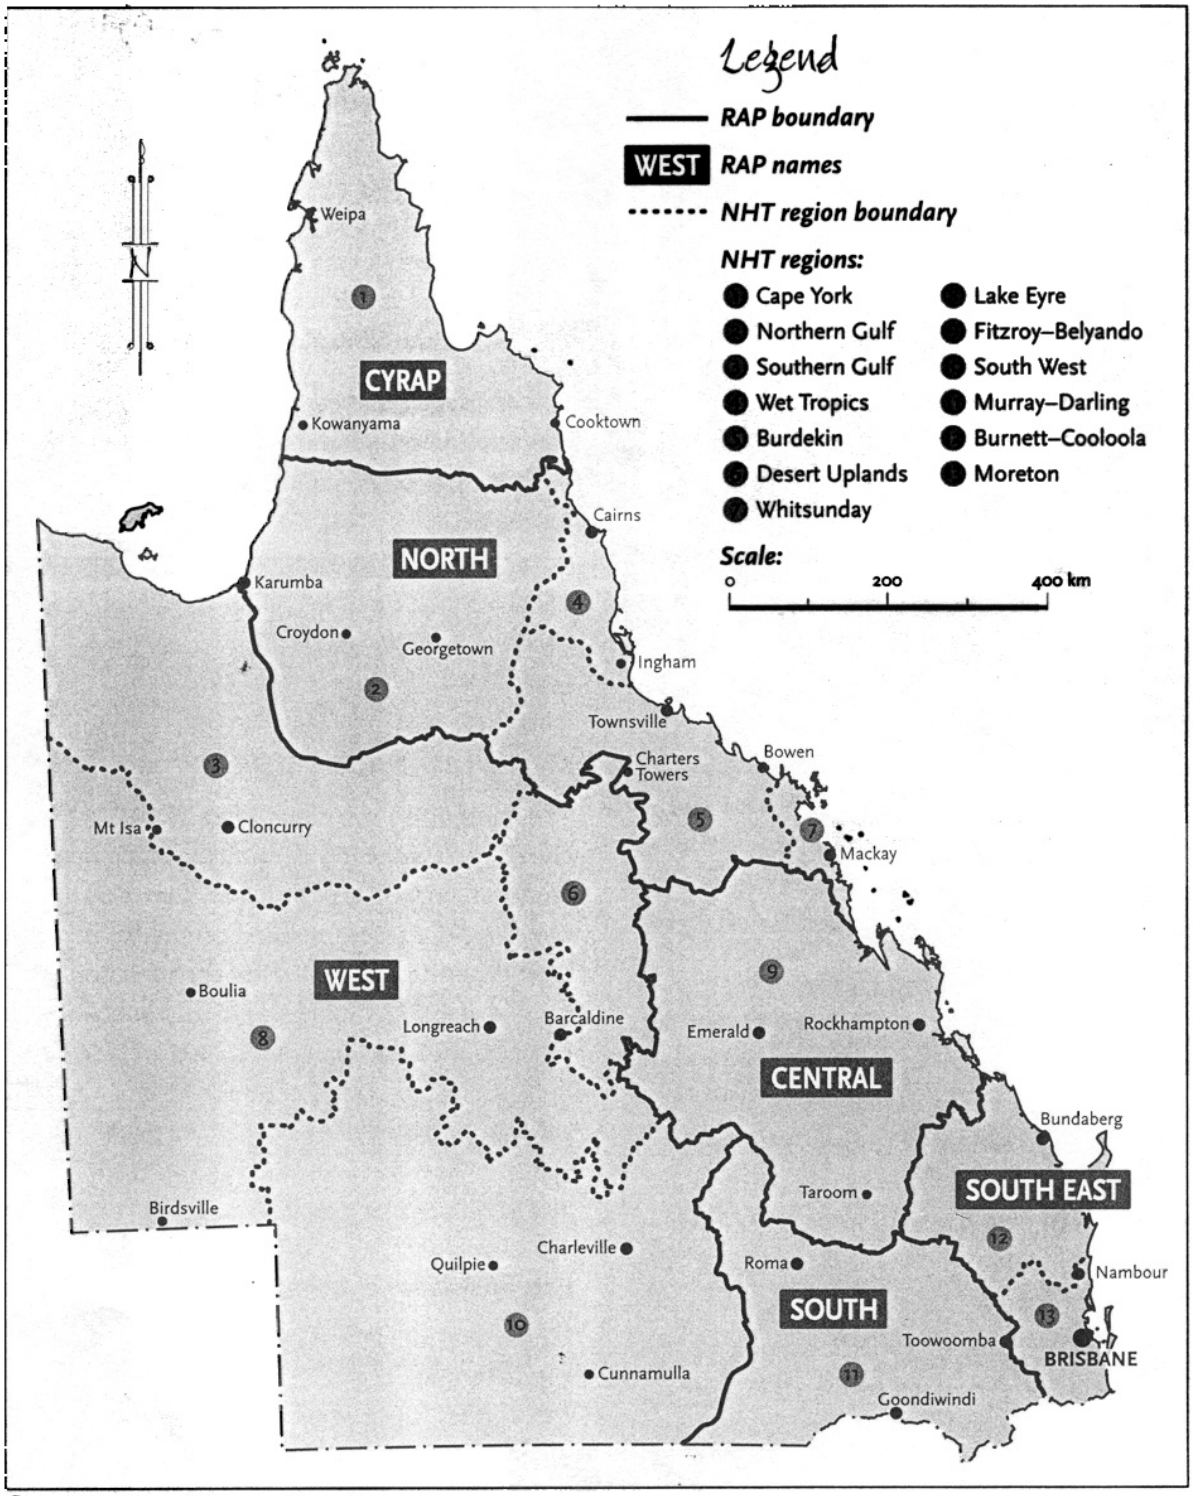

Figure 2 The NHT regional boundaries

People with skills in land, water, marine, vegetation, conservation, farming and indigenous land management should be included on each RSG as appropriate to the needs of each region. State and local government members must also be included in the RSGs.

Where possible the RSGs should build on, involve or use existing bodies rather than create new organisations. The membership structure of the RSGs should allow for differences between regions and ensure the most appropriate structure is established in each region.

Responsibilities of RSGs

The responsibilities of RSGs are as follows:

- To develop regional resource management strategies within the framework of State and national strategies and in accordance with State guidelines
- To identify priority issues to be addressed in the region.

- To develop action plans for the implementation of project activities by community groups and agencies in accordance with priorities identified in the regional strategy
- To maintain an overview of regional and community projects
- To identify gaps that need to be addressed to achieve priority outcomes identified in the regional strategy
- To commission project, where necessary, to deliver priority outcomes in the regional strategy and to address gaps identified by the RAPs and SAP.

It is envisaged that responsibility to manage the distribution of funds for approved projects across the regions could be developed to the RSGs.

Project Assessment
The LCMC will be responsible for establishing the annual NHT planning, assessment and evaluation framework (see Figure 3). Using the agreed procedures and guidelines, applications for project funding will be called for each year.

The regional assessment panels (RAPs) and State Assessment Panel (SAP) will assess the competing community, regional and State-wide bids in relation to Commonwealth, State, regional and local priorities and strategies. Applications for regional and community projects will be assessed by the RAPs. State-wide applications will be assessed by the SAP.

Regional assessment panels
Five RAPs are appointed by the NHCM in accordance with guidelines developed by the LCMC. RAPs consist of 8 to 10 community, local government and indigenous members, together with State agency staff.

The Cape York Regional Advisory Panel (CYRAP) has been established to provide advice to government on the implementation of the Cape York NHT Plan. It will also act as a RAP for the purposes of assessing NHT funding proposals from Cape York.

Membership Structure of RAPs
The community members of each RAP are chosen by a selection committee made up of community and agency people. Community members are recommended on the basis of their expertise in biodiversity conservation, natural resource management and sustainable production. Selection criteria also include skills in project assessment, monitoring and evaluation. The chairperson of each RAP is selected from the panel's community members and appointed for a three year term.

Responsibilities of RAPs
The responsibility of RAPs are as follows:
- To determine eligibility of projects for funding
- To assess, with technical support, project applications against regional strategies
- To recommend the regional funding bid to the SAP
- To identify and advise RSGs of needs not addressed in the regional bid.
- To monitor and evaluate regional and local projects
- To report on the progress of projects in achieving stated outcomes and provides feedback to project proponents

Under the arrangements established for Cape York, CYRAP will not recommend its funding bid to the SAP, but will deal directly with the NHCM.

The State Assessment Panel
The SAP has been appointed by the NHCM, in accordance with the LCMC guidelines. SAP membership is skills-based and includes expertise in the following areas: local government issues, regional and State biodiversity and natural resource management strategies, biodiversity and nature conservation, vegetation management, sustainable production, fisheries management and indigenous land use.

Membership structure of the SAP
The SAP has 18 members which include:
- An independent community chairperson appointed by the NHCM
- The chairpersons of the five RAPs
- One member each from the Local Government Association of Queensland, Greening Australia – Queensland, the Queensland Conservation Council, Threatened Species Network (World Wide Fund for Nature), Queensland Farmers' Federation, Queensland Commercial Fishermen's Organisation of Sunfish, the Aboriginal and Torres Strait Islander Commission and the LCMC
- One representative each from DNR, DoE, DPI and DLGP

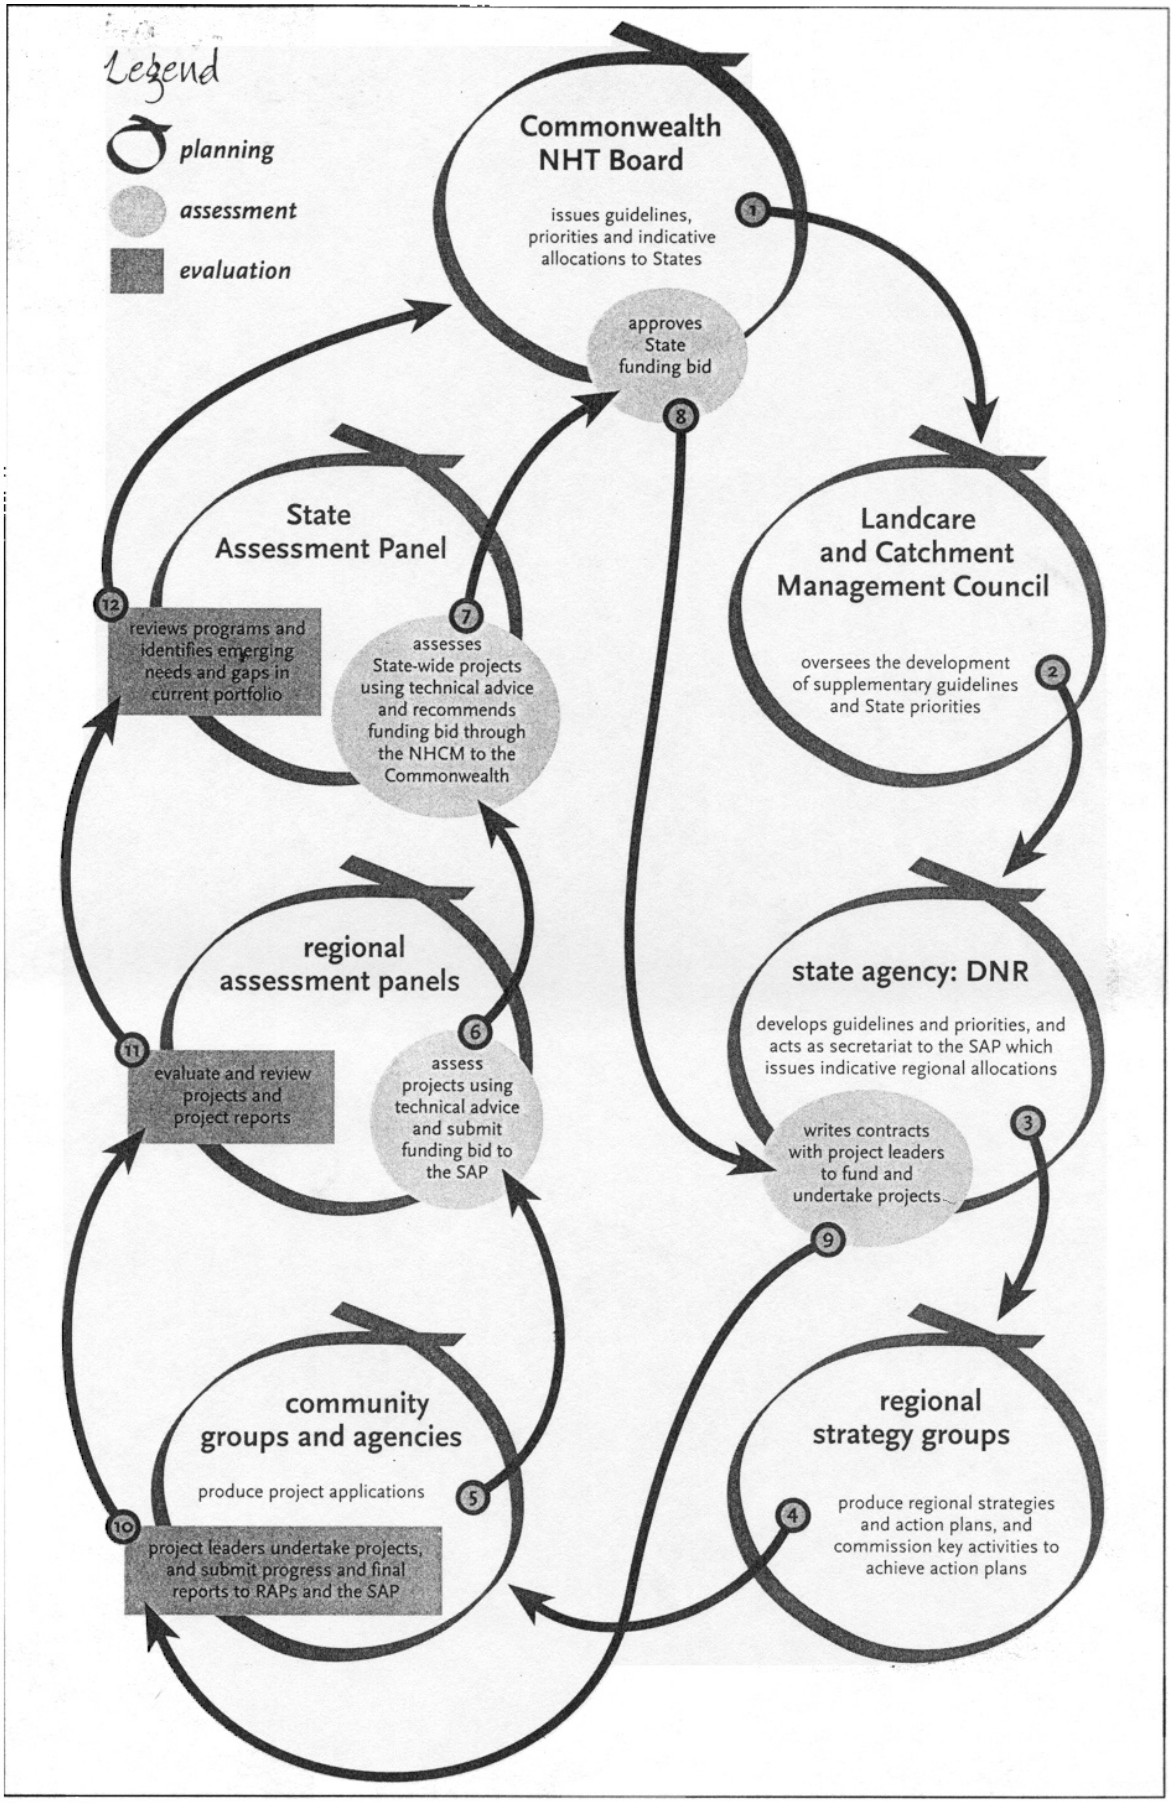

Figure 3 **The NHT planning, assessment and evaluation cycle**

Responsibilities of the SAP

The responsibilities of the SAP are as follows:

- To assess State-wide projects against the State-wide strategy

- To allocate funding across the regions based on merit and in accordance with priorities provided by the LCMC
- To integrate State-wide and regional project funding proposals into a State bid for approval by the NHCM
- To ensure open and accountable assessment or project applications in accord with State guidelines
- To oversee the monitoring and evaluation or State-wide projects
- To review programs and identify emerging needs and deficiencies in the current portfolio
- To report on the NHT operational arrangements as they impact on the State

Funding Arrangements
Following approval by the Commonwealth NHT Board, the Commonwealth Government will forward payments to DNR, the NHT lead agency in Queensland. DNR will generate project agreements between the State Government and community groups applicants for the implementation of projects. Community groups must be legal entities to receive payments.

DNR, through is regional offices, will forward approved NHT funds directly to community groups for the current year, for new and continuing projects

Funding for projects undertaken by other government agencies, for example the Department of Environment, are to be transferred to the agency under a generic agreement to cover all NHT funded projects for each year

4.2.5 A Strategic Analysis of Landcare and Rivercare Funding in Queensland: Report to the NHT State Assessment Panel. September 1999

Extract from Sue Rymer, (1999). Strategic Analysis of Landcare and Rivercare Funding in Queensland. Report to the State Assessment Panel, 27 September 1999. Publisher, DNR NHT Queensland State Secretariat.

Introduction

At the Queensland State Assessment Panel (SAP) meeting of 7 June 1999, the SAP considered an analysis of the geographical and thematic coverage of Bushcare projects in Queensland. This analysis had been prepared to assist the SAP in determining any "gaps" which may exist in Bushcare activity across the State. This Report presents similar information for Landcare and Rivercare projects. A summary of projects and funding covered by this Report is as follows:

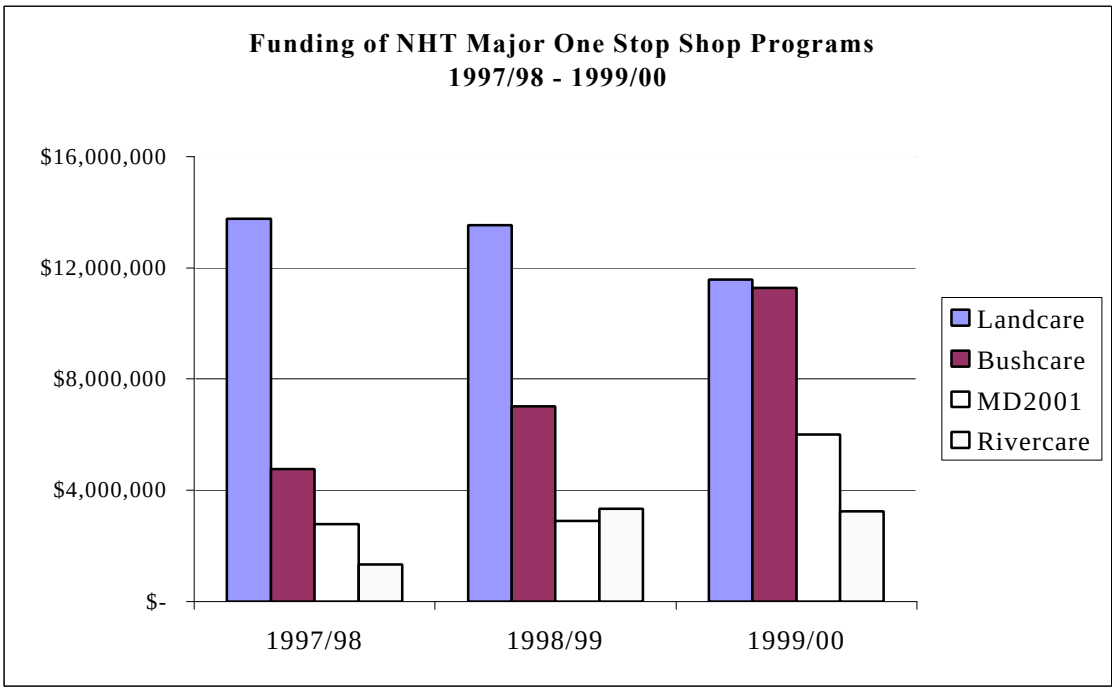
Table 1: Summary of Landcare Funding

	1997/98		1998/99		1999/00	
	No. of Projects	$'s Approved	No. of Projects	$'s Approved	No. of Projects	$'s Rec.
Continuing	108	7,539,544	135	9,761,703	127	8,450,746
New	120	6,216,991	58	3,769,491	42	3,130,682
TOTAL	228	$13,756,535	193	$13,531,194	169	$11,581,428

Table 2: Summary of Rivercare Funding

	1997/98		1998/99		1999/00	
	No. of Projects	$'s Approved	No. of Projects	$'s Approved	No. of Projects	$'s Rec.
Continuing	-	-	29	1,181,636	39	2,674,323
New	33	1,324,917	31	2,150,041	14	575,060
TOTAL	33	$1,324,917	60	$3,331,677	53	$3,249,383

To put these figures in perspective, the chart below indicates the relative levels of NHT funding over three years for the four largest One Stop Shop programs (99/00 figures are based on SAP recommendations only).The total funding for continuing/new projects is shown graphically below.



Methodology

The study included all approved 'one stop shop' projects for 1997/98 and 1998/99, as well as projects recommended for funding by the SAP in 1999/00. Cape York projects were not included in the study, as the Cape York RAP operates independently, and these projects are therefore not considered by the SAP. Two keys issues were addressed - the *geographic* and the *thematic* distribution of Landcare and Rivercare projects in Queensland.

The geographic distribution of projects was determined by analysing the proportion of funds approved and recommended for each RAP and NHT region. The NHT regions used are those specified in the document 'Natural Heritage Trust - Operational Arrangements in Queensland'

The thematic distribution of projects involved an examination of the activities and objectives of each project to determine the main Queensland strategy the project primarily addressed. The approved/recommended funding for that project was then allocated against that strategy. In developing the State bid for 1999/00, most of the projects recommended for funding were allocated against State strategies by Regional Coordinators, and for these projects this information was used to determine the primary strategy addressed. For other projects (ie. projects which finished in 1997/98 or 1998/99), allocations against strategies were primarily made on the basis of information in project applications and progress reports where available. Of course, there are some overlaps between strategies and many projects will address more than strategy. For example, although very few projects address community education and awareness as a primary strategy, most projects will have some outcomes in this area even if education/ awareness is not a primary objective. It should therefore be recognised that the results are providing an indication of the main emphasis of the funding.

The Queensland strategies are those specified in the document 'Queensland Natural Heritage Trust Strategic Priorities 1999/2000'. This document includes revisions made to the Queensland context section of the Partnership Agreement to reflect the current Queensland objectives, priorities and strategies.

State and community contributions to projects were also recorded, in addition to NHT funds, to give a better picture of the full investment in the projects reviewed. The term 'community' includes all contributions other than State Government funding (and includes, for example, local government contributions). As these contributions were taken from the information given in project applications it should be recognised that these figures are indicative only and must be viewed accordingly. For example, in project applications, some community groups identify only those contributions necessary to meet NHT cost sharing requirements, while others identify their full contribution to the activity. Similarly, other calculations, particularly in-kind contributions, are estimates only and community contributions may well exceed these estimations. Nevertheless, this data does provide a general indication of the level additional resources invested in NHT projects.

Discussion of Results -Landcare

The figure and table below present a summary of the geographic distribution of Landcare funding by NHT RAP Regions. Some of the key findings of the funding distribution between RAP regions are as follows:

- in general, Landcare funds have been distributed more evenly across RAP regions than Rivercare or Bushcare funds (for example, limited Bushcare funds were approved for projects in the West and Central RAP regions, with these regions receiving 3.4% and 5.2% respectively of total approved Bushcare funding for 1997/98 and 1998/99 combined);
- under Landcare, the Central region received the lowest proportion of funds in 1997/98 and 1998/99 (12% in each year), although this may change in 1999/00, with the Central region likely to receive the highest proportion (approximately 20%);
- while the North region received a significantly higher proportion of Landcare funding in 1997/98, this was largely due to the $1.3 million allocated to the Yungaburra Sewage Scheme in that year. As a result, the North region's allocation has dropped from 29% in 1997/98 to 16% in 1999/00;
- proportional funding for the other RAP regions (South, South East, and West) has remained relatively consistent over the three years, while Statewide funding has increased from 10% to 13% of total approved funds.

Table 3 Summary of Landcare Funding by Rap and NHT Region

NHT/RAP Region	1997/98 Approved $	%	1998/99 Approved $	%	1999/00 SAP Rec. $	%
Burdekin	822,926	6	867,243	6	578,406	5
Northern Gulf	390,274	3	69,798	1	109,350	1

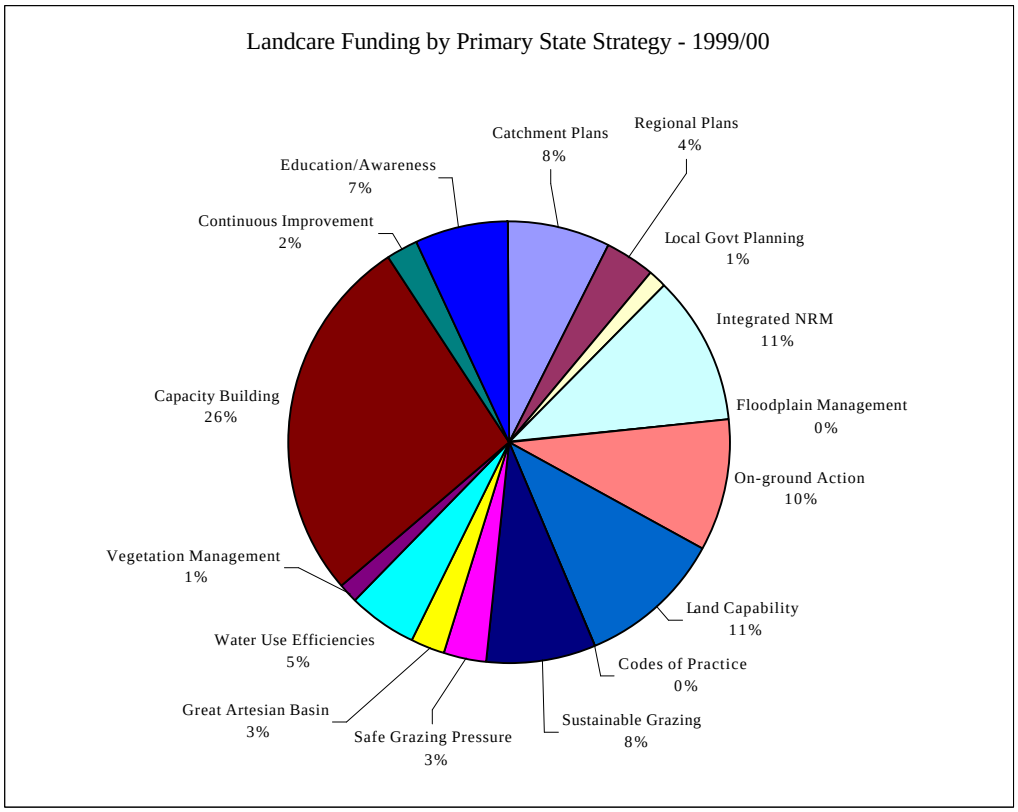
Whitsunday	591,455	4	613,072	5	504,415	4
NORTH RAP TOTAL	3,869,568	28	2,557,085	19	1,875,910	16
Murray-Darling	2,215,378	16	2,630,730	19	2,092,478	18
SOUTH RAP TOTAL	2,215,378	16	2,630,730	19	2,092,478	18
Fitzroy-Belyando	1,681,443	12	1,653,815	12	2,215,317	19
CENTRAL RAP TOTAL	1,681,443	12	1,653,815	12	2,215,317	19
Desert Uplands	185,003	1	295,151	2	176,040	2
Lake Eyre	1,390,396	10	1,243,950	9	635,117	5
Southern Gulf	98,998	1	70,500	1	234,367	2
South West	305,218	2	528,647	4	701,942	6
WEST RAP TOTAL	1,979,615	14	2,138,248	16	1,747,466	15
Burnett- Cooloola	1,479,126	11	1,636,176	12	1,366,327	12
Moreton	1,170,997	9	887,025	7	772,077	7
STH EAST RAP TOTAL	2,650,123	19	2,523,201	19	2,138,404	18
STATEWIDE	1,360,408	10	2,028,124	15	1,511,853	13
TOTAL	13,756,535	100	13,531,203	100	11,581,428	100

It is also important to look at the distribution of funds within RAP regions because in many cases this provides a better indication of the geographic spread of funding. The distribution between NHT regions highlights the following:

- the Northern Gulf, Southern Gulf and Desert Uplands regions consistently receive lower levels of Landcare funding than other NHT regions. These regions only receive around 1-2% of total funding each, and relatively low proportions of the funding allocated to the respective RAP region (eg. the proposed Northern Gulf funding of $109,350 in 1999/00 represents less than 6% of proposed North RAP Region funding);
- the Fitzroy, Murray-Darling, and Burnett-Cooloola NHT Regions are likely to receive the highest proportion of funds in 1999/00 (approximately 19%, 18% and 12% respectively);
- Lake Eyre region funding has dropped from 10% in 1997/98 to 5% in 1999/00, largely because the Great Artesian Basin Rehabilitation Project is expected to be funded from another program in 1999/00. The South West region's share of funds, while still relatively low, is increasing steadily (from 2% in 1997/98 to 3% in 1998/99 and 6% in 1999/00).

The figure below presents a summary of the thematic distribution of total Landcare funding by Key Result Area and Primary State Strategy.



A key feature is that in most regions there has been a major emphasis on strategy 4.3.4(a) (*Building the capacity and enhancing the business and strategic resource management skills of resource managers to sustainably manage land, water and related vegetation at a landscape and property scale*). This is consistent with NLP priority 4.2(b), which is to "improving the business and resource management skills of resource managers". The West Region, in particular, has a significant proportion of funds (45% in 1999/00) primarily addressing this strategy. This is particularly due to large projects such as 972741: PMP in the Arid Zone, and a new project 992624: Building Community Capacity to Determine Integrated Safe Carrying Capacities in Western Queensland. Most regions also have a strong emphasis on strategy 4.3.1(a) (*Community based groups to design and implement catchment based integrated action plans and resource management activities*). The only exception is the West Region where there appears to be a greater emphasis on regional rather than catchment based planning.

Other regional issues are also illustrated:

- the emphasis on environmental strategies (4.3.2(a) - *priority on-ground action* and 4.3.2(b) - *determining land capability*) is significantly greater in the South East region than in other regions, although the South region also has a significant proportion of funds (21%) addressing 4.3.2(a);
- statewide projects concentrate on people strategies (as would be expected) with almost half the statewide funding in 1999/00 addressing this Key Result Area.

In terms of total Landcare funding across the State, a number of other issues are also identified in Attachment C:

- the proportion of funding for integrated regional planning (strategy 4.3.1(b)) has remained constant, at 4% in each of the three years. There has been a slight increase in the proportion of funding primarily addressing strategy 4.3.1(a) - the design and implementation of catchment based plans (with funding increasing from 6% in 1997/98 to 8% in 1999/00. This is to be expected as regional plans are completed and the focus of activities moves towards implementation at a catchment level;
- limited funds have been directed towards enhancing local government planning schemes (strategy 4.3.1(c)), or to developing floodplain management guidelines (strategy 4.3.1(e));
- there are no projects which have, as a primary objective, the development of codes of practice and guidelines for natural resource management. As noted in the Queensland NHT State Bid for 1999/00, while the Fruit and Vegetable Growers, Cane Growers, and the cotton industry have produced Codes of Practice in recent years, other industries have not yet submitted proposals for funding guidelines or manuals in this area;
- the development and extension of vegetation management practices also receives limited funding, although many vegetation activities are included under strategy 4.3.2(a) (priority on-ground action) or would be funded under Bushcare;

- very few projects address strategy 4.3.3(b) (determining safe grazing pressure) as a primary objective, although a number of projects include grazing pressure as a secondary objective (for example, approximately 10% of projects funded over the three years address, to varying degrees, grasslands issues or rangelands management);
- strategy 4.3.3(d) (optimising and promoting water use efficiencies and irrigation best practice) receives relatively low funding, despite the improvement of irrigation water use efficiency in rural areas being a priority for the program;
- the proportion of funds going to education/awareness activities has increased to 7% in 1999/00 (from 6% in 1997/98 and 5% in 1998/99), despite this being a low priority strategy.

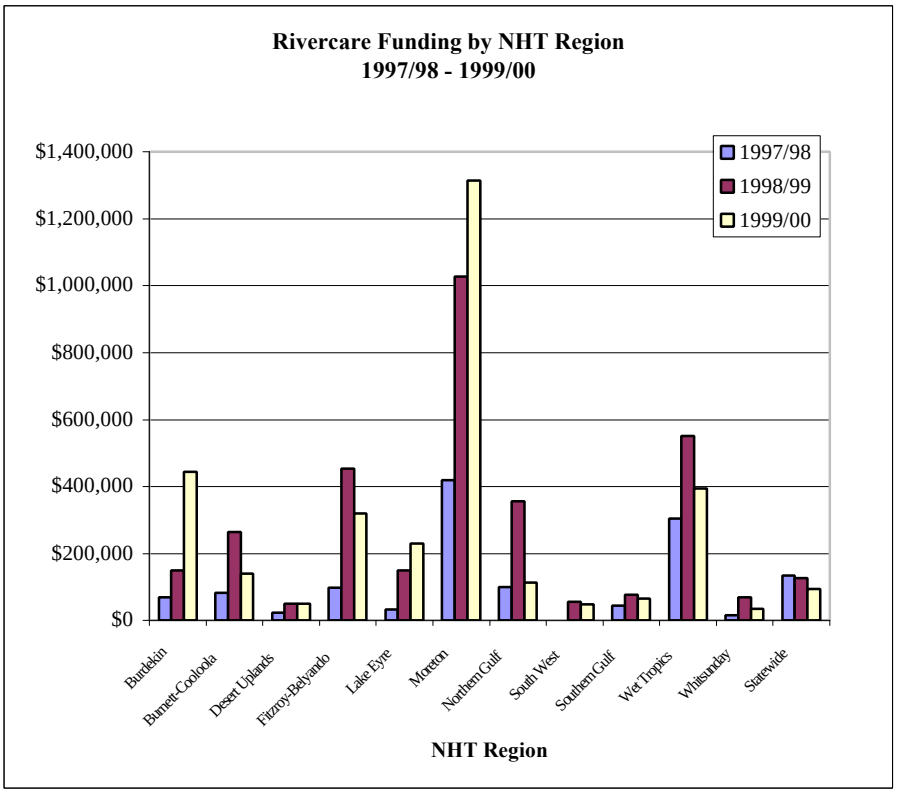
Discussion of Results - Rivercare

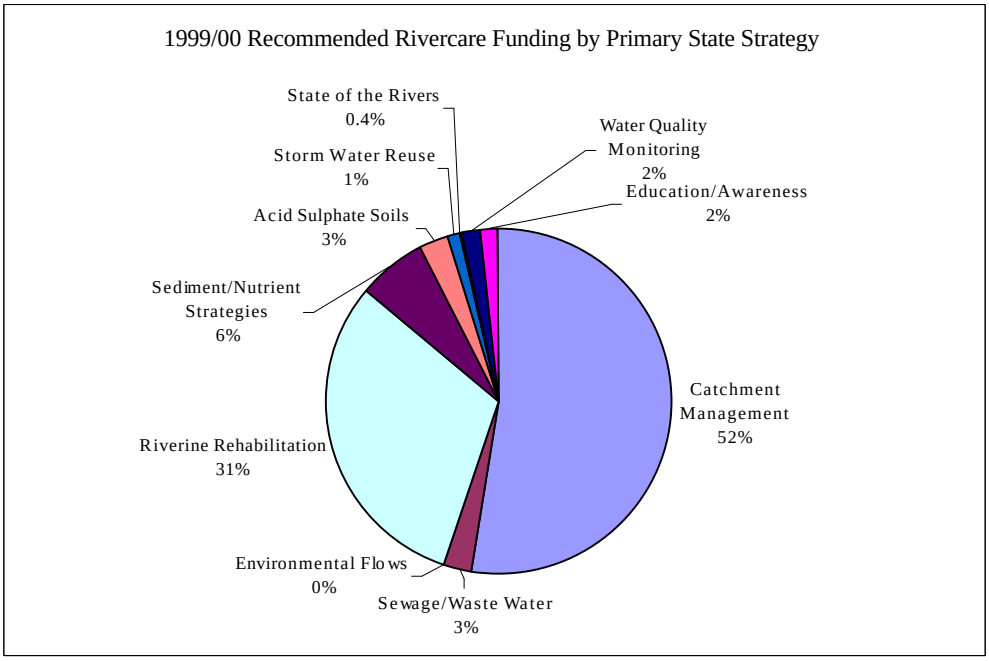
The table and figure below presents a summary of the geographic distribution of Rivercare funding by RAP region. There are no projects in the South region, as river restoration projects in that region are funded through the Murray-Darling 2001 program, which is not covered by this review. Some of the key findings of the funding distribution between RAP regions are as follows:

- the North and South East regions have consistently received significantly higher levels of funding than other regions, with the South East region's proportion expected to be 45% in 1999/00. This includes $350,000 recommended for one relatively large project: the Moreton Bay Catchment Water Quality Management Strategy (this represents 11% of Rivercare funding for the year):
  - one reason for this high level of funding in the south east is the high population density and high level of development which has resulted in significant water quality issues (for example, poor water quality, loss of riparian vegetation, un-coordinated planning, low community awareness, and loss of riverine values including in-stream habitat are common in closely settled areas);
  - the tropical, high energy nature of streams in the North region means that there are also significant issues to be addressed in this region (for example, flood damage, stream bank instability, loss of riparian vegetation, and loss of riverine ecosystems);
- the West Region's share of funding shows marginal increases over time (from 8% in 1997/98, to 10% in 1998/99 and a possible 12% in 1999/00), while Central region funding has varied, from 7% in 1997/98 to 14% in 1998/99, and back to 10% in 1999/00:
  - the relatively low levels of Rivercare investment in these two regions reflect the lower priority that river-related issues have in these drier, less settled areas where other natural resource management issues prevail;
- funding for Statewide projects has decreased from 10% in 1997/98 to 3% in 1999/00. It is likely that this is due to the shifting emphasis in NHT funding from broader planning and awareness raising activities to on-ground works.
- the South West, Desert Uplands, Southern Gulf and Whitsunday regions consistently receive lower levels of Rivercare funding than other NHT regions - around 1-2% of total funding each. This is a particular concern in the latter two cases, as the Mackay/Whitsunday and Gulf NHT regions are identified as priority regions under Rivercare for the development of community based river management strategies and action plans (see Attachment H – Rivercare priority 4.2(a));
- the Moreton catchment receives significantly higher funding than other NHT regions (eg. 39% of recommended 1999/00 funding), with the next highest proportion in 1999/00 being the Burdekin (13%). In addition, the proportion of funding for the Moreton region has been steadily increasing, while funding for the other South-East region, Burnett-Cooloola, has steadily declined (from 11% to 4%). These three NHT Regions are all identified as Rivercare priorities;
- other priority regions include the Wet Tropics region (where the proportion of funding has dropped steadily, from 23% to 12%), as well as Fitzroy-Belyando and the Northern Gulf, which have received reasonable levels of funding, although the proportion going to the Northern Gulf has dropped to 4% in 1999/00.

Table 4 Summary Of Rivercare Funding By Rap and NHT Region

NHT/RAP Region	1997/98 Approved $	%	1998/99 Approved $	%	1999/00 SAP Rec. $	%
Burdekin	69,000	5	150,000	5	444,000	14
Northern Gulf	100,000	8	356,875	11	113,900	4
Wet Tropics	304,156	23	551,597	17	394,793	12
Whitsunday	15,000	1	70,090	2	34,150	1
NORTH RAP TOTAL	488,156	37	1,128,562	34	986,843	30
Fitzroy-Belyando	97,264	7	454,467	14	320,288	10
CENTRAL RAP TOTAL	97,264	7	454,467	14	320,288	10
Desert Uplands	24,000	2	49,500	1	49,500	2
Lake Eyre	33,875	3	148,706	4	229,700	7
Southern Gulf	45,000	3	76,167	2	65,000	2
South West	-	0	56,620	2	49,070	2
WEST RAP TOTAL	102,875	8	330,993	10	393,270	12
Burnett- Cooloola	82,930	6	264,086	8	140,983	4
Moreton	419,802	32	1,027,109	31	1,314,279	40
STH EAST RAP TOTAL	502,732	38	1,291,195	39	1,455,262	45
STATEWIDE	133,890	10	126,460	4	93,720	3
TOTAL	1,324,917	100	3,331,677	100	3,249,383	100





The figure above presents a summary of the thematic distribution of total Rivercare funding by Primary State Strategy. Separate charts have only been produced for the South East and North RAP Regions for 1999/00, as projects in other regions only address a small number of strategies.

Clearly, the strongest emphasis of Rivercare projects is on the implementation of strategy (a) (which is to develop *'community-based approaches to catchment management; and prepare, coordinate and implement community based integrated river management action plans'*). This is consistent with priority (a) of Rivercare, which is to develop community based river management strategies and action plans.

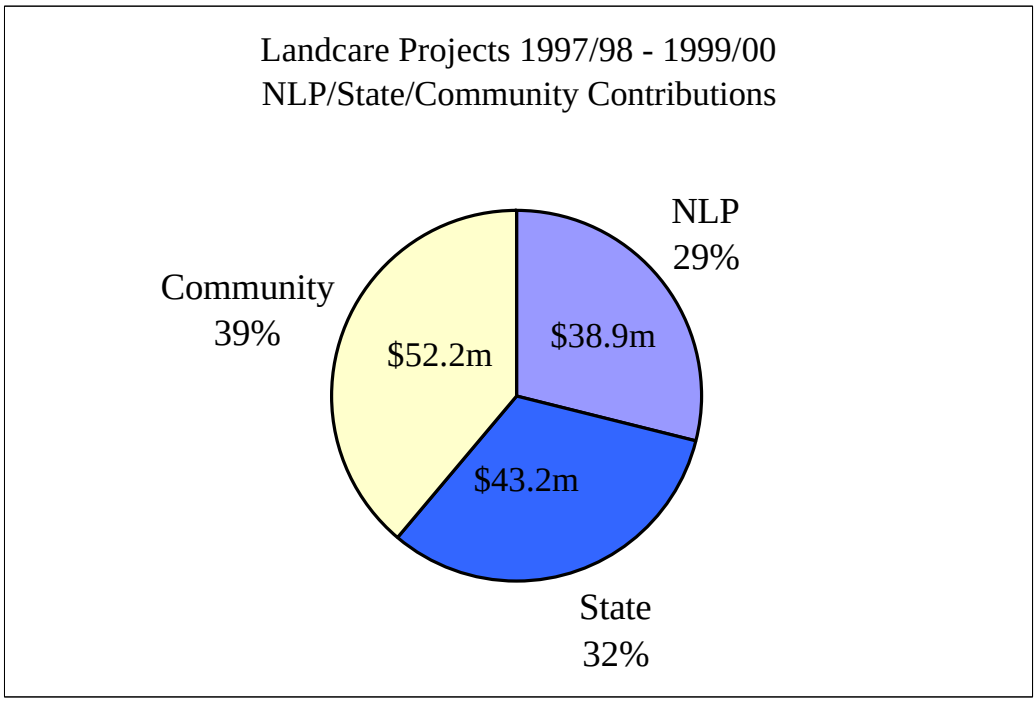
Strategy (d) (*protection and rehabilitation of riverine systems*) also receives a significant and increasing proportion of funds, which again is consistent with Rivercare priorities and strategies. This increase is also to be expected given the increasing onground emphasis of the NHT.

The figure also indicates that a number of other strategies are not being addressed through Rivercare projects:

- limited funds have been directed towards the promotion of alternative/improved sewage treatment and waste water reuse facilities (a high priority strategy). However, significant Landcare funding has addressed this strategy in the past. The Yungaburra Sewage Scheme project is an example. In addition, this strategy is likely to be addressed in the Moreton catchment through action arising from the Moreton Bay Catchment Water Quality Management Strategy;
- no projects address environmental flow requirements (another high priority strategy) as a primary objective. However, funding for this activity is provided through the National River Health Program and undertaken by the State via WAMPs;
- the implementation of pilot storm water reuse projects (strategy (g)) has also received little funding, although this is a medium priority strategy. Similarly, another medium priority, the amelioration of acid sulphate soil impacts, has also received limited Rivercare funds, although this issue is being addressed through some Landcare projects (eg. project *972712 - Statewide Acid Sulphate Soils Information: Extension and Coordination*. $79,800 has been recommended for this project in 1999/00).

Community and State Government Contributions

The following tables indicate the level of investment in Landcare and Rivercare projects by communities and the State Government. A breakdown of contributions by RAP Region for each program is provided at Attachment G. As these tables indicate, the relative contribution of NHT:State:Community funding for Landcare and Rivercare projects over three years has been roughly 30:30:40.



Conclusion

The study identified a number of gaps in the geographic distribution of Landcare and Rivercare funds in Queensland. In particular, the Northern Gulf, Southern Gulf and Desert Uplands NHT regions consistently receive lower levels of Landcare funding than other regions. In the case of Rivercare, the North and South East RAP Regions receive a significantly higher proportion of funds, with the South West, Desert Uplands, Southern Gulf and Whitsunday NHT regions consistently receiving limited funds.

The thematic analysis identified gaps in addressing state strategies for Landcare relating to the enhancement of local government planning schemes, addressing safe grazing pressure, the development of floodplain management guidelines, the development of codes of practice and guidelines for natural resource management, and the development of sustainable vegetation management strategies (although the latter three are only medium priority strategies). Rivercare strategies which receive limited funding include the promotion of alternative/improved sewage treatment and waste water reuse facilities, the determination of environmental flow requirements, the implementation of pilot stormwater reuse projects, and the amelioration of acid sulphate soils (again, the latter two are only medium priority strategies).

The analysis of State Government and community contributions gives an indication of the significant level of investment in NHT projects, above and beyond Commonwealth funding. On average, every NHT dollar generates well over two dollars of additional investment from Queensland.

Appendix 1 QUEENSLAND LANDCARE STRATEGIES

(Source: Queensland NHT Strategic Priorities - 1999/2000. A Guide for NHT Project Applications)

NATIONAL LANDCARE PROGRAM

4. Queensland Context

4.1 Objectives

a) To have strong community, industry and government partnerships in the management of natural resources.

b) To build the capacity and self reliance of land managers.

c) To maintain the stability and productivity of land resources.

d) To achieve the efficient and sustainable use of water resources.

e) To ensure the sustainable use of groundwater and improved groundwater quality management.

4.2 Priorities

a) Developing regional natural resource and environment management strategies for all regions of the State.

b) Improving the business and resource management skills of resource managers through the development and delivery of programs such as property management planning.

c) Maintaining the stability and productivity of the cropping and grazing lands of the State and floodplains in rural areas.

d) Improving irrigation water use efficiency in rural areas.

e) Sustaining groundwater use and management in:

- the Great Artesian Basin, including intake areas;
- groundwater areas where resources are over-committed - Atherton basalts, Pioneer Valley, Fitzroy Basin, Bundaberg, Lockyer Valley and Condamine; and
- areas subject to saltwater intrusion - Bundaberg and Pioneer Valley.

4.3 Strategies

Strategies	Priority
4.3.1 Integration and Institutional Strategies	
a) Community based groups to design and implement catchment based integrated action plans and resource management activities.	High
b) Develop integrated regional natural resource management and biodiversity conservation strategic plans.	High
c) Enhance local government planning schemes to address natural resource management and biodiversity conservation issues.	High
d) Develop integrated approaches to natural resource management at the property scale.	High
e) Develop floodplain management guidelines for rural areas and conduct appropriate planning.	Medium
4.3.2 Environmental Strategies	
a) Implement priority on-ground action consistent with integrated strategies and action plans.	High
b) Determine land capability and land suitability and monitor condition and trend of priority catchments.	Medium
c) Develop codes of practice and guidelines for natural resource management.	Medium
4.3.3 Sustainable Production Strategies	
a) Identify and or develop and extend sustainable grazing and cropping systems including integrated approaches to management of invasive weeds.	High

b) Determine safe grazing pressure and develop effective methods for managing total grazing pressure from domestic, feral and native pest animals.	High
c) Rehabilitate uncontrolled bores and construct pipelines to replace open bore drains in the Great Artesian Basin.	High
d) Optimise and promote water use efficiencies and irrigation best practice for the sustainable management of surface and ground water.	Medium
e) Develop and extend vegetation management practices and strategies to achieve sustainable and productive natural resource management systems.	Medium

4.3.4 People Strategies

a) Build the capacity and enhance the business and strategic resource management skills of resource managers to sustainably manage land, water and related vegetation at a landscape and property scale.	High
b) Encourage a culture of continuous improvement by primary producers of natural resources management.	Medium
c) Conduct community education and awareness raising activities.	Low

Strategies where the State provides support for agencies and community but are unlikely to receive NHT funding:

a) Develop and extend effective remedial measures for degradation and the impact of climate variability and drought.

b) Undertake risk assessment processes to determine groundwater systems where development of a management plan is a priority.

c) Develop water allocation and management plans for priority groundwater systems with major consumptive use demands.

d) Develop statutory water management plans for sensitive groundwater systems.

e) Develop groundwater management plans for priority groundwater systems with major consumptive use demands.

Appendix 2 NATIONAL RIVERCARE PROGRAM

4 Queensland Context

4.1 Objectives

a) To increase involvement and responsibility by industry, resource users and the community in the integrated management of natural resources on a catchment basis.

b) To maintain and enhance the water quality of river systems and associated wetlands.

c) To provide an appropriate balance between the consumptive and instream requirements of the water resources of river systems.

d) To maintain and enhance the ecological integrity and physical stability of river systems, including associated riparian zones and wetlands.

e) To provide high quality data and decision support systems which will support investment and decisions in relation to river health.

4.2 Priorities

a) Developing community based river management strategies and action plans for catchments in the Wet Tropics, Mackay/Whitsunday Coast, Burnett/Mary, Southeast, Burdekin, Fitzroy and Gulf NHT regions.

b) Addressing water quality issues, in particular eutrophication in the Fitzroy River basin and nutrient transport in river basins discharging into the Great Barrier Reef lagoon and Moreton Bay.

c) Developing and implementing:
- water allocation and management plans for the Fitzroy, Barron and Logan River basins and in the longer term for the Burnett, Burdekin, Pioneer, Mary, Brisbane and other river basins with defined water allocation issues.
- water management plans for the Cooper Creek and Mitchell River basins and in the longer term for the Herbert, Flinders and other river basins with defined water allocation issues.
- flow management plans for the Calliope/Boyne River basin.

d) Improving ecological integrity and physical stability of rivers in the Mackay/Whitsunday Coast, Wet Tropics, Burdekin, Burnett/Mary and Southeast regions, including the development and implementation of riverine quarry material management plans in stream reaches under extractive pressure.

e) Develop decision support systems and associated databases for natural resource allocation and management activities in the Wet Tropics, Mackay/Whitsunday Coast, Fitzroy, Burnett/Mary, Southeast, Burdekin, Lake Eyre Basin and Gulf regions.

4.3 Strategies

	Strategy	**Priority**
a)	Community-based approaches to catchment management; and prepare, coordinate and implement community based integrated river management action plans.	High
b)	Promote alternate/improved sewage treatment and waste water reuse facilities that reduce the flow of nutrients into rivers.	High
c)	Determine environmental flow requirements for river, estuarine and coastal ecosystems.	High
d)	Protect and rehabilitate riverine systems to provide stable, functional waterways that support healthy riparian and instream ecosystems, including weed, erosion and stock management.	High
e)	Develop and implement sediment, nutrient and pesticide management strategies to address their impacts on water quality and aquatic fauna in river systems.	High
f)	Develop and implement management strategies to ameliorate the impacts of acid sulphate soils.	Medium
g)	Implement pilot storm water reuse projects in rural and regional urban areas.	Medium
h)	Conduct integrated State of the Rivers/fish habitat surveys for priority rivers and document freshwater fish habitat requirements.	Medium
i)	Promote community based water quality monitoring activities.	Medium
j)	Conduct community education and awareness raising activities.	Low

Strategies where the State provides support for agencies and community but are unlikely to receive NHT funding:

a) Assess and report on conditions and trends of water quality of catchments.

b) Develop regional and catchment approaches for improving river and instream health by minimising water extractions from river systems, including alternate sources of water supply and adoption of improved water use efficiency measures.

c) Undertake risk assessment processes to determine river systems where development of a management plan is a priority.

d) Develop water allocation and management plans for priority river systems with major consumptive use demands.

e) Develop statutory water management plans for sensitive river systems.

f) Develop flow management plans for priority river systems with major consumptive use demands.

g) Develop and implement policies and procedures for the establishment of transferable water entitlements.

h) Develop riverine quarry material management plans for priority stream reaches.

i) Develop decision support systems and associated data bases to support resource allocation and management decisions.

j) Develop fish transfer requirements and effective fish transfer systems.

4.2.6 Catchment Management Strategies Guidelines 1995

Philip Rowland, (1995). Catchment Management Strategies. Notes prepared for Catchment Coordinating Committee's Mini-Forum. Maleny 26 February 1995

Why have Catchment Management Strategies?

Catchment Management Strategies will need to be a suitable standard and possibly of similar format if they are to receive formal recognition by State government (through Cabinet), local government and industry. While there is a degree of variation in the structure and content of strategies produced so far by catchment groups, a common set of topics are emerging.

'Strategies' and 'big picture plans' are all the rage at present in government and semi-government agencies. Most of the bodies who are potential sources of funding for catchment works are these types of agencies. A CMS provides a clear message to these bodies about what needs to be done.

A CMS is not an end in itself but a means to an end (see notes from a workshop in Ingham in 1993).

Rather than each catchment having to reinvent the wheel, it would be worth looking at CMS already prepared and using the structure, not the content, in preparing new CMS.

CMS should provide a framework or blueprint for resolving key issues of *catchment wide* importance in a catchment. It should be useful to groups and organisations within the catchment as well as to others outside (like funding bodies, state government etc) the catchment.

KEY COMPONENTS SUGGESTED FOR INCORPORATION IN A CMS ARE OUTLINED IN THE ATTACHED TABLE AND ARE DESCRIBED IN MORE DETAIL BELOW:

Setting the Scene

Physical, economic, biological and social attributes of the catchment should be described to set the context for natural resource management. The use and management of natural resources in the catchment need to be covered.

Describing the Vision

A general one-statement (or series of statements) describing of a vision for the catchment. It is important that this vision is generally accepted by all the key interests in the catchment.

Identifying Issues

Key general issues are determined. A maximum of eight issues is considered a workable number. Ranking these issues provides a basis for further planning.

Analysis of the issues and the identification of the causal factors and trends is a necessary requirement of the strategy. Scientific (qualitative and quantitative) as well as local knowledge should be used in the description and analysis of the issues.

A check on the issues once they have been identified is to ask the question - What key components of the catchment need to be changed to resolve the issue and assist if achieving the vision?

Goals for each issue need to be described.

For each Issue

Setting Objectives
Specific objectives for each goal are described. They need to be specific, measurable, achievable, relevant and timely.

Outcomes
Statements on the proposed outcomes resulting from the implementation of the CMS should be included. Indicators of these outcomes could be described as well as monitoring and evaluation processes.

Strategies
To achieve the objectives, one or more strategies are described. Major components of these strategies include:
- Activities to be carried out
- Organisations, government departments or agencies, local authorities and other key stakeholders that need to be involved.
- Resources (time, money, manpower) needed to carry out the activities

Performance Indicators
- The performance indicators identify the attributes that should be measured or determined to assess progress toward the objectives. The performance indicators do not relate specifically to the strategies to be used to achieve the objectives. Because of this they cannot necessarily be used to assess the effectiveness or otherwise of the individual strategies employed.
- The performance indicators are just that, indicators of achievement or otherwise of objectives. However, the lead agencies identified for each objective, in conjunction with the CCC, need to determine what change in the indicator represents acceptable progress toward the objective.
- In designing performance indicators, the resources and effort needed to determine the indicator need to be considered. There is no point in coming up with performance indicators that are impossible or very expensive to measure. Preferred indicators include those that are currently being monitored or can be readily assessed.

An additional optional section on outputs could be included.

Outputs

Outputs need to be framed within the context of the whole catchment and have applicability in the catchment. Specific outcomes need to take the form of
- Policies for use by local and state government, industry groups and other agencies.
- Guidelines for the use and management of natural resources in the catchment.
- Operational plans to redress or prevent degradation of loss of value with natural resources in the catchment.
- Institutional arrangements necessary to achieve better use and management of natural resources.

Implementation

This section should outline the various mechanisms and structures to be used in implementing the strategy. A good example is contained in the strategy prepared by the Johnson River CCC.

Evaluation and Review

Evaluation and review of the performance of the strategy should be built in from the start through the actions and performance indicators. However, there is an additional need to describe how the implementation of the strategy will be monitored so that appropriate changes can be made if necessary.

Preferred Structure of Catchment Management Strategies

Section	Contents	Size (pages)
Introduction	Set the scene, history, mention issues, directions	1
Summary	Stand alone description of the strategy	2
The Catchment Coordinating Committee	Describe who is involved, interests, roles of committee	2
Catchment Management Strategy	Goals/objectives of this document	0.5
Vision for the catchment*	A brief statement which captures a description of the catchment in 50 years time. It should reflect common values eg. quality of life, prosperity, conservation.	0.5
Issues	For each major issue (between 4 and 8), a brief description of the issue, its scope and causes	0.5 per issue
Strategies	For each major issue, objectives and outcomes are defined, strategies stated and actions outlined. Performance indicators for the objectives are also described	2 pages per issue
Implementation	Future role of the committee. Who does what about putting the actions in place.	3
Evaluation/Review	Describe how progress in getting the CMS implemented will be monitored	1
	Total	20-30

*Could be in the form of a series of principles

4.2.7 Catchment Management Strategies Guidelines 1999

Essential Characteristics of Regional and Catchment Management Strategies

Michael O'Brien
(Source: Queensland Department of Natural Resources, March 1999 - Draft document)

Characteristics of Effective Resource Management Strategies

Introduction

This checklist identifies a range of characteristics that relate to the document context and process associated with developing an effective resource management strategy. It is derived from a number of documents related to the preparation of resource management strategies, including:

- Australian Local Government Association. 1997. *Regional Environmental Strategies: How to prepare and implement them*;
- Greening Australia. 1997. *Regional Strategy Checklist: Essential Characteristics of Natural Resources Management Strategies*; and
- DNR. 1998. *Interim Guidelines for the Development of Natural Resources and Biodiversity Conservation Regional Strategies*

The checklist is intended as practical tool for use during the development of a resource management strategy. It identifies key content that should be presented in an effective strategy, and gives an indication of the philosophy and key processes that lie behind effective resource management. This checklist is intended to compliment a range of publications that may be of assistance in the preparation of a resource management strategy.

What is necessary for preparing an effective management strategy?

The preparation of an effective regional or catchment management strategy involves a synthesis between the processes used in preparing the strategy and the actual content within the finished document.

It is essential that a comprehensive process of community and government involvement and consultation takes place, in order to clearly define a regional vision, and to identify the key management issues within the region. Additionally, adequate community consultation, followed by the seeking of endorsement by community and government will help to ensure that the community and government accept the actions outlines within the strategy. It also helps to establish that community and government agencies or groups are made accountable, with actions able to be signed off upon completion by the appropriate agency or group. Equally important is that process of ongoing benchmarking and collection of information, which will ensure that the resource inventory for the region is continually improving, and that monitoring and review throughout implementation of the strategy leads to the development of appropriate future management actions.

However, process alone does not guarantee an effective management strategy. It is also necessary to provide within the strategy sufficient background information to clearly identify the region, its patterns of development and the particular natural resource issues that are to be managed, and to then put those issues into their proper context. It is also necessary to include enough detail of the various stakeholder groups so that their role in the overall development and implementation of the strategy is clear. This professionals and the community to understand and that lends itself towards achieving effective natural resource management.

Why use a checklist?

During the preparation of a management strategy, it may be useful to have at hand a checklist of the key requirements, particularly if the strategy is being prepared with a view towards having is assessed and endorsed by government and/or planning agencies.

By using such a checklist, it is much easier to ensure that important processes have taken place, such as sufficient community, consultation and endorsement, or to make certain that the structure and content of the document contains all the necessary information. This may include a regional background, identification of the regional vision, identification of issues, setting of management objectives , and evidence of accountability for management actions under the strategy.

Characteristics of effective Regional and Catchment Management Strategies

What type of information should the strategy include and/or identify?

VISION
- Is the regional vision adequately and clearly defined?
- Is there a timeframe identified in which to achieve the vision? (consider short, medium, long term)

VALUES
- Do the values identified reflect the social, economic, environmental and cultural significance of the region?
- Does the strategy identify the way in which these special values will be addressed and managed for?
- Has the significance of each value been clearly identified in relation to the local, regional, state, national or international values?

KEY ISSUES
- Have the key issues of importance within the region been identified? (issues should be defined according to the current regional situation and the desired situation, encompassing economic, cultural, environmental and social aspects)
- Have these regional issues been prioritised?
- Have specific limitations in achieving the objectives of the strategy identified and addressed, if they exist? (consider specific resource needs and availability)
- Is the timeframe for implementing the management strategy identified?
- Have the key regional issues and their management been related to similar issues at the state and national level?

OBJECTIVES
- Are the objectives clear and easily understood?
- Is it clear that the objectives work towards achieving the vision?
- Are the management objectives in agreement with the broader planning and management framework for the region?
- Have the objectives been prioritised appropriately?
- Do the objectives lead to the clear development of actions now and in the future?

PRINCIPLES
- Is the strategy consistent with the overarching principles of effective resource management (eg. ICM, ESD)?

STRATEGIES
- Have previously successful strategies to deal with issues been identified?
- Is there evidence that the necessary partnerships to deal with issues have been established?

What is an effective resource management strategy?

The following issues need to be considered in order to produce an effective management strategy.

PURPOSEFUL
- Are the reasons behind the strategy's development communicated clearly?

- Have the pressures for change been highlighted?

VISIONARY
- Is the vision held in common and supported by the majority of the stakeholders?
- Is the timeframe for implementation of the strategy appropriate for achieving the:
    *Vision
    * Goals
    * Objectives
- Does the strategy promote a proactive to achieving the desired outcomes?

INFORMATION BASE
- Have information gaps been identified?
- Has the opportunity to fill information gaps by utilising the knowledge of stakeholders as a resource been investigated?
- Has the integrity of the various data sources for economic, social, cultural and ecological processes been documented?
- Has the current understanding of processes been documented?
- Is there confidence in the integrity of the information contained in the strategy, and in information used in its development?

SYSTEMATIC REGIONAL APPROACH
- Have external impacts or flow on effects resulting from the strategy been identified?
- Has compromise been made between the social, cultural, ecological and environmental objectives to ensure acceptance by the community?
- Does there need to be a systematic and systematic perspective of the region?
- Does the strategy focus on a variety of regional issues?

INTEGRATED
- Have all other plans and strategies (all scales) appropriate to the management of the region been identified and their role integrated into the strategy?
- Has the hierarchy of the related plans been identified? (consider the priority of implementing the strategy in relation to other regional plans)
- What are the existing priorities and strategies within the organisations that are required to support the implementation of the strategy?
- Have the constraints, difficulties and limitations in linking this strategy with other plans been identified?
- Have possible resolutions to these been suggested?
- Does the NRM strategy conform to the statutory plans used by local and state government when dealing with development pressures?

SCALE
- Does the strategy address the issues at an appropriate scale to ensure effective management?
- Have mechanisms been provided to address issues across legal boundaries?
- Has the future role of the strategy in the management of the region been identified?

FOCUS
- Has the strategy aimed to achieve a balanced approach towards satisfying the rights of current and future generations of all stakeholders?
- Have the overriding foals of the strategy remained consistent throughout its development?

ACTION ORIENTED
- Does the strategy aim toward the identification of appropriate and 'do-able' actions?
- Do the prioritised objectives provide a good sense of direction for action plans to be developed from?

GENERATION & EVALUATION OF OPTIONS
- Have a variety of options and alternatives for addressing issues been identified?
- Have the positives and negatives of each alternative been documented and evaluated?
- Have the costs and benefits of each option (as they relate to environmental, social and economic resources) been considered?
- Have options been prioritised in an appropriate yet flexible manner?

ADAPTIVE
- Is the strategy adaptable to ongoing improvement and reshaping resulting from evaluation and feedback during all phases of the strategy?

COMMUNICATION
- Are the key messages clearly and effectively communicated to the reader?

STAKEHOLDERS
- Have all the relevant stakeholders been identified (eg. community interest groups, NGOs, Government agencies, Indigenous groups etc …)
- Was the stakeholder input reflective of the importance of developing a regional strategy?
- Have the responsibilities of the various stakeholder groups been clearly defined and endorsed (signed off) by them?
- Has a lead agent been identified and accepted by the stakeholders as responsible for coordinating and promoting the endorse strategy?
- Has the stakeholder involvement been consistent and facilitated through appropriate methods through all stages of the strategic plan (ie. planning, implementation, review phases)
- Do community members respect the creditability of organisations and agencies involved in the strategy?
- Have the stakeholder groups that already deal with particular issues (if they exist) been identified?

ENDORSEMENT SECTION
- Have written endorsements from all stakeholders supporting and committing to implementation of the strategy been obtained?
- Has the priority of implementing the strategy within the leading organisations been indicated, given prior responsibilities?
- Is there a process of conflict resolution to the alleviate concerns of stakeholders who may not necessarily be prepared to endorse the strategy?

COMMUNITY CONSULTATION
- Has sufficient and effective consultation been carried out throughout the planning, implementation and evaluation stages?
  Consider: appropriate time and resources committed, suggestion and promotion of mechanisms to facilitate feedback throughout the life of strategy.
- Was the method of community consultation appropriate for the various stakeholder groups involved?
  Consider: education and literacy levels, knowledge of topics, facilitation and promotion method, potential conflicts, objectives of consultation made clear from onset, local relevance of issues, representatives for stakeholder groups communicated outcomes effectively
- To what degree have the consultation methods fostered an atmosphere of community ownership and commitment? (Reflected in the stakeholder signatures in the Endorsement Section and in acceptance of responsibilities for carrying out actions)
- Has justification been provided for those issues where public participation was not used?

MONITORING AND EVALUATION
- Has a framework for monitoring and evaluation of the planning, implementation and review phases been provided and is it appropriate?
  Consider: does it provide feedback and confirmation to the stakeholders, satisfy decision-making needs and is it realistic given available resources?
- Have appropriate performance indicators been suggested to measure the effects of implementation of the strategy?
- Does the evaluation method provide a balanced mix of tools to determine the costs and benefits if management initiatives to be implemented?
- Is research encouraged throughout the strategy to fill information gaps and to facilitate ongoing sustainable development?

Evaluation and endorsement of Resource Management Strategies

A key element in the preparation and implementation of resource management strategies is the need to gain endorsement at a State Government level, which ideally involves a comprehensive and rigorous yet standardised evaluation process. The following set of evaluation criteria has been developed with the intention of addressing concerns and problems associated with the consistency and subjectivity of current evaluation procedures, and is intended to provide a useful tool for the evaluation of resource management strategies throughout the state. They are primarily for use by the LCMC in assessing management strategies, however, in the interests of transparency in the assessment process, it is seen as beneficial to make the criteria available to regional and catchment groups.

In order to further standardise and streamline the assessment process, the criteria also include a "Statement of Compliance", which is to accompany the completed strategy document upon submission. It provides a means for the groups to identify how and where in the document they have addressed each of the criteria, and to make any other comments that relate to getting their strategy endorsed.

The criteria are intended to complement 'Guidelines for the Development of Natural Resources and Environmental Conservation Regional Strategies' (Elliot 1998), prepared by the Queensland Department of Natural Resources. This document serves to guide the preparation of resource management strategies in a way that will facilitate not only more efficient endorsement of such strategies, but also general improvements in the preparation and implementation of resource management initiatives throughout Queensland.

These criteria are designed to be easily applicable and efficient in assessing the content of and processes undertaken in developing a management strategy. It is critical to note that these criteria represent a decision tool to aid in assessment and endorsement of regional strategies, but they are not the only indicators of an effective strategy. By providing strategy groups with these criteria, and explaining how they are to be used by the assessment panel, it is hoped that there will be greater understanding of and transparency in the assessment process.

How to use the Criteria

The criteria provide for the assessment of each strategy document based on the actual content contained therein, and on evidence provided of the processes that have been followed in developing the strategy. Key aspects of a strategy or steps taken in its preparation are listed in the far-left column. For each of these, one or more questions about the strategy are asked. These help to focus attention on to a particular topic or issue, and also help ensure that all of the people assessing the strategy are looking at it from essentially the same point of view.

For each of these questions, there may be one or two sets of possible criteria, spread across a range of scores, which in turn relate to the standard of the strategy in that area. Where one criterion is contained in its own cell, it is to be considered independently of all other criteria. Where two criteria are contained in one 'box', but separated by 'And/or', they may be considered independently or together. This allows for an assessor to allocate a score within a bracket: eg. meeting both criteria in the high bracket may result in a score of 5; meeting only one criteria in the same bracket may only result in a score of 4.

For example: The Introductory Section has two separate criteria in each of the high and low score brackets. These are to be considered independently. The middle bracket has two criteria separated by 'And/or'. A strategy may meet one or both of these criteria, and the degree to which this occurs will result in a score ranging from 2-4.

Each question on the criteria sheet, regardless of how many 'criteria' there are, receives only one single score (one box: one number). In this way, the score that the strategy receives for each question is based on the degree to which the strategy meets the range of criteria, as in the example above.

Each individual aspect of a strategy to be considered in the assessment is given a weighting or priority, according to its relative importance in the overall finished strategy. For instance, although it is a useful and necessary part of the physical document, the introductory section has a lesser priority with respect to endorsing the strategy than does evidence of adequate community consultation and acceptance. A high weighting requires that the initial score be multiplied by 3, medium by 2 and low by 1.

The weighted score for each criterion is therefore determined by multiplying that the initial score for each criterion by the appropriate weighting factor. The maximum score a strategy could receive is 250; the minimum score that is required for a strategy to receive interim, endorsement is 150 (or an unweighted score of 3 for each criterion). The last aspect, which is 'Readability of the document' involves a qualitative rather than quantitative assessment, and is simply an indication of whether the document is 'user friendly' and effectively communicates the message to the reader using a variety of written and visual communication methods (text with maps, diagrams, tables, etc where useful). However, it is not the final score, but rather the comments generated through the assessment process that serve the most useful role in determining the quality of a strategy.

Form 1: Strategy Endorsement Criteria - Version 4 March 1999

Endorsement Criteria	Questions	Little or no improvement required	Strategy would benefit from Improvement	Significant improvement required	Score	Weighting	Weighted Score Low (score x1) Medium (score x2) High (score x3)
Introductory Section	Does the introductory section provide a sound foundation for interpreting the strategy?	Document provides reader with a very clear understanding or the rationale behind strategy	Introductory section provides reader with general understanding of regional management issues - **And/or** Sufficient information is provided to give the reader a basic regional overview	Introductory section lacks adequate structure and is misleading to the reader		Low	
		Introduction presents a well-defined regional overview which is descriptive and relevant		Regional overview is of minimal standard or is completely missing			
Integration	Does the strategy integrate with other plans, strategies and resource management initiatives applicable in the region?	Effective multilateral integration with existing plans & strategies. Clear evidence of understanding of the hierarchy of other plans or strategies	Some attempts at integration with existing plans & strategies. Evidence/understanding of hierarchy of other initiatives is adequate	Weak integration. Hierarchy of plans not provided.		Medium	
		Constraints & limitations of linking with other strategies are clearly identified	Poor identification of constraints & limitations of linking with other strategies.	Constraints & limitations of linking with other strategies are not identified.			
Information Base	Is the information base documented?	Information base & integrity of data is thoroughly assessed & detailed and fully supports management objectives	Sufficient detail of information base & integrity of data provided to support management objectives	Little of any detail of information base & overall integrity of data documented		Low	
	Have opportunities to fill information gaps been investigated?	Comprehensive identification of information gaps (if they exist), with clear identification of information sources to fill these gaps	Some information gaps have been identified.	Few information gaps (if any) have been identified		Medium	
		Clear attempts to integrate scientific & community knowledge to achieve effective resource management	Information sources to fill these gaps identified but with limited integration of scientific and community knowledge attempted	Little knowledge of available information sources with little or no attempt to integrate scientific & community knowledge			

Endorsement Criteria	Questions	Little or no improvement required	Strategy would benefit from Improvement	Significant improvement required	Score	Weighting	Weighted Score Low (score x1) Medium (score x2) High (score x3)
	Is there an ongoing process of resource assessment and adding to the resources inventory?	Extensive and ongoing collection of information with excellent benchmarking of standard and extent of available information for use in review process.	Some evidence of ongoing improvement of resource and information inventory - Adequate use of benchmarking into requirements for future information capture	Minimal (if any) evidence of ongoing improvement of resource and information inventory. Little or no use of benchmarking techniques		High	
Vision/values principles	Is the vision clearly defined and based upon the values within the community?	Clear definition of regional vision, with strong evidence of community input.	Vision is stated, and shows evidence of community involvement.	Development of vision is not clearly apparent, with little evidence of community involvement		High	
	Does the strategy follow the basic principles of effective natural resource management (eg. Integrated Catchment Management, ESD)?	Overarching principles of NRM have clearly been considered and are evident throughout management initiatives.	The strategy shows evidence of consideration of essential principles of NRM.	Minimal evidence of consideration of essential principles of NRM		Medium	
	Does the overall strategy represent an Integrated and evenhanded approach to resource management within the region?	Thorough & unbiased consideration of social, economic, cultural & environmental elements specific to the region	Adequate representation of the social, economic, cultural & environmental elements of the region.	Clearly some elements of concern have not been considered		Medium	
Objectives/key issues/strategies	Do the objectives, issues and strategies work together to achieve the desired outcomes?	Objectives, issues & strategies are strongly related & complement the broader planning & management framework.	Moderate relationships evident between objectives, issues and strategies. Some conflicts present with the governing planning & management framework.	Little attempt to ensure consistency between objectives, issues and strategies		High	
		Objectives & strategies are realistic & achievable given timeframe & resources	Most objectives & strategies are achievable given timeframe & resources	Practicality of objectives & strategies is questionable			
	Are the issues, objectives and strategies prioritised with justification of method?	Issues, objectives & strategies are clearly prioritised **And/or** Method of prioritisation is clear, transparent, equitable and well documented.	Majority of issues, objectives & strategies are prioritised **And/or** Prioritisation methods and their justification are not easily understood	Little or no attempts made to prioritise objectives, issues and strategies **And/or** Little attempt to justify methods of prioritisation applied		High	

Endorsement Criteria	Questions	Little or no improvement required	Strategy would benefit from Improvement	Significant improvement required	Score	Weighting	Weighted Score Low (score x1) Medium (score x2) High (score x3)
	Does the strategy provide the necessary direction for resource management in the region?	Objectives address all key issues, and provide strong strategic direction for achieving planning outcomes and meeting the regional vision.	Objectives adequately address regional issues, and provide a good direction for achieving planning outcomes and the regional vision.	The document provides generally weak direction for achieving planning outcomes and meeting the regional vision		High	
Implementation/ Monitoring and review	Has a process and framework of monitoring and review been suggested for implementation?	Monitoring & review programs are realistic and suitable for the purpose of the strategy	Adequate monitoring & review programs suggested	Monitoring & review programs, if present are inappropriate for the strategy		High	
		Relevant and realistic performance indicators specified for all key outcomes detailed in the plan.	Performance indicators specified for the key outcomes are acceptable but their relevance is not clearly identified.	Performance indicators (are not) specified for key outcomes (and/or) have little relevance and lack realism		Medium	
	Has a reporting framework for signoff of actions during and after each stage of implementation been established?	Reporting requirements identified and framework clearly established.	Reporting requirements are identified, with some discussion of reporting mechanism.	Limited or missing identification and discussion of reporting framework		High	
	Has a synopsis or detailed set of action plans guiding the implementation of the strategy been provided?	Synopsis covering directions and guidance towards achieving on-ground results **or** Extremely clear & proactive set of action plans for guiding implementation	General synopsis explaining the guidance of the strategy to on-ground actions **or** Action plans outline in a general sense the direction of the strategies and some on-ground direction	Limited detail on how on-ground activities will be undertaken **or** Action plans, if present, provide minimal guidance for on-ground activities		Medium	
	Has the RSG identified its limitations and capabilities, and the future roles of agencies and groups?	Limitations and capabilities in implementing the strategy clearly identified - future roles of agencies and groups clearly spelt out.	Capabilities or limitations of group identified - some indication of future roles	Minimal identification of capability of group to implement the strategy		High	
Endorsement/ community consultation/ stakeholders	Are stakeholders identified, involved and committed to the strategy at the endorsement level?	Detailed list of stakeholders and their involvement - role of other groups and agencies clearly identified and endorsed through partnerships and memorandum of understanding	List of stakeholders is not comprehensive - role of other groups or agencies is identified with some indication/evidence of level of endorsement	Few if any stakeholders listed with little evidence of their support		High	

Endorsement Criteria	Questions	Little or no improvement required	Strategy would benefit from Improvement	Significant improvement required	Score	Weighting	Weighted Score Low (score x1) Medium (score x2) High (score x3)
	Has an appropriate method of community consultation been utilised to develop the strategy?	Clear processes of community consultation identified and strong justification for the methods applied **And/or** Very high degree of community consultation and involvement in the development of the strategy	Processes of community consultation adequately identified, yet lacks justification **And/or** Adequate degree of community consultation and involvement in the development of the strategy	Little or no identification and justification of community consultation methods applied **And/or** Insufficient degree of community consultation in the development of the strategy		High	
	Has a process been identified to address any need for conflict resolution during development and implementation of the strategy?	Clear process for resolution of conflict	Some evidence of thought into conflict resolution techniques	Little or no mechanism for resolution of conflict		High	
Process appraisal	Have appropriate processes been utilised and applied throughout the development of the strategy?	All processes used throughout the development of the strategy are suitable and justified with additional detail where necessary	Some faults present with the processes applied to the development of the strategy. Overall still acceptable	Major faults with the processes utilised throughout the development of the strategy		High	
Readability of document	Is the document clear and concise, and easy to read?	Very good format - use of variety of methods to convey message - effective use of visual communication aids (tables, diagrams, maps etc)	Useful format with general readability being sufficient for document to be useful	Extremely poor format, logic and development of ideas difficult to follow		Qualitative (No Score)	TOTAL SCORE

Note:
Except where indicated through the use of And/or as a separator, endorsement criteria should be considered independently of others
A minimum interim level of endorsement would be based on a strategy meeting the middle level (some improvement necessary), or receiving a total weighted score of 150 (maximum possible score = 250)

Statement of Compliance

The statement of compliance is intended to provide strategy groups with a means of showing how and where they have addressed key requirements in preparing their strategy, and for assessment panel members to provide any additional comments or feedback. The SoC is based on the assessment criteria, and provides a strategy group with a number of questions to consider which relate to each aspect of the strategy to be assessed. It also provides a means for the strategy group to 'sign off' that they have covered each issue, and to indicate where in the document they have done so.

Form 2: Statement of Compliance

Endorsement Criteria	Questions	Considerations	Statement of Compliance	Relevant Section	Assessors Comments (to be completed by assessor)
Introductory Section	Does the introductory section provide a sound foundation to interpret the strategy?	Is there adequate rationale to interpret strategy, with sufficient background information and regional overview to identify and justify regional issues?			
Integration	Does the strategy integrate with other plans, strategies and resource management initiatives?	Does the document demonstrate understanding of hierarchy of related plans and strategies, constraints of linking with other plans; coordination between broader government policies and local action plans; consideration of coinciding with other management initiatives and/or international treaties?			
Information base	Is the information base documented?	Is there evidence of integrity of qualitative/quantitative data having been verified? Is information comprehensive in coverage? Have information gaps been identified? Is the information base sufficiently up to date to account for current management needs?			
	Have opportunities to fill information gaps been investigated?	Have issues relating to resource condition and impediments to change been investigated? Have information sources and the need for ongoing improvement of resource and information inventories been considered? Consider ongoing improvement of information inventory			
Vision/values/principles	Is there a clear association between the vision, values and management principles of the strategy?	Consider the relationship between each aspect, and whether continuity is attained between sections in achieving outcomes.			
	Do the vision, values & principles reinforce an integrated approach to the management of the region?	Is the regional vision clearly defined in the eyes of all relevant groups and agencies? Is there evidence of broad cooperative involvement and agreement across sectors of government and the wider community? Consider inclusion of social, economic, environmental, cultural and technological aspects.			

Endorsement Criteria	Questions	Considerations	Statement of Compliance	Relevant Section	Assessors Comments (to be completed by assessor)
Objectives/key issues/ strategies	Do the objectives, issues and strategies work together to achieve the desired outcomes?	Have key issues and their local importance been identified and prioritised? Do objectives complement each other; do they complement the broader planning and management framework; and do they provide the necessary direction for NRM in the region? Are key issues defined in terms of both resource condition, and cultural importance to these resources?			
	Are the issues, objectives and strategies prioritised with justification of method?	Are the approaches to prioritise issues and the means to address them suitable for ongoing regional management? Is there adequate justification for the allocation of priorities on issues and the means to manage for them?			
Implementation /monitoring and review	Has a process and framework for ensuring accountability, and for ongoing monitoring and review been suggested as part of implementation?	Have appropriate performance indicators been suggested to measure the strategy's effect on the social, cultural, environmental and economic trends of the region? Have desired outcomes and performance indicators for each strategy been defined? Is the process realistic?			
	Has a synopsis or detailed set of action plans guiding the implementation of the strategy been provided?	Is there provision for future actions? Are the action plans/synopsis realistic? Is there strong guidance and direction in developing and implementing action plans? Is there provision for signoff on completion of actions by the relevant organisations?			
	Has a synopsis or detailed set of action plans guiding the implementation of the strategy been provided?	Does the strategy lead towards the development and implementation of action plans to deal with priority NRM issues in the region?			
	Has the RSG identified its limitations and capabilities, and the future roles of agencies and groups?	Does the strategy identify the role of the RSG through the whole process? Has the RSG outlined any limitations in their ability to implement the strategy? Has the strategy provided details of the roles of other stakeholder groups and agencies throughout the life of the strategy?			

Endorsement Criteria	Questions	Considerations	Statement of Compliance	Relevant Section	Assessors Comments (to be completed by assessor)
Endorsement/ Community Consultation/ stakeholders	Are stakeholders identified, involved and committed to the strategy at the endorsement level?	To what degree has community consultation been essential to the development of the strategy throughout the planning, implementation and evaluation stages? Are appropriate time and resources committed to facilitate feedback throughout the life of the strategy? Is there the necessary level of endorsement from the relevant government agencies and organisations, and other necessary groups?			
	Has an appropriate method of community consultation been utilised to develop the strategy?	Was the method of community consultation appropriate for the various stakeholder groups involved? Was there sufficient attempt to obtain a wide spread of community representation, in consultation? Was the method of obtaining information valid and suitable given the significance of a regional strategy?			
Process Appraisal	Have appropriate processes been utilised and applied throughout the development of the strategy?	Consider attempts collect necessary background information and other data; prioritisation of issues and objectives, adequate consultation and community involvement, degree of assistance/direction from government agencies, evidence of seeking required endorsements			
Readability of document	Is the document clear and concise, and easy to read?	Consider terminology, inclusion of glossary; flow and structure; correct grammar and appropriateness of style			

4.3 Progress

4.3.1 Catchment Coordinating Committees

In 1992 there were three Catchment Coordinating Committees (CCCs) which expanded to thirty-two CCCs in 1997. CCCS are not recognised under legislation however, the committees are encouraged to be incorporated and most are formally recognised under the State government's ICM initiative. Membership of the recognised CCCS is diverse and the CCCS also have at least one officer from DNR as a member and active members from other government departments as well.

Membership of all recognised CCCs is diverse. All CCCs have part-time or full-time coordinators or administrators, which originally were provided by the State government, but CCCs are increasingly employing their own staff. However, they have at least one officer from the DNR as a member, and most committees have active members from other government departments as well. (Rowland and Begbie, 1997: 3)

Support for CCCs comes from a variety of sources. All endorsed groups of access to grants for establishing and operating the committee, although not all CCCs utilise the grants. Other CCCs receive a limited cash support from local governments as well as representatives from the local governments. Support is also received in kind, for example office space and administration from

some local governments and producer organisations such as 'Canegrowers' (Rowland and Begbie, 1997: 3).

Over 77% of the state is covered by catchment committees, the major areas not currently involved in ICM are the upper Burdekin catchment area, areas in Cape York, and some areas on the coastal south east. (Rowland and Begbie, 1997: 3)

4.3.2 What are the goals of a Catchment Coordinating Committee and What does a Catchment Coordinating Committee do?

(extract taken from: Queensland Department of Primary Industries (DPI). 1994. *Integrated Catchment Management - Guidelines for the Formation of a Catchment Coordinating Committee.* Queensland Government, Department of Primary Industries, Brisbane, p.13.)

What are the goals of a Catchment Coordinating Committee?

All CCCs need to have goals to work towards. Each CCC will need to determine its own goals, which may include the following.

- Promote community understanding of the interactions between land, water and related biological resources, and the value of a coordinated, catchment-wide approach for managing these resources.
- Minimise detrimental environmental effects due to the use of land, water and related biological resources, within and beyond the catchment boundaries
- Provide for ecologically sustainable development of river catchments in a constructive and balanced way
- Develop practical solutions to complex and interrelated problems in land and water use and management through public and government participation.

What does a Catchment Coordinating Committee do?

Each CCC needs to consider the work it may perform/ The functions of a CCC should include the following.

- Provide a forum for public discussions on catchment management issues identified by community action groups, agencies or members of the public.
- Foster communication and interactions between landholders, community action groups, local governments and government agencies.
- Identify important catchment-wide problems, and initiate or coordinate action to address these problems through the development of catchment management strategies
- Promote and use sound land and water management practices
- Receive briefings and reports, offer advice to government and semi-government bodies, and provide a direct link between the community and the State government
- Identify, encourage and foster the coordination 9and where necessary the integration) of government and semi-government agencies for key catchment issues

4.3.3 Guidelines for Obtaining Endorsement and Support Funding for Catchment Coordinating Committees

(Extracts taken from Queensland Department of Primary Industries (DPI). 1995. Integrated Catchment Management - Guidelines for obtaining endorsement and support funding for Catchment Coordinating Committees. Queensland Government, Department of Primary Industries, Brisbane, p.2-3)

What does it mean to be endorsed as a CCC or RCCC?

Once a CCC or RCCC has been established it can apply for endorsement. This gives them formal recognition by Government under the Queensland Integrated Catchment Management (ICM) Strategy. Endorsement provides opportunities for committees to access specific support available from the ICM initiative of the Queensland Government. This includes public liability and personal accident insurance, operating grants and project grants. To obtain endorsement, CCCs and RCCCs need to have features described in the following sections.

Catchment Coordinating Committees

Catchment coordinating committees should have the following features to be eligible for endorsement under the Queensland ICM Strategy:

1. They should cover an entire named river basin or a major sub-basin covering significant parts of at least two local government areas.

2. Membership should reflect the interests of the major sectors of the community including:
    - Local governments
    - Key relevant primary industry organisations (for example, Canegrowers, Graingrowers, fruit and vegetable cooperatives, commercial fishing organisations)
    - Landholders in proportion to the range of land uses in the catchment (for example, cane, fruit, hobby, urban, grazing)
    - State Government agencies
    - Community groups and organisations (for example landcare groups and service clubs)
    - Recreation and conservation interests (including recreational fishing)
    - Secondary industry (for example, millers, processors, light and heavy industry)
    - Major stakeholders outside the catchment where relevant (for example the Great Barrier Reef Marine Park Authority, downstream users, out of catchment users,)
3. Membership should be determined by open election or through nomination by community groups, agencies and the general public.
4. Achievable objectives should be set that are consistent with the functions of a CCC as outlined in the *Queensland Integrated Catchment Management Strategy*.
5. A whole catchment perspective should be taken rather than being restricted to a single issues such as soil erosion or stream bank revegetation
6. A demonstrated ability to be accountable for the administration of funds and the management of projects is important. This can be indicated by the committee being incorporated and having an active executive.

It may not be necessary for committees to completely fulfil all these criteria to be endorsed under the ICM Strategy. While an eligible committee should ideally meet all criteria, the Catchment Management Coordinating Committee is able to exercise discretion in the extent to which a CCC needs to meet specific criteria

Regional Catchment Coordinating Committees

Regional catchment coordinating committees should have the following features:

1. They should cover an entire river basin. These basins include the Burdekin, Fitzroy, Burnett, Brisbane, Murray-Darling (Queensland) and Lake Eyre river systems. The RCCC should cover the area of interest of at least two CCCs.
2. A majority of members must be representatives or nominees of CCCs in the basin or region. Additional members should represent major industries, organisations and community, professional and government bodies with a major role or interest in the management of the whole basin or region. All CCCs in a region or basin must be represented on the RCCC.
3. Achievable objectives should be set that are consistent with the functions of a RCCC as outlined in the *Queensland Integrated Catchment Management Strategy*.

4.3.4 ICM Groups in Queensland July 1999

Table: Progress of ICM Groups in Queensland July 1999

Group	Catchment	Formation Steering Group	Incorporated	Endorsed CCC	Catchment Management Strategy
Annan & Endeavour Catchment Management Group	North East Cape York				Strategic Plan for the catchment areas
Barron River Integrated Catchment Management	Barron				Barron River Catchment Management Strategy.
Border Rivers Catchment Management Association	MacIntyre, Weir, Moonie rivers			Yes	Endorsed. Part of the Murray-Darling Basin. Full time coordinator.
Bremer Catchment Assoc. Inc.	Brisbane		Yes		Draft.

Group	Catchment	Formation Steering Group	Incorporated	Endorsed CCC	Catchment Management Strategy
Burdekin	Burdekin-Haughton, Don, Ross-Black	Burdekin Dry Tropics Interim Catchment Management Steering Committee			Regional ICM/Landcare groups are developing three sub-regional strategy plans
Burnett Catchment Care Inc.	Burnett-Kolan		Yes	Launched on 21st August 1996.	In progress. Public comment early March 99
Caboolture Shire Council	Burpengary Creek, Caboolture River, Stanley River	July 1992, Caboolture Catchment Advisory Committee			
Cardwell Shire Catchment Coordinating Committee	Tully and Murray Rivers			Interim CCC was organised and endorsed by the Minister	Draft Tully/Murray Rivers Management Strategy
Condamine Catchment Committee	Condamine River and tributaries above Miles			Yes	Condamine Strategic Plan Endorsed Dec' 96 Part of the Murray-Darling Basin. Full time coordinator. Full review of strategy to take place in 1999.
Dawson Valley Association	Dawson River	Formed in 1991	Yes November, 11 1992	Yes	Dawson Rover Catchment Strategy For Endorsement (released Dec 1998)
Douglas Shire Catchment Coordinating Committee	Mossman-Daintree				Interim.
Fitzroy Basin Association	Fitzroy River Basin	Interim CCC formed February 1993.			Central Queensland Strategy for Sustainability (CQSS)
Herbert River Catchment Coordinating Committee	Herbert River	March 1993		Yes	Interim Full-time coordinator.
Hodgson Creek	Hodgson Creek	Pittsworth, Bambooya and Clifton Landcare Groups			In Progress
Johnstone River Catchment Coordinating Committee	North and South Johnstone Rivers	Formed in early 1991.		Yes	Pilot Study. Endorsed. Full time coordinator.
Lake Baroon Catchment Care Group	Obi Obi Creek above Baroon Pocket Dam				Endorsed. Within the Mary River catchment. Financial and facilitation support provided from the Mary River Pilot Study Project.
Lake Eyre Basin Coordinating Group	Diamantina Georgina Thomson Bulloo	Formed in 1995			In progress. Issues papers published Sept 1997
Lockyer Catchment Coordinating Committee Inc.	Lockyer Creek - part of the Brisbane River system	Formed in early 1991.	Yes	Yes	Draft. Pilot Study. Land use planning guidelines strategy released 29/3/94 Full time coordinator.

Group	Catchment	Formation Steering Group	Incorporated	Endorsed CCC	Catchment Management Strategy
Logan River	Logan River catchment	Logan River Management Coordinating Committee, December 1988			
Maranoa/ Balonne Catchment Management Association	Balonne River, the lower section of the Condamine, the Maranoa River and associated creeks	Formed 28th February 1993	Yes Incorporated on 28th Feb 1995	Yes	Maranoa-Balonne Catchment Strategic Plan Endorsed. Part of the Murray-Darling Basin. Full time coordinator.
Maroochy – Mooloolah Catchment Care Network	Maroochy River		Yes		In progress.
Mary River Coordination Association Inc.	Mary River		Yes	Yes	Endorsed. Pilot Study. Full time coordinator.
Mitchell River Watershed Management Working Group	Mitchell and associated rivers	Formed in 1990.	Yes	Yes	Pilot Study. Draft. Part time coordinator
Murray-Darling Basin Coordinating Committee (Queensland)	Paroo-Wallam Creek Condamine-Balonne Border Rivers-Moonie		Yes, June 1998		Natural Resources Management Strategy for the QLD Murray Darling Basin April 1993
Noosa River Catchment Management Committee	Sunshine Coast Catchment			Launched on 30 August 1996	In progress. Complete draft Catchment Management Strategy by June 1999.
North & South Pine Rivers Integrated Catchment Association Inc. (NASPRICA)	Sunshine Coast Catchment		Yes	Launched on 11 Feb 1996	Draft.
Pioneer River Catchment Coordinating Committee	Pioneer River and Sandy and Bakers Creeks	Formed in September 1991, completing its report in May 1992.		Yes	Pilot Study. Catchment management strategy released March 1994. Full time Coordinator.
Pumicestone Region Catchment Coordinating Committee	Brisbane		Yes		Draft
Russell/ Mulgrave Catchment Coordinating Committee	Russell and Mulgrave Rivers			Yes	Endorsed.
South West Natural Resource Management Group	Warrego, Paroo Rivers and east to Wallum Creek	Warrego/ Paroo CMA Inc	Yes	Yes	Natural Resource Management strategy. Aiming for endorsement by the LCMC. Part of the Murray-Darling Basin.
Southern Gulf Catchments Incorporated	Eastern Gulf Flinders Western Gulf		Yes		Draft Regional Resource Management Strategy

Group	Catchment	Formation Steering Group	Incorporated	Endorsed CCC	Catchment Management Strategy
Weipa Catchment Coordinating Group	West Cape York		October 1996		Dec '98 - close to completion of draft strategy
Whitsundays Rivers Catchment Management Association	Proserpine		Yes		In progress.

5. REVIEWS OF ICM IN QUEENSLAND

At the time of writing, ICM has been running for a decade in Queensland. (1990-99). During that time it has been continually evaluated and improved. Reviews have conducted at regular intervals by state agency staff supporting the program, most notably the major 1993 review. That was a "watershed" review confirming the relevance and success of the program and ensuring its continuation indefinitely. It could have died. Extracts from that review are included here.

Given that the Queensland ICM was experimental and substantially dependent on bottom up interest and commitment, the reviews focus not only on the overall success of the program, but ways to make it work better. The program was adaptive to feedback from the reviews. There was a growing cadre of experienced facilitators and catchment coordinators who contributed to this effort. Since 1995, the Queensland ICM program has organised a number of conferences and forums – especially targeted at the chairs of committees and the catchment coordinators with first hand experience of the operation of the program. They reviewed achievements and shared experiences as a learning opportunity for those catchments representatives and facilitators without the same level of experience. These forums were held at Maleny (1995), Rockhampton (1994), Cairns (1998) and Mt Isa (1999), the latter two combined with Landcare. Summary notes from those forums are included here.

There have also been a number of external reviews. In 1995, AACM conducted a nationwide review identifying the strengths and weaknesses of ICM programs in each state. The Queensland section of that review is included here. McDonald and Shrubsole and then McDonald Bellamy and Fereia conducted surveys of chairs and coordinators in 1995 and then again in 1997. Those repports are elsewhere in this series. The Rowland and Begbie review (1997) is also an important statement on the progess of ICM and is included in Section 3 of this document.

5.1 Review of Catchment Management Component of ICM Initiative

Department of Primary Industries, 1993
("Review of Integrated Catchment Management Initiative", Ch.2)

Introduction

The economic viability and lifestyles of present and future rural and urban communities depend on the maintenance of a balance between economic development and conservation of natural resources. However, the ability of these resources to continue to meet our needs in the future is under threat due to a number of issues including:

- The impact of land use on water quality;
- Soil erosion and sedimentation of watercourses;
- Instability of bed and banks of watercourses;
- Salinity induced through clearing of vegetation;
- Loss of habitat on land, in rivers and streams;
- Flood mitigation and floodplain management;
- The impact of land and water use on coastal and marine environments;
- Productivity decline due to the degradation of land and water resources;
- Spread of weeds by water; and
- Increasing demands on land and water resources for agricultural, industrial, residential, transport and recreational uses and environmental conservation

These issues involve a number of people and organisations, including landholders and other resource users, government agencies, local authorities, conservation groups and rural industry groups, each of which is responsible for a different part of a river catchment or specific activities within it. In many cases, fixing problems such as these is difficult and requires coordinated action by a number of people and organisation and also requires a supportive legislative framework.

To address these complex issues and to provide an overall framework for the better management of the inter-related land, water and biological resources, the Queensland Government in 1990 launched a Catchment Management program as the key element of its ICM initiative

The Catchment Management program initiative involved:
- Creating community awareness of catchment management principles;
- Conducting catchment management pilot studies;
- Establishing a policy and coordinating framework for addressing catchment management issues; and
- Fostering catchment management programs in priority river catchments

Outcomes Desired
- All resource users and managers aware of river catchments and accounting for the interrelationships between natural resource in management decisions.
- Common natural resource management goals, strategies and coordinated action by community and government with river catchments.
- Sustainable and productive land and water use and balanced ecosystems

Goals

The goals of Catchment Management Program were:
- To improve community understanding of the relationships and interactions between natural resources and the need to manage these resources in an integrated way to achieve their sustainable use.
- To increase cooperation and coordination between government agencies, community groups and individual resource users in the integrated planning and management of natural resources for sustainable use
- To increase community responsibility for planning the integrated management of land, water and related biological resources for the sustainable and balanced use
- To increase community ownership and responsibility for implementing sustainable land and water use and management policies and practices

Strategies Adopted

To achieve the goals for the Catchment Management program, four broad strategic directions were adopted.

Community Awareness and Education
The sustainable and balanced use of land and water resources depends on landholders and other resource users, the community in general and government agencies and authorities having a sound understanding of the interactions between land and water, and of the need for a coordinated approach for addressing issues affecting these resources. The broad community was targeted to develop awareness and understanding of catchment management principles. Key strategies included:
- Preparing a communication plan for ICM in Queensland;
- Establishing a corporate identity for ICM;
- Preparing and distributing information on catchment management;
- Preparing educational resource materials;
- Promoting action learning programs on natural resource management; and
- Developing communication strategies for priority target audiences

Catchment Management Pilot Studies

A key strategy of the Catchment Management program involved the use of pilot studies to trial and promote an integrated approach to the planning, use and management of land, water, forests, wetland and related natural resources. Key strategies included:

- Establishing pilot studies in key catchments;
- Forming community-based Catchment Coordinating Committees (CCC);
- Assisting CCC to prepare catchment management strategies for addressing key issues;
- Providing a catchment coordinator to assist the CCC;
- Coordinating technical support to develop the catchment strategies;
- Conducting local community awareness activities to foster and encourage community involvement in natural resource management

Policy and Coordination Framework

The pilot studies were designed to evaluate different approaches to the preparation and implementation of catchment management strategies. The results of the pilot studies and experience in other States were used to develop a policy framework and coordinating mechanisms to provide for the on-going development and implementation of the Catchment Management program. This involved:

- Preparing a State ICM Strategy to provide the framework for an integrated and community-based approach to catchment management;
- Establishing the Catchment Management Coordinating Committee to guide the development and implementation of the Catchment Management program;
- Developing guidelines for the establishment and operating of Catchment Coordinating Committees;
- Encouraging the development of communication networks for transfer of natural resource management information within the community;
- Reviewing existing legislation and establishing a legislative framework; and
- Consulting with the broad community in the development of policies, guidelines and strategies.

Catchment Management Support in Priority Catchments

While catchment level activity was focused on the pilot study catchments, the education and awareness strategies were designed to promote a catchment based approach to the planning, use and management of land, water, forests, wetland and related natural resources in all river catchments. As the education and awareness strategies stimulated community interest, the following strategies were employed to provide support in priority catchments at a lower cost than that of the pilot studies:

- Fostering the formation of community based Catchment Coordination Committees in priority river catchments to prepare and promote local natural resource management strategies;
- Providing operating and establishment grants to community based catchment management committees; and
- Providing project grants to community based groups and local authorities to undertake catchment management projects in accordance with an overall catchment management strategy

Budget Allocation

Over the three year period of the ICM Special Allocation, a total of $2 927 000 was allocated to the Catchment Management program. Approximately $442 000 was spent on awareness and education, $1 209 000 on pilot study activities, $701 000 on policy and coordination, and $575 000 on catchment management programs. A summary of expenditure for each of the three years is presented in Table 2.1

Table 2.1 Summary of expenditure for the Catchment Management program, 1990 to 1993

	1990/91 ($'000)	1991/92 ($'000)	1992/93 ($'000)	Total ($'000)
Strategy				
Awareness/Education	106	114	222	442
Pilot Studies	94	426	689	1209
Policy Coordination	111	239	351	701
Catchment Management Support		47	528	575
Total	311	826	1 790	2 927

Results Achieved

Community Awareness and Education
Progress Towards Objectives
A Principal Extension Officer manages and leads the development and implementation of the promotional campaign. A temporary Graphic Artist and a temporary Extension Officer assist with the production of materials and delivery of the program. Major achievements include:

- ICM corporate identity established with Catchment Care resource folders, stickers, banners, signs and logo, June 1991;
- Catchment care brochure released, June 1991 (30 000 copies);
- Audio-visual ICM display developed for the ABC Green Train, June 1991 and visited by more than 20 000 people;
- Catchment Care education kits including students books, teachers guide, catchment poster and catchment game developed June 1991 and distributed to all schools in Queensland;
- ICM display updated for the Brisbane RNA show, August 1991 and 1992;
- ICM Strategy printed and released, October 1991, together with a Strategy Summary brochure (10 000 copies);
- Major displays on local ICM themes developed for Expo 12 (Gatton), Farmfest (Toowoomba), Agrotrend (Bundaberg), other major regional events at Mackay, Emerald and Rockhampton and more than an additional 40 other regional and urban events;
- Corporate identity established for three pilot study Catchment Coordinating Committees – Johnstone, Pioneer and Lockyer;
- Newsletter – "The Source – ICM News and Views" produced three times per year with a circulation of 5 000 copies;
- Community Awareness brochures developed for the Lockyer and the Pioneer pilot studies;
- Land use planning display developed for the Lockyer Resource Management Group;
- Communication strategy developed for ICM in Queensland, January 1993, identifying key target audiences for detailed communication plans;
- Video titled "Everyone lives in a catchment" produced for the Mary River pilot, march 1993;
- Integrated display planned for ICM and Landcare at the Rocklea Research and Education Centre, April 1993;
- Condition of River Catchments in Queensland report published, May 1993; and
- Pilot Waterwatch program developed and trialed in the Pioneer River pilot catchment in 1993.

A list of publications (including awareness and educational material) is shown in Appendix Ia.

Client Interest and Satisfaction

Community awareness and understanding of ICM has been significantly increased, as evidenced by an increasing and on-going demand for information about catchment management, for example:

- More than 20 000 people passed through the ICM display on catchment management at the 1991 and the 1992 Brisbane RNA exhibitions;
- The ICM display has been solidly booked by local community based groups for local shows and public events from February through to the end of June 1993;
- Over 500 people brought water samples for testing at an ICM water testing station on World Environment Day 1992; and
- The video produced about catchment management in the Mary River has been well received by the community in that catchment. In the 3 months since it was produced, over 300 people have viewed the video at public meetings and 150 copies have been distributed to community based organisations within the catchment.

Catalytic Effects
The increased community awareness has led to increased involvement in catchment management activities.

- An ICM sponsored study tour in June 1992 by Prof. Bill Stapp, University of Michigan, USA, to examine the development of water quality monitoring as an action learning school and community activity, has led to a pilot Waterwatch project in the Pioneer River pilot study area involving local schools, industry and community organisations and local authorities. The project attracted financial support of $10 000 in 1992/93 under the National Waterwatch Program, with continuing support expected in 1993/94 and beyond.
- Numerous schools and community groups have indicated a desire to undertake a Waterwatch program in their local catchments. External funding through the National Landcare Program has been obtained to develop appropriate materials, resource kits and methods for a major Waterwatch initiative in Queensland.
- Promotion of ICM activities has resulted in local authorities, river improvement trusts and water boards in catchments such as Logan, Caboolture, Maroochy, Fitzroy, Barron and Tully-Murray Rivers, using and ICM approach to address local catchment management issues and incorporating ICM principles in planning schemes.

Coordination and Cooperation

- Inter-disciplinary and inter-organisational working groups have been established to develop and promote the Waterwatch program
- An integrated proposal is being developed for an inter-active, educational display at the Rocklea Research and Information Centre.
- ICM displays and promotional material were developed in collaboration with officers in appropriate Government departments.

Pilot Study Catchments

Progress and Milestones Achieved

The following lists progress in achieving milestones in the pilot study catchments. A timetable with the major milestones is shown in Figure 2.1.

- Community- based Catchment Coordinating Committees were formed in the Johnstone, Mitchell, Pioneer Rivers and Lockyer creek. A catchment management steering group was formed in the Mary catchment in May 1993
- A comprehensive draft catchment management strategy was produced for the Johnstone River catchment. Issues addressed include land and water management and environmental concerns.
- Four draft "Code of Practice" have been developed for the beef, dairy, horticulture and cane industries in the Johnstone Pilot study.
- A four part report on the status of stream banks in the Pioneer Valley was produced.
- In the Lockyer Valley, a detailed strategy for land use in the catchment was prepared and is in the final stages of redrafting following extensive community consultation. Recommendations contained in the strategy are being used in the preparation of the Gatton Shire Plan.
- All Catchment Coordinating Committees in the pilot study areas have the services of catchment coordinators employed by the Department. They also have substantial support from the DPI and other government departments and agencies.
- A Geographic Information System for the Johnstone catchment was established and a 28 map "Atlas of Resources" was produced.
- A school and community based educational program "The River" was produced and is being trialed in the Mitchell Pilot study catchment.
- Community involvement in ICM activities in all pilot studies has substantially increased.
- All Catchment Coordinating Committees have representatives from various government departments as active members of the committee.
- Officers from most business groups in DPI, officers from other departments and researchers and academics from a range of institutions have been actively involved in the studies.

Figure 2.1 – Milestones in the ICM Pilot Studies

1990	-	Formation of Mitchell River Watershed Management Group
	-	Formation of Johnstone River Catchment Management Steering Committee
1991	-	Formation of Lockyer Valley ICM Steering Committee
	-	Formation of Johnstone River Catchment Coordinating Committee
	-	Johnstone Catchment Coordinator appointed
	-	Formation of Lockyer Resource Management Group
	-	Lockyer Catchment Coordinator appointed
	-	Johnstone River Catchment Technical Advisory Group formed
	-	Formation of Pioneer Valley ICM Steering Group
	-	*The River* educational program produced for the Mitchell River catchment
1992	-	Pioneer Catchment Coordinator appointed
	-	Formation of Pioneer Valley Catchment Coordinating Committee
	-	Johnstone River Catchment Centre established
	-	Mary Catchment Coordinator appointed
	-	Reports on stream bank stability in the Pioneer River released
	-	Draft document outlining Principles and Guidelines for Land Use Planning in the Lockyer Valley released by the Lockyer Resource Management Group
1993	-	Mitchell Catchment Coordinator appointed
	-	A computer based catchment model of the Johnstone River completed
	-	Release of Draft Catchment Management Strategies in Johnstone and Lockyer studies
	-	*Waterwatch* program initiated in the Pioneer River Study

Outcomes from the pilot study areas have shown that there are three distinct phases in catchment management. These phases are shown in Figure 2.2. In Phase 1 community awareness of issues increases and a catchment coordinating committee was formed. Phase 2 involved the preparation of a catchment management strategy for key issues, while Phase 3 involved community and government action in response to the strategy. This model will be used to guide the management of future catchment studies

A list of publications from the pilot studies is included in Appendix Ia.

Figure 2.2 Model Program for ICM Catchment Studies

Phase 1. Formation of Catchment Coordinating Committee

Activities include formation of a steering committee, community education and awareness and establishment of a representative catchment coordinating committee.

Phase 2. Strategic planning exercise

Activities include preparation of a vision for the catchment, identification of issues and development of objectives and strategies

Phase 3. Implementation

Activities include the implementation of Catchment Management Strategies. Preparation of action plans and implementation by stakeholders

Client Interest and Satisfaction

- Members of catchment coordinating committees give voluntary of their time and wear the total cost of participating in the studies. Attendance of members at meetings and other activities has been high. Many members contribute substantially of their time and expertise.
- Industry and local government interests, particularly in the Johnstone and Lockyer study areas, have made major contributions to the ICM studies. Their involvement is an indication of the community support for the ICM approach to addressing important resource management issues.

Catalytic Effects

- Over 327 man weeks of effort have been donated by senior community, government, industry and agency personnel to undertake ICM activities in the pilot study areas. Many of the people making this commitment are the leaders of community groups, local authorities and managers in government departments
- Landcare and other community groups have formed or have been stimulated to action by ICM studies in the Lockyer, Pioneer and Johnstone River catchments.
- A $500 000 research project (predominantly externally funded) investigating the movement of nutrients in farming systems have been commenced by the DPI in the Johnstone catchment as a result of the pilot study.
- Issues like riparian zone management, water quality, stream bank stability and the off-site effects of non-point run-off have become more important to a better informed community in the pilot study areas.
- Community interest in catchment management has increased and this is reflected in a recent edition of "World Around Us" on Channel 7. This edition entitled "Waters of out Life" featured the health of Queensland rivers and the important role of catchment management. Catchment management activity in the Johnstone River was featured.
- Many members of the DPI as well as other departments have increased their knowledge of and skills in public participation and community consultation through their involvement in ICM.

Cost Effectiveness of Delivery

- The Catchment Management program, while government led, has adopted a participatory and "ground up" approach. Increased knowledge and awareness of issues has stimulated voluntary action which otherwise would have required costly legislation and regulation. For example, in the Johnstone River, the cane, dairy, beef and horticulture industries are working on "Codes of Practise" which will be adopted by the industry organisations. While not compulsory, the influence of these initiatives by the industries themselves will carry substantial weight. Many of the changes recommended by these "Codes of Practice" are not currently controlled by legislation and it would be very difficult to do.
- Improved land use planning which will reduce land degradation, provide for growth while minimising the adverse social impacts, and reduce land use conflict will result from the ICM study in the Lockyer Valley. Other regional planning process do not appear to have the same potential, and are much more expensive exercises.
- In the Pioneer and Mary River catchments, strategies produced to address stream bank erosion have the potential to minimise wasted effort by better focusing attention of priority areas. Also, revegetation and riparian zone management to prevent stream bank erosion will reduce damage and restoration costs caused by flooding.

Coordination and Cooperation

- In all pilot study catchments, catchment coordinating committees have provided the only community forum for the diversity of interest involved in natural resource management to jointly address important issues.
- Catchment coordinating committees have provided a constructive mechanism for dealing with issues. While conflict has been encountered in the pilot studies, it has been confronted and treated such that positive outcomes have resulted.
- Working relationships established in catchment coordinating committees have flowed on to other aspects of community and government interaction.
- Many agencies and organisation (for example, 24 in the Johnstone) have voluntarily cooperated in various aspects of the studies in all pilot areas.
- Pilot studies have proved a useful vehicle to coordinate work by departmental and other agencies in the pilot catchments. For example in the Mary Valley the University of Queensland, Griffith University and DPI are cooperatively providing GIS information on important catchment issues.

A brief outline of progress in each of the Pilot Studies is provided in Appendix Ib.

Policy and Coordinating Framework
Progress Towards Objectives

- Formation of a State Catchment Management Steering Committee to oversee the development of a State ICM Strategy;
- Development of the ICM Strategy for Queensland, released in October 1991;
- Appointment of a Catchment Management Coordinating Committee in August 1992, with representatives from Catchment Coordinating Committees (CCC), industry, community and professional groups, government agencies and river improvement trusts and water boards;
- Guidelines developed for the formation of Catchment Coordinating Committees;
- Guidelines development for the payment of establishment and operating grants to community based Catchment Coordinating Committees;
- Policy and procedure developed for the provision of the catchment management project grants to community based catchment management committees; and
- Review of the need for ICM legislation in Queensland commenced as part of a broader review of Natural Resource Management legislation; and
- Draft priorities for catchment management activity in the State have been prepared by the Catchment Management Coordinating Committee. These are shown in Appendix Ic.

A list of policy and coordination publications is included in Appendix Ia.

Client Interest and Satisfaction

- A call for catchment management project grants in February 1993 resulted in 33 applications for funding, indicating widespread community interest in catchment management activities.
- In the two months after March 1993 release of policy and guidelines on operating and establishment grants, seven (7) applications for these grants indicating a high level of community interest in the program.

Coordination and Cooperation

- A multi-disciplinary task force has been established to review Natural Resource Management legislation in Queensland. Officers from Water Resources, Forest Services and Land Use and Fisheries Business groups of DPI are working with officers of the Departments of Lands, Environment and Heritage and Housing, Local Government and Planning to prepare issue and discussion papers on different aspects of natural resource management, including catchment management.

- ICM principles and structures have been incorporated into policies and discussion papers presented by other documents, SEQ2001 and other regional planning activities. For example, ICM principles are required to be followed in the preparation of Environmental Management Operation Strategies (EMOS) for the operation and rehabilitation of mine sites.

Catchment Management Support in Priority Catchments
Progress and Milestones Achieved.

- A Pilot Catchment Management Project Grant Scheme was established in 1993 to support local action directed at the preparation and implementation of CMSs.
- Significant interest in and use of ICM has developed in areas other than the designated pilot study catchments. Catchment management activity is occurring in over 11 catchment outside the pilot study areas. Figure 2.3 shows the increase in catchment management groups, both within the pilot areas and in other catchments.
- A Catchment Coordinating Committee in the Herbert River (the first non-pilot catchment) was established in March 1993. Four committees are seeking appointment in the Dawson River, Border Rivers, Warrego/Paroo Rivers and the Logan River catchments. Figure 2.4 shows progress and proposed milestones in conducting ICM studies in the pilot areas and other catchments.
- A strategy for Management of the Murray-Darling Basin in Queensland was released in March 1993.
- 16 Catchment Management projects valued at $368 000 were initiated by community groups, industry organisations, and local authorities in 1993. The ICM special allocation contributed $188 000 to these projects through catchment management project grants.

Publications relevant to catchment management are included in Appendix Ia.

FIGURE 2.3 CATCHMENT MANAGEMENT GROUPS IN QUEENSLAND

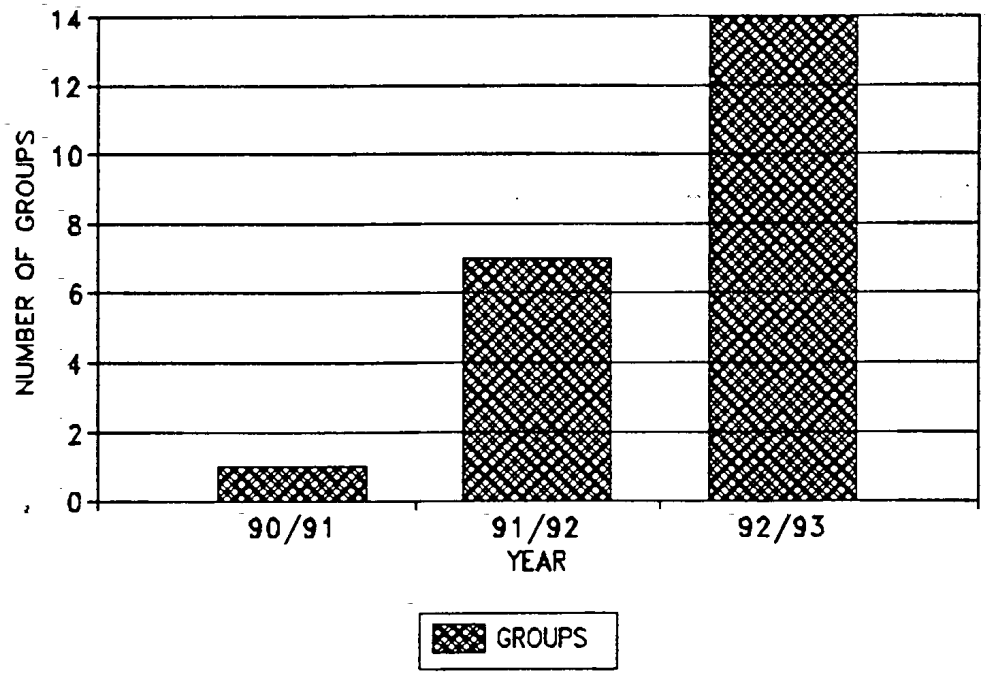

Figure 2.4 - Progress and proposed milestones in Conducting ICM Studies[1]

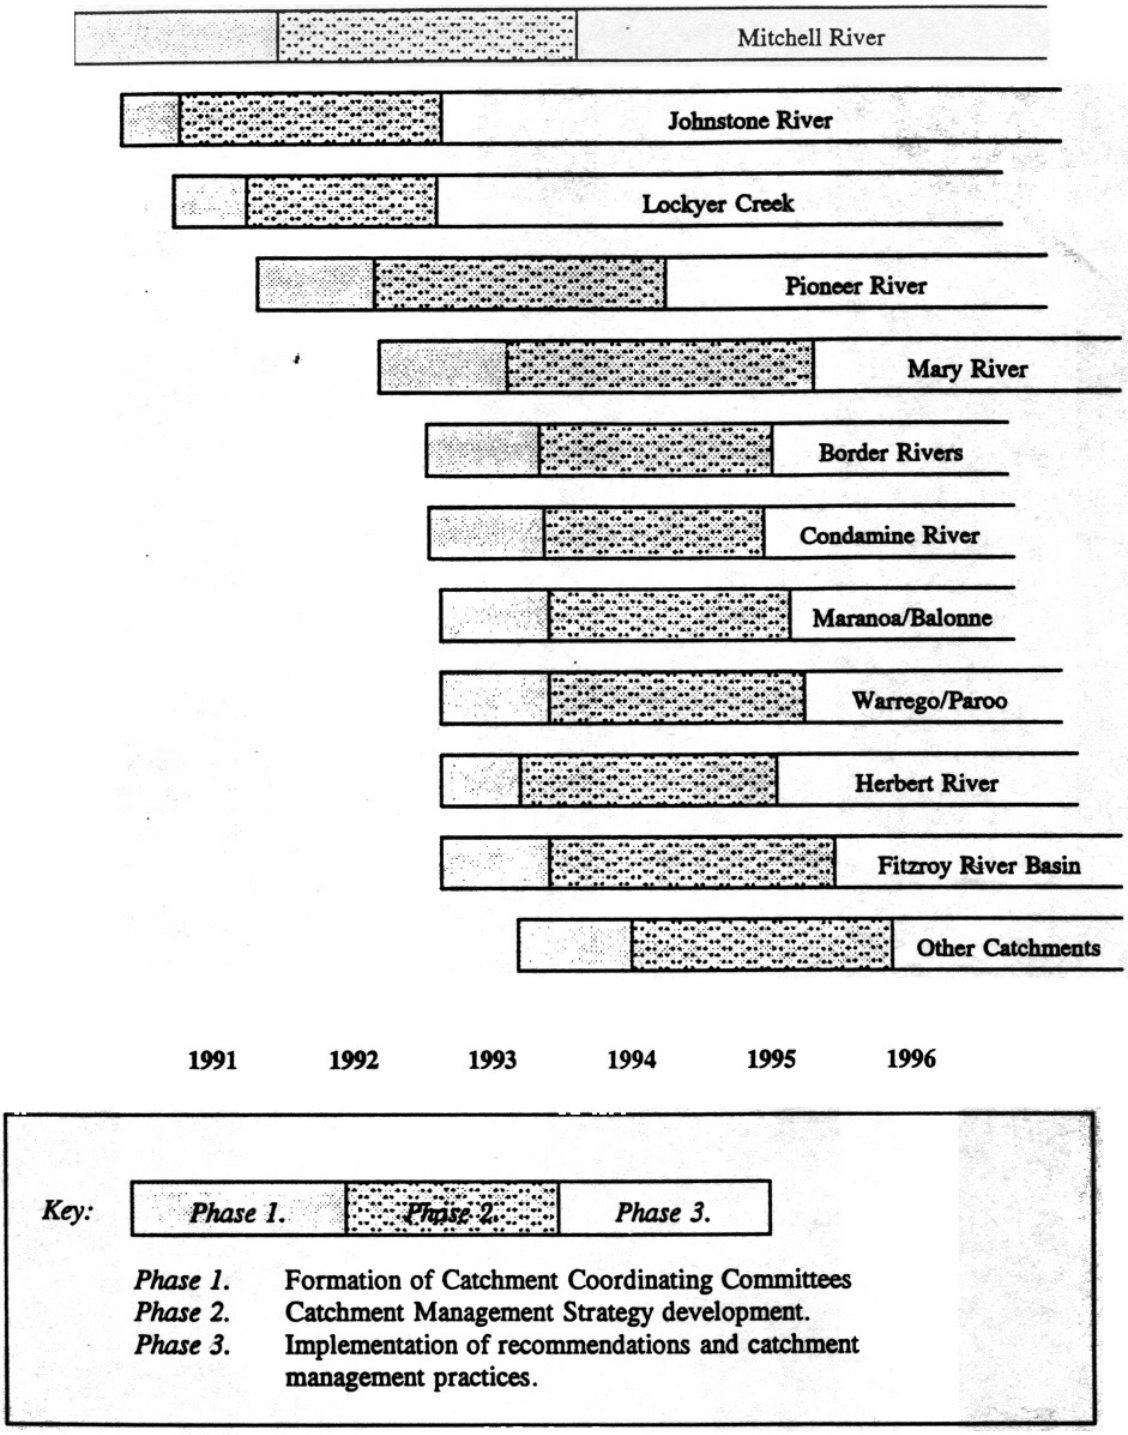


[1] **Note:** It is not possible nor practical to prepare catchment management strategies which address all significant issues in a catchment simultaneously. In a catchment, as significant problems arise, the planning and implementation cycle will be repeated a number of times.

Client Interest and Satisfaction

- ICM has proved a useful framework for many community based initiatives in natural resource management. For example, the Maroochy Catchment Area Network is using ICM to prepare a management strategy for the Maroochy River. The Dawson Valley Association is also using ICM to investigate possible development opportunities in the Dawson River catchment.

Catalytic Effects

Much of the activity in catchments outside the pilot studies has been initiated and largely resourced by community organisations and local authorities. DPI support and limited funding has provided the needed catalyst to stimulate considerable activity. For example:

- Caboolture Shire Council, through a catchment management group, is seeking (and getting) community endorsement of the need to retain key areas of remaining native vegetation as well as cultural and historical sites.
- A catchment management symposium on the Fitzroy River basin, held in November 1992, was organised by the local community. As a result of this symposium, an interim Catchment Coordinating Committee was formed in February 1993.
- The Queensland Branch of the Soil and Water Conservation Association of Australia organised a catchment management symposium and field tour in the Condamine River catchment in March 1993.

The availability of catchment management project grants has acted as a major stimulus for community based groups to seek external resources to undertake catchment management activities, for example:

- The Herbert River Catchment Management Coordinating Committee has obtained commitments from local authorities, industry organisation, statutory bodies and community groups to provided local contributions towards a catchment management project for their catchment. The Committee has also sought funds under the National Landcare Program to support this project.

Cost Effectiveness

- Catchment Management Project grants requires a 30% contribution by the submitting organisation. More often this ends up closer to 50%, making grants at least in terms of inputs, a very cost effective mechanism for achieving catchment management objectives. Many of these projects would require substantially more resources if they were conducted by the Department or by consultants. Local community groups are involving and obtaining input from a whole range of people and organisations who are not normally available to assists government departments to achieve common goals.
- It is difficult to value the local ownership that occurs as a result of project grants. For many ICM issues like stream bank re-vegetation and changes in land use, it is only through communities and individuals supporting a project that it is able to be conducted and achieve its goals.

Coordination and Cooperation

- In individual catchments, substantial cooperation and coordination between various interest sector groups has been achieved. For example, a catchment management group in the catchment of Baroon Pocket dam in the Sunshine coast hinterland has brought together dairy, conservation and urban interests. Jointly they are developing a catchment management plan to address blue green algae problems in the dam

Activities in catchments apart from the pilot studies are shown in Appendix Id.

Future Directions

The first stage of the Catchment Management program has focused on the formation of five (5) Pilot Study areas and the development of Catchment Coordinating Committees of catchment management strategies for priority issues in those catchments. Results from the Pilot Studies and initiatives in the first stage of the program have stimulated tremendous community interest and action in other key catchments.

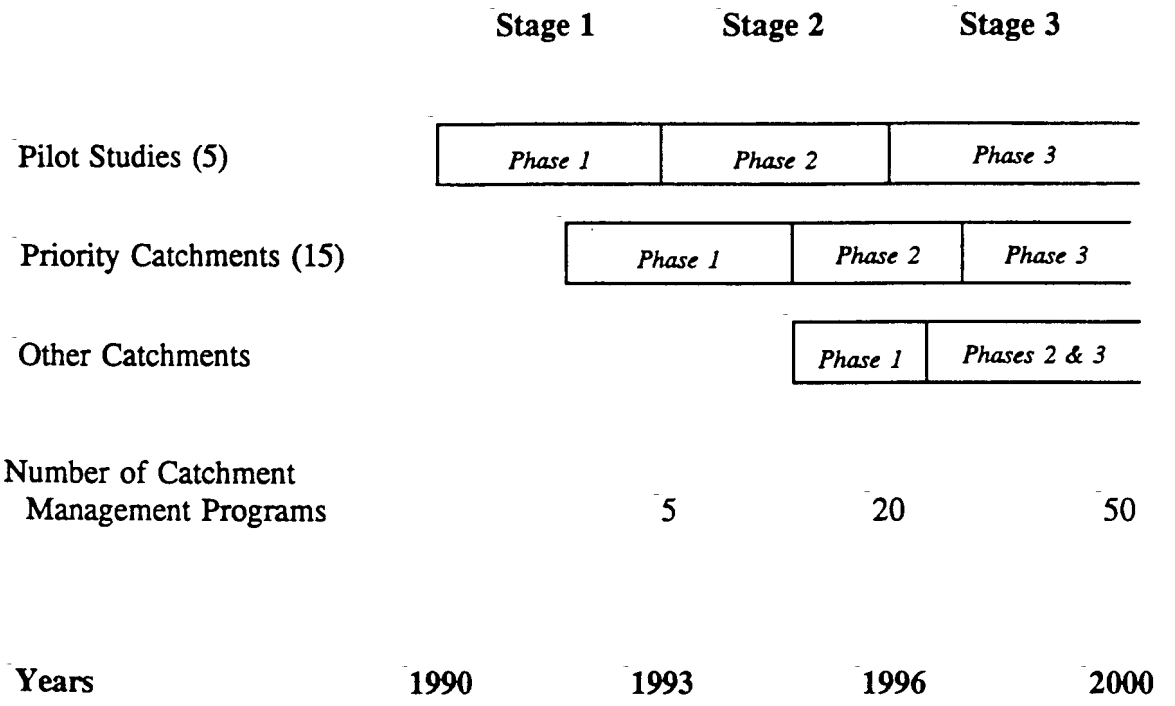
It is anticipated that Catchment Management programs will need to be adopted in approximately fifty (50) catchments or major sub-catchments to adequately deal with the catchment management issues currently identified. The Catchment Management Coordinating Committee has prioritised the river basins in Queensland as shown in Appendix 1c. These priorities will be used to guide the future direction of the program.

Based on the current funding allocation and community interest and support for ICM, the Catchment Management program will need to continue until at least the year 2000 to enable the program to be extended to all river catchments.

In the next stage of the program, emphasis needs to shift to implementation of the catchment management strategies developed in the Pilot Study areas and the development of strategies for key issues in fifteen (15) priority catchments. This includes the four (4) catchments in the Murray-Darling Basin and the Herbert River where catchment management program are currently commencing. This stage will take until about 1996.

The third stage of the program will then focus on strategies to encourage government departments and local communities, including local authorities, river improvement trusts, water boards and Landcare groups, to adopt a catchment management approach in undertaking activities to address key catchment management issues in the remaining catchments in the State. This will take until the end of the Decade of Landcare in the year 2000. An overview of the strategic directions for the Catchment Management program is presented in Figure 2.5.

Figure 2.5 - Strategic directions for the Catchment Management program



Key:

Phase 1	Community awareness, Catchment Coordinating Committee formation and catchment management strategy development
Phase 2	Implementation of catchment management strategies
Phase 3	On-going action planning, strategy development and implementation

During the next two stages, the DPI will continue to take the lead agency role for the Catchment Management program. However, local communities and industry organisations will play an increasingly important role in encouraging a catchment management approach and developing and implementing action plans.

Key Issues

- Community interest in the use of ICM to deal with a range of natural resource management issues is growing rapidly across the State.
- The considerable community effort expended in the development of Catchment Management Strategies has heightened expectations for action.
- Communities in the _Pilot Study areas have expended considerable energy in developing catchment management strategies and anticipate that Government support will continue for the implementation of these strategies.
- Local government planning and legislation controlling natural resource management are changing.
- Local authorities are playing an increasingly important role in controlling the use and management of vegetation and other natural resource as well as land.

- Valuable experience has been gained in the Pilot Study Areas and is available to be applied in other catchments.

In consideration of these key issues, catchment management in ICM will remain focused on the four existing strategic directions: Awareness and Education; Pilot Study Areas; Policy and Coordinating Framework; and Catchment Management Support.

Broad directions for the next three years
At the end of the next three years of the Catchment Management component of the ICM program, it is intended that the pilot studies will be essentially completed. Work will continue in the Pilot Study Areas particularly in the implementation of catchment management strategies but the level of funding through the ICM program will decrease.

Other catchment groups (in non-Pilot Study areas) will have made substantial progress in resolving significant catchment problems. These areas will become the primary focus of catchment management activity. Project grants and external funding sources will be used in the non-pilot areas to achieve outcomes similar to the Pilot Studies.

In three years the number of catchment coordinating committees will have increased significantly. Catchment coordinating committees will be operating with full policy and possibly legislative support. To complement this, it is planned that community and government awareness and understanding of ICM and their catchment will also have increased significantly. Funding support for Policy and Coordinating Framework and Awareness and Education will decrease as this is achieved.

Objectives for the next three years
The following objectives are proposed for the next stage of the Catchment Management program:

Community Awareness and Education
- Develop a communication plan for key target audiences.
- Increase awareness, understanding and support for ICM by local and state government and the community.
- Enhance community understanding and use of catchment management practices that address key issues identified in catchment management strategies.

Catchment Management Pilot Studies
- Prepare catchment management strategies for key issues in each of the pilot study areas.
- Evaluate catchment management activities in the pilot studies and highlight lessons learned in the planning and implementation of catchment management strategies.
- Initiate implementation of catchment management strategies for key issues by relevant government agencies, industry groups and the community.

Policy and Coordinating Framework
- For local authorities to implement suitable planning and regulatory conditions to assists in the achievement of objectives identified by catchment management strategies.
- Increase cooperation and coordination between government agencies, community groups and individual resources users in the planning and implementation of catchment management strategies.

Catchment Management Support in Priority Catchments
- Develop three catchment management strategies which focus on key issues each year for the next three years.
- Form effective and representative catchment coordinating committees in five catchments each year for the next three years.
- To have all relevant government agencies and industry groups actively involved in the implementation of catchment management strategies.
- Increase community ownership and responsibility for implementing sustainable land use and management policies and practices.

Strategies
Specific strategies designed to achieve the objectives for each strategic direction are:

Community Awareness and Education
- Promote ICM and specific issues in catchment management through the media and through public displays, newsletters and other methods.
- Assist Waterwatch activities in individual catchments by increasing community and government awareness of water quality issues.
- Develop and implement a statewide communication strategy
- Implement communication plans targeting the role of local authorities and state government in ICM.

Catchment Management Pilot Studies
- Facilitate and support the development of catchment management strategies for priority issues.
- Develop strategies and methods with catchment coordinating committees to enable the committees to obtain financial and technical support.
- Provide assistance in developing local and regional processes for the implementation of catchment management strategies.

Policy and Coordinating Framework
- Identify priority catchments for the development of catchment management strategies and facilitate the formation of Catchment Coordinating Committees.
- Provide technical support for Catchment Coordinating Committees through existing departmental and other agency personnel.
- Develop policies and procedures to ensure the implementation of catchment management strategies.
- Improve statutory mechanisms for the implementation of catchment management strategies through changes to existing legislation and by-laws and the production of new ones.

Catchment Management Support in Priority Catchments
- Provide project grants to community groups and local authorities to encourage catchment management activities and to enable their use.
- Formulate techniques and methods of community consulting to streamline the development of catchment coordinating committees.
- Provide training and educational opportunities for community groups to improve community ownership and responsibility for natural resource management.
- Lead and ensure the availability of resources for ICM activities in the Queensland section of the Murray-Darling Basin.

Outcomes
Application of the strategic directions are designed to produce the following outcomes.

Community Awareness and Education
- Substantial community and government understanding and support for ICM and catchment management strategies.

Catchment Management Pilot Studies
- Community based groups and organisations, industry organisations, government and statutory authorities will have commenced implementation of the strategies.
- Local authorities in catchments where catchment management strategies have been developed will have incorporated the strategies into their planning documents.
- Catchment Coordinating Committees will be self directed and less reliant on Department leadership and financial support.
- Significant improvement or resolution of the main issues identified in the catchment management strategies.

Policy and Coordinating Framework
- Planning and implementation activities of government agencies, community groups and individual resources users will be coordinated.
- Integrated policies and programs for the management of natural resources in catchments with catchment management strategies.

Catchment Management Support in Priority Catchments
- Catchment management strategies for key issues produced by Catchment Coordinating Committees within two years of formation.
- At least one significant catchment management issue resolved by each Catchment Coordinating Committees with two years of formation.
- Effective data bases on natural resources in catchments complied and available.

Milestones
The following milestones will be reached over the next three years:

Community Awareness and Education
- Waterwatch programs established in five (5) catchments by June 1994.
- Communication plan developed for key target audiences by December 1993.
- Communication plan implemented for local authorities by June 1994 and for key government departments by June 1995.
- Integrated educational display and program developed for Rocklea Information Centre by June 1994.

Catchment Management Pilot Studies

- Finalise draft land, water and fire management strategies for the Lockyer Creek pilot by June 1994.
- Prepare draft catchment strategies for the Mitchell, Pioneer catchments by June 1994 and for the Mary River pilot by June 1995.
- Arrangements made to implement the Johnstone pilot strategy by June 1994 and strategies for the other 4 pilots by June 1996.
- Review outcomes/approaches in the Johnstone and Lockyer pilots by June 1995.
- Review approaches used in all pilots by June 1996.

Policy and Coordinating Framework

- ICM statutory incorporated into Natural Resource Management legislation by June 1994.
- Guidelines for the formation and incorporation of catchment coordinating committees finalised by June 1994.

Catchment Management Support in Priority Catchments

- Additional five (5) Catchment Coordinating Committees each year.
- Catchment Management strategies developed by four (4) catchment in the Murray-Darling Basin and five (5) other priority catchments by June 1996.
- Training program for Departmental staff, community group leaders and Education Department regions developed by June 1994.
- Catchment management project grants provided for up to projects each year to eligible community based groups and local authorities.

Proposed budget 1993-96

Over the three year period, decreasing emphasis will be given to the pilot study areas as they complete the development of catchment management strategies. Emphasis will be given to the implementation of these strategies. This will be encouraged by the provision of catchment management grants to community based groups and local authorities.

Increasing emphasis will be given to priority catchments outside the pilot areas. This will be supported by the provision of operating and establishment grants and catchment management project grants. A relatively constant emphasis will be given to awareness and education to encourage the participation of key target audiences and the development of community based, action learning activities such as Waterwatch and resources for the Rocklea Research and Information Centre. An outline of the proposed budget is presented in Table 2.2. The anticipated level of contributions from external funding agencies and from local communities is also indicated in Table 2.2. Contributions from these sources are expected to increase over the next three years.

Table 2.2 Proposed budget for the Catchment Management program, 1993 to 1996

	1993/94 ($'000)	1994/95 ($'000)	1995/96 ($'000)	Total ($'000)
Special Treasure Allocation				
Awareness/Education	220	200	180	600
Pilot Studies	510	450	350	1 310
Policy and Coordination	300	270	270	840
Catchment Management Support	763	943	1 100	2819
Sub-Total – Special Treasury	1 793	1 863	1 900	5 569
Other Contributions				
National Landcare Program	500	620	700	1 820
Natural Resource Management Strategy (Murray-Darling Basin)	200	250	300	750
Waterwatch	90	90	90	270
Local Community Matching Contribution	350	450	500	1 300
Sub-Total – Other Contributions	1 140	1 410	1 590	4 140
Total	2 933	3 273	3 490	9 709

5.2 ICM Coordinators and Chairpersons Reviews

5.2.1 CCC Mini-Forum Maleny, 29 February 1995, Notes

Introduction

A meeting of representatives of interested CCCs was held on Sunday morning following the 'People Power in Catchment Care' Conference held at Maleny, 24-25 February, 1995. These notes constitute the minutes from the meeting. You are welcome and encouraged to use this material. The meeting, I believe, was worthwhile and some important learnings and concerns were shared.

Minutes

1. Achievements of CCCs – a brief description

Baroon Pocket Catchment Care Group – Peter Oliver
- 'People Power in Catchment Care' Conference
- Design and preparation of a joint project with Barung Landcare Group on water quality monitoring in Walkers Creek
- Demonstration of pasture management project

Mary River CCC – Steve Kelly
- working groups/sub-committees identified and formed
- Research forum to be held at Maryborough in April
- Cod forum this week. Workshop format to generate ideas for getting Mary River Cod back in the catchment. Recovery Plan being developed.
- Septic Tank Working Group is conducting a survey of councils in the catchment.
- Feedlot working group.
- Education and Awareness Working Group is holding Mary River congress. CCCs has written to councils requesting a $1 a ratepayer levy for Waterwatch Activities (Update: a meeting of Mayors of the council's in the catchment is to be held in late March to discuss this and other issues – meeting was initiated by the Mayor of Hervey Bay).
- MRCCC members reporting back to their industries has prompted several to generate policies on catchment issues.
- Catchment Management Strategies – is these a commitment to implementation?

Dawson Valley Development Association – David Barratt
- Office opened in Taroom as a resource centre.
- Draft strategy on water (including development options) is being prepared.
- Catchment Caravan to schools etc during March.
- Recent rain welcomed and has filled dams.

Lockyer Resource Management Group – John Atherton
- ICM coordinator re-appointed (70% time commitment)
- Pilot ICM Appraisal Study nearly complete.
- Fire Management Strategy nearly finished – need recommendations for various stakeholders (the stakes are probably a bit charred)
- Implications of guidelines of land use in local government plans being looked a through a project – consultant being sought.
- Kerry Hogan appointed to prepare water management strategy, includes Waterwatch program involving 200 bores.

  Operation Lockyer Revival Projects
  - landholder inventory of water related resource, 20 people collecting data; inventory and map to be prepared
  - Catchment Centre established in Hunt Street, Forest Hill. (Gaming Machine Benevolent Fund provided some $). Currently looking for a manager. Assured funding needed for proper administrative support.
- Chairman has done a lot of work (over 10hrs/week, 3 000km) over the 3 months without a coordinator

Condamine CCC – David Carberry
- Piggeries debate is hoting up
- Natural Resource assessment document being prepared.
- Landcare month – WIN TV promotion of catchment management

- Water Forum – March 15 – water requirements
- Wane in interest by some committee members. How can this be reversed?
- State of the Rivers study and RCS Hassall Sustainable technologies project completed. River Improvement Trusts doing a major scoping study. Interest from industry to take sustainable technologies project further.

Maranoa/Balonne CCC – Narelle Campbell
- Series of workshops held
  - kangaroo industry
  - weeds particularly parthenium
  - minerals and oil
- Work progressing on strategies
- 22 strong CCC – how incorporate?
- Phase 2 of the Lower Balonne Floodplain Management Program progressing
- Difficult for community members to remain motivated when there is insufficient operating funds for travel etc.

Herbert River CCC – Rob Hunt
- Mapping Consortium to prepare orthophotos and other projects
- GIS Consortium to use ARC INFO/ARC VIEW for a needs analysis
- Major cane expansion occurring
- Lot of time spent patching up problems caused by poor planning – problem with Department of Lands not consulting with other stakeholders.
- 5% catchment is cane, the rest is grazing
- Sub-group forming in the Upper Catchment

Pioneer River CCC – Grant Paterson
- Strategy in final throws – with referees
- Waterwatch going well
  - 1200 students/40 schools the aim for 1995/96
  - Plain Creek Project includes Sugar Mill, ethanol plant and sewage treatment
- Corporate support difficult to get
- Fine management strategy being prepared by DEH. Part-time person to be appointed.
- Fish re-stocking group (recreational) in six months has 200 members; $30 000 corporate funding; set up hatchery.

Warrego/Paroo – Lisa Herbert
- Lisa Herbert appointed coordinator; 3 weeks on the job
- CCC is 2 years old
- Meetings have stagnated recently; need to be social events
- Catchment tours were useful
- Working on pilot project for piping bore drains
- Local Radio Station has applied to MDBC for funding for publicity.

Border Rivers – Scott Sturgess
- Water Quality Monitoring project underway; tied to project in NSW.
- Common Qld/NSW catchment committee mooted; community support; bureaucratic difficulties.

Murray/Darling Basin RCCC (Qld) Scott Sturgess
- Draft strategy for CCC (Qld) prepared
- Action plans the focus at the sub-catchment level; driven by NRMS.
- Difficulties
- will strategies be taken seriously?
- collect data to avoid decisions
- Tour of Murray/Darling catchment being planned for later in the year.

2. Key Issues arising from reports/discussions
- Sourcing, interpreting and acting on data and information by CCCs and responsible agencies
- Administrative (including expenses) support for CCCs
- Departments and Government Agencies need to have stronger links with each other and CCCs.
- Keeping motivation of CCC members and preventing burnout
- Strategies and other documents – getting good comment and quality control.
- Government (Federal, State and local) commitment to recommendations of CCCs. (Focus particularly on federal and State government).

3. Revisit Rockhampton - Update

- Notes on the Rockhampton meeting have been prepared and circulated. Attention was drawn to the future achievements of CCCs working out at that meeting.
- Membership of the CMCC. Ken Stallman wrote to the Minister expressing concerns from the Rockhampton Forum over CCC representation on CMCC. A working party from the CMCC has been established to look at options and to solicit comments.

Legislation for CCCs. Two issues papers were circulated – ICM and NRM Statutory Bodies. These papers are to be considered by the NRM Policy Council on 28 February.

Considerable debate ensured and the following changes were recommended.

ICM

- Recommendation (3) that CCCs *'to be encouraged'* to prepare CMS; delete '*broad'*
- (4) 'CCCs *oversee* preparation of action plans etc'
- third dash; 'State government agencies and local authorities be required to formally *consider* CMS, etc' Note: Committees want feedback on why or why not their recommendations were/were not accepted.

NRM Statutory Bodies

- (3) 'That NRM Statutory bodies can be formed etc'.

Comments from the meeting were to be relayed by Philip Rowland to the Project Manager, NRM Policy and Legislation

The meeting recommended obtaining professional legal advice on the aspect of liability of members of CCCs

4. Strategies

Notes on catchment management strategies were distributed. Due to lack of time there was little discussion. However, there were a number of participants who spoke in favour of the preparation of strategies (although they may not be every keen about them) and could see some value in them. Concerns about implementation and the effort and resources needed to prepare strategies were raised.

Participants were asked to consider the notes and provide comments to Philip Rowland.

5. Implementation of ICM

A briefing paper prepared for the CMCC outlining a new initiative funding proposal for ICM was distributed.

The meeting was in general agreement with the proposal and the following arrangements were recommended.

- Groups and agencies develop action plans with support from CCCs.
- Funds to be allocated to CCCs for implementing action plans.

The meeting felt the credibility of CCCs would be enhanced by administering the funds. Concern was raised about the ability of CCCs to consider the environmental aspects of the impacts of the projects.

6. State Forum

It was recommended that a State Forum of all CCCs and RCCCs be held in September. Possible locations were Rockhampton or Emerald although no firm recommendations were made.

5.2.2 CCC Forum Rockhampton, 8 - 9 November 1994, Notes

Introduction

ICM and catchment coordinating committees have formally been under way in Queensland for four years. In this time substantial progress has been achieved, some mistakes were made and many lessons have been learned.

Ken Stallman, who has been involved in the ICM initiative in Queensland since 1991, suggested that there would be significant benefits in bringing many of those people actively involved in catchment committees together. The idea was canvassed with existing committees and the enthusiastic response led to a forum of catchment coordinating committees in Rockhampton on 8 and 9 November 1994.

While there is a very wide range of people involved in ICM, it was felt that more could be achieved by focusing on catchment coordinating committees – their achievements, aspirations and tribulations. The chair (or proxy) and the

coordinator of the 14 endorsed catchment committees in Queensland were invited. At least one representative from all committees attended.

These notes comprise the written output of the Forum. As many of the comments in the notes are brief, if you are interested in more detail please contact one of the participants or myself.

Overall, most participants considered the Forum worthwhile. I would welcome any comments from participants or others on the potential for future events of a similar nature.

Philip Rowland
State Coordinator, ICM

EXPECTATIONS OF ICM: What do you realistically expect ICM to achieve in the next 3 to 5 years?

SUMMARY
Horses for courses approach needed depending on catchment
Role in changing community (including government) attitudes
- is what I'm going to do going to adversely affect the catchment?
- what can I do to improve the catchment?

Maintain/enhancing ability to compete on world market (clean green produce)
Need to see that government agencies have picked up the paradigm of ICM and are running with it (Main Roads Dept. etc)
Governments need to talk to each other (inter-departmental)
A true working together between government and community
See catchment management groups in a self-sustaining base (not just the same 1 or 2 people putting in time)
- inherently self-maintaining

Taking long term view – government and politicians
CCCs provide the direction for the program
ICM groups do not have to be incorporate – liability covered by the State

ACHIEVEMENTS OF ICM: What do you realistically expect ICM to achieve in the next 3 to 5 years?

SUMMARY
- Credibility for CCCs through:-
  - performance
  - awareness and education
- Funding/resources for:-
  - implementation
  - group operation
- Awareness and Education of
  - ICM
  - Issues
- Implementing strategies
  - having a process
  - clear targets
  - monitoring – are we going in the right direction?
- Community ownership and involvement
- Government agencies (Local and State) incorporating ICM in their activities/planning
- CCCs have a clear direction and process for achieving their goals

CONSTRAINTS AND OPPORTUNITIES: What are the opportunities that can be built on the constraints to be overcome to assist CCCs meet their expectations?

SUMMARY

Constraints	Groups	Opportunities	Groups
Inter-agency communication	SG	Funding for operation of group - equity - value decisions	CCC SG LG FG
Alignment of policies	SG	Tap into educational initiatives of other players	CCC
Technical support for CCCs	CCC	Network with research/universities	CCC
Departmental boundaries (regions)	SG	Government wants ICM to work	SG
Elitist attitude of researchers/scientists	CCC	ICM can help community understand government policy	CCC
Resistance by Local Government – stifling community activity	LG	Need for ICM/Landcare to have input in government policy	CCC
NRM Discussion Paper	SG	Help agency with consultation	CCC
Blockers on committees	CCC	DPI community consultation guidelines	SG
Hypocrisy of government	SG	More Local Government involvement	LG
Apathy of interest groups	COM	Industry more on side	COM
Coordinators selling government policy	CCC	Network with other organisations	CCC
Varying visions of CCC members	CCC	NRM Education - Landcare - ICM	CCC
Community vs government	COM	Cabinet Support (political will)	SG
Environmental Protection legislation	SG	Group dynamics	CCC
Hidden agendas	SG		
Lack of government flexibility	SG		
Equity of funding amongst CCCs	CCC		
Incorporation	SG		
Lack of women involvements	CCC		
Time available for ICM by community members – recognition of input	CCC		
Who owns the process? (water or land)	SG		
Conflict of interest of government	SG		
Community not accepting technical information	CCC COM		
Invasion of 'turf' eg ICM – local government (Regional government)	LG		
Lack of shared responsibility for legislation	SG		

Key to Groups;
SG – State Government
CCC – Catchment Coordinating Committee
LG – Local Government
FG – Federal Government
COM – community/industry

Summing Up
In his introduction yesterday, Ken Stallman indicated that the objectives of the workshop were to share experiences and provide positive ideas that would set the future direction for:

- Catchment Coordinating Committees
- The CMCC and the State ICM Program
- The proposed NRM legislation

During the workshop, we have certainly shared many ideas which will help to set the direction for ICM in this state.

Achievements
In the first session on achievements by individual CCCs, the presentations indicated considerable variation in progress within individual catchments – some are still grappling with identifying issues and preparing strategies, while others have their strategies and are more concerned with implementation

A number of speakers made similar points:

- ICM in *community* driven
- CCCs must be credible
- CCCs have increased community awareness of catchment management issues and the catchments in which people live.
- CCCs are using different approaches (some adopt a single issue or piecemeal approach, other a comprehensive/multiple issue approach).

However, it was Bruce McCarthy's analogy which caught my imagination, when he likened ICM to the tributaries of a stream, with everyone eventually coming together. Bruce also mentioned the 80/20 rule, and stressed the importance of putting our limited time into the issues where 20% of out effort achieves 80% of our results.

Realistic Expectations
The two sessions dealing with realistic expectations of ICM and CCCs produced similar conclusions:
- Strong community awareness, involvement and ownership of ICM.
- CCCs with a clear direction and process for achieving their goals.
- Real progress with the implementation of catchment strategies (including funding for groups for implementation).
- Local and State Governments cooperating and implementing catchment strategies.
- Credibility for ICM and CCCs.

Action Plans
Key actions for achieving the realistic expectations were identified for the following sectors
State Government
- Clarify the process which exists for achieving coordination between government departments
- Recognise and consult CCCs about regional planning activities
- Align departmental regions on catchment/NRM boundaries
- Provide statutory mechanisms for overcoming difficulties with incorporation
- Provide equitable and adequate funding for CCC members

Local Government
- Encourage local governments to integrate ICM principles into their codes of practice and to refer environmental impact assessments and planning schemes to CCCs.
- Develop closer linkages between CCCs and River Improvement Trusts
- Issues a policy statement to resolve local government's concerns about regionalisation associated with CCCs

Community and Industry
- Involve industry organisations in CCCs and catchment management
- Establish clear linkages between government and community
- Develop mechanisms to enable community members to continue to participate in ICM and CCCs
- Involve more women in CCCs and catchment management
- Carry out more educational activities such as 'catchment crawls'

Composition of the CMCC
Consideration of the role and composition of the CMCC led to the following conclusions:
- That the composition of the CMCC is no longer appropriate, and greater representation from CCCs is needed
- That the use of the proposed catchment regions is a basis for CCC representation on the CMCC be referred to the CCCs for consideration

NRM Legislation
While time did not permit consideration of ICM requirements in the proposed legislation, it was agreed that the establishment of CCCs under the NRM legislation should be investigated to overcome the need for individual Committees to become incorporated.

Conclusions
The workshop has been a major milestone for ICM in Queensland.

In less than four years, 14 communities have established CCCs and many of these communities now have clear strategies, energy and are achieving results. They are now in a good position to influence and help set Government policy and the direction of the whole ICM program.

This workshop has demonstrated the ability and desire of CCCs to provide positive ideas and directions for ICM. Because of the positive approach and achievements, I am confident that this gathering of CCC representatives will evolve into an ongoing forum which will be a powerful force in ICM in Queensland.

5.2.3 Forging the Links
Inaugural Landcare and Integrated Catchment Management Annual Conference – Cairns, 29 June – 1 July 1998

1998 Conference Resolutions

Maroochy Landcare Group Inc

No.1
(a) *Governments establish a value for native vegetation. If it worth preserving it must have a value.* **Carried**
Speaker: Esma Armstrong, Secretary, Maroochy Landcare Group Inc
Seconder: Rick Templeton, Treasurer, Maroochy Landcare Group Inc

No.2
(b) *Landcare groups be exempt from certain bank chargers eg. account keeping fees.* **Carried**
Speaker: Rick Templeton, Treasurer, Maroochy Landcare Group Inc
Seconder: Esma Armstrong, Secretary, Maroochy Landcare Group Inc

Marlborough District Landcare Group Inc

No.3
That the government bodies responsible for funding the National Weeds Strategy and programs such as SWEEP be approached by Queensland Landcare and Catchment Management Council, to direct more funds to these and other strategic weed initiatives. **Carried**

Background
Weeds are among the most serious threats to Australia's primary production and natural environment. They reduce farm and forest productivity, displace native species and contribute significantly to land degradation. The cost of weeds to agricultural industries alone has been estimated at over $3.3 billion per annum (Combellack 1987), an estimate which does not take into account the reduction of conservation, aesthetic and recreation value, loss of biodiversity, or the impact on human health caused by weeds. Weed problems affect everyone through their adverse impact on economic, social and conservation values, which should be recognised when governments apply the 'beneficiary pays' principle.

The National Weeds Strategy provides the mechanism to reduce the impact of weeds on the sustainability of Australia's productive capacity and natural ecosystems, and will benefit the whole community.

Of the $1.25 billion Natural Heritage Trust, only $24 million has been directed at the National Weeds Strategy over 5 years.

Speaker: Sandy Paton, Boguntungan
Seconder: Lyn Kelman, Lake Maraboon Committee Inc.

No.4
That the bodies responsible for guidelines governing NHT funding be approached by LCMC, to make funding available for strategic, regionally planned weed control projects, especially in areas of Queensland where weeds have been identified as a regional priority.
Carried.

Background
As above, the costs of weeds on productivity and biodiversity is enormous, and the benefits of reducing their impact will benefit the whole community. Regional, strategic planning provides the most effective method of controlling weeds.

During the process of community consultation and discussion in preparing the CQ Strategy for Sustainability, weeds were identified as a high priority issues across the region. The Strategy will be used by RAP to guide NHT funding in the area, however projects addressing this high priority issue may be ineligible for funding:

- "Responsibility for weed and feral or pest animal control rests primarily with State and local governments and with landholders. Accordingly we provide only limited support for these activities" (98-99 NHT Guidelines, Q28, p.13)
- Ineligible activities "activities that are required by law, such as managing or destroying designated weeds or pests" (97-98 NHT Guidelines, p.12)

In the 1997-98 round of funding 10 Central Queensland projects which had weed control components were recommended by Regional Assessment Panel (on the basis of them being strategic and addressing broader issues), yet were denied funding by the Commonwealth.

This resolution is also in compliance with the Decade of Landcare Plan Priority Actions 1997-2000 document, where on of the high priority actions is:

*** Seek to have federal funding broadened to include on-property works with community benefit (eg. **strategic weed initiatives**, water management banks and drains). Chapter 10, action 3

Speaker: Sandy Paton, Boguntungan
Seconder: Viv Chase, Burnett Catchment Care Group

Both these resolutions are supported by the Morinish Landcare Group

Atherton Shire Landcare Committee

No.5
That the Natural Heritage trust system of grant applications be simplified and shortened to make it more user-friendly for community groups. **Carried**

Background
Simplification of NHT Applications

Members of community groups are volunteers and do not necessarily have accounting and computer skills. They are discouraged from making applications for NHT grants by the amount of detail required, particularly for grants over $10 000. The filling of application forms takes a long time. The need for accountability is understood, but this should not make the whole process too complex.

It is suggested that the application form from 1998-1999 should be simplified while retaining the same explanatory booklet form put together in Canberra as it was in 1997-1998.

An alternative would be that the DNR should supply enough extension officers to help all community groups complete the forms.

No.6
That during the Natural Heritage Trust grant award process, grass-roots community groups are accorded a priority with sufficient fund allocation to ensure they are enabled to work effectively. **Carried.**

Background
Sufficient funds for Community Groups

In the press release concerning the allocation of NHT grants in the Kennedy electorate, considerable emphasis was placed on the benefit the grants would bring to the community and presumably to community groups.

On our analysis of the figures, community groups such as Atherton Shire Landcare Association and T.R.E.A.T. received only 24% of the money while departments and councils received 74%. Applications which were fully expected to succeed were not approved.

In order to be fair and to encourage community groups to continue to work effectively for the environment, more money should be allocated in future by Canberra to community groups which make good applications.

Community groups are the back-bone of the workforce for improvement of out environment. "Start-up projects" are needed to encourage groups to get going. The balance between funding for smaller groups, and departments and councils needs to be restored so that groups get a better proportion.

Speaker: Mark Knowles, Atherton Shire Landcare Association
Seconder: Joan Wright, Atherton Shire Landcare Association

Lower Burdekin Landcare Association

No. 7
That the Landcare and Catchment Management Council seeks assurance from DNR that:

1. *Management plans for habitat areas set aside within the BRIA will be developed and implemented as a matter of priority*
2. *Future land and water for irrigation projects development accords with the principles of sustainable development, in particular that:*
   - *Habitat retention and wildlife corridor planning precedes development activities*

- *Areas of appropriate size are retained; and*
- *That mechanisms are put in place to ensure that these areas are effectively managed.* **Amended and Carried .**

Background
During the development of the Burdekin River Irrigation Area (BRIA), planning for wildlife corridors and habitat retention was not initiated by the State Government Agencies concerned until significant amounts of clearing and other development activities had already occurred. This has resulted in well recognised limitations in the area of diversity of retained habitat areas particularly in the farm areas developed earlier where no wildlife corridors were retained. Further, all service corridors and road verges were left devoid of native vegetation in these areas.

It is acknowledged that during the BRIA development in more recent years, the wildlife corridors and conservation areas that have been set aside present one of the best examples of planned habitat retention within a cane growing district in Australia. However, no effective management plans have been developed or implemented for these areas and as a result they have deteriorated in environmental quality, have become pest and weed refuges, and present wildlife risks to adjoining cane lands.

If the Department of Natural Resources expects private landholders to follow their example in the retention of habitat areas and wildlife corridors it must provide leadership in the demonstration of best practice management for these areas.

Speaker: Terri Buomo, Secretary, Lower Burdekin Landcare Association
Seconder: Alan Barton, Chair, Townsville Thuringowa Landcare Association

Theodore Landcare Group Inc

No.8A
That the Queensland Landcare and Catchment Management Council convey to Government the need for collection and removal of unwanted farm chemicals and pursue a resolution of the matter. **Carried.**

Background
Old and dangerous chemicals are currently being stored on many farms with the onus of safe storage being on the farmer. Many farmers do not wish to have the responsibility (often inherited) of these chemicals and wish to dispose of them, however, there is currently no means by which they can legally do so.

Speaker: Claire Breckenridge, Coordinator, Theodore Landcare Group Inc
Seconder: Mick Alexander, Taroom Shire Landcare Group Inc.

Maranoa Regional Landcare Association

No 8B
That the LCMC strongly urge the Federal, State and Local Government to take immediate action to develop a workable strategy to dispose of the banned and illegal agricultural and veterinary chemicals such as organochlorines and arsenic etc held on rural properties and that such a strategy be implemented accordingly. **Carried**.

Background
A resolution requesting action on this matter was carried at the State Landcare Conference last year. However very little action seems to have resulted at the government level. The issue is still a very important one, because for the most part the problem chemicals are still out there.

Each year that passes means that containers are rusting away, allowing the deadly chemicals to seep out into the surrounding environment. The cost of collecting and disposing of the chemicals will be considerable; therefore many landholders might feel that the cost burden is too high. Because of the cost to the environment that would result from doing nothing, the disposal cost should be borne by the Federal and State Governments in the interests of environmental protection

Speaker: Bill Petrie, Maranoa Landcare Association
Seconder: Malcolm Topp, Maranoa-Balonne Catchment Coordinating Committee

Note: This matter was pursued at some length with added weight as the result of the resolution carried at the Roma Conference in 1997. See Annual Report. There is a plan but no funding from the Federal Government for collection of Organochloride Pesticides (OCP) nor from the States for other unwanted agricultural chemicals. Carriage of this resolution would add weight to follow-up letters from LCMC. John Tadman

Calliope Soil Conservation Association Inc

Funding for exotic grasses for rehabilitation

No. 9
That the Landcare and Catchment Management Council ask the Natural Heritage Trust for consideration to be given in future to on-ground projects that include finding for introduced species to combat existing soil degradation – especially those that have proved to be cost effective and beneficial to the environment. **Lost.**

Background
That the objective of Landcare is to reach outcomes that are sustainable both economically and for the protection of the environment.

Introduced species can at times be the most suitable species for obtaining these goals with minimum risk of them becoming weeds in the ecosystems.

There is a general feeling that anything introduced is not good for the environment.

The reluctance on the part of Landcare funding bodies to consider these applications seems very short sighted.

It is recognised that any grass will have been thoroughly tested for its ability to become a serious pest in the catchment in which it is proposed to be used.

Speaker: Robyn Leahy, Coordinator, Calliope Soil Conservation Association Inc
Seconder; Mark Forrest, Calliope Soil Conservation Association Inc.

Mary River Catchment Coordinating Committee

No. 10A
That the LCMC and the Department of Natural Resources acknowledge the role of Landcare Facilitators and ICM Coordinators. Further that integration of the previous bodies under the LCMC should not be used as an opportunity to spread scant DNR support resources more broadly across the existing community group network. This position should not alter the current role of ICM Coordinators to liase with Landcare groups with the aim to optimising opportunities for implementation of catchment strategies.
Amended and Carried.

Background
The Mary River Catchment Coordinating Committee has been made aware of suggestions for the multi-skilling of Catchment Coordinators and Landcare Facilitators. Based on its own experience it considers that it is important that catchment management and Landcare activities within a district are integrated. However its of the opinion that facilitation of Landcare groups to achieve on-ground outcomes, should be seen as a function distinct from coordination of the strategic initiatives of Catchment Coordinating committees. It is concerned that broadening the roles of Catchment Coordinators could result in a loss of momentum in the implementation of Catchment Strategies.

Speaker: Margaret Thompson, Mary River Catchment Coordinating Committee
Seconder: Esma Armstrong, Mary River Catchment Coordinating Committee

Johnstone River Catchment Management Association Inc

No. 10B
The LCMC take note that it be an absolute priority that ICM and Landcare committees be resourced with facilitator/project manager support with the necessary planning skills and focus to drive forward execution and implementation of their individual strategy plans.
Carried.

Background
Explanations:
- "facilitator" means ….. facilitator, coordinator, project manager, manager, mentor, extension officer, administrator.
- "necessary planning skills" means … Suitably qualified people equipped to be able to coordinated the activities of the community group and its stakeholder constituents in natural resource management … People with communication skills enabling them to network stakeholders within the group, and also assist the group in its communication with agency and administrative structures …. People with the ability to coach or train new members of community groups in the concepts and principles of natural resource management.

- "focus" means … people whose principle function is to understand and drive the implementation of the strategy. It may be that a group is involved in activities of sufficient scope to merit their own 'tame' facilitator on a part time or full time basis. It may be a facilitator is shared by geographically neighbouring groups, provided that this person's principal focus is the management strategies and is not distracted by a multiplicity of other duties.

Justification:

- Each management strategy represents a considerable public investment

Such investment is comprised of:
(a) taxpayer funds
(b) government agency time and expertise
(c) ratepayer funds and local government support
(d) industry time and commitment
(e) community time and commitment
(f) R&D Corps funds and commitment
This is our contention that without facilitators as described above this investment will be squandered or at best not realise the dividend it promises.

- We support this contention with the following reasons.

(a) Apart from exceptional circumstances if community groups are left to their own devices the quality of expertise contained therein will diminish with the passage of time. This is a simple consequence of the rollover of membership, and there being no mentor to coach new members.
(b) a suitably qualified and resourced facilitator will provide continuity of understanding and focus on the intent of the strategy.
(c) a strategy is a mobile document. The facilitator described bring expertise which helps to ensure that the strategy will neither stagnate nor develop in a manner which loses the plot
(d) with all the goodwill in the world it is unrealistic to expect community members to be able to supply all of the time and resources necessary to efficiently drive the implementation of a natural resource management strategy unaided.
(e) the notion that there are latent coordinators lurking around all the corridors of your local DNR office awaiting your phone call is a fantasy

Execution

We are neither empowered nor financially resource as community groups to appoint facilitators as our sole responsibility. We are most certainly responsible as partners in natural resource management to strive to ensure that the outcome we are seeking will deliver the dividend implied by the public investment made.
We respectfully suggest that the expenditure of a funding pool such as NHT without allocation of a portion of that fund for administration and management is very poor business indeed. We cannot conceive of any works program which does not budget a part of its cost for management and administration.

If, say, 10% to 15% of funds were budgeted as suggested then it follows that 85% to 90% will end up as works on the ground. Factor in the matching community contribution as required and 170% and 180% is a fair result, achievable in a respectable time frame. Remove the administrative component and we wager the result will be a 100% expenditure of funds but the quality of community contribution will be valued at a pittance by comparison.

Speaker: Sam Pagano, Chair, Johnstone River Catchment Management Association
Seconder: Ray Burns, Malanda Landcare Group

Mary River Catchment Coordinating Committee

No. 11

That the Department of Natural Resource endeavour to maintain base funding for the long term employment of ICM Coordinators to ensure security of tenure and continuity of support for Catchment Coordinating Committees as opposed to creating a system which is dependent on the vagaries of the Natural Heritage Trust grant system. **Carried**

Background

The merger of the Landcare and Catchment Councils at a state level has the opportunity to ensure that activities under the two programs are better integrated. Members of the Mary River Catchment Coordinating Committee who are also active landcarers consider that the benefits of the merger may not be related if the desired relationships between groups formed under the two organisations is not clearly enunciated. Development of succinct guidelines and an administrative structure based on desired communication channels between, and outputs from, Catchment Coordinating Committees, Landcare groups, and the LCMC will help to reduce duplication and enhance cooperation between groups - if based on the results of consultation with grass roots players

Speaker: Esma Armstrong, Mary River Catchment Coordinating Committee
Seconder: Margaret Thompson, Mary River Catchment Coordinating Committee

Waggamba Landcare Group

No. 13
Move that NSW irrigators cease irrigating from the GAB until it has been satisfactorily ascertained that the amount of water being taken out of the GAB, and intake area, is surplus to the requirements for the replenishment of the GAB and further that a full EIS be completed. **Carried.**

The Waggamba Landcare Groups wants LCMC to address this issue with the minister concerned and with the GAB Council.

Background
In 1995 the Waggamba Landcare Group (WLG) became aware that water from the Great Artesian Basin was being used in the North Star - Croppa Creek area of NSW for irrigation. This area is just to the south of Goondiwindi. The continued use of this water for irrigation is causing water pressure to drop in stock bores in the Waggamba Shire (particularly in the east of the shire where there have been reports of the water level dropping by 11 metres in the last 2 years). This water is a vital resource in this area as many farms rely completely on bore water, having no creeks running through them and an inadequate fall for dams.

The background information on this situation has been provided by DNR and NSW groundwater technical officers.

Groundwater licenses for the purpose of GAB irrigation first began being issued in early 1993. Approximately 60 licenses endorsed for GAB irrigation have been issued in total. Of these, 35 are currently active with others being in the process of installation. Allocations total 30 000 megalitres (ML). One licence per land title may be issued up to a maximum of 486ML. Bores are accessing the Mooga Sandstone (200-250m) and Piliga Sandstone (350-400m).

These facts were brought before the Queensland Landcare Council in December 1995. However, no progress was made on the issued as an officer from the Water and Catchment Management division of the then DPI stated and I quote:

> "The use of groundwater for irrigation in the North Star area of NSW should not have any effect on the Great Artesian Basin, as it comes from the intake area, not from the GAB itself. In the intake area there is a surplus above that which can move into the artesian parts of the GAB"

There is a fundamental error with this train of though, which was pointed out to no avail to the officer when he spoke to the WLG. No one yet knows whether this water being taken out is surplus to the requirements of the GAB. No studies have been done on this issue. Further, as later studies have shown some of the bores are not in the intake zone.

There was no environmental impact statement completed on the effects of these bores prior to issuing of these licenses. There was not even an obligation to advertise the proposed bores.

The Local Government Association, on the request of the Waggamba Shire, has raised these concerns with the Minister for Primary Industries in 1996 and were also met with the same response, ie. that the water is surplus to the requirements of the GAB.

We would like to point out the study on whether this water is 'surplus' to GAB requirements has still not been completed (May 1998). The NSW water authority agrees it is extremely difficult to quantify how much of the GAB flows in from this area. The fact that water pressure has been dropping at a constant rate for several years in the Waggamba Shire (due to the number of bores drilled, flowing bores etc), yet has dropped rapidly only in the last few years, would indicate that this irrigation is affecting our bores. The irrigation bores are drilled into the same Mooga Sandstone layers from which the Stock and Domestic bores on the Queensland side of the border attain their water. In the Yetman, North Star, Croppa Creek Area of NSW stock and domestic bores have ceased to flow and graziers are forced to drill new bores or deepen old ones at their own expense.

Speaker: Viv Cranney, Waggamba Landcare Group
Seconder: Mary Woods, Waggamba Landcare Group

Johnstone River Catchment Management Association Inc

No. 14
That the rules for election of one community representative (and one reserve) per DNR Region to membership of LCMC be altered to require preferential voting rather than 'first past the post' voting in all Regions for which there are more than two candidates for election. **Carried.**

Background
The history of the voting process is briefly as follows:
- The first combined postal/conference ballot for three positions for the whole of Queensland on the Queensland Landcare Council was conducted in accordance with a QLC resolution, and finalised at the Annual Conference at Gatton in 1994.
- The rules were arrived at after discussions between the Executive Officer of QLC and the Queensland Electoral Commission, and were adopted by the QLC.
- The decision to use 'first past the post' voting for the QLC ballot was based on advice that for the numbers involved, preferential voting would seldom alter the result, but would entail a longer and more involved (ie. electing three from up to ten candidates for 100-200 potential electors) counting procedure.
- When the need to elect one representative from each of five regions arose, the Landcare and Catchment Management Council (LCMC) agreed to use the old QLC rules, modified as necessary to suit the new requirements.
- The relative virtues of the various voting systems were not discussed, so the 'first past the post' system was retained and used in 1998.

In view of the relatively large number of candidates and the small number of voters in the changed scenario (eg. the 6 candidates and about 20 voters quoted for North Region), the preferential system would appear to be the better choice.

Any system is susceptible to 'politicking and lobbying', but a straight preferential system can guard against vote-splitting tactics. By this method, the successful candidate is usually the first or second choice of more than 50% of the voters.

Speaker: Sam Pagano, Chair, Johnstone River Catchment Management Association
Seconder: Dave McCarty, Johnstone Shire Council

North East Downs Landcare Groups Inc

No. 15
That Queensland Landcare and Catchment Management Council consider changing Landcare month from March to June. **Lost.**

Background and Reasoning

March is a bad month for Landcare month, for the following reasons -
- Many groups go into recess over the Christmas and school holidays and do not meet until February, leaving no time to organise activities for March
- The correspondence for Landcare Month does not get out to Landcare groups in time, again due to the holiday break
- Further to the above point, many Landcare groups only meet bi-monthly, which by the time the correspondence does reach many groups, Landcare Groups has come and gone

At the 1997 Landcare Conference, a resolution put by North East Downs Landcare, regarding the short notice given for activities such as Landcare Month, and urging QLCMC to endeavour to promote these activities earlier, was carried unanimously. Unfortunately, nothing has changed with promotional material being presented to some groups during March, and later.

Reasons for changing Landcare Month to June -
- All the above reasons against March
- June would be an ideal month, being in the middle of the year, and giving groups several months to prepare activities
- The month of June would be promoted as Landcare Month, to culminate in the Landcare and Catchment Management Conference. This would have the double effect of promoting Landcare Month and State Conference together.

North East Downs Landcare urges delegates to support this resolution

Speaker: Peter Crawford, Project Officer, North East Downs Landcare Groups Inc
Seconder: Sandy Paton, Boguntungan

West Moreton Landcare Group Inc

No. `16A
That every reasonable effort be made by LCMC to secure sales tax exemption for all (non-profit, community) Landcare, catchment management and Waterwatch groups. **Carried**

Background
- most groups receive a large part of their funding from government and give a proportion of is straight back in the form of sales tax
- sales tax exemption would reduce the amount of money for which groups apply, resulting in funds being more widely available (this situation would not be detrimental to NHT funded projects and beneficial to non-NHT funded projects)
- this reduced funding would encourage more groups to seek support from other sources
- tax deductions and sales tax exemptions are available for profit industries and businesses who support Landcare, yet non-profit groups are still required to pay sales tax

Support
- This idea was floated at a recent south east regional meeting and gained verbal support from almost every attendant
- In his 1997 annual report, National Landcare Facilitator Lachlan Polkinghorne stated in Recommendations, 4.1.2 Far, Business Viability, that 'Landcare groups are exempt from sales tax'

Speaker: Patti Semmens, Coordinator, West Moreton Landcare Group Inc
Seconder: Percy Manz, Atkinson Buaraba Landcare Group

Maranoa Regional Landcare Association

No. 16B
That the LCMC lobby the Federal Government to change policy to allow Landcare Groups to enjoy Sales Tax Exemption on all classes of items which, when purchased by a primary producer for Landcare purposes, would be sales tax exempt eg. fencing materials.
Withdrawn

Background Explanation
The items would be Sales Tax exempt when purchased by a primary producer for similar purposes, so why should Landcare Groups have to pay Sales Tax upon them?

Speaker: Bill Petrie, Maranoa Regional Landcare Association

No. 17
That the LCMC urge the State and Federal Governments to ensure that education of Landcare and catchment management issues be given a higher priority in funding allocations, without reducing other important funding allocations. **Carried**

Background Explanation
It appears that the positions of some Landcare Education officers have recently been axed. This would seem to be a deplorable situation in a society which desperately needs to increase public awareness of Landcare issues in the younger community because of the importance of maintaining the sustainability of natural resources for future generations.

Speaker: Bill Petrie, Maranoa Regional Landcare Association
Seconder: Mary Woods, Waggamba Landcare Group

5.3 Enhancing the Effectiveness of Catchment Management Planning

Activity Review - Queensland

AACM International Pty Limited

(Source: AACM with the Centre for Water Policy Research. 1995. *Enhancing the Effectiveness of Catchment Management Planning. Annex B: Activity Review.* AACM House, Adelaide, pp. 26-38)

Institutional Setting

In 1990, the Queensland government initiated an integrated catchment management program (ICM) in response to community interest in a river catchment approach to dealing with resource degradation issues. Five pilot study areas were identified - the Johnstone, Lockyer, Mary, Mitchell, and Pioneer catchments. The Johnstone and Mary are reviewed here.

Unlike New South Wales, ICM in Queensland evolved after the National Landcare Program, and so ICM committees were able to work with and complement existing community groups interested in natural resource management issues. There is some confusion about the place of ICM and Landcare within the state institutional hierarchy. Some Landcare groups see ICM as a threat which aims to control them - acting as an umbrella coordinating group. Other Landcare groups see ICM as a complementary activity. This is a strategically important issue which must be resolved quickly to avoid it becoming a barrier to implementation of integrated catchment management activities in Queensland.

Local authorities have widely supported Landcare groups in many areas of Queensland. DPI and other departments work with Town Planners and City Engineers in a collaborative but informal relationship. There are 12 shires in the Mary River Catchment, and a single regional association of local authorities. There are 2 shires in the Johnstone River Catchment.

Catchment resources are managed under a number of legislative instruments which,. Along with the policy setting, are reviewed in Annex A - Policy Review.

Mary River Catchment

Project Background
The Mary River Catchment is located in South East Queensland and runs parallel to the coast for more than 180 kilometres from the Conondale Ranges in the south to Hervey Bay in the north. The catchment comprises about 9 600 km^2 with a mean annual discharge of about 2 300 000 ML, and includes all or part of 12 local authority areas. There are 8 Landcare groups active in the catchment, three natural resource planning groups, the Mary River Catchment Planning Committee, the Mary River Catchment Coordinating Committee (CCC) and 20 or 30 other environmental special interest groups. The population of the area is approximately 80 000 and rising rapidly - with significant growth areas around Gympie, Maryborough and Hervey Bay

Project Assessment
An ICM coordinator has been appointed by DPI for the Mary River since early 1993. DPI provided $85 000 to the CCC in 1994 but that includes the coordinator and secretarial services provided to the committee.

The Mary River Catchment Coordinating Committee was established in November 1993 and is in the early stages of identifying its own philosophy and products. At the moment any CCC members have strong parochial interest which are a barrier to integrated resource management in the catchment. There are also some tensions between the Planning Committee and the CCC - although their interests largely the same and both groups represent partnerships between private sector and government interest, the Planning Committee is independent of formal government institutional structures.

The CCC considers its overriding focus to be to :-

- concentrate on causes not symptoms;
- take a whole catchment focus;
- emphasise a longer-term vision;
- take a balanced view from all aspects; and
- work towards an economically sustainable future for primary producers in the catchment

Since its formation, the CCC has established working groups for:-

- coordinating water watch monitoring of water quality in the Mary catchment;

- conservation of the Mary Cod;
- management of septic tank effluent; and
- survey of stream bank erosion

The CCC is working with DPI to prepare a State of the River report for the Mary River. The CCC has taken an active role in the contentious regional debate about water supplies for rapidly expanding residential populations in Hervey Bay, Maryborough and Gympie as well as along the Sunshine Coast. Several Landcare groups have been supported with funds and advice from the CCC. The CCC is also helping industry groups to develop Best Management Practices (BMP).

The CCC currently sees its role as a source of advice and consultation on current issues affecting the catchment - rural land subdivision policies, water supply, water quality, riparian zone management and biodiversity conservation in the catchment. Catchment planning, or development of a process for catchment planning, is not an early priority for the CCC.

The CCC does not have a developed strategy for working with Landcare groups. There are strong concerns in some Landcare groups about the ICM approach to natural resource management - that it is another layer of bureaucracy and another division of funds to administration rather than field works. Those Landcare groups which recognise the multi-disciplinary and political nature of natural resource management and integrated catchment management will successfully work within the ICM policy framework.

Strengths

- State guidelines for integrated catchment management *philosophy* based on integrated environmental management *product*
- Strong community leadership and vision across a range of sectors, pre-dating ICM and Landcare programs
- Land Use Plan and Future Forest documents provide initial targets for ICM activities in collaboration with Landcare and other community groups.
- Technical packages for solutions exist for many resource management problems
- Employment of journalist to promote and publicise CCC activities and the ICM *philosophy*.
- Diary Industry Group has self-regulation process to monitor and manage dairy effluent in catchment - the starting point for community monitoring strategies.
- Water quality and land use planning elements are understood and broad linkages between poor water quality symptoms and land degradation causes are clear.
- Waterwatch coordinator for whole catchment - leading to community generation of valuable water quality datasets.
- Project logically evolved from earlier activities (often supported by NSCP, Save-the-Bush, and NLP) which set information and community awareness foundation for successful implementation of catchment management project.
- Use of modified Rapid Resource Appraisal techniques by CCC to develop spatial extent of key degrading processes in whole catchment
- Several local authorities have existing environmental levees ($10 per property) which contribute funds to Landcare and ICM activities in the catchment.

Weaknesses

- Catchment is not recognised as basic management unit by any participating groups in CCC or government institutions.
- Lack of *process* for identification of priorities, integration of community and agency skills to design and implement activities, and monitoring and evaluation of program activities - especially within DPI and CCC.
- Very little whole catchment planning being considered or implemented - despite several local authorities preparing 'Town' Plans and Mary River Catchment Planning Committee preparing a Catchment Land Use Plan.
- Lack of established Landcare relationship or non-threatening process for integrating activities with Landcare groups.
- Strong pro-development lobby with influence on local authorities and little regard for long-term costs and resource requirements for rapidly increasing populations.
- Weak bio-physical data sets on which to base ICM planning activities - and little recognition of ability of community to generate much of these data for their benefit as well as ICM planning.
- Communication within and between government agencies remain a barrier - including state government and local government agencies
- Weak integration of skills and activities to solve catchment management problems - especially between DPI and Local Government.
- Poor identification of linkages between community priorities and catchment management priorities, and poor integration of technical resources from DPI and DEH to develop innovative solutions to community and catchment management problems

- No use of resource economic analysis to identify priorities and allocate costs and benefits between public and private sectors
- Weak and unimaginative use of cost benefit analysis is assess most efficient investment scenarios for supplying water to Hervey Bay, Maryborough and Noosa.
- Poor integration of native vegetation rehabilitation and management into riparian zone and upper catchment management strategies.

Opportunities

- Use ICM process and CCC institution to develop *philosophy* and *process* for planning and implementation of integrated catchment management activities in the Mary River catchment.
- Promote sustainable water supply as primary *product* from ICM as local authorities and developers recognise constraints imposed by limited water supplies.
- Use of resource economics and cost benefit analysis to identify potential benefits of increased quality and quantity of water harvested from Mary River Catchment - to quantify the investment which local authorities with growing residential populations would be justified in making as a contribution to the cost of implementing catchment management plans.
    - Negotiate a deal with landholders for fencing riparian zone and land slips, and with developers for a more sustainable approaches to subdivision, with cost share agreement for infrastructure capital costs, in return for minimum adoption rate in each sub-catchment necessary to have tangible impact on quality of water harvested from Mary River.
    - Build on DPI experience with Strategic Balance Sheet approach to incorporate resource economics into ICM and CCC activities.
    - Use Best Management Practices to develop linkages between landholder priorities, local authority practices and catchment management priorities.
    - Establish cost sharing arrangements related to co-management partnership with catchment community. In addition to encouraging ownership, this provides an opportunity for a stronger relationship between the CCC and Landcare groups in the catchment
    - Recognition that GIS is a useful tool for planning such a large catchment and that, if managed as a tool for community use, can be related to practical decision making.

Threats

- Parochialism and strong development and frontier approach of industry groups in CCC.
- Community perception of CCC as another layer of bureaucracy - require quick and successful run of activities to establish CCC presence in the political structure of the catchment.
- New land uses (for example alternative lifestyles, micro-industry) and socio-economic structures (for example semi-intensive rural residential developments) will have different impacts on catchment resources - many of which are not within the skills or mandates of DPI or local authorities
- Unclear linkages between ICM and Landcare groups could undermine activities in catchment.
- Many strong egos amongst community leaders - potentially leading to conflict if focus or momentum is not maintained.
- Short-term political issues diverting the attention of community leaders - especially in local authorities - from longer-term planning and vision to develop and implement ICM *process and philosophy*.

Johnstone River Catchment

Project Background

The Johnstone River catchment is a rich and diverse region supporting dairy and beef cattle grazing, intensive horticulture, sugar cane production, marine fisheries, wilderness and tourism enterprises.

The catchment covers more than 1 600km^2 on the wet tropical coast of Far North Queensland. The catchment has been divided into four broad physiographic regions - Tableland Area (30%), World Heritage Area (45%), Undulating Lowlands (20%) and Floodplain and Estuarine Zone (5%).

The catchment drains one of the wettest regions in Australia, with average annual rainfalls ranging from around 1 800 mm to in excess of 4 000mm. The Johnstone River Catchment contributes on average, almost 3 million megalitres of runoff each year, although annual variation is significant.

The natural and social resources of the catchment have been documented in a Johnstone River Catchment Atlas which was produced by the ICM program in conjunction with other government and community agencies. A Johnstone Shire River Improvement Trust has existed for many years under the *River Improvement Trust Act* (Qld., 1940). However, this institution has lacked leadership and a vision and is essentially superseded by the CCC.

The Johnstone River Catchment Pilot Study was the first attempt to implement the ICM concept in Queensland. The Pilot Study commenced in early 1991 with the establishment of a community based Catchment Coordinating

Committee (CCC) to direct and oversee the Study. Membership of the CCC is representative of a wide cross-section of the catchment community, covering agricultural, industrial, tourism and community interest. The CCC is supported directly by a Catchment Coordinator from DPI and indirectly by other technical services staff from DPI, DEH and DOL.

The Pilot Study operates from a Catchment Centre, separate from Government offices, located in a shop front office in the centre of Innisfail. This arrangement helped establish an independent and community oriented presence of ICM in the catchment. It also contribute to the effective functioning of the Coordinator and the CCC, particularly in relation to liaising with industry and community organisations, local authorities and Government agencies.

The major roles of the CCC in the Pilot Study identified by CCC members, were to:

- address complex natural resource management issues that involve the community and government;
- provide a forum for stakeholder input and discussion;
- prioritise issues; and
- develop and promote the adoption of catchment management strategies to address priority issues.

The CCC determine that it would carry out this role in the following manner:

- act as a coordinating agency to bring together people and organisations in the catchment who have responsibility for land and water use;
- consult, examine issues, identify solutions and agree on actions;
- encourage by publicity, demonstration and example, sound management practices to achieve long-term sustainable use of catchment resources;
- review the programs and activities of Government agencies and local authorities and offer advice on priorities as seen from a community point of view;
- provide the Minister for Primary Industries with an independent and broad industry and community view on the management of the catchment; and
- act as an independent arbitrator in assisting with the resolution of disputes involving the use of land, water and other natural resources in the catchment.

The CCC is also discussing succession strategies for changing membership of the committee. The current approach is re-election of one third of the CCC each year with a three year term and a maximum of two consecutive terms for each member.

The CCC is also assessing strategies for self financing, with the option for raising levees or fees to contribute the private share of committee costs. Several community groups have backed the ICM program with industry funds, provision of office space and other activities as part of their contribution to the operation costs of the CCC and other ICM activities. For example, the Atherton Tableland Cooperative Dairy Association has appointed an industry funded Environmental Officer in a Resource Management Centre at Malanda. This person works with the ICM and Landcare groups to help dairy farmers implement best management practices consistent with the ICM strategy on their properties.

Project Assessment

The Johnstone River Catchment Pilot Study has been well resourced because it was the first pilot project and because of personal commitment from the Minister of Primary Industries. However, community and government groups in the catchment - including the Johnstone River Management Trust - identified the need for integrated natural resource management in the late 1980s and were therefore prepared for the policy changes and opportunities which came with the new Government in Queensland.

The major focus of the Pilot Study in developing the ICM concept has been the preparation of a Management Strategy for the natural resource of the Catchment. This document was released by the Minister for Primary Industries on 13 October 1994. It builds on the Draft Management strategy which was released for comment in March 1993. The Draft Strategy was reviewed extensively by Government Institutions, local authorities, industry associations, community groups and research organisations. The Management Strategy focuses on four key issue areas - land management, water management, riverine management and habitat management. Lead agencies responsible for implementation of activities under each strategy are identified.

The implementation *process* developed by the CCC is one of the most advanced and well thought out in Australia. It has yet to be implemented, but it addresses many of the weaknesses identified in other ICM projects in Australia. Biannual meetings of the CCC are designed to set priorities, allocate resources, negotiate Memoranda of Understanding with relevant parties for implementation of activities under each strategy and monitor progress of implementation.

The three key process elements which the Johnstone River CCC have identified are:

- allocation of priorities as the first step for implementation of activities under each strategy;

- allocation of responsibilities for implementation; and
- negotiation of Memoranda of Understanding between different parties with responsibility for contributing to the implementation of activities under priority strategies.

These are the key elements of successful ICM programs in other countries.

The pilot project has effectively developed a process and a Management Strategy - reflecting the skills and background of the Catchment Coordinator. The ICM program has a high profile throughout the catchment but it now has to start implementing activities on the ground.

The CCC and DPI recognise this need. The CCC has appointed a part-time forester as a Strategic Revegetation Coordinator. She is working with the many community and Landcare groups in the catchment with revegetation and conservation activities. DPI has appointed an Extension Officer to focus on implementation of activities given priority in the Management Strategy. He is working with industry groups, local authorities workers and landholders to develop and implement field activities for land management and riverine management strategies identified in the Johnstone River Management Strategy.

Strengths

- Small size and compact nature of catchment with strong community leadership and vision across a range of sectors, predating ICM and Landcare programs
- First ICM catchment with strong support from DPI and Minister for Primary Industries.
- State guidelines for integrated catchment management *philosophy* based on integrated environmental management *product*.
- Process well advanced and logically through out - although not yet implemented
- Product and philosophy well documented and though out - with strong industry and local authority involvement.
- Independent ICM office location in main shopping precinct - away from DPI, Local Authorities and other agencies.
- Identification or priority activities and responsible institutions for implementation.
- Technical packages for solutions exist for many resource management problems.
- Performance based Shire Planning Strategy recently developed by Johnstone Shire and approved State Cabinet.
- Strong bio-physical data sets on which to base ICM planning activities.
- Appointment of Extension Officer and Strategic Revegetation Coordinator to support implementation of priority activities in the catchment management strategy.
- Development of Best Management Practice guidelines for each agricultural industry as a means of compliance with the Codes of Practice for Agriculture under the *Environmental Protection Act* (Qld, 1994).
- Recognition of the need to source funds from outside public sector, to share costs according to split of public:private cost benefit analysis
- Willingness of CCC to incorporate and operate as project manager and investment planner.
- Resolved the dispute between Landcare and ICM with clear and constructive role for both groups in the implementation process.
- Dairy Industry developing self-regulation process to monitor and manage dairy effluent in catchment - the starting point for community monitoring strategies.

Weaknesses

- ICM strongly pushed by DPI, although in Johnstone many community and institutional groups had identified the need for an integrated approach to catchment management.
- Catchment is not widely recognised as basic management unit
- Independent and uncooperative culture of Wet Tropics Management Authority - responsible for management of nearly half the catchment area.
- Emphasis on planning and consultation rather than action on the ground - community is now ready for some activity
- Expectations have been raised in the community - CCC and ICM credibility requires delivery of activities on the ground. This has been recognised.
- Communication within and between government agencies remains a barrier - especially within and between state government agencies.
- Under-resource and poorly focused DEH office in Innisfail.
- Poor identification of linkages between community priorities and catchment management priorities and poor integration of technical resources from DPI and DEH to develop innovative solutions to community and catchment management problems.
- No use of resource economic analysis to identify priorities and allocate costs and benefits between public and private sectors

Opportunities

- Implementation of Best Management Practice Guidelines for ICM as well as complying with the Codes of Practice for Agriculture under the *Environmental Protection Act* (Qld, 1994)
- Implementation of new Johnstone Shire Planning Scheme in close consultation with CCC to complement – and form an integral part of ICM activities.
- Use of resource economics and cost benefit analysis to identify potential benefits of improved resource management and habitat conservation – to quantify the investment which the public sector would be justified in making as a contribution to the cost of implementing catchment management plans.
- Build on DPI experience with Strategic Balance Sheet approach to incorporate resource economics into ICM and CCC activities.
- Use Best Management Practice guidelines to develop linkages between landholder priorities, local authorities priorities and catchment management priorities.
- Establish cost sharing arrangements related to co-management partnership with catchment community. In addition to encouraging ownership, this provides an opportunity for a stronger relationship between the CCC and Landcare groups in the catchment.

Threats

- Agricultural industries, feeling threatened by conservation impact from World Heritage and Forest Conservation, are motivated by fear rather than positive or educated responses to natural resource management.
- Declining public resources for implementation activities – may result in community expectations not being realised which would threaten current momentum towards widespread implementation of catchment management activities.
- Parochialism and strong development and frontier approach of industry groups in CCCs.
- Many strong egos and political undercurrents amongst community leaders – potentially leading to conflict if focus or momentum is not maintained.

5.4 ICM in Queensland: History and Intent

G.T. McDonald and D. Shrubsole
University of Queensland

(Source: "What You Told Us - A Survey of the Views of Queensland ICM Chairs and Coordinators and Herbert River Catchment Coordinating Committee Members" (Part 2) (This publication. Vol. 2 No. 1 pp ???

Integrated Catchment Management in Queensland

The quest for effective natural resource management has been pursued by governments worldwide. Often, water has been a prime focus of attention because a catchment provides a natural system from which the interactions among people, water and related land resources can be considered and the coordination of relevant public and private resource managers enhanced. To these ends, the State Government of Queensland, Australia released *Integrated Catchment Management* (ICM) in 1991 in order to:

> *integrate the management of land, water and related biological resources in order to achieve the sustainable and balanced use of these resources. It provides a framework for fostering cooperation and coordination between many landholders and other resource users, community groups and government agencies involved in the use and management of land and water resources* (Queensland, 1991: 1)

While it was recognised that other government initiatives such as the State Conservation Strategy, State-wide environmental programs (eg. Landcare) and broad regional strategies such as South East Queensland 2001 Growth Management Strategy and Coastal Protection Strategy would be important activities, ICM was perceived to be unique for two reasons. First, it was to involve all sectors of the community. Second, it was to be multiple, rather than single issue based.

ICM Principles

Five principles were to guide the ICM process. First, since land and water resources are basic and interactive parts of natural ecosystems, effective management was best achieved by using the catchment as the administrative unit. Second, since river catchment are continuously changing in response to natural processes and human activity, management strategies should anticipate, adapt and respond to these changes. Third, decision would be based on the best available information. Fourth, individual users and managers would be informed about water and land management issues and solutions. Fifth, ICM would provide for a 'balance between economic development and conservation of land and water must be maintained' (Queensland, 1990: 1). By using these five principles to guide the formulation of catchment strategies, the following goals would be achieved by promoting:

- community understanding, coordination and cooperation
- common goals and community action, and
- economic and ecological sustainability

Catchment Care Council and Catchment Coordinating Committees were to be the driving forces behind ICM. Supported by QDPI which would provide information, education and training services about ICM, CCCs and CCCs were to provide the following functions:

- foster coordination between landholders, community action groups and government agencies in their land and water resource management activities;
- promote community understanding of the interactions between land, water and related biological resources and the value of a coordinated, catchment-wide approach for managing these resources;
- provide a forum for community and government discussions on catchment management issues for resolving conflicting demands on natural resources;
- identify and prioritise interrelated land and water resource issues in the catchment;
- develop catchment management strategies that address priority issues;
- promote and foster voluntary implementation of catchment management strategies by landholders and other resource users through community action groups and government agencies;
- provide advice and recommendations to landholders and other resource users, community action groups and government agencies on catchment management issues;
- monitor, review and report to Government and the community on progress and performance of catchment management strategies and activities (CCCs must report annually to Minister of DPI); and
- recommend improvements in the administrative procedures and statutory requirements of government agencies to avoid duplication and conflicting requirements.

Implementation of ICM would foster a whole-of-government approach by providing a strategy which was consistent with policies and guidelines of all levels of government

ICM as a Process

ICM was to be a State-wide initiative. While the Queensland Department of Primary Industries (QDPI) would be the agency responsible for administering ICM, the important role of other agencies such the Departments of Environment and Heritage (QDEH), Lands (QDOL) and Housing and Local Government (QHLG) in supporting relevant aspects of ICM were recognised (Queensland, 1991). Collectively, State Government agencies would, within the scope of available resources, support and assist Catchment Care Groups (CCGs) and Catchment Coordinating Committees (CCCs). These two types of bodies would be formed in order to harness local and public agency involvement in order to formulate the catchment strategy document. CCGs would be less formal than CCCs and 'link the activities of landholders, community action groups and government agencies' on relatively simple issues which involve a limited number of participants (Queensland, 1991: 2). Providing a forum for community discussion and fostering the cooperative development of solutions are the major roles of these groups. The initial intent was to form CCCs under legislation to address complex issues involving a large number of participants. In practice, legislation was never enacted because of a significant perception that ICM could result in another and unnecessary level of government. Instead, the level of support provided through QDPI has signalled to it and is ineligible for the $500 establishment grant. CCCs receive these types of support. Where a catchment was divided among several CCCs, Regional Catchment Coordinating Committees (RCCCs) could be formed to coordinate individual CCC activities. RCCCs are also ineligible for the $500 establishment grant.

The State Government encouraged that CCGs and CCCs take a pragmatic approach which focused on 'manageable and resolvable issues of high priority to the community rather than all issues' (Queensland, 1991: 20). When completed, the strategy would identify and describe major issues; describe relevant activities, guidelines, policies and action plans; identify mechanisms to achieve objectives; and provide appropriate monitoring and review mechanisms. Unless special legislation were passed, the requirements of the strategy would not be legally binding on any landowner or government agency.

ICM as a Product

The primary final product of the ICM process is a Catchment Strategy which prioritises catchment issues and identifies appropriate implementation mechanisms. Three options for implementation were identified. The preferred choice would see the CCC seek the voluntary adoption of catchment management strategies by landholders and resource users, community action groups, and government agencies. Presumably, the strategy development process would educate resource managers about the need for specified resource management activities. Where voluntary implementation was jeopardised, CCCs could request the appropriate state minister (eg. QDPI, QDE, QDOL, QHLG) to have local and state agencies consider catchment management strategies in their routine operations. The final option would see the establishment of a catchment trust or similar statutory body for specified issues such as soil conservation, floodplain management or river improvement. This issue was considered in the 1994 document *The Sustainable Use and Management of Queensland's Natural Resources.*

The general intent of ICM may be summarised as follows. It is a voluntary approach which relies on local initiative to establish the need for the formation of a CCG or CCC. Both CCGs and CCCs and subsequent strategies lack legislative authority. Voluntary compliance by relevant private managers (landowners and corporate) and public agencies is the preferred method of implementation. Education of these managers through the exchange of information and the development of the Catchment Strategy is to facilitate the adoption of required actions. ICM Committees are to be composed of major stakeholders who have an interest or are influenced by significant resource management problems. Another dimension of this stakeholder approach, is the joint funding for relevant activities from both the State Government and relevant local participants. Catchment strategies are to focus on several important resource management issues operating on a catchment scale in order that an integrated consideration of problems and solutions is provided. While the State Government has identified a number of requirements for all catchment strategies, local groups must seek their own approaches in the formulation of that document. Monitoring is to be an important element of all catchment strategies.

Forming and Operating a Catchment Coordinating Committee

The State Government identified ICM principles, processes and products. Local communities are to consider the need for ICM, and if appropriate, pursue the formation of catchment coordinating groups or committees. In this matter, ICM in Queensland should merge 'top down' and 'bottom-up' management. Both CCGs and CCCs are comprised of 'representatives of the major sectors of the community and government which are involved in, or influenced by, the management of land and water resources in the catchment' (Queensland, 1991: 2). They are to work with state agencies and local groups in forming catchment strategies thus furthering the principle of partnership between state government and local government and groups.

CCGs and CCCs must encompass an administrative region of at least two local government areas and be catchment or sub-catchment based. The membership should 'reflect the interests of the major sectors of the community' including local governments, key relevant primary industries, landholders in proportion to the range of land uses in the catchment, state government agencies, community groups and organisations, recreation and conservation interests, secondary interest and major stakeholders outside the catchment (eg. Great Barrier Reef Marine Park Authority, World Heritage Parks)(Queensland, 1995: 2). The membership should be determined by open election or through nomination by community groups, agencies and the general public. Membership of RCCCs is drawn mainly from CCCs within the basin.

Once groups within a catchment have decided to form a CCC or CCG, they should apply for endorsement under the Queensland's ICM Strategy which provides them with access to operating and project funds, liability and accident insurance. Appropriate activities are funded from a number of sources. As the administering agency, QDPI provides seed funding for CCGs, CCCs and projects. A one-time $500 establishment grant if available to both CCCs and RCCCs. To cover the full costs of establishment, CCCs are to seek the financial and in-kind support from interested and member organisations. Operating grants are set at $2 000 per year for three years and $1 000 afterwards. CCCs west of the Great Dividing Range and in the Fitzroy and Burdekin Districts are eligible for an increased level of grant up to $5 000 per year for three years, and $2 000 thereafter. Applications for additional project funding could also be submitted to funding agencies such as Landcare and LWRDCC and other government and non-government agencies.

Review of State-wide ICM Activities (1991-1996)

By May 1993, 5 catchments - the Lockyer Valley, Johnstone River, Pioneer River, Mary River and Mitchell River - had been identified as pilot study areas. By October 1995, there were 13 CCCs and 1 CCG formed throughout the state, with most located along the eastern coastal catchments. There was initial concern that ICM and Landcare, which was launched in 1992 as a means of conserving natural resources and protecting the environment would be seen as overlapping exercises. However, QDPI saw these initiatives as complementary.

> *ICM is about the 'big picture' or the condition of the whole catchment on a broad scale. Landcare deals mainly with localised issues on a property or small catchment scale … Both are flexible and can be moulded to suit the needs of the community* (The Source, April 1991: 8)

Several conferences such as the Downstream Effects of Agricultural Pollution (DEAP) have been held. The role of local government in ICM was highlighted in a 1994 study (QDPI *et al.*, 1994). A newsletter titled *The Source* provide information to all ICM members, coordinators and interested participants. Between April 1992 and February 1996, 10 issues have been published.

The state government has also introduced a number of initiatives which influence the formulation and implementation of ICM strategies. These include the 1994 natural resource management discussion paper, environmental protection legislation and propose reforms to the *Local Government (Planning and Environment) Act*.

As mentioned earlier, new legislation was initially considered as necessary to support ICM. In 1994, it became clear that this alternative would not be pursued. In a 1994 discussion paper titled *Sustainable Use and Management of Queensland's Natural Resources* the State Government identified its preference to amalgamate existing legislation within existing administrative arrangements, rather than create new agencies (QDPI, 1994). The overall objectives of the new framework are to 'produce an integrated natural resource management (NRM) policy with non-regulatory strategies and a minimum of legislation' and to integrate the existing natural resource legislation administered by QDPI 'to see an effective planning and management framework in place that provides for ecologically sustainable development for natural resources' (QDPI, 1994).

Like implementation of ICM, the Queensland Government prefers voluntary compliance with its NRM requirements. However, if resource degradation was significant and effective community-based measures (eg ICM) were not forthcoming, QDPI could establish additional regulations and/or special statutory bodies under the NRM initiative. These would be in addition to and would probably supersede policies developed through the local planning and ICM process. If this situation is to be avoided, it is a community's interest to actively and effectively participate in the development and implementation of local plans, ICM strategies and Codes of practice. Non-involvement will detract from one's standing within the community and contribute to the possible imposition of QDPI regulations and special statutory bodies. Local control would be reduced.

The need to reform existing legal arrangements within QDPI was also recognised in the discussion paper. Legislative options to overcome the 'overly prescriptive', 'highly variable' and 'fragmented' nature of QDPI-administered Acts included: a single piece of legislation to replace the nine existing Acts and which incorporates Integrated Catchment Management (ICM); retention of the existing nine Acts with amendments, together with the preparation of an additional piece legislation for ICM; preparation of umbrella legislation that sits across the existing Acts and that for ICM and; amalgamation of the existing Acts introduces three broad category Acts of Land, Forests and Water.

5.5 Summary and Synthesis

The following is a *SWOT* analysis of ICM in Queensland by Rowland and Begbie (1997). It is not exhaustive, however it provides a basis for thought and discussion of the issues. It is presented in the SWOT format.

Strengths

- Broad and somewhat nebulous goals provide opportunities for a variety of ways of doing ICM and for tailoring the approach to suit the situation.
- Network of CCCs has been established and a mass of people have been exposed to, and had the opportunity for, some involvement in ICM.
- ICM has become institutionalised within DNR, and there is considerable support (at least at a policy level) for ICM in other government departments and local government.
- Both levels of government, the community and industry have responded to the philosophy of catchment management in a variety of ways. The broad goals of ICM provide for a range of interests to be involved and contribute to achieving these goals.
- The participative approach has been well received by most sectors of the community. It has assisted in making catchment plans and management activities consistent with local needs and goals.
- Most CCCs have used a representative model for membership of the management committee. This has resulted in a broad diversity of interests coming together on the committees – often for the first time – with generally very positive results.

Weaknesses

- Breadth of the program has resulted in the need for individuals and groups to gain an understanding of what s trying to be achieved and how to apply it. This is a costly and time consuming process (for example, it takes up to five years for catchment groups to become fully operational).
- Financial resources to achieve these broad but ambitious goals have been erratic and low.
- CCCs have no statutory powers or revenue raising capability.
- Participants are concerned that the linear planning then implementation approach to ICM has resulted in questions being asked about the availability of resources to implement once all the planning is completed.
- Complex planning processes are required, with no single process being used. Each catchment group has needed to invent its own.
- Absence of a 'whole of government' approach, commitment or involvement.
- Emerging problems like biodiversity conservation and nutrient enrichment of waterways (particularly in the estuarine and marine areas) are not well defined technically, and ICM groups have found it difficult to focus their priorities and activities where these are key issues.
- Implementation mechanisms for catchment strategies are non-existent or unclear.

- Funding guidelines and arrangements keep on changing, making the targeting of these resources difficult.
- The public generally has a low level of awareness of natural resource management issues.
- Only a small percentage of the public are active participants in catchment management activities.
- Lack of monitoring and feedback mechanisms to provide data on the impacts of ICM and the effectiveness of the approach.
- Representative model used to form management committees is not always effective in getting the right individuals involved. It leads to assumptions about the quality of communication between the group and the constituent member organisations. There is a need for all members to take a whole-of-catchment view of issues – to protect sectarian interests.
- Differences in perceptions between the chairs and coordinators of progress in achieving the aims and objectives of catchment groups.

Opportunities
- Clear technical solutions exist for many of the natural resource management problems in Queensland.
- A critical mass of people has been established with an understanding of ICM and skills in its application.
- ICM has challenged people to understand causes and respond to them through targeted action to get real changes (for example, much of the riparian zone management and rehabilitation activities.
- Local government is being increasingly involved in catchment management in a variety of ways (from stormwater management to rural residential design). Interest by local government continues to grow.
- Among those involved in, or at the fringes of groups doing ICM, there is a much greater acceptance of the need for a planned and strategic approach than seven years ago. The challenge is in translating this interest into practical action.
- The planning that has already occurred provides those groups with opportunities to tap into funding resources that require strategic and integrated solutions to problems (for example the NHT regional component).

Threats
- High expectations of what ICM can deliver by the community and government.
- Over-reliance on voluntary contributions by community and industry without commensurate rewards, particularly in the short term.
- The level and breadth of skills needed to actually implement the complex catchment management plans produced.
- Identification and establishment of the right implementation arrangements (structures, policy and resources) for it to go ahead.
- Ongoing resourcing of what are very large, voluntary-based organisations.
- Ongoing commitment to technical and administrative support by government agencies, local government, industry organisations and tertiary institutions is required for the partnership between these bodies and the community to work. Voluntary community people involved in catchment groups require this support. (Rowland and Begbie, 1997: 4-5).

6. Landcare and ICM

There is a strong relationship between the structure and linkages of ICM and Land Care. A clarification of the roles and functions of both ICM and Landcare was discussed in the discussion paper: Landcare and ICM Working Together. This clarification was required because the frameworks of ICM and Landcare overlap. There was confusion about the different roles and objectives of ICM and Landcare and the respective coordinators and facilitators. Additionally, there was confusion about the level of coordination and support, particularly at the regional level, which address resource management issues (DNR Queensland, 1997: 2).

ICM and Landcare have a complementary relationship. There are strong similarities in the approaches to natural resource management and use, which are community based and focused on sustainability and balance. However, the main difference between ICM and Landcare is that ICM deals with the condition of entire catchments, whereas, Landcare deals mainly with local issues on a much smaller scale, either property or small-catchment. (*The Source - Integrated Catchment Management News and Views*. April 1992. 1.Pg. 8.)

Nevertheless, ICM and Land care are both flexible and adaptable to the needs of individual communities. ICM and Landcare are both important approaches to natural resource management because each makes important and unique contributions to management. Together, ICM and Landcare can provide an effective way to achieving the sustainable and balanced use of natural resources. (*The Source - Integrated Catchment Management News and Views*. April 1992. 1.Pg. 8.)

6.1 Landcare & ICM
Report and Recommendations Paper
Review of Integrated Catchment Management and Landcare Arrangement

Department of Natural Resources, 1997.

This paper outlines recommended arrangements which promote the objectives of natural resource management and the interlinking of ICM and Landcare within a simple framework.

List of Recommendations

Recommendation 1:
That separate but closely linked Landcare groups and catchment committees be retained; that catchment/landcare subregions be used as the basis for preparing integrated resource management strategies; and that Regional Resource Management Coordinating Committees be formed to coordinate natural resource management action across subregions and catchments.

Recommendation 2:
That roles and responsibilities of support staff be redefined to include both landcare and catchment management.

Recommendation 3:
That a combined body called the Landcare and Catchment Management Council (LCMC) be established to replace the existing Queensland Landcare Council and the Catchment Management Coordinating Committee

Recommendation 4:
That membership of the LCMC consist of an independent chairperson and 18 members comprising:
- 5 representatives of landcare and catchment management groups;
- 5 industry representatives (extensive agriculture, intensive agriculture, grazing, water industry and fishing);
- 4 State Government representatives (DNR, DPI, DoE, DLG&P)
- 1 representative each from the Local Government Association of Queensland (LGAQ), Queensland Conservation Council (QCC), Greening Australia-Queensland (GA(Q)) and the Great Barrier Reef Marine Park Authority (GBRMPA).

Recommendation 5:
That the chairperson and the 5 industry representatives be selected through advertisements calling for expressions of interest; that invitations be issued to DNR, DPI, DoE, DLG&P, LGAQ, QCC, GA(Q) and GBRMPA to nominate a member each to serve on the council; and that 5 landcare and catchment management representatives be elected annually by appropriate processes in each region.

Recommendation 6:
That the LCMC be established as soon as possible after 30 June 1997 and no later than 1 January 1998.

Recommendation 7:
That sitting fees be paid, in accordance with guidelines set by the department, to the chairperson and members of LCMC who are not already paid for their time, and that expenses be paid for reasonable costs of travelling, accommodation and meals in line wit Public Service Aware rates.

Recommendation 8:
That consideration of closer integration of the various resource management, environment and sustainable production advisory committees and possible incorporation into the Queensland Natural Heritage Council (QNHC) be deferred until the focus of the Natural Heritage Trust (NHT) and its operation arrangements become clearer.

Introduction

For some time there has been confusion about perceived similarities between Landcare and ICM. At the Landcare Groups Conference at Bundaberg in June 1996, the Minister for Natural Resources, the Hon. Howard Hobbs MLA, announced that a review of the structure and linkages between Landcare and catchment management would be undertaken at the State, regional and local levels.

The overall purpose of this review was to propose arrangements which promote the objectives if natural resource management and the interlinking of ICM and landcare within a simple framework. That framework should enhance the development of community and government partnerships in planning and implementing natural resource management policies and programs.

An ICM/Landcare Review Committee was formed to guide the review process. Members include the representatives of the Queensland Landcare Council, the State Catchment Management Coordinating Committee, and the Department of Natural Resources. Terms of reference and members of the Review Committee are listed in Appendix 1.

A Discussion Paper was released in January 1997 with the closing date for comments being 17 March 1997.

Extensive consultation was undertaken with clients, stakeholders, relevant government departments and agencies, landholders and departmental officers. Meetings were held with key clients in January and February 1997.

This document reports the outcomes of the review and outlines recommended arrangements that promote the objectives of natural resource management and the interlinking of ICM and Landcare within a simple framework.

Background

There is a general lack of understanding in many sectors of the community of the roles and functions of landcare and ICM. It is often perceived that both groups are competing for the same community members, community and industry support and the same funds. They are also often seen to be attempting to address similar or overlapping issues.

The need therefore exists to clearly articulate and effectively communicate the roles and functions of both landcare and ICM so that all parties have a clear understanding of both movements.

A need also exists for better integration and linking of the actions of landcare and ICM. In particular, a need has been identified to establish an efficient partnership to effectively harness industry, client and government input into these community-led approaches to natural resource management.

Issues

The following issues were raised as a basis for discussion:
- Confusion about the roles and objectives of landcare and ICM, particularly at the regional level;
- Confusion over the roles of landcare and ICM coordinators and facilitators;
- Inadequate coordination and support at the regional level to address resource management issues;
- The need for both landcare and ICM to exist as both have valid functions, however, the activities of each need to be clearly defined;
- Current structures reflect the present situation only in landcare and catchment management – the need for a visionary approach as we look to the future;
- The need for broad integrated strategies to be developed on other than a catchment basis where the areas of interest do not conform with catchment boundaries.

Consultation

Nearly 2000 copies of the Discussion Paper were distributed to key community groups, organisations, departmental officers and landholders. These included:
- Queensland Landcare Council
- Catchment Management Coordinating Committee
- Industry organisations
- Landcare groups
- Catchment Coordinating Committees
- The State Government departments of Primary Industries, Environment, Local Government and Planning and Natural Resources
- Local Authorities
- Landcare facilitators and catchment coordinators

A total of 63 responses were received. Table 1 indicates the number of responses from the various sectors of the community.

Table 1: Responses to the Discussion Paper

Respondent	Number
Landcare groups and catchment committees	23
Individuals	15
Landcare coordinators/project officers	3
Local Governments	8
Industry bodies and organisations	10
Government departments	1
DNR district officers	3

Summary of Responses

Vision for ICM and landcare for the year 2006

There was broad support for the vision stated in the Discussion Paper, which identified the following key elements as central to the vision for ICM and landcare for the year 2006.

- The community taking the lead
- Government focusing on policy and regulatory roles
- The community developing priorities and delivering actions through a regional approach with coordination at regional and State levels.
- Strong local action at both the catchment and landcare group levels working within catchment/regional strategies
- Landcare and catchment management retaining their identity with groups at the local, catchment and regional scales, but linked through a Regional Resource Management Coordinating Committee.
- The CMCC and QLC merging into one body at the State level to provide policy and advice to the Minister and to the community through regional groups/committees.
- The catchment/regional focus as the basis for setting priorities and actions, with action at the local level consistent with achieving the wider catchment/regional priorities.
- The Regional Resource Management Coordinating Committees and the merged State body assessing projects and determining priorities for funding.

Of the 37 responses to this issue, 14 specifically stated that they supported the vision for ICM and landcare. Supporting comments included:

- Desire to see successful amalgamation of ICM and landcare principles, ideals and philosophies.
- Vision looks great – is what people in landcare have been saying for a long time
- The vision meets the desired outcome of the maintenance of 'grass roots' actions on landcare/catchment management with better coordination on a regional/State basis
- Support for the vision, but stress the community, industry and government working in partnership to develop policy and deliver actions.
- Support for a concerted effort rather than ad hoc projects undertaken at the local level without real communication between interested parties
- While it was necessary to retain identity for landcare and ICM at the local level, they should be combined at the regional level.
- It is important to remember that landcare and ICM committees are community groups and as such need to be run and owned by local communities if they are to succeed.

Other relevant comments included:

- The vision is well thought out and presented. However, could see no reason for retaining separate identities for landcare and catchment management at any level – let the whole framework be integrated.
- The vision would depend on the option chosen, and that by putting up the vision, the cart was being put before the horse.

Roles and Responsibilities

Generally, there was agreement to the roles and responsibilities proposed for the modified landcare and catchment management framework. Of the 35 responses to this issue, 10 specifically stated that they supported the proposed roles and responsibilities. Comments included:

- Planned roles and responsibilities of the State, regional and local committees are appropriately focussed and complement each other.
- Current roles of QLC and CMCC tend to overlap and differences between them become blurred.
- Agreement with the proposed roles for Regional Resource Management Coordinating Committees (RRMCCs) – they would contribute to the attainment of landcare and ICM objectives in a strategic and resource efficient manner, possibly removing perception of duplication of services. They would be in a strategic position to prioritise projects and allocate funds according to priorities.

- The catchment level should not be involved in the assessment of projects – only with implementation, with assessment at the regional level. Issues should be identified at the catchment level and issues then prioritised at the regional level.
- Regional committees must foster community ownership of local groups initiatives.

Respondents also stressed the importance for landcare groups of planning and implementing on-ground action. Comments included:
- For continued success, landcare groups must be able to plan at the local level and have ownership of their projects.
- Landcare groups must be involved in implementation of on-ground works, not just planning, education and awareness.

Structure options at the regional level
There was support for the proposal to form informal Regional Resource Management Coordinating Committees as part of the modified landcare and catchment management framework. Comments included:
- A very workable and practical structure has been proposed
- Regional Assessment Panels (RAPs) should be retained in their present form for project assessment and evaluation. RAP boundaries should form the basis of the RRMCCs.
- Given the key roles of the RRMCCs, the lack of formal structure and informal meeting procedure is too vague.
- The proposed executive committee of the RRMCCs appears to be too heavily weighted with State government representation. DNR is the only department which should have representation on the executive. The other government departments could be coopted as and when necessary.
- It may be desirable to include local government on the executive of the RRMCCs.

Structure options at the State level
Of the 45 responses to this issue, 32 (or 73%) favoured a merged QLC/CMCC, i.e. options for a State resource Management Coordinating Committee (SRMCC) or Resource Management Advisory Committee (RMAC) Option B, with a direct reporting and advisory link to the Minister for Natural Resources.

A further breakdown of preferences is shown in Table 2.

Table 2: Respondent preferences for options listed in Discussion Paper

Option	Number of Respondents
State Resource Management Coordinating Committee	18
Resource Management Advisory Committee – Option A	4
Resource Management Advisory Committee – Option B	14
Community Advisory Committee	6
No Change	3
Total Responses	45

Comments in support of the merged QLC/CMCC included:
- The SRMCC looked the best of all options; a simplified structure is needed rather than making it more complex, and this looked to be the simplest solution.
- The structure was relatively simple compared with the other options and rightly emphasised the independence of landcare and ICM by amalgamating the peak bodies at State level.
- The name of the SRMCC should be changed to include the words 'landcare' and 'catchment', e.g. 'Landcare and Catchment Management Coordinating Committee' or 'State Landcare and Catchment Resource Management Committee'.
- RMAC Option B had the benefits of the status quo with the advisory committee responding to the Minister.
- RMAC Option B should improve coordination of both movements at the regional and State levels.

Regional boundaries
Of the 35 responses to this section of the Discussion Paper, 32 supported the concept of regions based on catchment and biogeographical boundaries. However, a number of respondents were concerned about the large size of some proposed regions, particularly those in the west of the State. There was also general support to further divide the Southeast region into probably three subregions due to the large population and wide diversity of issues. Comments included:
- The twelve regions appear fairly well thought out and could be reviewed if problems arise.
- Queensland Murray-Darling Basin should all be in the one region.
- Subdividing the State into regions is supported, and if possible, strategies should be developed in time for each of the regions.
- Support for boundaries, however because of the complexity and size of the North Region, question the logic of inclusion of Whitsunday in this region rather than the Central Region.
- South-east Regional boundaries are acceptable. However, there is a need for clearly defined subregions.

- Grouping Etheridge Shire into the North Region is Contradictory to the regional focus of the gulf Local Authorities.

Support structures required
Of the 27 who responded to this issue, 10 specifically stated that they supported the proposal for improved support structures at the local and regional levels. The support provided by local extension staff was highly valued and respondents felt it was essential to provide adequate permanent staff. Comments included:
- Fully support the proposal that permanency of staff be implemented
- Endorse support required at each level; local extension officers are a much needed asset; assistance provided to groups by government officers is highly valued.
- As strategies are implemented and landcare groups evolve, both organisations will have local community members employed and involved in natural resource management.
- Necessary support staff must be provided by government. However, if funded with NLP/NHT funds, it will mean less funds for on-ground works and grass roots activities.
- Reservations about excessive staff in administrative positions. The biggest percentage of money available to landcare and other conservation groups has got to be used for on-ground works.

Other general comments
Local Government
The matter of a role for local government was raised. Comments included:
- The role of local government in the delivery of services which are 'local' in nature, needs defining.
- A direct role for local governments had not been clearly defined other than being represented on the various landcare and ICM groups.

Funding
A number of responses indicated a concern about the proper use of funds. Comments included:
- The new structure should be cost effective to allow funding to get back to on-ground projects - structure not top heavy.
- The focus should be to get funding on the ground and not caught up in the bureaucratic system.
- Accountable structures must be delivered which can ensure wise investment of public dollars.
- Consideration needs to be given to some sort of remuneration for the time and effort the community members put in on these advisory councils.

Landcare and ICM roles
Comments on landcare and ICM roles included:
- Landcare and ICM essentially have the same objectives and purpose, and in the interests of more logical and cost effective administration, plans should be made for the two programs gradually to merge into one.
- It is necessary to have both landcare and ICM to achieve overall aims, and regular communication and liaison between both is necessary.

Timing of introduction
Comments on timing of introduction of any new arrangements included:
- The timing of the introduction of this new structure needs to be carefully considered in the light of elections to be held at Roma during the Queensland Landcare Conference in July 1997 for group representatives on the QLC.

Recommended Strategy

Following consideration of the responses to the community consultation program the Review Committee explored in detail the preferred future organisational arrangements for ICM and landcare.

Preferred local and regional arrangements
Arrangements proposed at the local and regional levels have been strongly supported. It is proposed to retain separate but closely linked landcare groups and catchment committees at the local level throughout the State with current roles and responsibilities and to form Regional Resource Management Coordinating Committees (RRMCCs).

It is recommended that the State be divided initially into twelve subregions based on a combination of catchment and biogeographical boundaries.

The need has been identified to further subdivide the proposed South-east Region into three subregions to better coordinate across the wide variety of issues and better cater for the large population base.

The need has also been established to re-examine boundaries in the Western and Gulf Regions to determine the most appropriate boundaries. For example, the Warrego-Paroo catchment is part of the Murray-Darling Basin

(MDB). Given Queensland's participation in the MDB Programs, there are logical reasons for the Warrego-Paroo to be included in with the other three catchments in the Queensland part of the MDB to form the one catchment/ landcare region. However, there are equally strong arguments for the Warrego-Paroo to be part of the West Region for project assessment and delivery of programs and activities such as the Southwest Strategy, which has a prime focus on rural reconstruction and natural resource management in the mulga lands.

Ultimately, the decision will need to be made by the local catchment community based on what makes best sense for that community. This is best done at the regional and local levels with the community groups concerned. If these proposals are implemented, this would lead to the formation of some 14 or 15 catchment/landcare subregions across the State. These subregions would be used as the basis for preparing regional resource management strategies.

RRMCCs will be needed to coordinate resource management action at the catchment/landcare and regional levels. The composition and level of formalised structure of these communities will be determined at the regional level. It will be influenced by operational arrangements for management of the Natural Heritage Trust. Different arrangements will probably be required for different regions and will be considered in the development of operational arrangements for the NHT.

Recommendation 1:

That separate but closely linked landcare groups and catchment committees be retained; that catchment/landcare subregions be used as the basis for preparing integrated resource management strategies; and that Regional Resource Management Coordinating Committees be formed to coordinate natural resource management action across subregions and catchments.

Guidelines and facilitation support may need to be provided from the State level to assist regions establish the RRMCCs. This task can be overseen by the proposed new merged landcare and ICM body when established.

Many groups now employ and manage their own project officers. This is seen as a cost-effective means of providing required support for groups. A network of extension staff in each region at the local level, supported by permanent DNR staff at the regional and State level, will be required to deliver the appropriate support on an on-going basis.

Local extension officers are highly valued by the groups. There was support for the roles of local extension staff to include both landcare and catchment management to reduce duplication of effort. However, this will depend on the particular circumstances in the subregion, such as the number of groups, size of catchment, etc. At the regional level, staff need to be experienced, with clearly defined roles, responsibilities and functions to ensure effective coordination across landcare and catchment management. In recognition of the very real constraints on funding, and the desire to maximise NHT funding for on-ground implementation, local and regional extension positions should, where possible, be filled by redefining responsibilities of current extension staff.

Recommendation 2:

That roles and responsibilities of current staff be redefined to include both landcare and catchment management.

Preferred State arrangements

There was wide support in favour of a merged ICM and landcare body at the State level (approximately 73% of responses). Consideration was given to the proposed organisational arrangement of a combined body, its name, linkages to other advisory bodies/committees and reporting arrangements, membership, functions and proposed implementation arrangements.

Title of combined body

All parties expressed a desire to adopt a title which was clearly identifiable with landcare and catchment management. The recommended name for a combined body is the "Landcare and Catchment Council". Other names were considered including "Queensland Landcare Council and Catchment Management Coordinating Committee", "State Resource Management Coordinating Committee" and the "Sustainable Resource Management Advisory Committee".

Recommendation 3:

That a combined body called the Landcare and Catchment Management Council (LCMC) be established to replace the existing Queensland Landcare Council and the Catchment Management Coordinating Committee.

Reporting arrangements and linkages to other advisory bodies/committees

The proposed Landcare and Catchment Management Council's (LCMC) principal advisory and reporting responsibilities would be to the Minister for Natural Resources. The LCMC would be represented on the Minister for Natural Resources' Ministerial Resource Management Advisory Council (MRMAC). The proposed structure for landcare and ICM is shown in Figure 1.

Linkages would be established and maintained with the Queensland Natural Heritage Council (QNHC), which is proposed to manage the administration and operation of the Natural Heritage Trust (NHT) in Queensland.

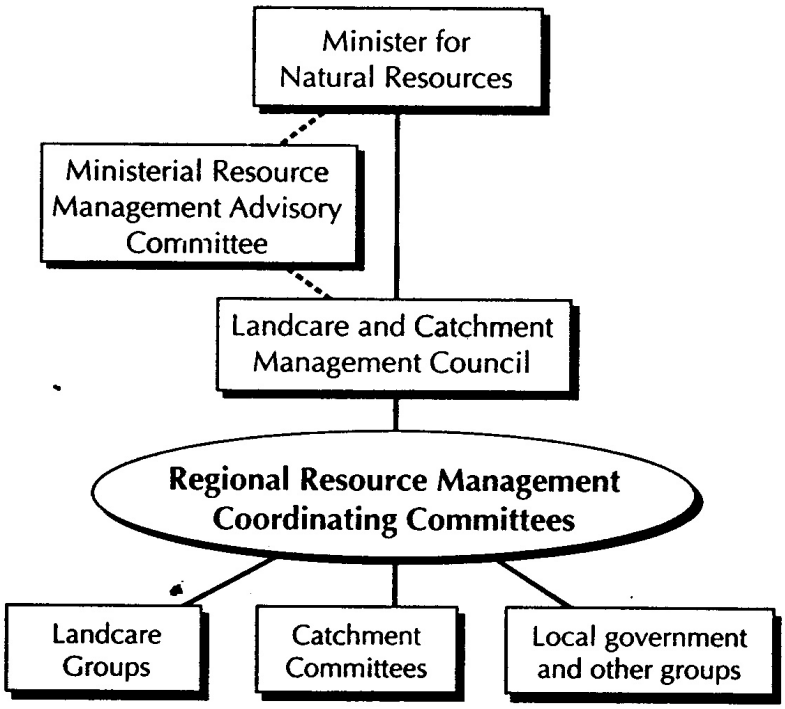

Figure 1: Recommended framework for the Landcare and Catchment Management Council

The LCMC would also link through the Minister for Natural Resources to the Ministerial Committee (consisting of the Ministers for Natural Resources, Environment, Primary Industries, and Local Government and Planning) proposed to be established to deal with issues relating to the NHT at a whole-of-government level. The Ministerial Committee would provide the means for better integration and coordination of effort at the State level across the broad areas of natural resource management, conservation, environment and sustainable agriculture. These linkages are shown in Figure 2.

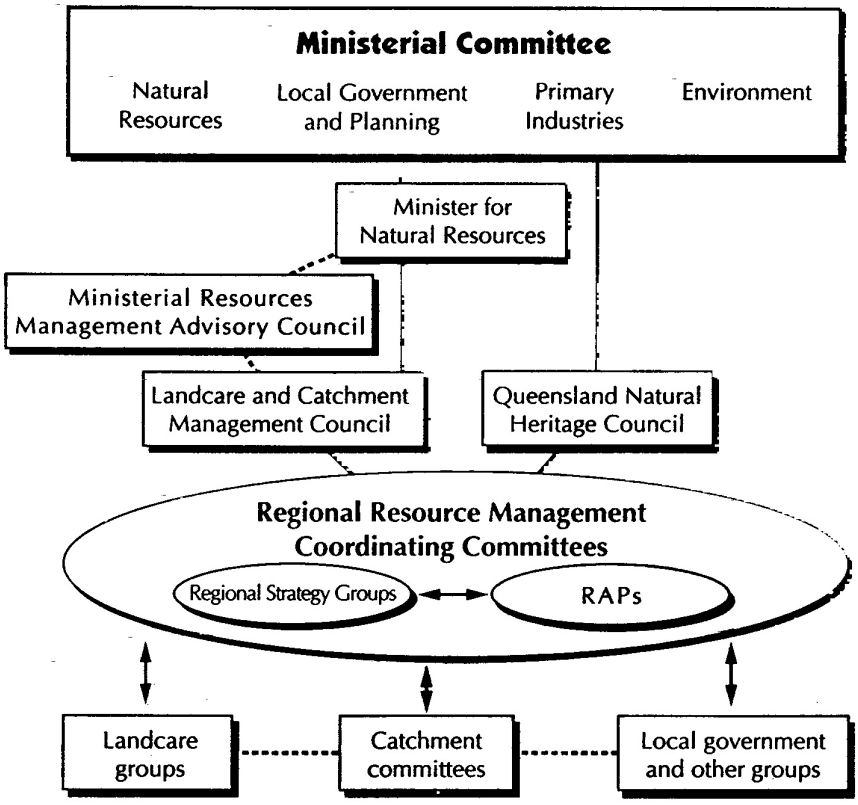

Figure 2: Links between the proposed Landcare and Catchment Management Council and the Natural Heritage Trust

It has already been argued that new arrangements need to be put in place to manage the NHT in Queensland. A separate Discussion Paper has been prepared outlining proposed arrangement for the operation of NHT in Queensland. It is proposed that the QNHC will take responsibility for endorsing regional resource management and environmental strategies. It would also set State priorities and strategies, oversee the assessment of project proposals and determine funding allocations across the NHT Programs. Five Regional Assessment Panels will assess project applications and State Assessment Panel will assess State-wide projects and report to the QNHC. Similar roles for the National Landcare Program were previously undertaken as responsibilities under either QLC and CMCC.

Membership

It is proposed that the membership of LCMC be composed of an independent chairperson and a committee of 18 members. The chairperson would be selected by the Minister for Natural Resources from nominations received through advertisement for people with broad expertise or experience in natural resource management. Committee membership is listed as per Table 3.

Table 3: Proposed membership of LCMC

Sector	*Number*	*Comments*
Landcare and catchment management groups	5	One from each NLP/NHT region, elected through appropriate processes in each region
Agricultural and fishing industries	5	Selected by the Minister for Natural Resources to represent extensive agriculture, intensive agriculture, grazing, water industry and fishing industries
State Government	4	One each from DNR, DPI, DoE and DLG&P
Local Government	1	Local Government Association of Qld
Conservation	1	Queensland Conservation Council
	1	Greening Australia-Queensland
	1	Great Barrier Reef Marine Park Authority

Recommendation 4:

That membership of the LCMC consist of an independent chairperson and 18 members comprising:

- *5 representatives of landcare and catchment management groups;*
- *5 industry representatives (extensive agriculture, intensive agriculture, grazing, water industry and fishing);*
- *4 State Government representatives (DNR, DPI, DoE, DLG&P);*
- *1 representative each from Local Government Association of Queensland, Queensland Conservation Council, Greening Australia-Queensland and the Great Barrier Reef Marine Park Authority.*

Proposed implementation arrangements

Arrangements will need to be put in place to establish the membership of the council. Advertisement could be placed, under the authority of the Minister, calling for expressions of interest for the position of chairperson of LCMC. Industry representatives would be selected by the Minister from nominations received through advertisement for people with expertise or experience in one or more natural resource-based industries.

The Minister would invite the four government departments, the Local Government Association of Queensland, Queensland Conservation Council, Greening Australia-Queensland, and the Great Barrier Reef Marine Park Authority to each nominate a member to serve on LCMC.

The annual Landcare Groups Conference currently elects three group representatives to QLC who could easily translate to members of any new Council. It is proposed that three catchment committee representatives would be selected in the first year by the Minister for Natural Resources by calling for expressions of interest. They would be appointed for a one year term. In subsequent years, one landcare and catchment management group representative would be elected in each region. Nominations could be announced at the annual groups conference.

Recommendation 5:

That the chairperson and the 5 industry representatives be selected through advertisements calling for expressions of interest; that invitations be issued to DNR, DPI, DoE, DLG&P, LGAQ, QCC, GA(Q) and GBRMPA to nominate a member each to serve on the Council; and that 5 landcare and catchment management representatives be elected annually by appropriate processes in each region.

The Landcare Groups Conference in July in Roma provides the ideal opportunity to launch the formation of the new council. Subject to Ministerial approval it is recommended that the new LCMC come into effect as early as possible after 30 June 1997 and no later than 1 January 1998.

Recommendation 6:

That the LCMC be established as soon as possible after 30 June 1997 and no later than 1 January 1998.

It is proposed that the LCMC would meet three times a year with a forth meeting being held in conjunction with the annual groups' conference.

The annual State Landcare Conference would continue but would broaden its focus to include catchment management. It would become known as the annual State Landcare and Catchment Management Groups Conference.

Functions
LCMC would have responsibility for fostering implementation of the Queensland Decade of Landcare Plan and the associated Priorities Actions 1997-2000 document and the Integrated Catchment Management Strategy. The Council will continue to deal with strategic priorities and policies for implementation of landcare and catchment management. Draft roles of the LCMC are presented in Appendix 2.

It is envisaged the LCMC will establish a series of committees involving council members to facilitate the business of council. As indicated above, the functions of State/regional assessment of NLP and related projects previously undertaken as a responsibility of QLC and CMCC, will become the responsibility of the QNHC. The draft roles of the LCMC may need to be modified when arrangements for the NHT are finalised.

Remuneration
Departmental policy on remuneration for consultative committees provides for the payment of sitting fees and expenses to chairs and members of consultative councils/committees which meet specific criteria. Daily fees would normally be paid to an agreed limit. However, an annual allowance may be paid at the discretion of the Minister where a chair (or other member) has a commitment averaging more than three days per fortnight. Sitting fees would be paid only to those members who are not already paid for their time.

The LCMC fits the criteria set for payment of sitting fees to chairs and members. Sitting fees would be paid for actual meeting days only, not for travel time, and expenses will be paid for reasonable travelling, accommodation and meal costs.

Recommendation 7:

That sitting fees be paid, in accordance with guidelines set by the department, to the chairperson and members of LCMC who are not already paid for their time; and that expenses be paid for reasonable costs of travelling, accommodation and meals in line with Public Service Award rates.

Possible future arrangements

With the establishment of the QNHC, consideration needs to be given to the future role of LCMC, QNHC and a range of other State committees with responsibilities for rural lands protection, Great Artesian Basin management, Property Management Planning and other resource management, conservation and environment protection roles. Linkages between these bodies are shown in Figure 3.

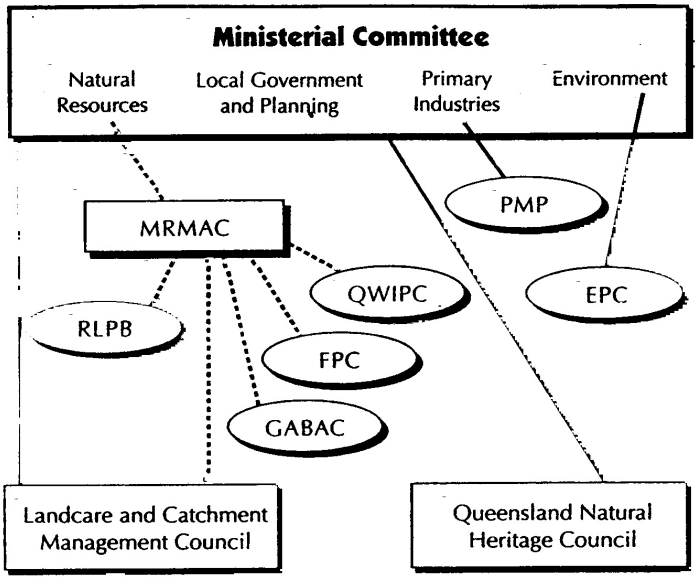
Each of these bodies has distinct functions that do not overlap. However, there is considerable scope for coordination of effort and a whole-of-government approach to maximise efficiency and effectiveness of client input to the advisory/consultative bodies.

A possible option to be considered in the future is for the LCMC and all the other natural resource and environment committees to become incorporated into the QNHC, as shown in Figure 4. A range of committees could be established under the QHNC to implement and investigate policies, priorities and actions for various elements of natural resource management, conservation, environmental protection and sustainable agriculture.

Investigation of this option needs to be undertaken at a later stage once the focus of NHT and its operational arrangements become clearer. Indications at this stage suggest that there may be adverse community reaction to further amalgamation of committees such as the Rural Lands Protection Board, State PMP Committee, etc and the incorporation of LCMC and QNHC.

Recommendation 8:

That consideration of closer integration of the various resource management, environment and sustainable production advisory committees, and possible incorporation of LCMC into the QNHC, be deferred until the focus of the NHT and its operational arrangements become clearer.



Legend: RLPB = Rural Lands Protection Board
MRMAC = Ministerial Resources Management Advisory Council
GABAC = Great Artesian Basin Advisory Committee
FPC = Forest Policy Council
QWIPC = Queensland Water Industry Policy Council
PMP = State Property Management Planning Committee
EPC = Environment Protection Council

Figure 3: Links between LCMC, QNHC and other State committees with resource management, conservation and environment protection roles

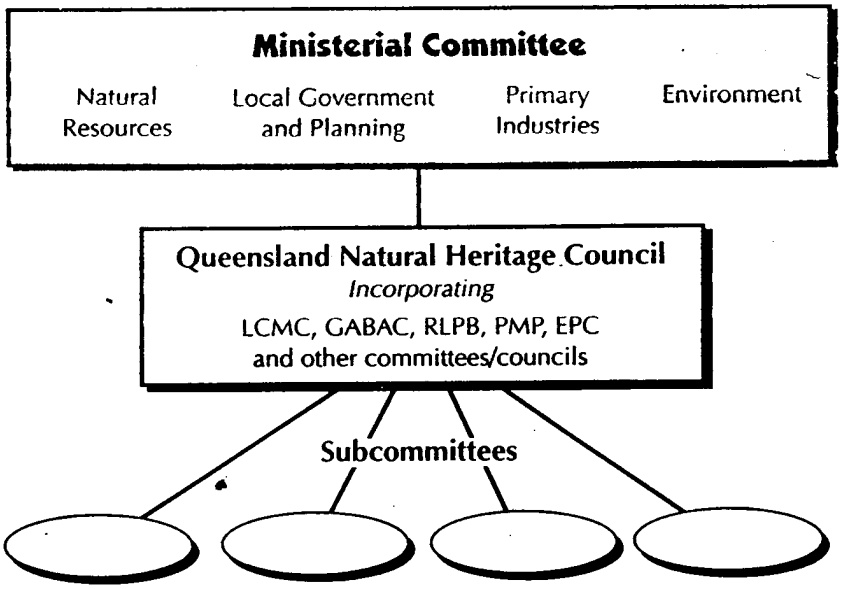


Figure 4: Possible future option for the incorporation of LCMC and other natural resource and environment committees into the QNHC

Conclusion

Following extensive consultation with a range of stakeholders, and considering a range of options as outlined in the Discussion Paper, the Review Committee has concluded that both the existing Queensland Landcare Council and the Catchment Management Coordinating Committee should be merged to form a new Landcare and Catchment Management Council (LCMC) to achieve better integration of landcare and catchment management strategies, priorities and policies at State level.

The new Council should be established as soon as possible after 30 June 1997 and no later than 1 January 1998.

Separate landcare and catchment management groups should be retained at the local level, with better integration and coordination being achieved through the establishment of Regional Resource Management Coordinating Committees and the preparation of integrated resource management strategies.

6.2 Interim Business and Operational Plan January 1998 – June 1998

Landcare and Catchment Management Council

Introduction

The Landcare and Catchment Management Council (LCMC) has produced the *Interim Business Plan and Operational Plan – January 1998 to June 1998,* to inform clients and stakeholders of its membership, structure, responsibilities, objectives and immediate order of business.

The business plan and operational plan are part of the LCMC's internal operations and are the responsibility of the Strategic Planning Committee. The purpose of the plans is to ensure that the LCMC's mission, objectives and specific roles are appropriate and realistic.

This interim version of the business plan will allow for all LCMC committees and working groups to finalise their roles and objectives. The LCMC will produce a final version of the business plan after a review in July.

Business Plan

Mission
The mission of the LCMC is:

To provide community leadership in partnership with government to achieve priority natural resource management, biodiversity conservation and sustainable production outcomes for Queensland.

Purpose
LCMC provides strategic advice to the Minister for Natural Resources on landcare, catchment management and the strategic direction for administration, management, operation, monitoring and evaluation of the Natural Heritage Trust (NHT) in Queensland.

Roles
The roles of the LCMC, as stated in its Terms of Reference are to:

1. Provide advice to the Minister for Natural Resources, either directly or through the Ministerial Resource Management Advisory Council or the Natural Heritage Committee of Ministers, on landcare, catchment management and NHT issues.
2. As part of the advisory role, identify State-wide priorities and develop policies, strategies and guidelines for the implementation of natural resource management, biodiversity conservation and sustainable production at a state and regional level in accordance with the principles of Ecologically Sustainable Development (ESD).
3. Maintain communication and landcare catchment management groups and encourage and support landholders and community groups to carry out landcare and catchment management activities.
4. Develop the framework and provide strategic direction for the operation, management and administration of the NHT in Queensland.
5. Foster co-ordination and integration between government agencies, industry and professional and community organisations, including appropriate national bodies, in resource management and NHT programs.
6. Co-ordinate the implementation of State-wide public awareness and education campaigns aimed at achieving an ethic of sustainable resource management in the community and widespread support for landcare, catchment management and NHT.
7. Co-ordinate development of regional resource management strategies and provide guidelines for their presentation and endorsement; ensuring that they advance and incorporate the implementation of national and state strategies and plans and other relevant regional and state planning studies.
8. Endorse regional boundaries for the efficient management of regional strategy development and project assessment and endorse regional/catchment strategies.
9. Develop guidelines for the membership and endorsement of Regional Strategy Groups (RSG), Regional Assessment Panels (RAP) and the State Assessment Panel (SAP), including the process and principles for selection of State and Regional Assessment Panels.

10. Develop guidelines to ensure open and accountable assessment of project applications by RAP and SAP; and ensure the monitoring, review and evaluation of the funded projects and the effectiveness of NHT Programs in Queensland.

Scope
The LCMC deals with landcare, catchment management and the delivery of the NHT in Queensland. As such, it has a primary focus on the delivery f natural resource management, biodiversity conservation and sustainable production programs in accordance with the principles of ESD.

Responsibilities
The responsibilities of LCMC (derived from the roles) may be regrouped under the areas of planning and advice to government, community leadership, and monitoring, as follows:

Planning and advice to government
- to advise the Minister for Natural Resources on landcare, catchment management and NHT issues
- to identify State-wide priorities and developing policies, strategies and guidelines for the implementation of natural resource management, biodiversity conservation and sustainable production
- to develop the framework and provide strategic direction for the operation, management and administration of the NHT in Queensland.

Community leadership
- to develop guidelines for the membership and endorsement of RSGs, RAPs and the SAP
- to develop guidelines to ensure open and accountable assessment of project applications by RAPs and SAP
- to provide guidelines for the preparation and endorsement of regional/catchment resource management strategies
- to endorse regional/catchment strategies and regional boundaries for the efficient management of regional strategy development and project assessment
- to foster support for landholders and community groups in carrying out landcare and catchment co-ordination activities
- to co-ordinate the implementation of State-wide public awareness and education campaigns
- to foster co-ordination and integration between government agencies, industry and professional and community organisations.

Monitoring
- to monitor, review and evaluate funded projects and the effectiveness of NHT programs in Queensland.

Reporting Relationships
LCMC will have the following reporting requirements:
1) LCMC will hold four meetings per year, one of which will be held immediately after the annual conference of landcare and catchment management groups.
2) LCMC will report to the Minister for Natural Resources after each meeting, and more frequently at the Chair's discretion.
3) LCMC will present an annual report to the Minister and to the annual conference of landcare and catchment management groups.
4) In order to fulfil its NHT roles, LCMC will liaise with RAPs, RSGs and the SAP (which will report to the Natural Heritage Committee of Ministers).

The reporting relationships of the LCMC in its NHT role as shown in Figure 1.

Structure
Membership
LCMC will have an independent chair, deputy chair and 18 members appointed by the Minister for Natural Resources, being:
- two members nominated by the Queensland Conservation Council, one with expertise in marine or in-stream freshwater habitat conservation.
- one member nominated by Greening Australia – Queensland
- three members nominated by the Queensland Farmers' Federation to represent extensive agriculture, intensive agriculture and grazing industries
- one member nominated by fishing interests
- one member nominated by the water industries
- one member nominated by the Local Government Association of Queensland
- four government representatives – one each from the Department of Natural Resources (DNR), Department of Primary Industries, Department of Environment (DoE) and Department of Local Government and Planning (DLGP)
- five community members, one elected from each of the five DNR regions

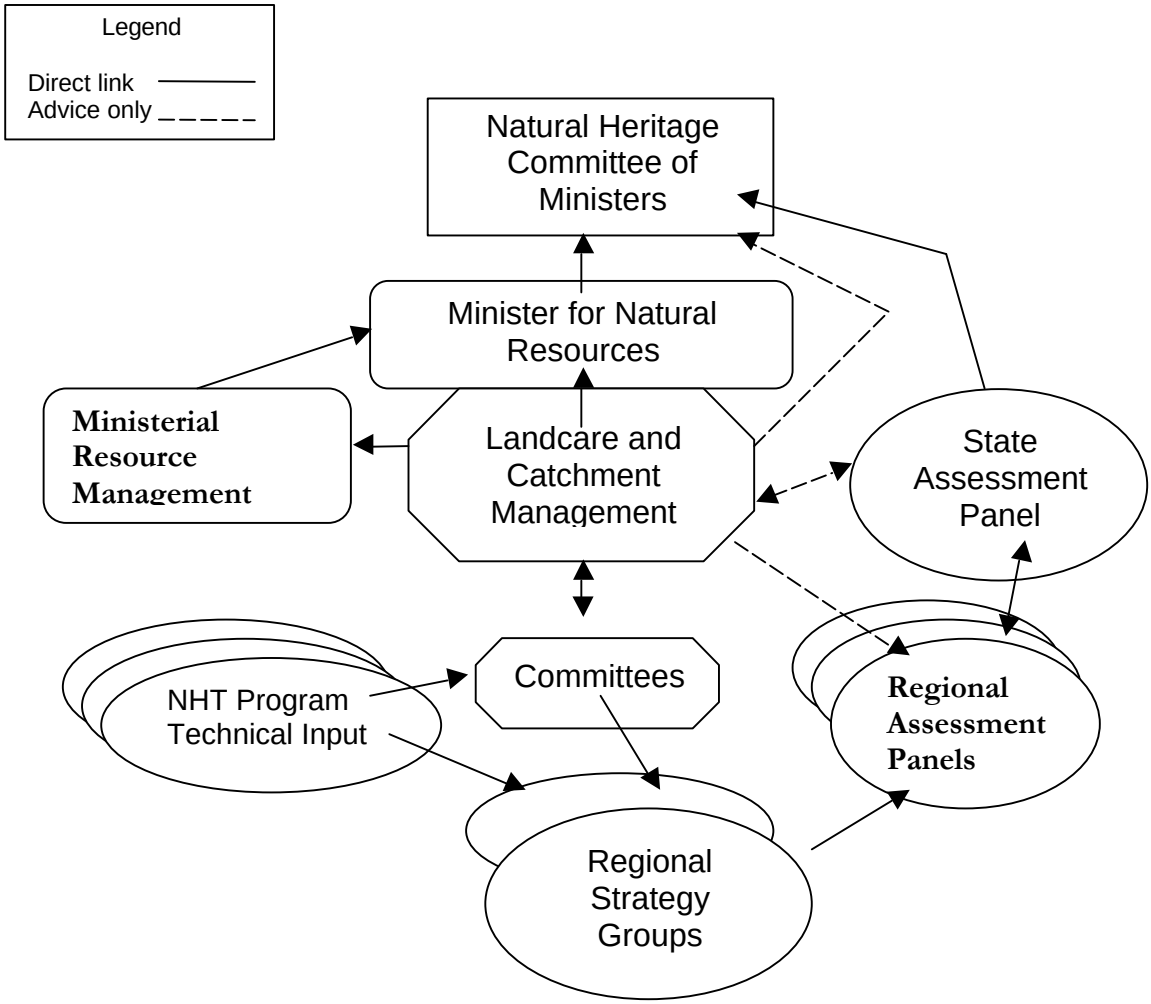

Figure 1. Reporting relationships of the LCMC in its NHT role

Operations
DNR will provide executive support for LCMC.

To reflect its various roles, LCMC has developed a committee structure that has been approved by the Minister for Natural Resources. LCMC committees may form working groups and co-opt expert advisors to progress specific issues.

The Executive Committee, consisting of the chair and deputy chair of LCMC, plus the committee chairs, may progress urgent matters between full LCMC meetings. LCMC committees may formulate policy recommendations for endorsement by LCMC (or in urgent circumstances, the Executive Committee).

Committees
LCMC will have four separate committees:
- Executive Committee
- Promotion and Education Committee
- Implementation Committee
- Strategy and Planning Committee

The structure of LCMC is shown in Figure 2.

Roles and working groups
Each committee will assume responsibility for achieving outcomes against the relevant roles of LCMC.

LCMC has recommended that each committee form working groups that have specific tasks and timelines (sunrise and sunset clause). Working groups are to report to the committees who in turn will make specific recommendations to full council.

Executive Committee

The Executive Committee is responsible for:

1. Dealing with urgent business of council between meetings
2. Carrying out the directions of council between meetings
3. Overseeing the implementation of LCMC policy between meetings.

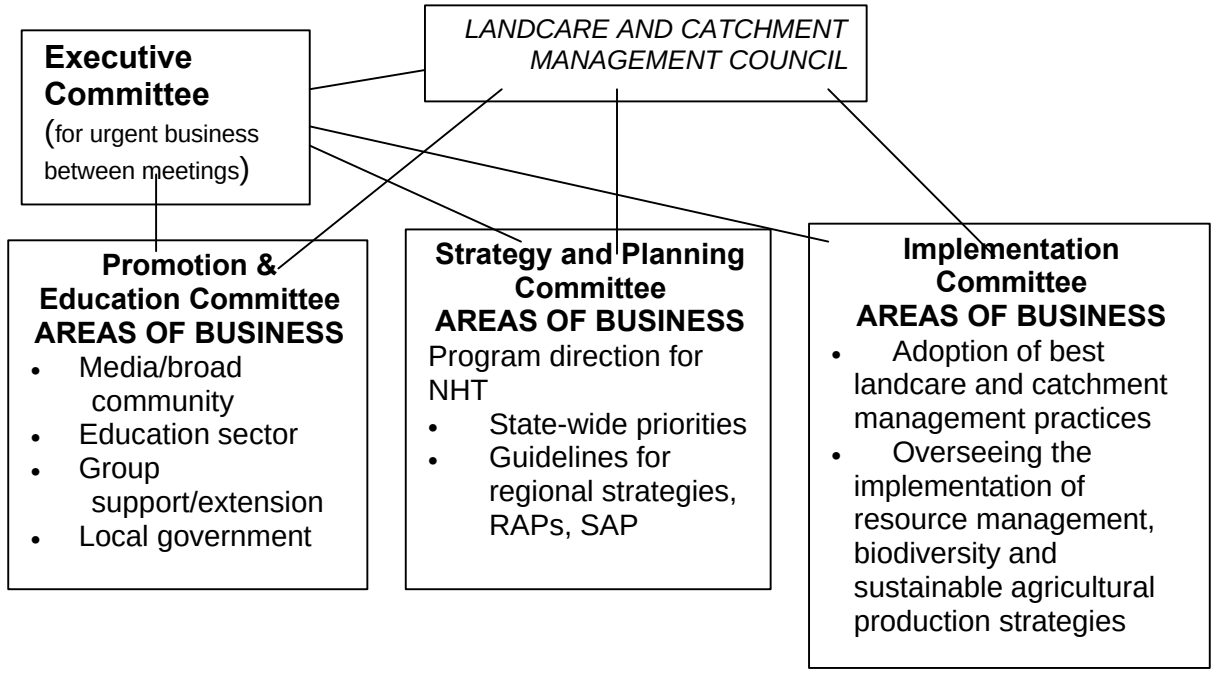

Figure 2. Structure of LCMC

Promotion and Education Committee

The Promotion and Education Committee is responsible for:

1. Maintaining communication with landcare and catchment management groups and encouraging and supporting landholders and community groups to carry out landcare and catchment coordination activities.
2. Fostering c-ordination and integration between government agencies, local government, industry, professional and community organisations, including appropriate national bodies, within resource management and NHT programs
3. Coordinating the implementation of State-wide public awareness and education campaigns for landcare, catchment management and NHT.

This committee will have several working groups including:

- Media/Broad Community Working Group
- Education Sector Working Group
- Community groups/Extension/Rural Industry/ Landholders Working Group
- Local Government Working Group.

Implementation Committee

The Implementation Committee is responsible for:

1. Overseeing the implementation of resource management, biodiversity and sustainable agricultural production outcomes as determined by LCMC by:
   a) liaison with groups and facilitator networks which are implementing resource management, biodiversity and sustainable production outcomes
   b) receiving, identifying and reporting on recommendations from these groups requiring LCMC actions; and ensuring that feedback occurs.

This committee will address a number of issues including:

- performance indicators for measuring progress against the partnership agreement
- reporting framework for LCMC
- internal operations and performance measures for the LCMC.

Strategy and Planning Committee
Taking account of Commonwealth interests, and in the context of the partnership agreement, the Strategy and Planning Committee is responsible for:

1. Setting priorities across the State
2. Reviewing the partnership agreement and recommending changes where necessary
3. Providing strategic advice to the Minister on implementation of national outcomes and state priorities
4. Providing guidelines for SAP/RAP and regional strategies
5. Overviewing and advising on regional arrangements
6. Endorsing regional/catchment strategies that comply with state guidelines

The whole committee is responsible for reviewing the partnership agreement and setting priority directions for the State. This committee will have a number of working groups, including:

- RAP/SAP guidelines and arrangements
- regional strategy guidelines
- catchment/regional strategy endorsement.

Support staff
Each committee will have executive support for organising, coordinating and conducting committee business. The departmental and work group responsible for executive support, or the committee members will provide administrative support. Each working group will have a convenor, who will be responsible for arranging appropriate administrative and executive assistance for the working group.

Executive Committee
The Executive Committee (EC) comprises the Chair of LCMC, Garth Ilett, the chairs (or nominees) of the three committees – Pat Fennell, Jennifer Marohasy and Ken Stallman. The LCMC Chair will chair the EC. DNR Manager (Landcare and Catchment Management) Don Begbie will provide executive support to the EC Chair. The LCMC Executive Assistant, Annette Leadbetter, (Landcare and Catchment Management) will provide administrative assistance to convene meetings, arrange meeting venues and provide minutes. A policy officer will provide policy support.

Promotion and Education Committee
The DNR Manager of the Community Education and Extension Support Group (CEES), Melva Hobson, will provide executive support to the Promotion and Education Committee Chair. CEES, Resource Sciences Centre, Indooroopilly, will provide administrative support.

a) Education Sector Working Group
   DNR Senior Education Officer Paul Hauenschild will provide executive support to the education sector working group convenor. CEES will provide administrative support.
b) Media/Broad Community Working Group
   DNR Senior Extension Officer Alison Moore will provide executive support to the Media/Broad Community Working Group convenor. CEES will provide administrative support.
c) Community Support Working Group
   DNR Acting State Coordinator (Landcare and Catchment Management) John Tadman will provide executive support to the Community Group/Extension/Rural Industry/Landholders Working Group convenor. The Landcare and Catchment Management Group will provide administrative support.

Implementation Committee
DNR Manager (Land Management) Mick Capelin will provide executive support to the Implementation Committee Chair. Land Planning and Management Group, DNR, will provide administrative support.

Strategy and Planning Committee
DNR Manager Don Begbie will provide executive support to the Strategy and Planning Committee Chair. The Landcare and Catchment Management Group will provide administrative support.

a) Strategy Review Working Group
   DNR Manager, Don Begbie, will convene meetings, arrange meeting venues and carry out the necessary endorsement procedures for the Strategy Review Working Group. The Landcare and Catchment Management Group will provide administrative support.
b) Regional Strategy Guidelines Working Group
   DLGP Officer Mike Bradby will convene and supply meeting venues and secretarial staff for minutes, etc., for the Regional Strategy Guidelines Working Group. DNR Manager Don Begbie, with assistance from DoE, will deliver the guidelines and the consultation processes.
c) RAP/SAP Guidelines Working Group

DNR Manager (External Funds) Brian Venz will convene meetings and arrange venues for the RAP/SAP Guidelines Working Group. The External Funds Group, Community Program Development, DNR, will provide administrative support.

Resourcing

LCMC will not employ its own staff. DNR will provide executive and administrative support for LCMC. Other departments will contribute resources to the effective operation of the relevant committees and working parties, principally through the in-kind contribution of personnel for technical and administrative support.

LCMC will prepare a three year business plan and an annual operational plan outlining its objectives and targets (together with timelines and performance measures necessary for reporting). The Minister for Natural Resources will approve the business and operational plans.

DNR will provide financial resources for the operation of LCMC, including executive and administration support for the Executive Committee. DNR and the LCMC Executive Committee will negotiate an annual budget that will be, subject to budget allocation, commensurate with the requirements for the delivery of the agreed business and operational plans of LCMC.

The annual budget will include sitting fees, members' expenses, costs of meetings and the salary and operating funds for executive and administrative staff. A budget of approximately $220,000 has been allocated for LCMC in 1997/98.

Figure 3 presents a model budget.

Statutory Status

The Landcare and Catchment Management Council is an advisory body to the Minister for Natural Resources. It is not recognised or constituted under any current State legislation and therefore does not have a statutory role.

6.3 Landcare and Catchment Management Strategic Plan 1998-2001

Landcare and Catchment Management Council

(Source: The State of Queensland, Department of Natural Resource, 1999)

Mission
To provide community leadership in partnership with government to achieve priority natural resource management, biodiversity conservation and sustainable production outcomes for Queensland.

Vision
By 2001 there will be enhanced natural resource management, biodiversity conservation and sustainable production outcomes being delivered through active partnering at State, regional and local levels between industry, governments, land-holders and the community.

Purpose
LCMC provides strategic advice to the Minister for Environment and Heritage and Minister for Natural Resources on landcare and catchment management issues. It also provides the strategic direction for the administration, management, operation, monitoring and evaluation of the Natural Heritage Trust (NHT) in Queensland.

A whole-of-government approach is achieved through Queensland's Natural Heritage Committee of Ministers for the Natural Heritage Trust. The committee consists of the Minister for Environment and Heritage and Minister for Natural Resources (as the lead minister), the Minister for Communication and Information, Local Government and Planning, and the Minister for Primary Industries.

At the Commonwealth level, ministerial responsibilities for NHT rest with the Minister for Agriculture, Fisheries and Forestry and the Minister for Environment and Heritage.

LCMC deals with landcare, catchment management and the delivery of NHT funding in Queensland. As such, its primary focus is on the delivery of natural resource management, biodiversity conservation and sustainable production programs. These programs are in accordance with the principles of ecologically sustainable development (ESD).

> *By 2001 there will be enhanced natural resource management, biodiversity conservation and sustainable production outcomes being delivered through active partnering at State, regional and local levels between industry, governments, land-holders and the community***.**

Achieving the Vision
LCMC's vision will be achieved through the pursuit of four strategies. Each strategy gives rise to multiple activities. These are as follows.

Strategies for Achieving the Vision

1 Coordinate and foster collaboration across governments, industry, land-holders and the community to achieve enhanced natural resource management, biodiversity conservation and sustainable outcomes.
2 Encourage the development of appropriate natural resource management and biodiversity conservation policies, strategies and plans at the State, regional and local levels and foster industry, government, land-holder and community ownership and commitment to these policies, strategies and plans.
3 Encourage the implementation, monitoring and evaluation of natural resource management, biodiversity and sustainable production strategies and plans across the State.
4 Foster an understanding of and a capacity to participate in natural resource management and biodiversity conservation by governments, industry, land-holders and the community.

The following key objectives are contained within the LCMC Business and Operational Plan

A Improved quality and timeliness of outcomes resulting from a greater cooperation between government, industry and the community.
B The development of strategic plans which demonstrate alignment and integration between State, regional and local activities.
C Outcomes which meet the requirements of funding bodies and the people of Queensland. The result of these outcomes will be increased levels of investment in natural resource management and biodiversity conservation.
D A growing community understanding of the value and benefits of participating in cooperative approaches to natural resource management and biodiversity conservation.

Strategy Overview

STRATEGY 1

Coordinate and foster collaboration across governments, industry, land-holders and the community to achieve enhanced natural resource management, biodiversity conservation and sustainable outcomes.

A clarification of and commitment to the roles of governments, industry, land-holders, community groups and individuals in the development and delivery of natural resource management and biodiversity conservation is critical to the strategy's success. LCMC will achieve this in the following ways.

A Clarify the roles of all levels of government, industry, land-holders and the community through the development of principles for natural resource and biodiversity management.

B Continue to inform industry, governments, land-holders and the community of the opportunities to participate and cooperate in the development and delivery of natural resource management and biodiversity conservation.

C Promote the effective delivery of natural resource management and biodiversity conservation programs at State, regional and local levels.

STRATEGY 2

Encourage the development of appropriate natural resource management and biodiversity conservation strategies and plans at the State, regional and local levels and foster industry, government, land-holder and community ownership and commitment to these policies, strategies and plans.

Understanding the issues, their priorities and how they will be addressed is a critical step in ensuring that commitment to action is developed and that any actions taken will deliver the outcomes required. LCMC will achieve this in the following ways.

A Coordinate the development of a natural resource management and biodiversity conservation framework for the State, forging a partnership between government, industry, land-holders and the community.

B Provide advice to government on industry and community concerns and expectations in relation to natural resource management and biodiversity conservation matters.

C Encourage the development of biogeographic regions and the identification of agreed priority natural resource management and biodiversity conservation issues, including research, which form the basis for operational activity for governments, land-holders and the community.

D Seek to ensure that there are linkages between strategies and plans developed by local, regional and State organisations and that these linkages optimise the efforts of groups involved in their development and implementation.

LCMC's vision will be achieved through the pursuit of four strategies. Each strategy gives rise to multiple activities.

STRATEGY 3

Encourage the implementation, monitoring and evaluation of natural resource management biodiversity and sustainable production strategies and plans across the State.

Attracting a commitment to actions and resources will be facilitated by a sound business approach. Defining the objectives and outcomes should also ensure that a realistic expectation of the results is established by investors and the community. LCMC will achieve this in the following ways.

A Encourage the development of best-practice guidelines for natural resource management and biodiversity conservation.

B Foster the development of a monitoring and evaluation framework that ensures that the results of programs and projects can be measured.

C Actively promote the benefits derived from actions taken and encourage investment and community participation at State, regional and local levels.

D Develop networks with groups involved in natural resource management and biodiversity conservation, and, where appropriate, seek to progress issues on their behalf at State and regional levels.

E Provide the strategic direction for the administration, management, operation, monitoring and evaluation of the NHT in Queensland.

F Influence the direction of research to ensure that natural resource management and biodiversity conservation best management practices are developed.

STRATEGY 4

Foster an understanding of an a capacity to participate in natural resource management and biodiversity conservation by governments, industry, land-holders and the community.

We all need to understand how best to access and manage information. We all need to develop the skills to be able to adequately participate in the planning and implementation of natural resource management and biodiversity conservation initiatives.

LCMC will achieve this in the following ways.

A Make appropriate representation to ensure that quality and timely information is available for stakeholder groups, and ensure that these groups have the necessary skills to make the best use of this material.

B Provide advice to government agencies regarding the need for extension services by community groups.

C Foster a better understanding of natural resource management and biodiversity conservation educational and training needs for the community, land-holders, industry and government agency staff.

D Develop an inventory of groups participating across the State and promote networking between groups.

E Encourage groups to share their experiences, knowledge and practices with each other.

F Contribute to the development of the capacity of industry, government and the community to effectively participate in natural resource management and biodiversity conservation programs.

Roles of LCMC

The roles of LCMC, as stated in its terms of reference, are as follows.

A Identify and influence State-wide priorities and develop policies, strategies and guidelines for the implementation of natural resource management and biodiversity conservation at State and regional levels in accordance with the principles of ESD.

B Maintain communication with landcare and catchment management groups and encourage and support land-holders and community groups to carry out landcare and catchment management activities.

C Oversee the development of the operational framework and provide strategic direction for the operation, management, evaluation and administration of the NHT in Queensland.

D Foster coordination and integration between government agencies, industry and professional and community organisations, including appropriate national bodies, in resource management and NHT programs.

E Coordinate the implementation of State-wide public awareness and education campaigns aimed at achieving an ethic of sustainable resource management and NHT.

F Coordinate the development of regional resource management strategies and provide guidelines for their preparation and endorsement, with the aim of ensuring that they advance and incorporate the implementation of national and State strategies and plans and other relevant regional and State planning studies.

G Endorse regional boundaries for the efficient management of regional strategy development and project assessment and endorse regional/catchment strategies.

H Provide advice to the Minister for Environment and Heritage and Minister for Natural Resources, either directly or through the Natural Heritage Committee of Ministers, on landcare, catchment management and NHT issues.

I Develop guidelines for the membership and endorsement of regional strategy groups (RSGs), regional assessment panels (RAPs) and the State Assessment Panel (SAP), including the process and principles for the selection of State and regional assessment panels.

J Develop guidelines to ensure the open and accountable assessment of project applications by RAPs and SAP, and ensure that processes are in place to effectively monitor, review and evaluate funded projects and the effectiveness of NHT programs in Queensland

LCMC will hold four meetings a year and report to the Minister and State and regional groups.

Reporting Relationships

LCMC will have the following reporting requirements.

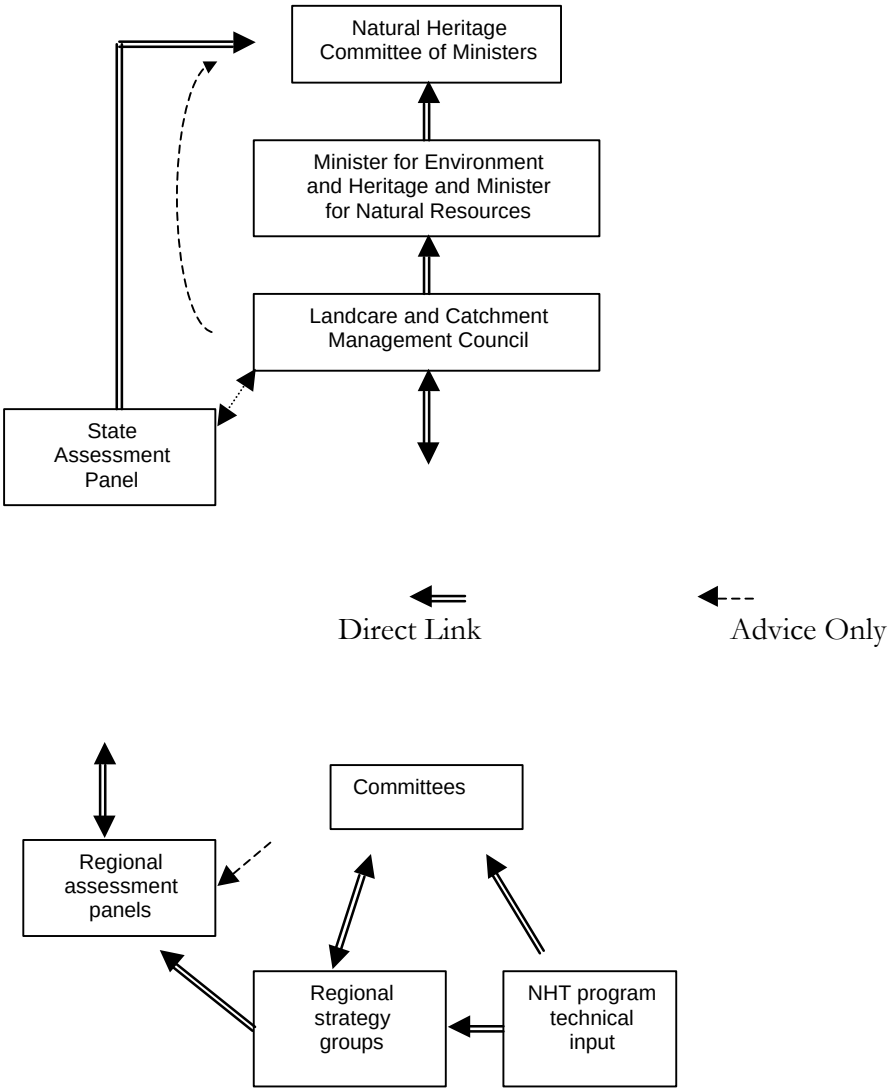
A Hold four meetings per year, one of which will be held immediately after the annual conference of landcare and catchment management groups.

B Report to the Minister for Environment and Heritage and Minister for Natural Resources after each meeting, and more frequently at the chair's discretion. Present an annual report to the Minister and to the annual conference of landcare and catchment management groups.

C In order to fulfil its NHT roles, LCMC will liaise with RAPs, RSGs and SAP (which will report to the Natural Heritage Committee of Ministers).

The reporting relationships of LCMC in its NHT role are shown in figure 1.

FIGURE 1 REPORTING RELATIONSHIPS OF LCMC IN ITS NHT ROLE



Structure

Membership

LCMC will have an independent chair, a deputy chair and 21 members appointed by the Minister for Environment and Heritage and Minister for Natural Resources, being:

- six community members elected from landcare and catchment management groups
- two members nominated by the Queensland Conservation Council, one with expertise in marine or in-stream freshwater habitat conservation
- one member nominated by Greening Australia Queensland
- three members nominated by the Queensland Farmers' Federation to represent the extensive agriculture, intensive agriculture and grazing industries
- one member nominated by fishing interests
- one member nominated by the water industries
- one member nominated by the Local Government Association of Queensland
- one member nominated by the indigenous community
- one member nominated by the Great Barrier Reef Marine Park Authority
- four government representatives - one each from the Department of Natural Resources (DNR), Department of Primary Industries (DPI), Environmental Protection Agency (EPA) and Department of Communication and Information, Local Government and Planning (DCILGP).

Operations

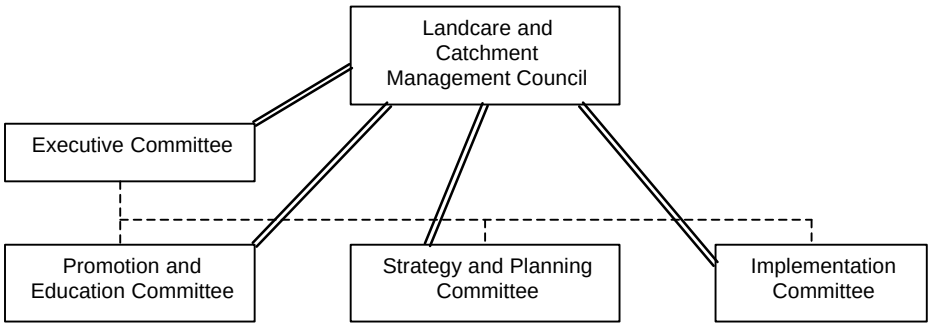
DNR will provide executive support for LCMC. To reflect its various roles, LCMC has developed a committee structure that has been approved by the Minister for Environment and Heritage and Minister for Natural Resources. LCMC committees may form working groups and co-opt expert advisers to progress specific issues.

The Executive Committee, consisting of the chair and deputy chair of LCMC, plus the committee chairs, may progress urgent matters between full LCMC meetings. LCMC committees may formulate policy recommendations for endorsement by LCMC.

Committees
LCMC will have four separate committees:
- Executive Committee
- Promotions and Education Committee
- Implementation Committee
- Strategy and Planning Committee

The structure of LCMC is shown in figure 2

FIGURE 2 STRUCTURE OF LCMC



Roles of Committees and Working Groups

Each committee will assume responsibility for achieving outcomes against the relevant roles of LCMC.

LCMC has recommended that each committee form working groups that have specific tasks and timelines (sunrise and sunset clauses).

Working groups are to report to the committees who, in turn, will make specific recommendations to full Council.

Executive Committee
The Executive Committee is responsible for:
- dealing with urgent business of Council between meetings
- carrying out the directions of Council between meetings
- overseeing the implementation of LCMC policy between meetings
- targeting investors

Promotion and Education Committee
The Promotion and Education Committee is responsible for:
- networking with groups involved in natural resource management, biodiversity conservation and sustainable production
- identifying needs and developing, delivering and promoting education and training in natural resource management, biodiversity conservation and sustainable production to raise community awareness, improve skills and increase the knowledge base
- fostering and promoting cooperation and integration among government, industry, professional and community organisations, including appropriate national bodies, within resource management and NHT programs
- coordinating the implementation of State-wide public awareness and education campaigns for landcare, catchment management and NHT, with links to national activities.

Implementation Committee
The Implementation Committee is responsible for:
- promoting good communications through networking with community groups and facilitator networks
- ensuring the maintenance of a two-way reporting framework which allows LCMC to identify successes and issues, and addressing concerns from community groups and facilitators which LCMC should progress
- ensuring that an effective monitoring and evaluation process is implemented to measure outcomes for reporting to investors and other interested parties
- acting as the Queensland Bushcare Reference Group as part of NHT program management
- identifying and establishing other reference groups to ensure that linkages are in place and progress is being made to meet natural resource and biodiversity outcomes
- providing oversight of and advice on regional arrangements for natural resource and biodiversity management participation and coordination.

Strategy and Planning Committee
Taking account of Commonwealth interests, and in the context of the Partnership Agreement, the Strategy and Planning Committee is responsible for:
- identifying and promoting action on the critical resource management and biodiversity priorities across the State
- reviewing the Partnership Agreement and recommending changes where necessary
- providing strategic advice to the Minister on implementation of national outcomes and State priorities
- providing policy and guidelines for SAP, RAPs and regional strategies
- reviewing regional/catchment and other strategies, and providing advice on alignment between State, regional and local issues and priorities and ensuring compliance with State guidelines
- making available information relating to the array of strategies, in place or under development, and the associated community group contact details.

Support Staff
Each committee will have executive support for organising and coordinating committee business. Support for the various committees will be provided by departmental officers as follows:
- Department of Natural Resources will support the Executive Committee and the Promotion and Education Committee
- Environmental Protection Agency will support the Implementation Committee
- Department of Primary Industries will support the Strategy and Planning Committee

Responsibilities for major tasks identified by committees will be negotiated at task development time. Any working groups established will have a convenor, who will be responsible for arranging appropriate administrative and executive assistance for the working group.

Resourcing
LCMC will not employ its own staff. DNR will provide executive and administrative support for LCMC. Other departments will contribute resources for the effective operation of the relevant committees and working parties, principally through the in-kind contribution or personnel for technical and administrative support.

LCMC will prepare a three-year business plan and an annual operational plan outlining its objectives and targets (together with timelines and performance measures necessary for reporting). The Minister for Environment and Heritage and Minister for Natural Resources will approve the business and operational plans.

DNR will provide financial resources for the operation of LCMC, including executive and administrative support fir the Executive Committee. DNR and the LCMC Executive Committee will negotiate an annual budget that, subject to budget allocation, will be commensurate with the requirements for the delivery of the agreed business and operational plans of LCMC.

The annual budget will include sitting fees, members' expenses, costs of meetings and the salary and operating funds for executive and administrative staff.

Statutory Status
The Landcare and Catchment Management Council is an advisory body to the Minister for Environment and Heritage and Minister for Natural Resources. LCMC is not recognised or constituted under any current State legislation and therefore does not have a statutory role.

7. Regionalisation

There are 13 regions in Queensland that are based on catchments, landscapes and vegetation types. The primary aim of defining the boundaries was to ensure the coverage of all areas in the State in a Regional Strategy and also to minimise duplication of effort from overlapping strategies. However, the boundaries were not intended to restrict local communities from developing a Regional strategy based on common community themes (DNR Queensland, 1998: 21).

The purpose of regional natural resources and biodiversity conservation strategy is to lay out clearly and concisely, the way sustainable management of natural resources and conservation is intended to be achieved in a long term commitment. Regional strategies aim to assist communities in working together to achieve the identified goals. The relationship between the process of the planning and the implementation is important because, experience with implementation contributes back into the planning process, to continually improve the strategies. (DNR Queensland 1998: 9)

7.1 Interim Guidelines for the Development of Natural Resources and Biodiversity Conservation Regional Strategies

Queensland Department of Natural Resources

(Source: Queensland Government Department of Natural Resources. October 1998. Interim Guidelines for the Development of Natural Resources & Biodiversity Conservation Regional Strategies. Department of Natural Resources, Brisbane.)

What is a Regional Strategy:

A Regional strategy consists of a number of sections. The sum of these is a clear unambiguous statement describing a community's vision for the future of the region and the process by which this vision in implemented. A Regional Strategy therefore answers the question "WHAT" does your community want the region to be like in the future and "WHAT" issues need to be addressed to make the vision real. To achieve this requires answers to a number of other questions. These are; "WHICH" issues should be addressed an in what order, "WHERE" are the issues located, "WHEN" should these issues be addressed, "HOW" will your community go about addressing the issues, and "WHO" will do the work.

Before progressing to a description of the steps involved in developing a Regional strategy (later in these guidelines), a distinction needs to be made between the role of a Regional strategy and the roles of regional Business plans and Action plans.

A Regional strategy's role is to provide a long term logical framework for communities to work together and address issues on a regional scale. Regional strategies are not designed to provide detailed day to day answers. These answers are addressed through regional Business plans and Action plans. (p.8)

Regional strategies answer the question "WHAT" through the vision and values statements. It also answers questions 'WHICH", "WHEN" and "HOW" but only in the context of setting long term objectives, priorities and strategies.

Regional Business plans links the long-term view of a Regional strategy with the short term, day to day imperatives of Action plans.

Action plans are the on-ground detailed operating instructions which actually translate the vision into reality.

The implementation, and the monitoring and evaluation sections of the strategy ensure that the Regional strategy, the Business plans and Action plans achieve what the community first set out to do – that is to change its vision into on-ground results. The monitoring and evaluation process is especially important as it allows the community to review the validity of the vision in light of current events and the progress made towards its fulfilment.

Why Develop a Regional Strategy:

Environmental and natural resource management is complex and developing more sustainable ways of managing our land, native vegetation and biodiversity takes a long-term commitment. Because of the long-term commitment required it is worthwhile spending time laying out in a clear and precise way, how we intend to achieve the sustainable management of the natural resources and biodiversity conservation. A Regional natural resources and biodiversity conservation strategy fills this role.

Good strategic plan is as much about the process of planning as it is about producing a document. A strategy should assist a community to work together to achieve goals. The relationship between planning and implementation is important, as experiences gained through on-ground activities can contribute to the continual process of improving the strategy.

It should also be kept in mind that if your RSG wishes to seek NHT funding support it is in its best interest to see that it operates in accordance with the guidelines developed by the LCMC and that its membership meets the requirements of the LCMC.

A well-developed strategy will:

- ensure public investment is directed to the highest priorities in your region, based on the knowledge and experience of local land managers and community interests (p9)
- create the potential to save money by reducing wasteful duplication and avoid counter productive actions;

- ensure all the issues related to sustainable natural resource management, biodiversity and environmental protection are addressed through a coordinated effort; and
- inform others in the community about activities in their area so that they can tailor their efforts to contribute to an overall improvement in the local environment.

A properly thought out Regional strategy should expose and help to resolve the tensions and options for trade-offs between short and long term objectives. For example, the tensions that exist between short term "one off" financial returns and long term ecological sustainability.

A Regional strategy should assist all stakeholders in your region to identify the importance of natural resources, including environmental, economic and social values, and help them work out how best to manage these resources for the long-term benefit of everyone.

All projects submitted for funding under the NHT will be considered on their individual merit. However, where projects submitted for funding have clear linkages to a Regional strategy these projects will be given a high priority and are more likely to receive funding. Communities which have not yet commenced or completed a Regional strategy, will still be able to receive funding for high priority community projects but in the future funding will be increasingly directed towards implementing agreed regional strategies. (p.10)

Endorsement of Regional Strategies:

Regional strategies will be endorsed by the Natural Heritage Committee of Ministers (NHCM) on the recommendation of the LCMC. This process is usually undertaken by a RSG for the purpose of applying for NHT and other public investment. Regional strategies are subject to criteria for endorsement (p.13).

Who Develops the Regional Strategy:

Developing an effective Regional strategy involves the participation and endorsement of as wide a cross section of your community as possible. This process is designed to draw out and reconcile your community's many and sometimes conflicting needs and expectations. To achieve the development of an effective strategy may require the establishment of a dedicated working group. If an organisation already exists in your region, having State government endorsement and wide community support, and having the capacity to fulfil the requirements of the RSG it may be convenient to use this body.

An effective strategy that will receive formal NHCM endorsement through LCMC, must be produced by people with skills and experience covering:

- environmental protection (including biodiversity conservation), (p.14)
- sustainable agriculture,
- natural resource management,
- the management of land, water, marine, vegetation, mining and indigenous land management

A RSG may consist of representatives from key groups in the community, such as;

- primary and secondary industries and business and commerce groups;
- conservation groups,
- indigenous groups,
- indigenous groups,
- tourism and recreational industries,
- local governments,
- senior representatives, such as Regional Managers or Regional Service Directors from relevant government departments including Department of Natural Resources and Environmental Protection Agency
- Regional Organisation of Councils (ROC), Regional Economic Development Organisation (REDO) and Regional Framework for Growth Management (RFGM) (p.15)

The Role of the Regional Strategy Group:

Once established the role of the RSGS is to:

- Develop a Regional Strategy within the framework of State and national strategies and in accordance with State guidelines
- Identify issues and potential issues and prioritise these issues, within the region
- Coordinate the implementation of these Action plans
- Commission projects, where necessary, to meet the requirements of the priority issues

- Monitor and report on the implementation of Regional strategy Action plans
- Provide the relevant Regional Assessment Panel (RAP) with information regarding local projects (p.16)

Figure 4 – Links between Strategy Types & Area of Coverage
Figure 4 illustrates how a Regional Strategy forms part of the continuous planning process being applied to natural resource management and environmental protection. It lies between individual resource planning carried out on a local scale and multi-national agreement between governments.

Figure 5 – The Six Components of a Regional Strategy
The components of a Regional strategy assists in clearly addressing the criteria for endorsement. This is not the only model capable of producing an acceptable result. Another approach that may be preferred in the RSG is the 'Pressure State Response' model utilised in the State of the Environment Reports.

8. Local Government

Local Governments play a fundamental role in ICM in Queensland (AACM & CWPR, 1995: 37). Their role is vital in the administration, coordination and implementation of natural resource management as a whole, as they have significant control and influence over planning and development activity and respond to social and economic change (DNR, 1996: 1). Additionally, the local authorities are responsible for the delivery of water and sewage service to urban areas, which confirms the local authorities' vested interest in water quality of delivery and discharge of the reticulation system.

However, the boundaries of local government areas and river catchments seldom correspond. River catchment boundaries are sometimes totally within a local government area and others extend over several local government areas for example the Condamine River Catchment. To ensure the success of ICM, the involvement and cooperation of local governments and the integration of local government activities is essential (DNR, 1996: 1). An example of cooperation of local governments is through the wide support of Landcare groups across many areas of Queensland (AACM & CWPR, 1995; 37).

Furthermore, the advancement of ICM in Queensland will be protected by the commitment of local governments to recognise and support the State's interests by cooperative action between mutually interested governments on matters of consequence to both governments (DPI, 1992: s5.3.3).

8.1 The Local Government and Integrated Catchment Management Communication Plan

Executive Summary

Catchment Management Unit, Department of Natural Resources

(Source: The State of Queensland, Department of Natural Resources. 1996. *The Local Government and Integrated Catchment Management Communication Plan. A Strategy for Greater Understanding and Involvement*. Brisbane. pp. vii-ix)

The Integrated Catchment Management (ICM) Strategy is a Queensland Government initiative which integrates the management of land, water, vegetation and biological resources of catchments. Through ICM, community, industry and government work together to develop and implement strategies for the better management of river catchments. The Department of Natural Resources (DNR) coordinates the ICM Strategy.

A state-wide committee of representatives from industry, government and the community oversees the implementation of the ICM Strategy. The Catchment Management Coordinating Committee reports directly to the Minister for Natural Resources. The Catchment Management Unit in DNR assists the CMCC in developing ICM guidelines and policies.

Local governments play a vital role in the administration, coordination and implementation of natural resource management planning. Because local governments influence local development and respond to social and economic change, they are key players in the success of ICM.

The Awareness and Education Sub-committee of the CMCC initiated a project to increase local government awareness and understanding of ICM. This project ran for 18 months and was jointly coordinated by the CMCC and the Local Government Association of Queensland and jointly funded by the Queensland Government and the National Landcare Program. The project, entitled 'Increasing local government understanding and involvement in ICM' determined the level of local government officers' awareness and understanding of ICM. Local government staff were surveyed in 1994. The survey results highlighted that a Communication Plan should increase the level of understanding of ICM concepts and provide 'best practice' information for local government officers to solve 'real life' catchment problems. The information gathered in the survey also provided the basis to evaluate improvements or changes in ICM awareness and understanding. One outcome of the project and its survey is this Communication Plan.

The Communication Plan identifies five important target audiences:

- planners
- engineers
- councillors
- chief executive officers
- the community.

The information needs of each of these target audiences have been addressed with a series of objectives. Using these objectives, 11 strategies were developed to address particular issues for each target audience.

The 11 strategies have been grouped according to the priority assigned to each by the CMCC. The three levels of priority are urgent, high and moderate.

The following table summarises the audiences, strategies and priorities of the Communication Plan.

Organisations may use the Communication Plan as a guide to undertake projects which support ICM objectives. Projects designed according to the recommended actions of the Plan's strategies will be supported by the CMCC, e.g. funding applications are more likely to be endorsed.

Many of the strategies will be conducted state-wide, using a key project officer to coordinate the actions across Queensland. In some cases, strategies may be run simultaneously across the State, using a different project officer for each regional area. In other cases, a strategy may be conducted in a single region, or even in a single catchment area.

Audience	Strategy
Planners	Planning and Development Assessment from an ICM Perspective *** ICM in Tertiary Education ** Increasing Awareness of Catchment Issues **
Engineers	Engineering Better Catchments *** ICM in Tertiary Education ** Increasing Awareness of Catchment Issues **
Councillors	ICM Saves Money *** ICM Presentations at District LGAQ Meetings ** ICM Workshop for Councillors ** ICM Awareness for New Councillors *** Communities and Councillors – Building Bridges * Targeting Local Government Forums *
Chief executive officers	ICM Saves Money *** ICM Presentations at District LGAQ Meetings ** Targeting Local Government Forums *
Community Groups	Communities and Councillors – Building Bridges * Community Networking *

Key: *** Urgent Priority Strategy ** High Priority Strategy * Moderate Priority Strategy

The Communication Plan shows local governments the 'how' as well as the 'why' of integrated catchment management.

It provides clear direction, coordination and implementation of future work with local governments. The Plan will be reviewed and updated very two to three years to ensure its strategies, actions and directions are still relevant to the changing local government situation.

8.2 Integrated Catchment Management and Local Government Information Bulletin of the ICM and Local Government Planning Schemes Project - No. 3 January 1991

Queensland Department of Natural Resources
Queensland Department of Communication and Information, Local Government and Planning
Local Government Association of Queensland
Landcare Queensland

Partners in Catchment Planning

This is the third information bulletin regarding the Natural Heritage Trust project titled 'Incorporating Integrated Catchment Management into Local Government Planning Schemes'. The aim of the project is to demonstrate how councils and catchment committees can successfully work together to identify catchment issues and implement planning solutions through local government planning schemes.

The NHT project in stages
There are three principal stages to the project
1. conduct and evaluation of four case studies in Queensland
2. preparation of a set of 'good practice' guidelines for councils and catchment committees
3. conduct of a training and education program for catchment committees, councils and other relevant organisations.

Stage 1 completed
All four case studies were completed during 1998. Representatives of the participating councils and catchment committees formed reference groups and:
- agreed on a catchment issue to address through the planning scheme
- developed the issue through workshops to assess current information
- contracted a consultant to provide a report on the range of planning options
- selected the preferred planning option
- presented the final report to Council for endorsement in principle
- monitored the public review process
- evaluated the success of the case study as a model to solve catchment issues.

Key findings from each case study
The following synopsis of each case study highlights some of the key findings identified in the respective ecological and planning reports.

Four River Case Study
The Bulloo ICM Reference Group's case study objective was to incorporate aspects of the management of intensive agricultural development within the catchments of the Bulloo, Paroo and Wilson rivers and Coopers Creek into the Bulloo Shire Planning Scheme.

The reference group established that the future land use management for the region:
- is contingent on the well-being and economic soundness of the Bulloo community
- ensures future development does not prejudice the continued natural/organic beef production industry
- seeks guarantees that water allocation from the river systems and the great artesian Basin will not impact upon the sustainability of these natural systems
- fosters a responsible tourism industry, with emphases on education and awareness of the region's values.

The ecological report found pressures on the environment needing future action were:
- over-grazing on native pastures
- visitor impact on popular camping sites
- exploitation of native fish
- uncontrolled flows from the Great Artesian Basin due to uncapped bores
- the need for additional input by the local community to regional development.

The Cooper Creek, Wilson and Bulloo rivers are generally in their natural state and contain only native fish species. The report identifies how cooperation action is successfully addressing contemporary issues such as pest management, the capping of bores and the establishment of water reticulation systems for grazing animals.

The amendments to the Bulloo Shire Planning Scheme are derived from the planning report. They are approved by Council and endorsed by the community and are presented in three parts:

- rural land management
- development requirements
- rural planning strategy

The scheme identifies grazing activities as 'of right'. All other rural activities are identified as intensive agriculture and require council consent. The planning amendments include new criteria for Council to assess future development applications and were approved in October 1998.

'The outcomes of the case study will significantly contribute to conserving the natural resources of this unique part of Australia,' said Scott Fraser, Mayor of Bulloo Shire council.

Condamine River Case Study

The case study objective was to incorporate aspects of the management of the riparian zone and flood plains of the upper Condamine River catchment into the Warwick Shire Planning Scheme.

The Warwick ICM Reference Group resolved that the priority issues to be investigated in terms of how they may be addressed in the planning scheme were:

- providing for a healthy stream and riverine ecosystem
- improving the water quality in watercourses in the upper catchment
- enhancing the physical and biological values of the riparian zone, flood plains and watercourses
- improving the biodiversity of riparian and flood plain fauna and flora
- integrating flood mitigation controls

A healthy Condamine River catchment is important because it is also the headwaters of the Murray-Darling Basin. The ecological report identified the following pressures upon the Condamine River:

- flood plain development
- requests for increases in water extraction
- poor management of stock access to watercourses
- stormwater run-off from urban areas and intensive husbandry sites.

The State of the Rivers report for the upper Condamine catchment (DNR, 1995) concluded that the overall condition of the river was good along 13%, moderate along 43%, poor along 41% and very poor along 3% of the river. Initiatives to address the pressures include:

- a water allocation management plan, using a whole-of-catchment approach
- Warwick Shire Council's environment management plan for waste including water, oil, packaging and refuse.

The planning report included planning provisions that are consistent with the *Integrated Planning Act 1997*. Five ICM-related desired environmental outcomes were prepared, each with performance indicators and measures to achieve the required success. These planning provisions provided the foundation for one of the four parts of the new Warwick Shire Council Planning Scheme.

The Warwick Planning Scheme will be available for public review from March to May 1999. 'The work undertaken in the Warwick case study will greatly assist in maintaining the integrity of the riparian area long the Condamine River', commented John Hasted, Executive Director of Eastern Downs Regional Organisation of Councils.

Herbert River Catchment Case Study

The Hinchinbrook ICM Reference Group sought to incorporate elements of the management of wetlands, riparian land and drainage systems within the Herbert River catchment, into the Hinchinbrook Shire Planning Scheme.

The reference group agreed that successful land use planning is a marriage between the conservation of locally important natural resources and the sustainable development of cane growing for the local economy.

The ecological report found that the shire is rich in natural fauna, but that many of the species are under pressure attributed to a range of human activities and natural phenomena. Findings include:

- 56 species of native animals, 13 of high conservation interest
- 47 resident species of water birds and 17 species of migratory birds, 24 under some level of threat
- 43 species of fish in the fish habitat areas, but declining diversity further up the flood plain.

The case study ecological report mapped the locally important wetland and riparian areas. The vegetation was mapped as being 'intact' or 'disturbed' or 'regrowth'.

The planning report provided a series of amendments to the Hinchinbrook Shire Strategic Plan and Planning Scheme. The effect of the amendments will mean that where a landowner intends to use land for intensive agriculture and where part or all of the land suitable for cane growing is considered Class 4 or 5, contains known wetland, fish habitat or abuts a fish habitat, is in an active coastal area, is below 3 m AHD, is a Wet Tropics area, or a known mahogany glider habitat, then a town planning impact assessment application and approval is required from the Hinchinbrook Shire Council.

The amendments were endorsed by the Hinchinbrook community in January 1999. The Mayor of Hinchinbrook Shire Council, Pino Giandomenico, said 'We are committed to ensuring there is a sustainable sugar industry for future generations in our shire. The outcomes of the case study contribute to this vision.'

Noosa River Catchment Case Study
The Noosa ICM Reference Group's case study aim was to incorporate planning solutions for the management of riparian lands within Noosa River catchment into the Noosa Shire Planning Scheme.

The ecological report identified that the pressures upon the riparian lands were attributed to increasing residential, industrial and agricultural activities in the shire, as well as some poor development practices which resulted in:

- increased sediment, nutrient and pesticide levels via stormwater run-off
- clearing of riparian vegetation, drainage of wetlands and building on flood plains.

A supplementary report by Noosa Landcare Group established the condition of riparian lands for each of the six sub-catchments:

- water quality – very good along all six sub-catchments
- bed and bank stability – moderate along Kin Kin and Noosa rivers, good along Lake Doonella and lower Noosa River, very good along Lake Cootharaba and Lake Cooribah catchments.
- riparian vegetation – very poor along Kin King Creek and lower Noosa River, poor along Noosa River and Lake Doonella, good along Lake Cooribah, and very good along Lake Cootharaba.

The planning report provided a range of complementary statutory and voluntary measures to address new development within the riparian lands of the shire. From a planning perspective the approach provides flexibility for Council by setting both general and specific objectives in place within the Noosa Shire Strategic Plan and Planning Scheme.

Noosa Shire Council commences stakeholder meetings in March 1999, prior to the public review in mid 1999. 'The case study successfully explored the mechanisms available to the Catchment Committee and Noosa Council, for addressing catchment issues through the planning process. The conclusions were excellent in adding value to the knowledge base of the Noosa River Coordinating Committee, in our endeavour to implement natural resource management in the region,' observed Colin Haste, Chair of the Noosa River Catchment Coordinating Committee.

Case study profiles
A profile has been prepared for each of the four case studies. The eight-page booklet is being published with the assistance of the Department of Natural Resources' Scientific Publishing Unit. The profiles will assist as an educational tool for the project's training program in June 1999. The profiles examine:

- the common ground between councils and catchment committees
- the character of each shire
- the important catchment issues
- the activities of each reference group
- the state of each catchment environment
- the community-endorsed planning solutions
- the agenda for further action

Monitoring and evaluation
Members of each reference group were asked to respond to a questionnaire to assist the Project Steering Committee in evaluating the four case studies.

The questions focused on the activities of the reference groups, their professional development and the achievements derived from the case studies.

There was a fifty per cent response rate to the questionnaire (i.e. 16 of the 32 members from the four reference groups responded to the survey).

Table 1 summarises the responses to the first four questions.

Table 1: Reference group responses to questions regarding the case study process and outcomes

Questions	Response options (a to e)	(a) needs significant improvement	(b) needs some improvement	(c) provides satisfactory outcomes	(d) was above average standard	(e) was of a very high standard	total responses
1. In terms of understanding the catchment issues selected, the case study process:		0	0	6	6	4	16
2. In terms of securing cooperation and agreement between councils and catchment committee, the case study process		0	2	7	4	3	16
3. In regard to the ecological report, planning report and mapping products, does the content support the planning solutions?		0	0	6	8	2	16
4. Are the issues and outcomes sufficiently informative to support the consultation process within the community, industry and government agencies?		0	0	9	6	1	16

Stage 2 – Good practice guidelines

Good practice planning guidelines based on the findings of the case studies will be published by the Department of Communication and Information, Local Government and Planning (DCILGP) around May 1999, and will include:

- guidelines on addressing ICM issues within planning schemes across Queensland
- a package of actual planning solutions for consideration by councils.

The good practice planning guidelines will be consistent with the Integrated Planning Act and will be available on the DCILGP Internet site. The guidelines will also be used as technical content in the proposed training and education program.

Stage 3 – Conduct of a training and education program

Reference group members have assisted the Project Steering Committee in determining the scope of the training and education program, which will be conducted throughout Queensland.

A training package will be developed by the Local Government Association of Queensland (LGAQ). The package itself will be designed for different audiences and their requirements. The range may vary from a short (30 minute) education and awareness presentation for specific audiences to a half-day workshop format. The training and education program will commence around June 1999 and conclude in November 1999.

Abstract
In 1990, the Queensland Government initiated an Integrated Catchment Management (ICM) program in response to community concerns about the sustainability of the states' natural resources. This paper outlines the characteristics of this new policy approach and reviews the progress of ICM implementation in the Johnstone River catchment (JRC) on the wet tropical coast (WTC) of Queensland. Conceptual and process aspects of ICM are detailed and the technical, economic and institutional environment in which ICM operates in the JRC are discussed. Mechanisms are presented to facilitate the implementation of the institutional and individual change required to translate the ICM philosophy and its associated planning activities into meaningful outcomes for stakeholders.

ACKNOWLEDGEMENTS

The authors wish to acknowledge the financial support of the Land and Water Resources Research and Development Corporation, which made this research possible.

The authors wish to express their extreme gratitude to all those people with have an interest or who are actively involved in the implementation of Integrated Catchment Management in Queensland and who gave time from their busy schedules to complete interviews or questionnaire survey forms that were fundamental to the success of many project activities. Of special note are the following people and agencies who willingly co-operated and provided valuable assistance to this five-year research project:

- The members of the Herbert River Catchment Coordinating Committee who actively participated and contributed their valuable time, views and knowledge.
- Dave Horsley, CSR Herbert River Mills, who was an invaluable source of information on natural resource management and related activities in the Herbert River catchment, provided substantial advice to the researchers and contributed actively to many of the research activities of this project.
- The Herbert River Catchment Coordinators, Rob Hunt and subsequently Andrew Petroeschevsky, who provided valuable comment and information as well as facilitating interactions with HRCCC members.
- Ray Quabba, Chair of the HRCCC, who gave his time, knowledge, invaluable assistance and encouragement to the researchers over the life of the project.
- Philip Rowland, Mike Merrin and Don Begbie, Department of Natural Resources, Queensland who have actively supported the project since its commencement and provided valuable assistance and access to information to the researchers involved.
- Luis Laredo, CSIRO Tropical Agriculture, Brisbane, who has provided valuable general computing assistance to the researchers involved and contributed actively to database development and management for some key research activities.
- Kathy Mitchell and Leesa Austin, CSIRO Tropical Agriculture Brisbane for invaluable assistance in the preparation of this publication.

INTRODUCTION

Until recently, local government had a limited role in land use planning in rural areas and in the management of natural resources generally. Local government planning schemes applied mostly to urban areas and to the expansion of urban related uses into rural areas. Local government has always been a significant provider of rural roads and a key player in localised resource management matters such as drainage and water resources. But the development and management of rural natural resources for agriculture, forestry and other uses and the protection of environmental quality and nature conservation has been historically a state agency matter in Australia.

Local government in recent years is playing a much more significant role in this due to:

- the Integrated Planning Act and IDAS which increasingly give local governments the role of development manager
- delegation under state legislation such as the Environmental Protection Act and the Nature Conservation Act
- emergence of local community based programs such as Integrated Catchment (ICM) and Local Agenda 21 programs
- increased commitment to integrated resources management

The scope of local planning schemes in relation to rural areas is changing in quite fundamental ways - giving local government the opportunity and responsibility for resource management to an unprecedented level. The prospect is that local government could become the dominant force in managing local resources for example vegetation management on private lands, water use and waste water emissions, wetlands and coastal management within parameters set at other levels of government. Local government plans will thus be dealing with a wider range of activities than ever before including a direct relationship with agriculture.

Recent progress in the Herbert River basin, administered by two local governments, Hinchinbrook and Herberton Shires provides a good case study of the evolution of the role of local government in natural resources management. This paper is particularly concerned with the lower Herbert and the role of the Hinchinbrook planning scheme in relation to natural resources management. This area, largely the alluvial floodplain of the Herbert River, is one of the most intensively cultivated districts in the state, being a highly significant sugar producing region which produces approximately 20% of Australia's sugar. It has a set of chronic but not acute resource management issues, most important being those associated with water management, flooding, drainage, river system quality as well as nature conservation for remnant terrestrial habitat and wetlands.

Land use and resource management in the area is influenced, managed and controlled by a complex web of natural resource management programs most important of which are the caneland development and assignments process, Crown land administration and development (including subdivision and sale, forest and other reserve management), nature conservation including World Heritage National Parks, habitat conservation), Drainage Board, Hinchinbrook Shire infrastructure and town planning among others.

A Catchment Coordinating Committee was established in 1994 under the Queensland ICM program. Its activities and development are the prime focus of the project.

The research presented here is part of a five-year project in the CSIRO Division of Tropical Agriculture with cooperation from the Department of Natural Resources, Hinchinbrook Shire Council, the CSR and others. Funded by the (Commonwealth) Land and Water Resources

R&D Corporation. Recently this project has worked in cooperation with an NLP project in the Department of Local Government and Planing which is investigating the use of town planning in natural resource management in a number of rural local governments in Queensland.

The Natural Resources of the Herbert River Catchment

The Herbert River catchment drains an area of approximately 10,000 sq km of the wet tropical coast of far north Queensland with its major river outlet flowing into the extensive mangrove areas of the Hinchinbrook channel (Figure 1). The catchment has a dominantly summer rainfall with approximately 75% on average falling between December and March. The lower catchment encompasses the shire of Hinchinbrook and the upper catchment area the shire of Herberton. The population in 1993 was estimated at approximately 18,000 people with 75% living in the lower catchment. The catchment has a rural economy based dominantly on primary production (ie. sugar, beef cattle, forestry), but given its proximity to the wet tropical coast including the Great Barrier Reef Marine Park fishing and recreational activities are also important contributors to the local economy.

The catchment comprises three separate environments: the tablelands, the central ranges, and the coastal lowlands, which are each described briefly below.

The Tablelands: encompass the upper catchment of approximately 6000 sq km. It includes the driest parts of the catchment with annual rainfalls ranging from 750 mm per annum in the west to 3,000 mm towards the coastal ranges in the east. Land use is dominated by extensive grazing on native pastures, with some fodder cropping, small pockets of dairying and horticulture in the north, and a number of operational and abandoned tin mines. Land tenure is mostly leasehold or Crown land and some areas of freehold.

Central Ranges: encompass the rugged high rainfall areas with 1500 to 3000 mm of rainfall per annum that separate the upper and lower catchment, and surround the tablelands areas in the north and east and the coastal lowlands in the north and south. They are mostly protected areas such as the World Heritage Area, National Parks and State Forest Reserves.

Coastal Lowlands: comprise an active river delta with relatively fertile alluvial soils which have been extensively cleared and developed for intensive crop production (dominantly sugarcane) and some more limited areas of improved pasture for cattle. Rainfall in the coastal lowlands varies widely ranging from an average of 1500 to 2200 mm per annum. This area is subject to regular inundation by flooding with major flooding occurring on average every 3.5 years and minor flooding almost every 2 years.

Sugarcane production which is confined to the lower Herbert coastal plain is expanding its area under production at about 7% per annum. Currently approximately 75,000 ha of land is cultivated to supply the two mills in the region (Victoria and Macknade). Only about 5,500 ha of this area is licensed to be irrigated from surface supplies. The rapid expansion of sugarcane in recent years has largely occurred on the more marginal lands for production, that is on poorly drained coastal wetlands, and previous grazing lands.

Natural Resources Management Issues in the Herbert River Valley

At the commencement of European settlement in the late 1800s, the Herbert catchment was heavily timbered with extensive freshwater wetlands in the coastal lowlands. The catchment has since undergone significant modifications with nearly 40% of the coastal lowlands cleared for crop production or improved pastures, and clearing of rainforest and open woodlands for

extensive cattle grazing and some small areas of cropping in the tablelands (Johnson and Murray 1997).

Concern over flooding has been a community issue in the lower catchment since the 1880s. However flood mitigation works and the development of uncoordinated drainage systems have been the cause of considerable community conflict. Since the 1970s, there have been a number of major studies commissioned by the Herbert River Improvement Trust (HRIT) and the Hinchinbrook Shire Council in collaboration with state government agencies that have examined water management related issues with respect to flooding management, rural drainage planning, and stream management planning (eg. Gutteridge Haskins and Davey 1976a , 1976b; Cameron McNamara 1980, 1984; and Ian Drummond and Associates 1993).

Table 1 summarises the natural resource management issues identified in some of these reports and also by community members and other industry and government stakeholders at a workshop held in 1995 (Bellamy *et al.,* 1995*).* This shows that perspectives on catchment issues now encompass a broader range of issues including concerns for impacts on tourism and recreation, wildlife and habitat management, riparian zone management, and water quality, and calls for greater community involvement in decision-making. Most significantly at the 1995 workshop (Bellamy *et al.,* 1995), the lack of long term planning of water management and rural land development was identified across several participant groups as a major issue needing to be addressed.

Perceived impacts of these natural resource management issues have evolved from an initial focus on productivity and infrastructure impacts to encompass loss of alternative use opportunities and environmental and ecological factors. Perceptions of the key mechanisms for resolution have also evolved from an initial focus on "engineering based" approaches to include policy incentives and legislative controls or individual action. The key mechanisms for a more integrated planning approach to resource management and land development were seen as an effective ICM process with the support of state government to foster cooperation, the development of industry codes of practice, and the use local government planning and development controls.

Layers of Resource Management

Table 2 details the current resource management legislative and administrative framework within which the sugar industry operates. It reflects the maze of state agencies and their often conflicting statutory responsibilities. This complex arrangement combined with high expectations from the "public" for effective involvement in decision making suggests that the sugar industry will have to respond to, and indeed lead, the implementation of ecological sustainable development in cane areas.

ESD principles, to some extent, have been recognised and incorporated into the areas of the industry's operations. The environmental audit of the sugar industry sponsored by Canegrowers demonstrates a general concern for the environment. At a local level, many cane assignment boards have established a number of conditions on new assignments. While this trend is encouraging, effective establishment and implementation of assignment conditions relies on adequate information about the natural environment (eg hydrology, land suitability, flora and fauna). Without adequate information, local boards are unable to systematically determine the desirability and feasibility of assigning land for cane growing. Similarly, current arrangements do not allow for the adequate monitoring of either adherence to assignment conditions or the impact of conditions on the natural environment.

At the farm level, ESD principles have been recognised with the use of Property Management Plans (PMPs). The development and implementation of PMPs is one voluntary method that can play key role in minimising environmental degradation (Queensland Landcare Council, 1991). Supported by Landcare and ICM groups, PMPs can be developed with a high level of owner involvement. Hence, PMPs provide another facility by which cane growers can more actively participate in farm management planning with the assistance of government officials. While PMP is receiving widespread acceptance on new cane lands, the industry must foster a similar approach on existing cane lands. Its future is dependent not only on an increased acceptance by existing growers but also improvements in the quantity and quality of natural resource and other information to guide effective decision making.

River Management to Catchment Management

As previously noted (see Table 1), the major focus in the past in the Herbert catchment has been on river management issues, especially issues relating to flooding and drainage associated with the major river systems. Solutions have generally been seen to be engineering works.

Flooding: The Herbert Catchment experiences regular major floods. Flooding is recognised as causing major damage to crops and property, considerable inconvenience to the community, and river bank erosion. Local governments have been responsible for providing protection for urban communities and the HRIT addresses the needs of the broader region. However the approach to flood protection has often been piecemeal and reactive to some catastrophe.

Drainage: Expansion of caneland in the lower catchment since the early 1900s has extended progressively into soils of poorer drainage. The drainage system for these lands was developed in an ad hoc way with a series of ?5 separate voluntary schemes and gazetted drainage boards evolving over time. Efforts to improve farm drainage were uncoordinated and often with little regard to adequacy or the downstream impact of farm outfalls. This has caused significant environmental impacts with social conflicts resulting. Substantial conflicts have also emerged between upslope and downslope farmers regarding cost-sharing arrangements for maintenance of drains and levees, and property damage.

Integrated Catchment Management: More recently increasing community calls have been made for greater community involvement, better coordination of decision-making, and a broader more strategic perspective that takes a long term view and encompasses both water management and land development planning on a whole catchment basis.

ICM commenced in the Herbert Catchment in March 1993 with the establishment of the Herbert River Catchment Coordinating Committee (HRCCC) on a voluntary basis by local community interests. The impetus for its formation was the recognised need for better community participation in decision-making relating to river management issues. Current representation on the HRCCC includes Canegrowers, Cattleman's Union, Rare Fruit Council of Australia, Queensland Commercial Fisherman's Organisation, CSR Herbert River Mills, HRIT, Combined Drainage Boards, Hinchinbrook Shire Council, Herberton Shire Council, Landcare, conservation, Hinchinbrook Citizens Association. Currently of the 15 members there is no State or Commonwealth Agency representation, and only one representative from the upper catchment.

The HRCCC's stated objectives are to:

- coordinate government agencies and the community to pursue common goals
- seek community involvement in catchment management
- identify and rectify natural resource degradation

- promote ways to prevent and reduce natural resource degradation
- promote the wise use of all natural resources within the Catchment
- identify key indicators of biodiversity and monitor as a measure of catchment health
- encourage the retention of significant natural habitats within the Catchment. (HRCC 1996).

The HRCCC activities since formation have primarily focussed around:
(i) single-issue activities to get 'runs on the board' rather than issues of strategic importance (eg., promotion of owl boxes for pest control);
(ii) being a referral agency for proposed projects and other catchment activities by state and local government (eg., SIIP proposal, Hinchinbrook Shire Planning Scheme)
(iii) the formulation of a draft Herbert River Catchment Management Plan for public review and comment.
(iv) brokering funding for others to undertake natural resource management activities in the catchment (eg., for recent round of NHT funding).

The draft Catchment Strategy is seen to provide a framework for future management of the Herbert River Catchment. It was prepared by HCCC members through a series of working groups and internal workshopping. The key management and planning issues identified relate to land management, water management, stream management, and habitat management. The key issues relating to each of these are identified in Table 3. For each of these issues the strategy identifies a range of actions, and suggest which landholders, Government agencies and resource users are responsible for doing it.

At this stage in the development of ICM in the Herbert, key HCCC members perceive the strategic plan development more as a means of getting funding rather than a framework for ICM implementation in the Herbert. Their perception of their role also is evolving from one of delivering outcomes or solving natural resource problems on the ground, to one more of facilitating ICM principles as a way of doing business, or facilitating a strategic direction for the catchment.

Local Government Planning and ICM in the Herbert

The Hinchinbrook Shire Council (HSC) has been involved in resource development of their Shire since its foundation in 1933 in many and various ways. HSC is a partner in the Drainage Board gazetted in 1977, in a number of voluntary boards for sub-catchments and of the recently established the Herbert River Information Centre. HSC councillors have been on the HRCC since its inception a role which expanded considerably in 1996 with the appointment of the Shire Chair as Deputy Chair of the HRCC along with another councilor. There are many and various informal means by which the HSC as the elected local government have had on resource management in the Shire - lobbying, negotiation, advice etc.

In 1995, the Shire determined to revise its town planning scheme and in doing so to prepare its first Strategic Plan. Until this time the HSC relied on a traditional zoning scheme and by-laws which were totally focussed on the regulation of urban development in the Shire, admittedly a modest challenge in an area with relatively little population growth. The new town plan preparation began in mid-1995 and a draft went on public display in October 1996. It was prepared by Sinclair Knight Merz since, in common with many rural local governments, the HSC does not have a professional planner on staff. Planning issues are managed by the CEO in conjunction with the engineer and the Deputy Shire Clerk. Following public display and objections, the revised plan was dispatched to the DLGP for review and approval in March 1997. That is where the plan rests at the time of writing.

It is also relevant to note that there is an NLP funded project "Integrated Catchment and Local Government Planning Schemes" (See QLGA, 1997) involving the Queensland Local Government Association and the Department of Local Government and Planning selected HSC as one of the four case study shires. This arose directly out of the review document and communication plan prepared in the same project. (QDNR, 1996) The Hinchinbrook Shire identified four priority issues in relation to ICM for this project. They were:

- wetlands and mangroves
- riparian vegetation
- drainage
- local roads and railways (including light rail)

Overview of the New Plan including the Strategic Plan, Zoning Scheme and Performance Standards

The new planning scheme consists of the normal battery of planning instruments:

- a strategic plan as an overall framework for guiding land use change (preferred future land uses) through a set of objectives,
- a zoning scheme which defines a (conventional) table of zones (without consent, subject to conditions, consent and prohibited),
- a subdivision by-law,
- general and use specific development standards and
- a range of administrative provisions.

Each of these elements has relevance to natural resources management and ICM but only the highlights will be reviewed here.

The Strategic Plan and its Objectives

In the Strategic Plan HSC makes a specific and substantial commitment to rural resource management and to ICM. It signals the approach to implementation largely through its stated likely response to development applications as illustrated in the following edited extracts from the plan.

Rural Objective 2(iii)

"Where future expansion of agriculture is proposed through a development application, the Council will require the submission of a property management plan where it has determined first that adverse environmental impacts may result from such development. Of particular interest to Council will be applications for new cane assignments in the areas of drainage paths, ground water resources, wetlands, riparian vegetation and associated stream bank stability, remnant areas of native forests, rural views and quiet rural amenity. The Council will not support any development application for agricultural expansion where it has determined that unacceptable environmental impacts will be caused by the development" (p6)

Rural Objective 5

"To protect existing rural values such as surface water (drainage paths) and ground water resources (recharge areas), soil and other land resources, riparian vegetation and stream bank stability, remnant areas of native forests, rural views, and quiet rural amenity."

The Council will only support those development applications which will contain potential adverse impacts within the site so that the costs of any rural activity are not widely spread and are not unfairly borne by others."

ICM Objectives

1. To identify and designate the catchments and the sub-catchments of the Herbert River which lie wholly or partly within the Shire. The Council will "take into account" the catchment strategies and assess proposals on that basis.

2. To ensure that, as a result of the development and use of land no environmental impacts affect any lands elsewhere within a catchment designated in this Strategic Plan. Implemented by a commitment to having "regard for" and "shall implement the principles of ICM" and the "may refuse to support any proposal which will generate unacceptable effects upon any land …", and " may require the preparation of an EIA" where detrimental downstream effects or impacts are possible.
3. To promote sensitive and sustainable land use practices through the development process. Discussion of implementation includes "all development and land uses will be required to adopt sound management practices so as to minimise, …..."; "The Council may refuse to support any proposal …"; and "logging of privately owned timber shall not entail the removal of any vegetation within 50 metres of a known creek or watercourse."

The Zoning Scheme
The conventional zoning scheme has only five zones, namely, Rural, Town, Village, Public Purposes, Special Activities. The Rural Zone covers most of the Shire. The most significant innovation in this zone is that intensive agriculture is listed as a use which may be carried out in this zone subject to the notification of conditions. Intensive agriculture which includes most farming activities, is a prohibited use in all other zones:

Intensive Agriculture: "means the use of land for the intensive production of crops, such as but not limited to sugar cane, at rates or production beyond the natural carrying capability of the land whether or not the land is irrigated for such purposes. The term includes the establishment of any infrastructure necessary for the conduct of the use. The term does not include small-scale agriculture conducted on premises or a site less than 5 hectares in area."

The Performance Standards for Intensive Agriculture (7.7.2)

I. In considering an application for intensive agriculture the Council shall have regard to the following matters:

    A. the extent of vegetation loss and earthworks proposed
    B. the likely changes to hydrological regimes for both surface and groundwater reserves within the catchment of a site
    C. the proposed manner of environmental management including the containment of downstream effects such as excessive water demand, the quality of run-off water; the maintenance of environmental flows in steams; the management of water tables to prevent salinisation; and the alteration of ecological processes
    D. [sic] the likely access requirements to the land having regard to projected production rates and operational schedules, and the capacity of the existing road and tram network to respond to increases in traffic flows;
    E. any other matter of relevance to the application

II. The Council may require a development application for "intensive agriculture" to be supported by an assessment of any of the matters raised in considering the application pursuant to provision 7.7.1 above

This plan clearly reflects a strong commitment by HSC to natural resources management and given that this is HSC's first plan, is to be commended. What now needs to be done is to create the details that will make such a plan implementable. In the elements extracted above there are ample powers to intervene in a significant number of rural development decisions. The Plan raises many questions as to what is the "small print" in relation to the various steps involved in regulating rural uses in this way, some of which are:

- What are the designated uses requiring approval ? - the intensive agriculture definition which is critical, could create confusion unless unambiguously defined. The Pest and Productivity Board in a submission to the Plan proposed that sugar not be regarded as an intensive use !
- What is the minimum area threshold ? - clearly very small areas should not require regulation but setting the minimum threshold too high could allow many significant developments to go unregulated. For example a minimum of 5 hectares as proposed in the draft HSC plan which is equivalent to a square area with sides greater than 220metres, seems too large.
- What are the criteria for approval of regulated uses, for example the relevant environmental issues, natural resource protection, off-site effects water quality and quantity issues, habitat and nature conservation issues etc. What are allowable changes to water courses and riparian zones, impacts on drainage and flood regimes. This requires the introduction of guidelines and specific performance standards and hopefully examples of good practice. These conditions need to be specified in planning documents in such a way to give clear prior guidance as to desired developments.
- How will development applications be assessed against those criteria - for example what are significant habitat areas and where they are specified ? (on what maps), Will applicants need Property Management Plans ? Who will appraise the plans/proposals against the criteria (which agency by what process)? Will the applicants require impact assessments ?
- Will there be any monitoring provisions? What will be monitored and who will do it ?
- What sanctions are proposed ?
- Are there to be any concomitant effects on other land use planning activities for example cane land assignment, land valuations and rates?

These questions pose some new challenges for local governments and their rural planners. There has been some progress in addressing these questions in the Herbert.

Riparian Vegetation

Protecting riparian zone has been one of the most contentious issues in the Herbert indeed in most rural areas. The main planning issues are: Should there be a buffer along watercourses, what is a water course, how wide should the buffer be and what management requirements apply to the buffer zone ? Each issue is contentious and has implications for the environment and property rights (and politics).

The protection of streambank vegetation in the Herbert is believed to contribute to bank stability through the physical binding provided by the tree roots, reduction in bank water content as well as to provide habitat corridors. The technical questions arising from the planning issues are to define water courses, determining the width of the riparian buffer be and examining the impacts of various activities in the buffer (for example should any clearing or logging be permitted). As an HRCC initiative, streambanks were evaluated in a detailed study of the lower Herbert River by Andrew Petrokowski. The provisions of the *Water Act* requires conservation of the riparian zone of major watercourses within a 40 metre buffer. This controversial requirement is criticised on the grounds that it is insensitive to local circumstance and needs. The Petrokowski study recommended a more sensitive approach that defines the width of the buffer zone in terms of two factors: flood risk and bank erosion risk. Only in areas of high risk would the full 40 metres be required whereas in other areas lesser distances would be calculated on the basis of an index of these two factors.

Drainage
As previously discussed uncoordinated drainage systems on canelands has been a long term issue creating significant social conflict in the Herbert. The HSC in conjunction with the HRIT has undertake a number of major studies in the lower in the lower Herbert. A significant outcome has been the move to amalgamate all existing gazetted and voluntary drainage boards into a combined body in support of a more coordinated and consistent approach to the drainage. This has been a fundamental element of the Herbert submission for funding under the Sugar Industry Infrastructure Package for support to major infrastructure works currently under consideration by the Commonwealth Government. The HSC successfully lobbied DNR to appoint a technical drainage expert to provide interpretation and advice on drainage issues. This officer should be able to resolve technical issues associated with development approvals required by the town planning scheme

Wetlands and mangroves
The expansion of intensive agriculture has already made significant changes to the area's wetlands environments. The HSC in collaboration with the HRCCC and industry has supported initiatives with industry and private landholders to foster the development of artificial wetlands which have dual purposes of nature conservation and the redirection of water emissions from the CSR mill to create artificial wetlands rather than direct disposal into local drainage lines. On individual farms the HSC is encouraging the construction of artificial wetlands for nature conservation with benefits to production on adjacent lands arising from water management.

Current mapping and assessment programs will provide a firmer foundation for defining what ecologically significant wetlands and mangrove areas are to be included with the regulated area. Included here is concern about acid sulphate soils which can create substantial ecological and productivity effects off-site if they are excessively drained. A problem here is the erratic distribution of risk areas

Local roads and railways (including light rail)
The HSC has been involved in negotiations with QR and DOT on the design of road and rail bridges and embankments on local drainage networks on the floodplain. There is now an agreed referral process amongst these authorities to coordinate drainage and to minimise the flooding effects of such works.

CONCLUSIONS

The expanded role of local governments into rural environmental planning has many challenges for planners. It introduces a whole new set of technical and political dimensions to their work for which they may have little training, no experience and can not call on well-developed precedents to guide the way. It will therefore be a significant learning period for councils, their staff and advisors.

The underlining planning process will have some similarities with conventional urban based planning in terms of land use control and setting of performance standards and managing the development approval process. The differences will be partly technical in dealing more with ecological and land resources issues but also more complex in that the planning and management will need to be more site and local landscape specific than normally applies to urban planning matters.

There are serious obstacles too, not the least of which is the potential for councils to be in conflict with land owners over loss of use rights, injurious affectation and potentially the need for compensation. Some of the suggested processes lead councils into unexplored territory, for

example the reliance on Property Management Plans, the application of EIA to small land development proposals

Unfortunately regulating new developments only through the planning process will not be effective in dealing with existing resources management problems. To the extent that existing uses are unsustainable or that minor variations in those uses will not be affected by any planning provisions, this approach will not contribute to ESD.

Substantial progress has been made in a relatively short time - better coordination between authorities and in extending the reach of town planning. HRCC through the ICM philosophy has had a significant facilitating role and forum for the diversity of interests involved on a day-to-day basis. It has opened lines of communication between previously unconnected groups and to get a wider range of perspectives on resource management issues

The challenge is to develop effective contributions of local planning schemes in natural resources management in a situation of little previous experience here in Queensland. What can be achieved ? What is best practice ? What are the obstacles in terms of the capabilities of local government organisations and their staff and what training and development programs will be required to overcome these obstacles ?

Table 1. Natural resource management issues identified in selected studies in the Herbert Catchment.

	Herbert Technical Studies 1976, 1980, 1984	Community Workshop August 1992	ICM Evaluation Project Stakeholder Workshop June 1995
Key Issues Identified	Lower Herbert Catchment focus: • flood mitigation • stream and river bank erosion • uncoordinated drainage on river floodplain	• flooding • sedimentation • bank erosion • major river course changes • rural drainage • tourism and recreation • biological issues (including wildlife habitats) • water quality and quantity	• lack of long term planning of water management and land development • lack of coordinated drainage strategies • conflict over flood protection works • riparian zone management • habitat management and protection • increased erosion and sedimentation in river • pest management planning • long term sustainability of agriculture • land development/conservation conflicts
Perceived Key Impacts	• economic consequences (e.g. major crop losses) • infrastructure and property damage	• loss of valued land • loss of production • infrastructure/asset damage • access difficulties • loss of recreational and tourism opportunities	• loss of crop production and profitability • land degradation • river aggradation • reduced stream capacity • stream bank destabilisation • habitat destruction/modification • water quality and quantity problems • localised flooding • conservation impacts • social conflicts • alienation of land for other uses
Key Mechanisms Identified for Addressing Issues	• a range of largely engineering-based studies to investigate stream processes/river morphology for flood management and rural drainage coordination • flood mitigation works (e.g. levees, floodgates, overflow channels, rock works) • removal of river vegetation	• a range of infrastructure and related works programs (eg. removal of river sediment, bank stabilisation; rationalisation of levee system; increased capacity of flood gates; stream bank revegetation) • review/reform of institutional structures and arrangements for river management ICM implementation to support a coordinated approach to decision-making and to facilitate community participation, community education and PR plan	• create a common understanding of ICM • foster and maintain a long term commitment to an ICM process which is seen as a "way of doing business" for government and the community • local government as action agency - use planning and development controls • state government to foster cooperation • use controls on leasehold land • industry codes of practice

Table 3. Key management and planning issues

Key Issues	**Recommended Strategies**
Land Management • inappropriate land use allocation and its impact on resources and natural systems • impacts of land management on productivity • impacts on other values of land and adjacent land and water resources	(i) Coordinate land use planning to achieve balanced use of land, water and related natural resources (ii) Encourage best management practices in all rural industries (iii) Implement arrangements to reduce adverse impacts of agricultural drainage on natural systems and existing developments (iv) Reduce adverse impacts of non-agricultural land uses.
Water Management • Full and over-allocation of existing resources • increasing demands on finite surface and groundwater supplies • limited monitoring of water quantity and quality • threats to quality of surface and groundwater supplies	(i) Assess available resources and develop appropriate allocation policies in consultation with stakeholders (ii) Promote efficient use of water resources in the Catchment (iii) Promote the coordinated planning and implementation of water management schemes in the catchment (iv) Reduce contaminant inputs to surface and groundwater systems from point and diffuse sources (v) Establish and promote water monitoring priorities and standards for the catchment.
Stream Management • lack of awareness of stream values shown in development actions • stream bank erosion and stream migration • sedimentation • impact of uncoordinated levee banks and flood mitigation schemes • impacts of degradation of riparian zones • instream habitat degradation such as weed invasion and loss of water holes	(i) Continue implementation of a strategic approach to stream management (ii) Facilitate appropriate management of riparian zones throughout the catchment (iii) Ensure development and engineering works associated with streams take account of all stream functions and issues (iv) Identify and protect sensitive areas, to retain the function and health of our stream systems (v) Develop fisheries and habitat management plan for the stream systems of the catchment, involving stakeholder groups and the broad community
Habitat Management • threats to significant terrestrial and aquatic habitats and species • loss of instream habitat quality and subsequent impacts on fish stocks • fragmentation of remaining habitats through loss of connectivity (ie. corridors)	(i) Promote the values of habitat retention and restoration to the broader community through awareness, technical support and incentives (ii) Maximise the habitat values of existing protected areas (iii) Ensure the retention of significant habitat values outside protected area reserves (iv) Protect and rehabilitate wetland habitats on the Floodplain (v) Re-establish and manage riparian vegetation on watercourses throughout the catchment and ensure retention of existing riparian vegetation.

ABSTRACT Rural local authorities are responding to environmental concerns by expanding their role in land use planning and the in management of natural systems. The implications this has for planning is that for the first time agricultural activity is being regulated through the planning process. Rural environmental planning has some similarities with conventional urban based planning in terms of land use control, setting of performance standards and managing the development approval process. However in addition to this, rural based planning needs to address ecological and land resources issues and planning and management needs be specific to the local landscape. This thesis evaluates planning and conservation measures that can be used by Rural Local Governments to protect wetland resources. To achieve this the theses identifies some of the issues precluding the conservation of wetlands in Queensland and the role that local governments have in overcoming these issues. With particular reference to the Herbert River Catchment in North Queensland environmental pressures and the impact of current management arrangements on wetlands are investigated. From this planning methods that can be used to conserve wetlands are identified and described and evaluated to determine their effectiveness in overcoming management issues and for implementation in a rural context.

Chapter 1:

INTRODUCTION AND METHODOLOGY

1.0 INTRODUCTION

Local governments across Queensland are having to resolve competing claims over finite land and water resources. Competition is also increasing for resources in rural areas causing conflicts between existing and potential uses for agriculture, tourism and recreation, urban encroachment, mining, forestry and conservation (Johnson et al, 1996, p1). Rural local authorities are responding to this by expanding their role in land use planning and management of natural systems. Traditionally local governments have had a limited role in planning in rural areas and in the management of natural resources generally (McDonald and Bellamy, 1997, p1). This newly expanded role reflects the increasing demands from the community that environmental concerns and aspirations be acknowledged by land management authorities (Bates, 1995). The implication this has for planning, is that for the first time agricultural activity will be managed by local authorities and as a result desirable ecological outcomes can become part of the rural development process. The implication this has on wetlands, is that rural local authorities will have the power to regulate land use to achieve their conservation.

Wetlands have traditionally been regarded as a hindrance to human progress fit only for reclamation, drainage and development. Fortunately this attitude is changing and governments and the community are beginning to recognise their value (Claridge, 1994). Among other things, coastal wetlands, swamps, billabongs and waterholes are important wildlife habitat areas, being an integral part of the hydrological regime and act as important nursery areas for several species of commercially important fish (Johnson et al, 1996). Unfortunately many of the coastal wetlands along Queensland's coast have already been cleared and converted to other uses. Key sources of environmental pressure on remaining wetlands in rural areas are associated with agricultural expansion. This is resulting in the destruction of wetlands, reclamation for agriculture, or loss of wetland quality due to the off site impacts of agricultural management practices.

Thus the challenge facing rural local governments is to develop effective methods to conserve wetlands through their planning responsibilities. This thesis identifies some of the issues precluding the conservation of wetlands in Queensland and the role that local governments have in overcoming these issues. With particular reference to the Herbert River Catchment in North Queensland, planning methods that can be used to achieve wetland conservation are identified and described. They are evaluated to determine their effectiveness in overcoming current management issues and for implementation in a rural context.

1.1 A CASE STUDY: THE HERBERT RIVER CATCHMENT

The Herbert River catchment has been selected as the focus for the study for several important reasons. Firstly the Herbert River Catchment is representative of many other rural local Authorities in Queensland. The northern sections of the Catchment are identified as part of the Wet Tropics and the area is also well known for the offshore Great Barrier Reef (Shrubsole, 1997). Consequently, the results of this study may be appropriate for other councils with similar environmental characteristics.

Additionally, the Herbert is representative because agriculture is the dominant land use activity in the catchment. The sugar industry is the largest intensive industry in the catchment. This reflects many other catchments in Queensland as sugar cane is an important part of the landscape along the eastern coast of the Queensland and Northern New South Wales (Shrubsole, 1997). Moreover the Herbert is representative of many catchments in Queensland because the regulation of agriculture by Local Government has not occurred before.

In addition, the Herbert River Catchment has been selected for a number of other important reasons. The location of the catchment and the environmental conditions experienced have produced wetland resources that are of national importance. Additionally the sugar industry is

undergoing rapid expansion in the Herbert. Since 1991 the area has been one of the most rapidly expanding cane growing areas in the country. The Hinchinbrook Shire Council has realised the potential environmental impacts that this growth can have and is changing the scope of the planning scheme to regulate rural expansion. Finally the Herbert River has an extensive technical information base provided in the Herbert River Information Centre which is a computerised geographical information system. As a result, there are few informational constraints for this project.

1.2 METHODOLOGY

The purpose of this document is to identify planning solutions to address the management of wetland areas and to evaluate their appropriateness for inclusion into the Hinchinbrook Shire Council Planning Scheme. To achieve this, a number of objectives have been developed.

1.2.1 OBJECTIVE ONE: To determine the management problem

To develop provisions to achieve the conservation of wetlands it is necessary to determine the value of the wetland resources and current management problems. This was achieved by reviewing wetland resources, by determining current environmental pressures, and by identifying current management arrangements.

Reviewing Wetland Resources

First, the wetland resources of the Herbert river Floodplain were reviewed through secondary data sources. This information was collected as part of the literature review and consisted of a number of reports, tables and wetlands mapping obtained from State and Local government agencies; the Australian Nature Conservation Agency and CSIRO, as well as other journals and reports. Additionally several field inspections were made with the help of Canegrowers, the Council, the Catchment Co-ordinating Committee and the Department of Natural Resources. This facilitated the inspection of a range of wetlands types to gain an understanding of the distribution and quality of remaining wetlands resources. This information provided a description of the type, quality, value and distribution of wetlands in the Herbert River Floodplain.

Environmental Pressures on Wetlands

The environmental pressures on wetlands were identified through field inspections, consultation with major stakeholder groups and through additional literature analyses. Literature analyses were obtained from a range of sources including State Government Agencies, CSIRO, the Herbert River Catchment Coordinating Committee, as well as other sources. This information was focused on threats to wetland resources and the significant impact that the sugar industry is having on wetlands of the Herbert River Floodplain.

Current Management Arrangements

Current management arrangements were identified by answering the following questions which were developed by Duncan (1993):

1. How does the present form of land tenure affect wetland management?
2. What planning controls affect the wetland? How effective are they?
3. What problems are evident with the development control process?
4. How does the management system cope with cumulative impacts?
5. What is the likely outcome if management proceeds in the same way?

This was achieved by undertaking an assessment of literature documents and by interviewing major stakeholder groups. A structured interview schedule was used to analyse the effectiveness of the Draft Hinchinbrook Shire Council Planning Scheme for Integrated Catchment Management. Major stakeholder groups were interviewed, including: the Herbert River Catchment Coordinating Committee; Hinchinbrook Wildlife and Preservation Society; Ingham Canegrowers; Planning Consultant for Hinchinbrook Shire Council; Department of Local Government and Planning; Department of Environment; Department of Primary Industries and the Department of Natural Resources.

Question 1 aimed to determine the respondents' commitment to integrated catchment management and their knowledge of the planning process. Question 2 aimed at determining the involvement of the major stakeholder groups in the scheme preparation. Questions 3 and 4 sought to determine the respondents' opinion of the draft planning scheme, particularly their opinion of the proposed regulation of intensive agriculture. Additionally Questions 3 and 4

sought to determine the effectiveness of the draft scheme for achieving integrated catchment management. Finally Question 5 asked respondents to recommend ways in which the scheme could be improved to better achieve integrated catchment management.

1.2.2 OBJECTIVE TWO: Identify suitable instruments to implement planning provisions for wetland conservation

Once the values and management issues have been identified it is necessary to identify planning tools that will most effectively implement planning provisions for wetland conservation. Possible planning solutions were identified by analysing a range of planning documents from State and Local Government agencies in Queensland and New South Wales. These documents have a specific focus on land use planning matters.

Planning schemes from the three councils of Hinchinbrook, Johnstone and Cardwell were examined to determine ways of achieving wetland conservation. Johnstone and Cardwell Shire Council Schemes were selected because they experience similar environmental conditions and pressures on wetland resources as the case study, yet they have adopted different approaches to wetland planning.

Additionally conservation strategies and management plans adopted by Brisbane City Council, the Queensland Departments of Local Government and Planning and Environment, and the New South Wales Department of Land and Water Conservation were also investigated for their means of achieving wetland conservation. The provisions contained within these documents provided suggestions as to methods for achieving wetland conservation.

1.2.3 OBJECTIVE THREE: To determine the suitability of proposed planning options

The suitability of the planning options have been determined by assessing each one against the following criteria:
1. Ability to achieve desirable environmental outcomes
2. Administrative processes associated with planning provisions
3. Socio-Political acceptability of planning provisions
4. Cost

This information was derived from consultation with government and management agencies that had implemented or tested management alternatives. The evaluation was also based on an analysis of a range of planning documents that provided a description and analysis of conservation methods. Additionally consultation with stakeholders in the catchment also enabled the evaluation of alternatives within the context of the case study area.

1.2.4 OBJECTIVE FOUR: To determine suitable planning provisions for wetland conservation that achieve the resource management objectives of the ICM program and provide solutions to identified management problems

A framework for management has been developed to achieve desirable ecological outcomes and sustainable development based on the management issues and constraints identified, the significance of wetlands, environmental pressures, and the evaluation of planning options. This framework reflects the resource management objectives of the ICM program for the Herbert River and aim also to reflect the aspirations of the local community. These provisions will enable local governments to achieve conservation of wetlands in a rural context.

Chapter 2:

WETLAND CONSERVATION IN QUEENSLAND: AN INTRODUCTION TO THE ISSUES

2.0 INTRODUCTION

Wetlands are among the most productive ecosystems on earth and are possibly also the least appreciated ecosystem type. Coastal wetlands play an important role in the productivity of coastal waters, biogeochemical cycling and geomorphological stability. Among other things wetlands act as nurseries and feeding grounds for crustaceans, fish and birds, repositories for pollutants, nutrients and organics, and as protection against wave attack (Carter, 1988). Traditionally wetlands have been regarded as hindrances to human progress, fit only for reclamation, drainage and development. Therefore despite their intrinsic value, wetlands have long suffered from human impacts. These include the direct appropriation of wetland ares for development and through peripheral impacts of road building, drainage and stream canalisation. This has had a significant impact on wetland areas and as a result more than half of Australia's wetlands have disappeared since the time of the first European settlement (Claridge, 1994; Carter, 1988).

Fortunately this attitude towards wetlands is changing and governments and the community are beginning to recognise their values. The values of wetlands are identified in Table 1 below.

Table 2.1 (Sources: Claridge, 1994; Carter, 1988; Sharley and Huggan 1994)

BENEFITS PROVIDED BY WETLANDS	
WETLAND BENEFITS	**DESCRIPTION**
Water supply	Extraction for domestic, agricultural and industrial uses Groundwater recharge Supply to another wetland
Flood control and flow regulation	Flood height reduction Maintenance of dry season flows
Prevention of saline water intrusion	To coastal aquifers To coastal water bodies
Protection from natural forces	Shoreline and bank erosion protection
Sediment retention	Cleans water of sediments
Toxicant retention	Removes toxic materials from water passing through wetlands
Nutrient retention	Outflows have lower nutrient levels
Source of natural products	On site Off-site, eg: through nutrient export
Energy production	charcoal, peat and tidal energy harnessed from tidal flows in estuaries
Water transport	
Conservation	Habitat for life cycle stages of plant and animal species (including wildlife corridors) Habitat for rare elements of the natural environment
Recreation and tourism	Swimming, boating, birdwatching, duck shooting
Research and education	Site for specific research Type locality Site for education
	Landscape and aesthetic values

Sociocultural significance	□ Association with religions and spiritual beliefs □ Wilderness Values □ Historical Values
Maintenance of existing processes and natural systems	□ Ecological, geomorphological and geological processes □ Prevention of development of acid sulphate soils
Breeding site for useful species	□ Birds which feed on insects on agricultural land
Gene bank	□ Commercial exploitation (improvement of domestic stocks) □ Maintenance of wildlife populations
Intrinsic Values	□

2.1 GENERAL MANAGEMENT ISSUES

While wetlands are beginning to be recognised for their values, a number of issues are hindering the management and conservation of these areas. They include legal issues, legal issues, land use and land management , poor coordination, information and knowledge, political will and education and awareness

2.1.1 Legal Issues

Wetland conservation is impeded by a lack of statutory control over rural land management and the legal problem of defining wetlands. Rural planning schemes have not traditionally regulated rural activities. Consequently conservation and management of rural lands have been achieved through voluntary programs such as Landcare and partnership agreements such as Integrated Catchment Management (ICM). ICM aims at integrating the management of land, water vegetation and other biological resources on a catchment basis in order to achieve the sustainable and balanced use of these resources (Queensland Department of Primary Industries, 1993). ICM is a community based approach to natural resource management and as a result it works by fostering voluntary changes in the way people use and manage their natural resources (ICM/Landcare Review Committee 1997). However, there is no specific legislation for ICM and consequently it does not have the statutory power to legally implement management strategies. As a result its ability to conserve wetlands is limited. (Department of Primary Industries, 1993).

Further issues arise over the legal definition of wetlands. Problems arise when trying to distinguish between terrestrial environments and wetlands and between wetlands and aquatic and marine environments. Additional difficulties arise over the scope of definition which can have significant implications on the range of lands that can be included as wetlands. This can cause problems, especially in politically or legally complicated situations (Duncan, 1993)

2.1.2 Land use and Land Management

Until relatively recently rural local governments have had a limited role in land use planning and in the management of natural resources generally (McDonald and Bellamy, 1997). This limited role in the regulation of agricultural land uses by local government has impeded the effective conservation of wetlands. In the absence of land use planning by Local Authorities, the development of rural land is based on largely on agricultural land suitability and therefore desirable environmental outcomes have received little attention in land use decisions (Shrubsole, 1997).

2.1.3 Poor Coordination

Lack of co-ordination between government agencies, local governments and catchment co-ordinating committees has precluded the effective management and conservation of wetlands. At an administrative level a lack of co-ordination between environmental and economic agencies is a key causal factor of many environmental and developmental problems (Johnstone, Shrubsole and Merrin, 1996, p 303). There is a need for a single authority to assume the lead role in co-ordinating land management to achieve ICM objectives.

Local Governments are well positioned to achieve the implementation of ICM strategies. Halliburton (1995, p4) has identified several important reasons why local governments have a major role to play in ICM: they are the major regulatory agency controlling land use (and land use changes) and have a responsibility in ensuring that environmental impacts on catchments are considered when assessing land use changes; local governments are local and directly accountable to the community; they understand local environments; they undertake the day to day management of environmental assets; they are able to control many potentially environmentally damaging activities; they provide a more holistic approach to local area management and; they have access to more detailed local information.

2.1.4 Information and Knowledge

Local governments, through their planning schemes, can improve catchment management. However, planners have not always addressed environmental and catchment issues in schemes because of a lack of information (Department of Primary Industries, Communication Plan, 1996, p9). Technical knowledge and information is an integral part of finding solutions for natural resource management issues. It is vital for the identification and understanding of the problem and for identifying solutions that will achieve ICM strategies through the planning scheme (Young, 1996).

Technical knowledge must be relevant, readily available and easily understood in order to enable the effects of development to be measured (Young, 1996). "...it is important to understand: what types of activity are likely to cause an effect; when and how a development assessment should be triggered; what information is required to inform that assessment; and finally, how to measure the effectiveness of the controls (or conditions) applied to an approved development" (Young, 1996, p375). Policy and planning cannot be expected to achieve societal goals in the absence of adequate data relating to biophysical, economic and social factors that impinge on resource use (Johnstone et al, 1996, p16).

2.1.5 Political Commitment

The first requirement in the achievement of ecologically sustainable land use planning is to want to do it (Nobbs, Rush, and McGregor, 1995). Traditionally there has been far less control over rural land use and management and statutory land use controls tend to be regarded by farmers as an infringement of their property rights (Hollick, 199_). Additionally, as local governments are held accountable by way of election, the extent to which local governments will be prepared to intervene in development activity (ie: by imposing statutory controls on land use) will be guided by the willingness of the community to support that intervention (Young, 1996). The extent of intervention is the subject of much debate between planners, economists and politicians (Johnson et al, 1996).

This has constrained wetland management on rural lands in the past. Political commitment is influenced by community knowledge of wetlands issues. Additionally political commitment is vital for the implementation of wetland conservation and it helps provide a sense of local ownership of ICM strategies (Halliburton, 1995). If government is to intervene to overcome the constraint of self-interested behaviour in catchment management, it must first clarify the precise balance between the rights of the individual rural landholder to develop or use the land or other resources and those of the Government seeking to implement policies to achieve wetland conservation to protect the broader public interest by maintaining environmental quality (Synott, 199_; Bates, 1995).

2.1.6 Education and Awareness

Strongly linked to political acceptability is education and awareness which is the key to the effective implementation of wetland conservation. While people are beginning to recognise the

significance of wetlands further education is needed at a policy and a community level to improve awareness of wetland functions and benefits (Claridge, 1994). Education and awareness is an integral part of the ICM process because it influences the degree to which local planners, engineers, councillors, chief executive officers and the community understand and values their wetland resources (Young, 1996; Department of Primary Industries, 1993).

The ICM and Local Government Survey which interviewed Local Government Staff in 1994 showed that the level of knowledge about ICM is generally low throughout local governments in Queensland (Department of Natural Resources, 1996). Education and awareness of natural resource management problems can stimulate voluntary action (Department of Primary Industries, 1993) and can also provide the political support for local governments to mange wetlands. The extent to which a local authority will be prepared to intervene in development activity will be influenced by the willingness of the community to accept controls for wetland management (Young, 1996, p375). Consequently, for wetland strategies to be effective, natural resource users and managers need to know and understand the impacts their decisions and actions have on wetland resources (Queensland Department of Primary Industries, 1993).

2.2 ROLE OF LOCAL GOVERNMENTS IN LAND MANAGEMENT AND WETLAND CONSERVATION

Local authorities have a significant role in managing the land to achieve Ecologically Sustainable Development (ESD). Local authorities also have an important role in integrating Integrated Catchment Management Strategies into their land use plans.

2.2.1 Ecologically Sustainable Development

Ecologically Sustainable Development (ESD) is defined as "using, conserving and enhancing the community's resources so that ecological processes, on which life depends, are maintained, and the total quality of life, now and in the future, can be increased' (National Strategy for Ecologically Sustainable Development, 1992, p6). In 1992 the Inter-Governmental Agreement on the Environment (IGAE) was signed by all State and Territory Governments, the Commonwealth Government of Australia and the Local Government Association of Australia. The agreement establishes seven principles towards the achievement of ESD:

1. Decision-making processes should effectively integrate both long and short-term economic, environmental, social and equity considerations
2. Where there are threats of serious or irreversible environmental damage, lack of full scientific certainty should not be used as a reason for postponing measures to prevent environmental degradation.
3. The global dimension of environmental impacts of actions and policies should be recognised and considered.
4. The need to develop a strong, growing and diversified economy which can enhance the capacity for environmental protection should be recognised
5. The need to maintain and enhance international competitiveness in an environmetnally sound manner should be recognised.
6. Cost effective and flexible policy instruments should be adopted, such as improved valuation, pricing and incentive mechanisms
7. Decisions and actions should provide for broad community involvement on issues which affect them" (Johnson et al, 1996, p6)

Through the IGAE Local Governments are committed to pursuing the principles of ESD, through its decision-making processes. This includes the preparation of local planning schemes and consideration of applications for planning permission, including environmental impact assessment, and commitment of funds to technologically advanced treatment of sewage and minimisation of all forms of waste. (Bates, 1995):

2.2.2 Integrated Catchment Management

Local Government has a major role to play in implementing catchment management strategies as it is the major regulatory agency controlling land use and land use changes (Halliburton, 1995). Local governments have an important role in implementing sustainability-based land use planning as it is estimated that perhaps 85% of land use decisions are made by local authorities (Nobbs, Rush, and McGregor, 1995).

As a result local authorities have an important role in bridging the implementation gap of the ICM program. Halliburton (1995) has identified several important advantages of implementing ICM at a local government level. Firstly, local government has significant opportunities to influence land use and land management through planning schemes. Secondly, local government is local. This is important as local ownership of problems, processes and solutions is a key to successful adoption of good catchment policies by landholders. Thirdly, political commitment by Local Government to ICM is necessary and helps provide a sense of local ownership. Political commitment is partially dependant on community knowledge which can be fostered by Local Government. Finally, local government has a major role in information management and dissemination through involvement as a "clearing house" for research, through involvement in research design and in the production of information for catchment landholders.

2.3 LEGISLATIVE CONTEXT

Local Governments have significant opportunities to influence land use and management through the Local Government (Planning and Environment) Act and the proposed Integrated Planning Act.

2.3.1 Local Government (Planning And Environment) Act 1990

The Local Government (Planning and Environment) Act 1990, is an act to provide for town planning and related environmental maters in local government areas. The objectives of the Act are:

a) To provide a code by which Local Government or the Minister may undertake the planning of an area to facilitate orderly development and the protection of the environment; and
b) To provide an adequate framework for a person to apply for approval in respect of a development proposal and to provide appropriate appeal rights in respect thereof. (Local Government (Planning and Environment) Act 1990)

Administration of the Act

The Act is administered by Local Authorities and the Minister for Housing and Local Government. Local Councils can administer planning controls to meet the economic, social and environmental needs and aspirations of their community.

Town Planning Scheme

The Town Planning Scheme is the basic tool for the administration of the Act and is composed of planning scheme provisions, zoning and regulatory maps, strategic plan, development control plans, and amendments to the planning scheme. The planning scheme gives Local Governments the power to regulate development through zoning controls and the strategic plan. In addition, Local Councils can further place regulations on development with Local Planning Policies which provide detailed guidelines for development assessment on specific matters. Further restrictions can be placed on a development if it lies within an area controlled by a Development Control Plan (Brannock and Hutchinson, 1995).

State Planning Policies

The Act also provides the Governor in Council with the power to prepare State Planning Policies on issues considered to be of "State Significance" such as State Planning Policy 1/92 "Development and the Conservation of Agricultural Land. This policy requires that Councils take into account the value of agricultural land in all strategic and rezoning decisions.

Environmental Impact Assessments (EIA)

Environmental Impact Assessments are a tool employed by the act to provide advice to decision-makers with respect to the environmental soundness of a development application. This is expressed in s8.2(1) of the Act which sates that "a local government, when considering an application for its approval, consent, permission or authority for the implementation of a proposal under this Act or any other Act, is to take into consideration whether any deleterious effect on the environment would be occasioned by the implementation of the proposal, the subject of the application."

An EIS will be required if an activity is defined as a "designated development", outlined in the Local Government (Planning and Environment) Regulations 1991. Wetlands are defined in the schedule as requiring impact assessment procedures. Further an EIS may be required for activities specified by Council in a Planning Policy or for other designated developments if the activity is proposed for a particular area, such as Wet Tropics. These are also listed in the Regulations. When considering a proposal for a relevant development on land within or neighbouring the wet tropics area, a local government must consult with, and have regard to the advice of, the Wet Tropics Management Authority.

2.3.2 Integrated Planning Act

The proposed Integrated Planning Act (IPA) seeks to achieve ecological sustainability by coordinating and integrating local, regional and state level planning, managing the process by which development occurs, and managing the effects of the development on the environment (Queensland Department of Local Government and Planning, 1997, p24).

The proposed Act rationalises the existing complex and multiple approvals systems under the Local Government (Planning and Environment) Act, and provides for a whole of government input into land use and infrastructure planning. The proposed planning system will combine the current separate assessment processes for development including: planning; building; plumbing; transport; heritage; coastal development; environmental licensing; subdivision (Queensland Department of Local Government and Planning, 1997, 2).

Planning Schemes

Under the Integrated Planning Act, a planning scheme will be a single instrument. The IPA promotes a planning scheme that links the strategic and operational elements or functions of a scheme in a logical and coherent manner. For example planning schemes will need to identify the desired environmental outcomes for the shire, and include measures that enable the desired environmental outcomes to be achieved, such as codes or policy intentions for particular areas (Queensland Department of Local Government and Planning, 1997, 37).

The proposed legislation does not prescribe the structure of planning schemes, but identifies core matters that the strategic and operational elements of planning schemes must deal with, and coordinate and integrate with other Local, Regional and State plans. These core matters include development and transport, infrastructure, valuable features (resources or areas of economic, ecological, social, heritage or visual significance) (Queensland Department of Local Government

and Planning, 1997, 38).

The Integrated Development Assessment System (IDAS)

The Integrated Development Assessment System (IDAS) integrates all State and Local Government assessment and approval processes for development (Queensland Department of Local Government and Planning, 1997, 74). The IDAS will replace a large number of separate processes contained in many different Acts and will create a more transparent and logical system, eliminate duplication, enhance time efficiency, reduce costs, and produce more publicly accountable documents (Queensland Department of Local Government and Planning, 1997, 3).

The proposed Act contains a comprehensive definition of development which will ensure that IDAS can deal with a wide range of development controls. Additionally, the Act will not require all development that is potentially covered by the definition to be controlled, unless this is specifically determined (Queensland Department of Local Government and Planning, 1997, 3). Types of development that will require assessment are specified schedule 8 to the proposed Act and includes all development currently regulated by State Agencies. Local Government will also determine the types of development requiring assessment in their planning schemes (Queensland Department of Local Government and Planning, 1997).

Development will either be assessed against specified codes or be subject to impact assessment. Impact assessment will determine the effects of development on the environment and ways of dealing with those effects (Queensland Department of Local Government and Planning, 1997, p226). Under current legislation, environmental impact is addressed by numerous separate pieces of legislation. The proposed Integrated Planning Act will promote a mainstream role for environmental matters as part of the overall planning framework. In addition it removes the unnecessary administration and duplication featured in the current system of multiple assessment. This new approach will ensure that environmental and land use conditions of development approval and consistent and compatible (Queensland Department of Local Government and Planning, 1997, p4).

2.4 IMPLICATIONS FOR WETLAND CONSERVATION

Therefore the main tools available to conserve wetlands under the Local Government (Planning and Environment) Act are planning schemes, development assessment and Environmental Impact Assessment. This system of planning is limited because it incorporates separate approval systems, and does not integrate various levels of management and decision making into a hierarchical organisation covering national, state, and local planning issues. This impacts on wetland conservation because it facilitates an uncoordinated approach to wetland management. In addition the procedures established for development and impact assessment do not consider the cumulative impact of development on the environment.

Changes central to the proposed Integrated Planning Act include a comprehensive integrated development assessment system that combines State, Regional and local policies in planning schemes, establishes a forum to achieve co-ordinated approach to issues extending beyond a local authority area, as well as implementing a system that incorporates environmental considerations into the planning and design stage of a project (Corrs, Chambers, Westgarth, 1995). Additionally the proposed legislation improves the current method of environmental impact assessment by adopting a more sustainable and comprehensive approach to wetland management by facilitating the impact assessment within a broader strategic framework. Therefore the proposed legislation appears to be more effective for wetland conservation.

In both pieces of legislation, the key tools available for local governments to achieve wetland

conservation still basically remain the same, however the processes will change. As local authorities have not had a major impact on rural development in the past any form of planning will be more effective in achieving wetland conservation than the current system of land development. However as the planning tools set up under both planning legislation's deal with changes to land use they can not control the on-going management of wetland resources on private land.

In a rural context planning controls need to deal more with ecological and land resources issues and planning and management needs to be more site and landscape specific (McDonald and Bellamy, 1997). Therefore to effectively achieve sustainable wetland management and integrated catchment management, planning schemes and development assessment may need to be integrated with other conservation tools such as financial incentives, land acquisition and conservation agreements.

Chapter 3:

HERBERT RIVER CASE STUDY

3.0 INTRODUCTION

Mangroves and wetlands of the Herbert River Catchment are of national and local significance. However their distribution has been dramatically reduced since European Settlement. Conservation of wetlands and mangroves has been ineffective because of fragmented management arrangements, a failure to address environmental issues in the rural land development process and limited ability to control harmful land management practices. The greatest threats to these areas at present are associated with the rapid expansion of the sugar industry. Until now this expansion has not been managed by Local Government and thus the challenge facing the Hinchinbrook Shire Council is to regulate the continued expansion of the Sugar Industry and in doing so incorporate environmental objectives into rural land development.

3.1 DESCRIPTION OF STUDY AREA

The Herbert River Catchment drains an area of approximately 1,0000km^2 to the Coral Sea and is the largest of the river systems located in Australia's sub-humid to humid tropical north east (Refer Map 1). With its source 8km north east Herberton, (1070m asl) the Herbert River winds 340km to its mouth, 7km north of Halifax (Herbert River Catchment Coordinating Committee, 1996).

Topographically, the catchment can be divided into three distinct sections. The upper catchment (approximately 6,000km^2) is bounded to the north and west by the Great Dividing Range and to the east by the Cardwell Range. In the intermediate catchment (1,000km^2) below Gleneagle (179km downstream) the River changes direction and flows south east for 70 km through a deep gorge before entering the lower catchment. The lower catchment, (3,000km^2) is bounded on the north by the Cardwell Range and on the south by the Seaview Range (Johnson and Murray, 1997, p1).

The Lower catchment contains the Floodplain and delta of the Herbert River and is characterised by reworked alluvial soils. The floodplain consists of flat and relatively low lying terrain which is subject to regular inundation from flooding (Herbert River Catchment Coordinating Committee, 1996, p4; Department of Natural Resources, 1996, p2). The Herbert River Delta is a major feature of the Queensland coast. (Johnson and Murray, 1997, p15). This thesis is concerned with the lower Herbert River Catchment as mangroves and wetlands occur in

this section. The administrative boundary of the Hinchinbrook Shire Council is also contained within the lower section of the catchment.

3.2 PHYSICAL FEATURES

The mangroves and wetlands of the Herbert River Catchment have evolved as a result of the physical characteristics and environmental conditions experienced in the area. Additionally, these physical features have also produced a landscape that is well suited to other uses such as agriculture, tourism and recreation, forestry, and urban development.

3.2.1 Climate

The catchment experiences warm humid to sub-humid summers and mild dry winters. Significant rainfall and temperature gradients exist across the catchment and variability of rainfall is also very high. Rainfall is strongly influenced by the incidence of cyclonic activity in the November to May period (Johnson and Murray, 1997, p5).

3.2.1.1 Rainfall

Rainfall regimes differ widely across the catchment. Over short distances regimes vary considerably because of changes in local topography, such as the height and orientation of mountain ranges, and the direction of the coastline in relation to the prevailing moist south east air stream. The mean annual rainfall for the catchment is 1370mm, which ranges from in excess of 3000mm atop the Cardwell Range to 750mm in the extreme west of the catchment. In the lower catchment, the wide coastal plain shows a drop in rainfall from coast to foothills (refer map 2) (Johnson and Murray, 1996, p5).

3.2.1.2 Temperature

Mean monthly temperatures in the lower catchment (Ingham) range from 32°C-25°C during the summer months. Mean monthly minimum temperatures range from 23°C during summer to 13°C in winter, with July having the coolest average minimum (Johnstone and Murray, 1996, p5).

3.2.2 Geology

The geology of the lower catchment comprises Quaternary alluvium and beach sands., Cainozoic basalts, Carboniferous granites, Carboniferous acid volcanics and undifferentiated Paleozoic quartzite (Johnson and Murray, 1996, p12).

3.2.2.1 Soils

Mapping of soils and soil suitability of the floodplain at 1:100 000 indicates that alluvial soils vary according to their associated landform and position in the landscape. Soils of lower areas suffer drainage problems due to topography and poor internal structure. Hence substantial low, swampy areas do exist (Herbert River Catchment Coordinating Committee, 1996).

3.2.3 Geomorphology

The lower catchment contains seven different patterns namely, mountains, hills, rises, alluvial fans, alluvial plains, beach ridges and tidal flats. Alluvial fans are characterised by gentle inclines with low relief. They have been formed by the deposition of materials washed from surrounding hills by sheet flow or channelled stream flow. As a consequence soil types vary with parent material and position in the floodplain. Alluvial creek plains, levees, terraces and prior streams consist of loamy earth soils derived from granitic and volcanic hills. Alluvial River plains include the landforms elements of channel benches, levees, plains, prior streams, scrolls, stream channels and swamps and consist of the alluvia associated with the Herbert and Stone Rivers and their larger tributaries (Johnson and Murray, 1997, p12).

3.2.4 Hydrology

The Wild, Herbert and Stone Rivers are the major drainage systems in the catchment (Refer map 3). The Herbert River has a catchment area of 1 213 000 ha (the largest river catchment in the Wet Tropics Bioregion)(Australian Nature Conservation Agency, 1996, p 388). Streams carrying most of the local runoff into the Herbert River Upstream from Trebonne are the Stone River and Gowrie, Lannercost, Dalrymple, Wigwam, Cane, Elphinstone, Broadwater, Stoney and Garawalt Creeks. Streams carrying most local runoff into the delta area are Ripple, Cattle (upper part), Francis, Waterview and Waterfall Creeks. Abandoned streams in the delta are old courses of the Herbert River and include the Seymour River and Cattle (lower part), Trebonne, Palm, Victoria and Gentle Annie creeks. These interconnected, abandoned streams still carry significant amounts of water during floods (Johnson and Murray, 1997, p15)

The entire Herbert River Catchment has a mean annual discharge of approximately 3.7 million ML. Coastal streams to the south of Ingham which receive flood overflow water from the Herbert River contribute around a further 1 million ML. Flooding of the Herbert and Stone River is almost exclusively confined to the wet season, which generally occurs from December to March. Heavy falls are usually the result of tropical cyclonic disturbances. Major floods in recent times have occurred in 1927, 1946, 1967, 1977, 1986, and 1991(Johnson and Murray, 1997, p19; Herbert River Catchment Coordinating Committee, 1996, p5) (Map 3).

3.3 BIOLOGICAL INVENTORY OF WETLAND RESOURCES

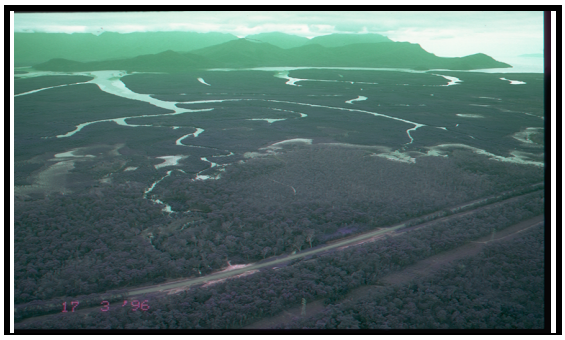
The climate, topography, geology, geomorphology and hydrological regime of the Catchment produce an environment that is favourable for mangrove and wetland development. The wetland resources of the floodplain include vegetation and fauna.

3.3.1 Vegetation

The natural vegetation of the Herbert River Floodplain has been dramatically reduced since European settlement. As a result, approximately 35-40% of the natural vegetation of the coastal lowland area has been cleared for crop production or improved pastures. (Johnson and Murray, 1997, p28). Approximately 12% of the floodplain is currently occupied by mangrove communities (Australian Nature Conservation Agency, 1996, p389). The range of mangrove species found on the floodplain form a complex mosaic and reflect changes in the hydrological regime. Approximately 2% is occupied by saline, largely treeless areas associated with mangroves. Four percent is represented by Melaleuca dominated swamp and riparian forests (consisting of *Melaleuca viridiflora*, *M. leucadendra*, *M. quinquenervia* and *M. dealbata*). Sedgelands (*Eleocharis dulcis*, *Lepironia* spp. and *Baumea* spp.) occupy approximately 0.4% of the floodplain with fresh or brackish lagoons also covering about 0.4% of the floodplain (Australian Nature Conservation Agency, 1996, pp389). Wetland communities including Melaleuca forest and woodland, Leichart (*Nauclea orientalis*) open woodland and sedgelands occur in poorly drained alluvials. Substantial areas of mangrove vegetation exist in tidally affected areas, bordered by salt water couch (*Spoorbolus virginicus*) and salt marsh species (Australian Nature Conservation Agency, 1996, pp389).

3.3.1.1 Values and Significance

The significance of the wetlands of the Herbert River Catchment is provided in the Directory of Important Wetlands in Australia produced by the Australian Nature Conservation Agency in 1996. The wetlands of the Herbert River Floodplain are a representative sample of wetlands in the Wet Tropics biogeographic region and are identified as nationally significant because:



1. "It is a good example of a wetland type occurring within a biogeographic region in Australia.
2. It is a wetland which plays an important ecological or hydrological role in the natural functioning of a major wetland system/complex.
3. It is a wetland which is important as the habitat for animal taxa at a vulnerable stage in their life cycles or provides a refuge when adverse conditions such as drought, prevail.
4. The wetland supports 1% or more of the national populations of any native plant or animal taxa.
5. The wetland supports native plant or animal taxa or communities which are considered endangered or vulnerable at the national level." (Australian Nature Conservation Agency, 1996, p2)

The seaward edge of the Herbert River delta is part of the most diverse and complex mangrove area in Australia (Missionary Bay-Hinchinbrook Channel-Halifax Bay) and is of international importance. The coastal edge of the delta along the shore of Halifax Bay towards Townsville provides a representative example of northern coastal wetland vegetation, which has become uncommon as a result of its location clash with human interests. The wetlands of the Herbert floodplain play a significant role in recharging groundwater and maintaining water quality in the river (e.g. by acting as filters and by supplying water to maintain flow during dry periods)" (Australian Nature Conservation Agency, 1996, p 389).

3.3.1.2 Distribution

The remaining wetland resources of the Herbert River Floodplain are small compared with the size of the floodplain (Australian Nature Conservation Agency, 1996). This is supported by Hogan and Graham who comment: "The first impression of the Herbert River floodplain we formed was the lack of freshwater wetland for the size of the floodplain. Obviously many lagoons and swamps had been drained and cleared or filled in" (Hogan and Graham, 1994, p2). Additionally they point out that the relatively flat nature of the topography has enabled the Herbert River to meander in the not to distant past, and consequently the floodplain should contain many remnant oxbow lakes and wetland areas. However reality, the amount of remaining freshwater wetlands is very disappointing (Hogan and Graham, 1994, p3).

Geographic data in the form of aerial photographs, other airborne imagery and mapping are among the most important information for both project specific or long-range environmental planning. Geographic data provide the basis: to calculate the distribution of mangroves and

wetlands in the catchment; to determine the impact of land use on wetlands; to formulate land use and coastal zone plans and to facilitate impact analysis using overlay techniques (Clark, 1996, p147). Mapping developed by the Department of Environment and CSIRO is useful to determine the distribution of remaining wetland habitats and as a tool for future planning and management.

C.S.I.R.O. Mapping

An analysis of the spatial and temporal distribution of wetlands within the Herbert River Catchment has also been undertaken by Johnson, Ebert and Murray. The study concentrates on coastal lowlands below 13m AHD (Australian Height Datum). A time series has been developed to demonstrate the spatial and temporal change in land cover for riparian and wetland areas (Johnson, Ebert and Murray, 1997, p10). To achieve this land cover of the lower Herbert River catchment was mapped from aerial photography taken in 1943, 1961, 1970, 1977, 1988, 1992, 1993, 1994 and 1995. 1996 land cover was mapped using SPOT Panchromatic and MSS imagery. From this land cover boundaries were mapped onto a geo-referenced digital base. Classification drew heavily on previous vegetation and soil surveys in the region. Classification of wetland areas was achieved using the method of Blackman et al (1992). Mapping units and mapped boundaries were ground truthed via vehicle and foot traverses. Classification of units and boundaries not inspected was undertaken by extrapolation form equivalent photographic units. Additionally an estimate of land cover prior to European settlement was produced through observed relationships between remaining stands of native vegetation and the known distribution of soils, topography, relief, hydrology and rainfall (Johnson, Ebert and Murray, 1997, p10).

This analysis found that prior to European settlement, the area was dominated by grassland, lowland rainforest and *Melaleuca* communities. By the 1940's extensive losses of riparian (rainforest patterns) and wetland (melaleuca dominated patterns; open water) areas had occurred and much of the native grassland had been converted either to grazing or sugarcane. Land cover remained relatively stable throughout the 1960's and early 1970's, however the period between 1977 and 1996 saw a dramatic expansion of sugar cane land. This resulted in a six fold decrease in the area of *Melaleuca* dominated patterns (four fold decrease between 1943 and 1996) and a 5 fold decrease in the areas of rainforest patterns when compared to pre European estimates of area. The distribution of mangrove communities has remained relatively stable since 1943(Johnson, Ebert and Murray, 1997, p14).

Department of Environment Mapping

Mapped information has been developed by the Department of Environment at a scale of 1:50 000. This information is recommended to be used at a scale of 1:50 000 for environmental purposes and at 1:100 000 for publishing. The purpose of this vegetation mapping was to provide up to date habitat and clearings information for lowlands habitat occupied by the Mahogany Glider and to provide a tool for conservation planning in the area. The vegetation units used for the project are based primarily on land type, with a strong emphasis on floristics. Structure further plays a part in the division of communities. Detail of mapping (ie: the smallest limit of polygon size) was determined by the smallest polygon physically possible to outline using a 0.3mm calligraphy pen on a 1:50 000 mapsheet. This equated to approximately 1mm diameter on the 1: 50 000 map or 50m on the ground.

3.3.2 Rare or Threatened Species

The Eastern Grass Owl occupies tall grass-tussocks in extensive swampy areas, grassy plains, swampy heaths, clumps of cane grass or lignum on floodplains and sedges. The only recordings in the catchment have occurred at Ingham. The Ingham area is an important bird habitat and

some 266 species of birds have been recorded. Reduction of habitat through clearing poses the greatest threat to the majority of rare and threatened species in the lower catchment is the loss of habitat due to clearing (Johnson and Murray, 1997, p35).

Several species of poorly known fish have been recorded in the floodplain of the Herbert River (Johnstone and Murray, 1997, p35). DPI fisheries biologists have conducted preliminary investigations into wetland habitats of the Herbert River Floodplain. Apart from this study there appears to be limited historical data available on the fisheries habitats of the catchment. The study found that the reduction in the total area of freshwater lagoons and wetlands is resulting in reduced catch rates (Hogan and Graham, 1994, p3; Australian Nature Conservation Agency, 1996, p288).

3.4 CULTURAL ASSETS

Five Aboriginal tribes, the Giramaygan, Bandjin, Wargamdygan, Njawaygin and Warunu, inhabited parts of the lower catchment. Aboriginal communities in the lower catchment still rely in part on the harvesting of natural resources. The National Register of the Australian Heritage Commission includes a number of sites and constructions within the lower catchment. Most sites are centred around wilderness areas, while the historically significant Gairloch Bridge and a historical stock route (Dalrymple Walking Track) also occur (Johnson and Murray, 1996).

3.5 CURRENT USES AND MANAGEMENT

Development has altered the condition of the Catchment (refer map 3). Most of the changes have been central to the economic development of the communities in the Catchment. The economy of the Catchment is based largely on primary production, principally sugar cane and beef cattle grazing. The principal land uses in the Catchment include beef cattle production; sugar cane production; horticulture and small crops; tourism and recreational use; urban and forestry (Johsntone River Catchment Coordinating Committee, 1996).

3.5.1 Beef cattle production

A substantial proportion (approx 696 000 ha) of the Catchment is dedicated to beef cattle production. Extensive pasture improvements have occurred in the lower Catchment however the area under improved pasture has been reduced to 2,000ha with the expansion of sugar cane production (Johnson and Murray, 1997, p40; Herbert River Catchment Coordinating Committee, 1996, p8). The present gross value of the grazing industry in the Catchment is estimated at 6 million. The vast majority of grazing takes place in the Tablelands section with some to the south and south-west of Ingham and is leasehold and crown land lining the foothills of the Hinterland. In the lower catchment most grazing take the form of small herds operated by cane farmers and occurs mostly on native pastures. (Johnson and Murray, 1997, p40)

3.5.2 Sugarcane Production

The sugar industry is the largest intensive agricultural industry in the Catchment (Johnson and Murray, 1997, p35). Raw sugar exports from the district was estimated at a gross value of $238 million (Herbert River Catchment Coordinating Committee, 1996; Shrubsole, 1997). Approximately 60 000 ha of land is devoted to cane and supplies the two sugar mills (Victoria and Macknade). Approximately 5420 ha is licensed to be irrigated from surface supplies. All sugar produced from the region is exported through a bulk sugar terminal located at Lucinda (Herbert River Catchment Coordinating Committee, 1996).

Cane farming is presently restricted to the Herbert Floodplain, although potential for expansion onto the Tablelands exists (Herbert River Catchment Coordinating Committee, 1996). At present cane is grown mainly in the area surrounding the two sugar mills and extending along the Herbert River to Abergowrie and the Stone River to upper stone and south from Yuruga to Crystal Creek (Refer Map 4). Sugarcane because of its many varieties, will grow on a wide range of soils (Johnson and Murray, 1996, p35).

Since 1991, the area has been one of the most rapidly expanding cane-growing areas in the country. The cane industry is presently expanding its area under production at around 7% per annum. It is forecast that approximately 70 000ha will be devoted to cane farming by the year 2000. (Johnson and Murray, 1997, p35; Herbert River Catchment Coordinating Committee, 1996; Shrubsole, 1997)

3.5.3 Horticulture and Small Crops

Other important crops in the Catchment include maise, sorghum, peanuts, and potatoes. Potato is the most significant crop (net value of $2.5 million). Large areas of the Catchment have suitable rainfall and climate conditions for timber production. There is significant potential for on farm forestry and timber production (Herbert River Catchment Coordinating Committee, 1996).

3.5.4 Tourism and recreational use

The lower Herbert Catchment provides a range of recreation and tourism opportunities including recreational fishing, nature based tourism, historical and cultural tourism based on sites from the early settlers, cattle and mining industries and the sugar industry. Nature based tourism takes advantage of National Parks and the Wet Tropics World Heritage Area which cover approximately 173 000 ha (Herbert River Catchment Coordinating Committee, 1996). Tourist visitation rates are relatively low compared to other wet tropical catchments. Lack of facilities and infrastructure and proximity to attractions are seen as the major factors limiting further development of this income source. Overall the Herbert River has the potential for greater recreation with a focus on wilderness experiences (Johnson and Murray, 1997, p43)

3.5.5 Urban

The Catchment supports a population of approximately 18 000 people. Major towns are Ingham (5100), Halifax (500), Lucinda (800), Herberton (950), Ravenshoe (880) Mount Garnet (380). Population expansion is occurring principally in beach townships to the east of Ingham and northern sections of the upper catchment around Ravenshoe. The lower Catchment is serviced by the Bruce Highway, arterial roads and Northern Railway (Refer Map 6).

3.5.6 Forestry

Large sections of the Catchment are developed for plantation forestry in both the upper and lower Catchment. Approximately 21500 ha are planned for developing exotic pines in the lower Catchment. The region has a large supply of crown land which is located close to outlets and markets and has suitable soils, topography and climate (Johnson and Murray, 1997, p39).

3.5.7 Management

Management of the Herbert River Floodplain is undertaken by a number of organisations

including: Sugar Cane Assignment Committees, Hinchinbrook Shire Council, Department of Primary Industries, Department of Natural Resources, Department of Environment, other Government Departments, Herbert River Catchment Co-ordinating Committee, Herbert River Improvement Trust, 6 local drainage boards, Landcare, Wildlife Preservation Society, Industry Organisations, and Individual Landholders (Herbert River Catchment Coordinating Committee).

Chapter 4:

ISSUES FOR WETLAND CONSERVATION IN THE HERBERT RIVER CATCHMENT

4.0 INTRODUCTION

Wetlands issues result form environmental pressures associated with new agricultural development and agricultural land management practices. Very closely related to this, is the current management framework which has also precluded conservation and is further contributing to wetlands issues. This chapter identifies the environmental pressures on the wetlands of the floodplain and describes the impact that current management arrangements is having in wetland resources.

4.1 ENVIRONMENTAL PRESSURES AND IMPACTS

The key sources of environmental pressure on wetlands are: the loss of wetland habitats associated with the expansion of the sugar industry; poor management within existing wetlands and poor management of land surrounding wetlands and for lands otherwise impacting on wetlands (ie: the off site effects of land management for example the alteration of drainage regimes, water quality issues, and the downstream effects of acid sulphate soils).

4.1.1 Loss of wetland habitats associated with the expansion of the sugar industry

The rapid expansion of the sugar industry is resulting in significant losses to the wetland resources of the Herbert River Catchment. As expansion is now occurring onto more marginal land, a higher degree of intervention is required before canegrowing is viable (Shrubsole, 1997). This is resulting in the destruction and drainage of swamps, billabongs and waterholes that provide important habitat areas and form an integral part of the hydrological regime (Johnson and Walker, 1997, p34). Rapid expansion also has the potential to cause erosion and sedimentation patterns, changes in freshwater runoff, the salinity regime and tidal flow patterns, the introduction of waterborne pollutants, destruction of submerged and fringing vegetation, inlet modifications, and loss of fishery habitat changes (Clark, 1996, p103). As recent expansions have occurred on relatively more marginal lands, resource managers need to ensure that only appropriate areas are developed for cane and that effective land management practices are adopted to achieve long term sustainability (Shrubsole, 1997).

4.1.2 Poor management of existing wetlands

Poor land management within existing wetlands has reduced wetland values. The largest threat is the destruction of wetlands for sugar cane production outlined above. Other threats include altered fire regimes associated with agricultural practices has disturbed the structure and composition of some wooded swamps (Australian Nature Conservation Agency, 1996). Infestation of wetlands by exotic plant species has also significantly degraded wetland quality by

outcompeting native species and eliminating them from some wetland areas. The Directory of Important Wetlands in Australia (Australian Nature Conservation Agency, 1996) identifies species posing the greatest threats to wetland quality. Aggressive introduced plant species common in some or most wetlands include Sensitive Weed *Mimosa podia*, Para Grass *Brachiaria mutica*, Blue Top *Ageratum houstonianum*, Salvinia *Salvinia molesta*, Water Hyacinth *Eichhornia crassipes*, *Urena lobata*, Rattlepod *Crotalaria incana*, Sicklepod and Yellow Guava *Psidium guavaja* (Australian Nature Conservation Agency, 1996, p389). Exotic plants impact on water quality by covering the waterhole in a thick mat. This stagnates the waterhole by preventing photosynthesis beneath the mat and increasing the accumulation of organic matter. Oxygen is depleted due to reduced photosynthesis and is consumed during the decay of accumulated organic matter (Australian Nature Conservation Agency, 1996). This has been linked to fish kills in the floodplain. (Hogan and Graham, 1994). Future large scale disturbance of mangrove and associated communities (especially melaleuca dominated communities) will increase the likelihood of invasion by exotic plant species (Australian Nature Conservation Agency, 1996, p 390).

4.1.3 Poor management of land surrounding wetlands and for lands otherwise impacting on wetlands

The management practices for land immediately adjacent to or otherwise impacting on a wetland area can significantly influence wetland quality. Runoff from agriculture may carry high nutrient and sediment loads thereby impacting on water quality (Australian Nature Conservation Agency, 1996). Additionally sediment from alluvial tin mining operations may be carried onto wetlands during periods of high flow.

The acidification of waters passing through or over disturbed acid sulphate soils negatively impacts on the water quality in wetlands, causing fish kills among other effects. Acid sulphate soils do not present a problem as long as they are sealed from the atmosphere, however, if they are exposed to oxygen (eg as a result of drainage works) chemical reactions take place that can reduce pH to levels as low as 2 or 3 (Australian Nature Conservation Agency, 1996; New South Wales Department of Land and Water Conservation, 1995).

4.2 CURRENT MANAGEMENT ARRANGEMENTS

Wetland conservation issues in the Herbert River Catchment are the result of current management arrangements. This has been determined by identifying the land tenure, planning controls, problems associated with the development control process, and the ability to cope with cumulative impacts, and the likely outcome if management continues in the same way.

Key features of the management system that are impeding wetland conservation include fragmented management arrangements and the failure to incorporate environmental considerations into the sugar industry expansion process. This is the result of limited ownership of wetland resources by the Crown or other management authorities, government policies, and also because of the limited role the Hinchinbrook Shire Council has had in regulating agriculture to achieve wetland conservation. Additionally the management system has no mechanisms to deal with cumulative environmental impacts. If current practices and management proceeds in the same way, wetlands of the Herbert River Floodplain will continue to be drained and filled for agriculture causing destruction of wetland areas and valuable mangrove ecosystems (Gutteridge Haskins and Davey, 1996, p6). This will have dramatic effects on the hydrology and ecology of the floodplain, river and marine environment.

4.2.1 Land Tenure

The tenure of wetlands effects conservation because it influences the planning and management controls that will be applicable, for example Crown land is not bound by the planning scheme.

Wetlands of the Herbert River Floodplain are contained within freehold land, leasehold land, Nipa Palms National Park, Wetland Reserves 033-018 and 033-019, and Fish Habitat Reserve 015-999 (part). They are surrounded by freehold and leasehold land, national park and state forest (Australian Nature Conservation Agency, 1996, p389). Currently the wetlands are being used for agriculture and conservation, and are surrounded by agriculture and conservation and state forest (Australian Nature Conservation Agency, 1996, p389) (refer table 4.1).

Table 4.1: (Adopted from Johnson, Ebert and Murray 1997, p7).

TENURE, LAND USE AND DISTURBANCE PROFILES FOR WETLANDS IN THE HERBERT RIVER CATCHMENT		
	ON SITE	**SURROUNDS**
Dominant Tenure	• Leasehold • Freehold • Water Reserve • National Park • Fish Habitat Reserve	• Leasehold • Freehold • National Park • State Forest • Marine Park
Dominant land use	• conservation • agriculture • recreation	• fishing • agriculture • conservation • recreation
Significant Disturbance/- Threats	• agriculture • weeds • runoff and drainage	• agriculture • weeds • runoff and drainage

4.2.1.1 Crown Land

Publicly owned wetlands are managed by the Department of Environment, and Department of Natural Resources. Potentially this facilitates increased planning and management for wetland conservation (Johnson and Cramb, 1992, Vol.6 p9). For example the lease of Crown land for grazing, and release of Crown land for agricultural expansion are both centrally planned activities that provide the opportunity to achieve effective wetland conservation. These processes permit a level of co-ordination that usually does not exist in areas where land fragmentation or alienation of land has occurred (Johnson and Cramb, 1992, Vol.6 p9).

Parts of the Herbert River delta have been declared as national parks by the Department of Environment. In addition, some mangrove and brackish wetland areas have been declared as wetland or fish reserves by the Department of Primary Industries. Some aspects of the Departments of Primary Industries' Sugar Industry Infrastructure Package for the Ingham region are aimed to maintain wetland values. The Department of Environment and Heritage's Sugar Coast Rescue Package and Mahogany Glider Rescue Package include acquisitions and conservation agreements that should, if implemented, facilitate the preservation of most of the remaining wetland habitat on the Herbert Floodplain. (Australian Nature Conservation Agency, 1996, p 390) These areas are regulated through management plans.

4.2.1.2 Freehold Land

The conservation of wetlands on private land has not occurred in the past. This is because authorities and agencies with the power to regulate freehold land have not incorporated environmental objectives into rural land development. The sugar industry through the cane assignment process and the Shire Council through the Planning Scheme both have significant powers to control land use for conservation purposes. The impact that of these two agencies on wetland conservation will now be considered.

Sugar Industry Expansion and the Assignment Process

The expansion of the sugar industry was partly stimulated by the *Sugar Industry Act 1991* which enabled a minimum expansion of 2.5% of sugar cane land (about 10, 000 ha) per year between 1991 and 1995, which has been exceeded. After 1995 the extent of further expansions were to be determined by the Queensland Sugar Corporation (QSC) based on an assessment of land suitability (Shrubsole, 1997). On granting assignments, conditions can be imposed on sugar cane development (refer Appendix 1) and it is through the conditioning of cane assignments that wetland conservation can potentially be achieved.

Traditionally land suitability has been the predominant natural resource issue considered in examining cane land expansion (Shrubsole, 1997). However expansion involves a whole range of environmental issues including wetland loss. To try and address these environmental issues through the assignment process, government agencies such as the Queensland Department of Natural Resources were to become part of the assessment process. However Shrubsole (1997) concludes that current institutional arrangements are ineffective in achieving this. In reality government agencies have not been informed about cane assignments through normal administrative channels. To solve this problem an *ad hoc* technical review committee was established in the Herbert River to evaluate proposed assignments (Shrubsole, 1997). However interviews with officers from government agencies in Ingham also suggests that this may be ineffective as assignments have been granted before assessment by referral agencies.

The Sugar Industry Assignment process provides the opportunity to influence freehold land development and provides a very useful management tool for industry planning to achieve wetland conservation. Unfortunately the assignment process has not maximised this potential. The cane assignment process can be more fully utilised to direct development away from key wetland areas and rationally plan farm development (Creighton, Dickenson and Golden, 1994, p1). "Property management planning involving the Cane Assignment Boards, assignees, Bureau of Sugar Experiment Stations, Department of Natural Resources, Department of Primary Industries and Department of Environment provides a means whereby farm development can be planned to maximise economic returns while minimising environmental impacts" (Creighton, Dickenson and Golden, 1994, p1).

However in reality the integrity of the assignment system is being questioned. Government policies are contributing to wetland loss by opening up marginal land for intensive agriculture. Growers have indicated that pressure from industry organisations to increase production has influenced them to utilise marginal land thereby draining wetlands, opening up saline areas and cutting down melaleuca swamps (Gutteridge, Haskins and Davey, 1996). Assignment boards are perceived by the community as acting too quickly, the Departments of Environment and Primary Industries have little real input into the outcomes of the system and there are no mechanisms to cease or address potential undue environmental damage (Gutteridge, Haskins and Davey, 1996)

Hinchinbrook Shire Council Planning Scheme

A rigorous environmental assessment by the Sugar Assignment Committee would facilitate complementary follow up action by Local Authorities. In the absence of this assessment the Hinchinbrook Shire Council needs to increase the regulation of rural development to achieve wetland conservation (Creighton, Dickenson and Golden, 1994). This expanded regulatory role has not been realised by Council in the past and therefore Council has had limited control over rural land use and management. Traditionally, statutory controls are regarded by rural landowners as an infringement of their property rights (Hollick, 199_) and the self interested behavior of Landholders has often makes it difficult to achieve landholder co-operation (Synott,

199_). This has been a major constraint in achieving wetland conservation on private property for community benefit (Crieghton, Dickenson and Golden, 1994). However this is gradually changing as pressure on land resources increases and the community values reflects greater concern about ESD.(Johnson et al, 1996, p11).

To overcome this the Hinchinbrook Shire Council is currently expanding their control over rural development through the Draft Planning Scheme for the Shire. This will be the first time that development will be controlled across the whole shire. The intention of the planning scheme is to provide Council with greater control over rural development. This is to be achieved through the Strategic Plan, regulation of agricultural uses and wetland conservation (McDonald and Bellamy, 1997). This will facilitate greater management of freehold land for nature conservation purposes. A detailed analysis of the implications of the draft planning scheme on wetland conservation is provided below.

4.2.2 Planning Controls Affecting Wetlands

The Local Government (Planning and Environment) Act 1990 provides the Hinchinbrook Shire Council with the power to control development through the planning scheme and impact assessment procedures. As has been outlined the Hinchinbrook Shire Council is in the final stages of preparing a scheme. This will influence the conservation of wetlands through the Strategic Plan, regulation of agricultural uses and wetland conservation (McDonald and Bellamy, 1997).

4.2.2.1 The Strategic Plan

Council clearly makes a strong commitment to natural resource management through the Town Plan. This is demonstrated through the Broad Aim of the Strategic Plan which seeks "To provide a framework to facilitate the continuing use and development of the Shire's resources according to sound environmental and catchment management practices, and, to promote the diversification of the Shire's economic base, for the long-term benefit of the community" (Hinchinbrook Shire Council, 1997). The overall thrust of the Strategic Plan, as reflected in the broad aim and the broad strategies, is to promote environmentally and economically sustainable development for the long-term benefit of the community and successive generations (Hinchinbrook Shire Council, 1997) (McDonald and Bellamy).

Council's obligation to wetland conservation is established through three broad Integrated Catchment Management objectives. The first is "to identify and designate the catchments and sub catchments of the Herbert River which lie wholly or partly within the Shire' (Hinchinbrook Shire Council, 1997). This is to be implemented through the assessment of planning and development proposals on the basis of the catchment system and potential impacts of development upon the natural resource of that system. Catchment management strategies and specific catchment data are to be "taken into account" in the assessment of any planning proposal (McDonald and Bellamy, 1997).

Objective two is "to ensure that, as a result of the development and use of land no environmental impacts affect any lands elsewhere within a catchment designated in this Strategic Plan" (Hinchinbrook Shire Council, 1997). This will be implemented by a commitment of having "regard for and shall implement the principles of ICM" and the "may refuse to support any proposal which will generate unacceptable effects upon any land...", and "may require the preparation of an EIA" where detrimental downstream effects or impacts are possible" (McDonald and Bellamy, 1997).

The third Objective is "to promote sensitive and sustainable land use practices through the development process" (Hinchinbrook Shire Council, 1997). This will be implemented by requiring and encouraging "all development and land uses... to adopt sound management

practices so as to minimise, mitigate and contain the impacts on the land, water and biological resources of the catchment system". Additionally "the Council may refuse to support any proposal which would prejudice the long-term values of the resources within the catchment system affected" (McDonald and Bellamy, 1997).

Implications for wetland conservation

The strategic plan establishes the broad intent to conserve natural resources and minimise the impact of development on the environment. This is to be implemented through the development assessment process, environmental impact process and by encouraging the adoption of sound land management practices. While the Strategic plan clearly establishes this intent the framework required to implement this has not been established in the scheme. The development assessment system does not specify the form that development applications will take, the criteria for approval or who is to appraise the plans or proposals against the criteria. Additionally the plan does not specify how proposals will be appraised against planning criteria, whether property management plans or impact assessments are required, or if monitoring provisions should be implemented (McDonald and Bellamy, 1997,).

4.2.2.2 Zoning Controls and Development Assessment
Hinchinbrook Shire Council has adopted a simple zoning scheme which divides the local authority into five zones these being Public Purposes, Rural, Town, Village, Special Activities (Hinchinbrook Shire Council, 1997). The planning scheme does not include any zone with the primary inent being to conserve natural resources. This limits the scheme's ability to protect core wetland areas.

REGULATION OF AGRICULTURAL USES

The draft planning scheme has sought to regulate agriculture to achieve Integrated Catchment Management objectives. The regulation of agriculture has been achieved by defining 'agriculture' and 'intensive agriculture' as separate land uses requiring different approval processes (refer table 1). This separation of the two rural uses could create confusion unless unambiguously defined (McDonald and Bellamy, 1997, p8), however it also has the potential to improve the conservation of wetlands through the planning scheme.

Table 4.2 (Source: Hinchinbrook Shire Council, 1997, p47)

Hinchinbrook Shire Council Planning Scheme Rural Purposes Definitions	
Agriculture	The use of land, and buildings on the land, for the purposes of producing primary products from cropping, grazing or stock, and horticulture including the use of the land for an ancillary activity necessary for the conduct of the principal use
Intensive Agriculture	The use of land for the intensive production of crops, such as but not limited to sugarcane, at rates of production beyond the natural capability of the land where the land is irrigated for such purposes and relies upon the regular and systematic application of fertilisers and other chemicals. The term includes the establishment of any infrastructure necessary for the conduct of the use The term does not include small-scale agriculture conducted on premises or a site less than 5 hectares in area ".

Designated Uses Requiring Approval

Agriculture is a "permitted development" in the rural zone. As a result, the land can be used for agriculture (as defined) and for small-scale agriculture conducted on premises or a site less than five hectares in area (as defined for Intensive Agriculture) without needing to apply to Council

for approval. This impacts on wetland conservation as sites of less than five hectares can possess wetland values that are worthy of conservation and in the case of small wetland habitats, can have an important role in the hydrological regime of the Herbert River Floodplain. However Council will have no control over the development of these sites. Clearly very small areas should not require regulation, but setting the minimum threshold too high could allow many significant developments to go unregulated (McDonald, and Bellamy, 1997, p8).

In the Rural Zone intensive agriculture is defined as a "permitted development subject to conditions". Consequently Council has discretionary power to assess an application for intensive agriculture and apply conditions where necessary (Bates, 1995). Council cannot refuse a permitted development subject to conditions. However it does have the power to impose conditions on development to achieve wetland conservation. Development assessment is initiated when the applicant applies to council if they propose to "use the land for the intensive production of crops, such as, but not limited to sugarcane, at rates of production beyond the natural capacity of the land where the land is irrigated for such purposes and relies upon the regular and systematic application of fertilisers and other chemicals. Additionally development assessment is initiated when an applicant seeks to develop infrastructure associated with intensive agriculture. This means that when an applicant wants to convert to sugar cane or establish infrastructure for the growing of sugar cane they need to apply to council for permission However this raises the question of what will be used for the definition of 'infrastructure'. Rural infrastructure differs from urban infrastructure and confusion may be created if this definition is not clear. As it currently stands, the definition could potentially include structures from farm sheds to access roads (even if they are dirt roads) and farm drains.

Neither agriculture or intensive agriculture require consent application under the planning scheme. Consent applications are different to permitted development applications in the application process and the options available to council in assessing the application. Firstly the proposal needs to be advertised to give the public the chance to comment on it. The range of issues that need to be considered by Council is greater including: whether the environment would suffer any unacceptable impact caused by the proposal; and if all objections which have been duly lodged within the prescribed time against the granting of consent by the Council. In accordance with the Local Government (Planning and Environment) Act, 1990, Council can grant consent; refuse to grant consent; or grant consent subject to reasonable and relevant conditions. Therefore unlike permitted development applications, Council can refuse to grant consent and therefore if a proposed development poses unacceptable effects on wetlands, it can be refused. Terms for refusal are also established in the scheme and those relevant to wetland conservation include if: flood mitigation, drainage of filling works required within the site would adversely affect surrounding land; the proposal will have an unacceptably long-term effect upon the environment; the proposal would be in conflict with any provisions of the Strategic Plan in effect in respect of the subject land.

Criteria for the approval of regulated uses

The planning scheme does not establish any criteria to facilitate development assessment or establish criteria for the approval of regulated uses. As a result it does not provide guidelines, performance standards or best practice for relevant environmental issues, natural resource protection, water quality and quantity issues. The planning scheme does not specify what changes can be made to drainage and flood regimes. These conditions need to be specified in planning documents in such as way to give clear prior guidance as to desired developments (McDonald and Bellamy).

Assessment of development applications against criteria

When determining conditions for intensive agriculture the planning scheme states that Council is to consider the character of the proposed development in relation to: the character of development on the adjoining land and in the locality; the adequacy of any proposed landscaping; the retention of existing vegetation and buffers to adjoining land and roads; the provision for storage and disposal of waste; the provisions of the planning scheme including the strategic plan and any Local Planning Policy of the Council, relevant to the application. However because no criteria has been established the scheme just identifies general considerations.

4.2.2.3 Wetland Conservation

The planning scheme has the potential to achieve the effective conservation of wetland resources, yet in reality this has not been achieved. Council's strong commitment to ICM and radical regulation of agricultural development is to be commended. The next step is to develop the details that will make this plan implementable (McDonald and Bellamy, 1997). Towards this end, the scheme needs to include performance conditions or development criteria that will assist development assessors achieve wetland conservation. It is particularly important that these tools are included in planning schemes, especially for Shires such as Hinchinbrook, where there is no professional planner on staff. Therefore it is imperative that the implementation framework reflect best practice and considers obstacles such as the capability of the Local Government (McDonald and Bellamy, 1997).

4.2.3 Problems of the Development Control Process

The suitability of the development control process to achieve wetland conservation is hindered by the inadequate regulation of rural development by state and local governments, poor co-ordination between management authorities and the influence of government policies.

4.2.3.1 Inadequate Regulation of Rural Development

Until now, the major problem with the development control process has been the inadequate regulation of rural activity by State and Local governments. The State Government through the assignment process and the Shire Council through the planning scheme both have the potential to regulate the expansion of the sugar industry and to achieve sustainable wetland development. Instead, current development appears to be based on direct economic comparisons (Johnson and Cramb, 1992, Vol.6. p14). Moreover, the development control process has failed to cope with incremental changes and the cumulative impact on wetland environments (Duncan, 1993).

4.2.3.2 Lack of Co-ordination Between Management Authorities

Fragmented institutional structures has precluded the effective implementation of measures to achieve wetland conservation (Johnson, Shrubsole and Merrin, 1996). At the strategic planning and administrative levels, a lack of co-ordination between those management agencies responsible for managing land and water resources has produced a complex web of policies, plans and approval processes. This, combined with a lack of communication and information sharing between government agencies, is a key causal factor of current wetlands issues. Integration is required between and within government agencies, the Hinchinbrook Shire Council and the Herbert River Catchment Co-ordinating Committee (Johnson, Shrubsole, and Merrin, 1996, p303).

4.2.3.3 Government Policy

State Government policies are inadvertently encouraging the loss of wetland habitats and causing subsequent soil and water degradation. Some growers have indicated that perceived pressures to increase production had influenced many growers to utilise marginal land, thereby draining wetlands, opening up saline areas and cutting down melaleuca swamps (Gutteridge, Haskins and

Davey, 1996, p20).

Policy decisions at the Local Government level are influenced partly by the relevant planning legislation and partly by the willingness of the community to support increased regulation. Support by the community is influenced by their understanding of and value of their natural resources (Young, 1996, p375). Poor understanding of wetland resources and their benefits in the past produced local government policies that afforded little protection to wetland habitats. Fortunately, an expanding understanding of the benefits of wetlands has caused a shift in policy direction resulting in the increased regulation of rural activity.

4.2.4 Cumulative Impacts

Current wetlands issues are the product of a tyranny of small decisions, the cumulative impact of which is the increasing degradation of wetland habitats. While planning schemes can provide a statutory basis for the achievement of Integrated Catchment Management, they are ineffective to deal with cumulative impacts on natural resources. Planning Schemes have limited scope in this regard because they do not apply retrospectively and are effective only when a development application is made. Each application is considered independently, and planning schemes have limited power to ameliorate impacts beyond the immediate site of the development (Young, 1996, p375).

4.2.5 Likely Outcomes if Management Proceeds in the Same Way?

If management proceeds in the same way there will continue to be losses in flora, fauna and fisheries habitats, serious environmental problems, greater conflict between landholders, increased expenses (to maintain drainage schemes) and long term productivity losses.

CONCLUSION

Issues for wetland conservation in the Herbert River Catchment include environmental pressures associated with the expansion of the sugar industry and poor land management practices in and surrounding wetlands. Additionally, the land management/development framework is also impacting on wetland conservation. Pressures are being placed upon the wetlands of the Herbert River Floodplain from surrounding agricultural development. These development pressures have caused, or have the potential to cause adverse environmental impacts on wetland benefits. Many of the current management problems affecting the Herbert River Floodplain are the result of a lack of coordination between government agencies and poor planning decisions in the past. Wetland conservation is also complicated by a lack of ownership by management authorities which restricts available policy options.

Chapter 5:

DEFINING WETLANDS AND DESIRED ENVIRONMENTAL OUTCOMES

5.0 INTRODUCTION

Towards the achievement of objective two, the identification of suitable planning provisions to achieve wetland conservation, several major components are involved. Firstly it is important to define wetlands requiring protection in a manner that could be included in the planning scheme. Following on from this, it is necessary to determine the ecological conditions of wetlands that must be maintained if they are to be conserved. Finally it is necessary to identify planning methods that can potentially be used to conserve wetlands. This chapter identifies a suitable definition of wetlands for the Herbert River Floodplain and determines the desired environmental outcomes for wetlands.

5.1 DEFINING WETLANDS

Actually defining a wetland is a very difficult task. The difficulty in definition arises when attempting to differentiate between terrestrial environments and wetlands, and between wetlands and aquatic and marine environments. Additional difficulties arise over the scope of the definition which can have significant implications on the range of lands that can be included as wetlands. This can cause problems, especially in politically or legally complicated situations (Duncan, 1993). From a land use planning perspective there are several benefits of defining wetlands through the planning scheme. Firstly, by clearly identifying wetlands they can be more effectively managed for conservation purposes. Secondly, identification will provide greater certainty for Governments, landowners, and the wider community by facilitating the easy detection of areas that will be subject to greater restrictions on land use. Thirdly, as planning schemes are statutory documents, definition in the scheme can be a valuable guide in legal or other challenges. Therefore to achieve their conservation, wetlands need to be defined and provisions need to be incorporated into the planning scheme.

Not all definitions of wetland are suitable for the conservation of wetlands on the Herbert River Floodplain. In determining a suitable definition, a range of current definitions will be evaluated. These include International & National Definitions, State Definitions, Regional Definitions and Local Definitions.

5.1.1 International & National Definition

The international definition of wetland established by the Ramsar Convention has been adopted at the national level. This is supported by the 'Directory of Important Wetlands in Australia (2nd edition)' which uses the Ramsar definition. It interprets wetlands as "areas of marsh, fen, peatland or water, whether natural or artificial, permanent or temporary, with water that is static or flowing, fresh, brackish or salt, including areas of marine water the depth of which at low tide does not exceed six metres." (Australian Nature Conservation Agency, 1996, p2).

While the Ramsar definition is one of the most accepted definitions of wetland, its value in the Herbert River setting is limited. This definition is very broad and uses terms such as fen, which are not easy to define in the North Queensland context (Claridge, 1994). To be more effective the definition would need to reflect the environmental characteristics of the study area (ie: by specifying landform types, soil characteristics, and vegetation communities).

5.1.2 State Definitions

At the state planning level, wetlands are defined in the Local Government Planning and Environment Act and includes "Wetland, whether fresh, brackish or marine, including coral reefs, mangrove areas, mudflats, sandflats, sandy beaches, seagrass beds and tidal marshes" (Queensland Local Government (Planning and Environment) Amendment (No1), No118, 1994). This definition of wetlands is very broad and is based on landform type only. It does not refer to wetland indicators such as the permanency of the wetland system, the frequency of inundation, predominant vegetation type, or soil characteristics. The words "wetland, whether fresh, brackish or marine" open up the question of "what is a wetland?" to many areas on the Floodplain because of climatic and other environmental conditions. Consequently this definition, if it were to be adopted for the Herbert River Floodplain, could easily include lands that possess few wetland qualities.

5.1.3 Regional Definitions

Wetlands have been defined at a regional scale by the Department of Environment and CSIRO. Regional mapping undertaken by the Department of Environment covers the whole of Hinchinbrook Shire, northern parts of Thuringowa Shire and the Southern end of Cardwell Shire. The system defines a range of vegetation communities based on predominant vegetation

species, structure and composition, and soils and landform characteristics including frequency of inundation. From this information, it is possible to define communities that are wetlands or have a wetland affinity. This system provides a more suitable definition of wetland by including a number wetland values such as frequency of inundation, predominant vegetation cover, soil type and landform characteristics. Consequently the resulting wetland areas reflect the local characteristics of the Herbert River Floodplain

5.1.4 Local Definitions

Local Authorities often include a definition of wetlands in their Planning Schemes to allow the identification of these areas through the development control process. Unlike National or State Governments, Local Authorities can use specific definitions that suit local conditions. In doing so, the definitions adopted by Local Authorities will vary between government boundaries. Therefore, it is useful to consider the constitution of alternative definitions and the implications they might have for wetland conservation. Definitions included in the planning schemes for Hinchinbrook Shire Council, Cardwell Shire Council and Johnstone Shire Council will be examined.

5.1.4.1 Hinchinbrook Shire Council

The planning scheme for Hinchinbrook does not establish a definition of wetlands. Several "Wetland" and "Coastal Wetland" areas have been identified through the Planning Study, however this is not a statutory document under the Act and is therefore limited in its ability to achieve wetland conservation. Consequently the definition of wetlands established in Schedule 2 of the Local Government (Planning and Environment) Regulations for impact assessment procedures would be the sole consideration. However, as has been discussed previously this definition is not sufficient to afford protection to significant wetland environments.

5.1.4.2 Cardwell Shire Council

Neighbouring Hinchinbrook Shire to the north, Cardwell Shire defines wetlands as "areas whether permanent, seasonal or ephemeral, conceptually between terrestrial and aquatic environments that are subject to freshwater or saltwater inundation with sufficient frequency to support aquatic macrophytes and similar vegetation. Tidal wetlands are characterised by mangroves and saltmarsh, with Melaleuca (tea tree) species generally associated with freshwater wetlands. The term includes retention and detention basins, lagoons, swamps, sedgelands and billabongs" (Cardwell Shire Council, 1997).

This definition is more specific for the conservation of wetlands in a local area. It defines wetlands by differentiating between marine and terrestrial environments. The definition has been tailored to suit local conditions by referring to wetland characteristics including landform type and the influence of inundation upon vegetation characteristics. However this definition does not refer to predominant soil types or a map of wetland areas.

5.1.4.3 Johnstone Shire Council

The Johnstone Shire Council defines wetlands in the Draft Planning Scheme as follows:

"Wetland: means where:

(a) hydric soils are present
(b) where the water table is at, or above the soil surface for thirty consecutive days a year; and or
(c) the following vegetation conditions occur
    (i) the aerial extent of wetland and transitional species or any combination thereof, in the selected stratum (canopy, sub canopy, or ground cover) is greater than 50 percent of all the plant species for that stratum
    (ii) the aerial extent of the wetland species in the selected stratum is greater than 10 percent

of the aerial extent of all the plant species in that stratum

(iii) the aerial extent of the wetlands species in the selected stratum is greater than the areal extent of upland species in that stratum; as well as areas identified as wetlands on Regulatory Map R3, Wetlands, based on the vegetation communities described in the planning study" (Johnstone Shire Council, 1996, pB-18)

Again this definition is specific to Johnstone's local environment. The wetland indicators used are soil types, length of inundation and resultant vegetation conditions. Additionally, the definition refers to wetlands already identified through mapping and it addresses the issue of permanency by using an empirical qualifier which is relevant in the local context. By being very specific it increases certainty for landowners, the community and Council over the definition of wetland areas.

5.1.5 Conclusions

From the above analysis it is evident that Hinchinbrook Shire Council needs to include a definition of wetland within the scheme. To effectively do this a number of wetlands qualifiers are required that reflect the characteristics of the Herbert River Floodplain. Consequently desirable elements of a definition would include:

- landform characteristics of wetlands of the Herbert River Floodplain
- soil wetness or frequency of inundation
- soil types typical of wetlands on the Floodplain
- predominant vegetation communities for wetlands on the Floodplain
- wetland mapping to be included in the scheme and referred to in the defintiton.

It important that the Hinchinbrook Shire Council incorporate a suitable definition into the planning scheme for wetland conservation.

5.2 DESIRED ENVIRONMENTAL OUTCOMES

To manage wetland areas, conservation measures must address current wetland issues and pressures and should reflect principles of ecologically sustainable development. Additionally, conservation measures need to ensure that the functions of wetlands are maintained or enhanced. This can be achieved by identifying desired environmental outcomes for wetlands which will become the criteria for approval in the development assessment process and the criteria for evaluating the effectiveness of planning solutions. This may be as easy as identifying the key functions of wetland areas. Kent suggests that wetland functions can be used as a base for the establishment of regulations for a variety of land and water related planning issues(Kent, 1994, p56). Viewing wetlands as an ecosystem, their major functions can be identified as including:

- hydrology (volume, movement, properties and use of water)
- pedology (soils)
- morphometry (landform characteristics)
- biology (flora and fauna)

5.2.1 Hydrology

Water is a key element in all wetlands and includes water depth, flow rates, flow patterns flood attenuation for storm or flood waters, natural water quality improvement, groundwater recharge, shielding other areas from wave action, erosion, or storm damage, and storage for storm or flood waters (Kent, 1994, p57). The hydrology of the wetlands on the Herbert River Floodplain is influenced by the key elements of water quality and quantity.

5.2.1.1 Water Quantity

Water quantity is a key factor impacting on wetland habitats. The volume of water in a wetland

influences the resultant landform type, permanency of the wetland or frequency of inundation, resultant soil conditions, and dominant vegetation characteristics. Therefore the volume of water entering the wetland, the volume remaining in the system and the volume of water draining from the wetland has a significant impact on the function of wetland habitats.

Intensive agriculture can alter the hydrological regime of wetlands by reducing water flows into wetlands by modifying natural drainage paths to direct water elsewhere and reducing the water in wetlands by draining and filling them. Alternatively, agriculture has the potential to significantly increase the flow of water into wetlands by expanding the areas that drain into wetlands. Other effects on the hydrology regime include the use of dams and other structures to retain water in wetlands and altering water flows both in and out of wetlands over a short period of time (Hogan and Graham, 1994)

5.2.1.2 Water Quality

Water quality is important for the maintenance of the biological resources of the wetland. It is influenced by agricultural runoff which if, nutrient enriched, can lead to the eutrophication of wetlands. Additionally, chemicals and pesticides and other toxants from agriculture can pollute water, sedimentation can lead to the smothering of aquatic habitats and has been linked to fish kills (Hogan and Graham, 1994, p2)).

5.2.1.3 Desired Environmental Outcomes

- maintain water quality in wetlands
- maintain the hydrological regime of wetlands

5.2.2 Pedology

The quality of soil within wetlands and also from lands on wetland environments can have a significant effect on wetland functions. Wetlands soils are characterised by anaerobic conditions which are the result of permanent or periodic inundation (soil saturation) (Kent, 1994, p58). Acid sulphate soils are typically found in coastal lowland areas (eg mangrove tidal flats, salt marshes or tea tree swamps).

5.2.2.1 Acid Sulphate Soils

Acid sulphate soils are acidic soil horizons resulting from the aeration of previously waterlogged soil materials, rich in iron sulphides (primarily pyrite - FeS_2). When drainage or aeration brings oxygen into these previously waterlogged soils, the pyrite is oxidised to sulfuric acid. If the production of acid exceeds the neutralising capacity of the soils, so that the pH falls to below 4, these soils are known as actual acid sulphate soils (AASS). Potential acid sulphate soils (PASS) are waterlogged soils rich in pyrite that have not been oxidised. Any disturbance which admits oxygen will lead to the development of actual sulphate soil layers. Potential acid sulphate soils are completely innocuous to the environment if kept under water. However, when drainage or aeration brings oxygen into these previously waterlogged soils, they are oxidised into sulfuric acid and become acid sulphate soils (New South Wales, 1995, p 3).

Increasing pressure is being placed on lands containing potential acid sulphate soils, for agricultural production. If unmanaged, rapid expansion into wetlands can create acid sulphate soils and cause soil problems (New South Wales, 1995, p12). On site, the effect of AASS includes the lowering of the pH of the soil to extreme levels, at times less than three (3). Highly acidic conditions in the soil result in toxicities including increased solubility of aluminium, iron and sometimes manganese and nutrient deficiencies can be severe. Oxidisation of pyrite can also contribute acid salts to the soil causing a high degree of salinity. This causes real problems for farmers wanting to improve the agricultural productivity of an area (New South Wales, 1995). Off-site, heavy rains on AASS following dry periods causes the flushing of extremely acid and aluminium-rich toxic water. This can have profound effects on the aquatic populations of

estuarine systems by causing massive fish kills and estuarine habitat degradation and impacting on commercial estuarine fishing (New South Wales, 1995).

5.2.2.2 Desired Environmental Outcomes
- minimise the impact of acid sulphate soils and other soil contaminants in wetlands

5.2.3 Morphometry (Landform Characteristics)
The surrounding landform characteristics also impacts on the functions and values of wetlands. Important landscape characteristics includes location, drainage area, surrounding land use, area, slope of surrounding land, and perimeter to slope area. As most wetlands are located in topographic depressions, the surrounding landscape can have a significant bearing on wetland functions (for example it influences sediment trapping ability) (Kent, 1994, p58).

The landform characteristics of the Herbert River Floodplain influence the form and function of the wetlands in the system. The landscape influences the location of wetlands, the depth of the wetland depression, the quantity of water that would naturally drain into the system, and the permanency of the wetland. In addition this influences the types of vegetation species typical of a wetland. For example very slight drainage depressions on creek and river alluvial plans will produce seasonal swamp/riparian Melaleuca woodlands, whereas depressions or deep sections of water courses of the alluvial plans may produce swamp sedgeland/herbfield (Department of Environment, 1997). The location of the wetland in the landscape and the predominant vegetation species will influence the type of fish and bird species present.

Large scale alteration of the landscape will impact on the form and function of wetlands. In the past this has occurred by changing the form of wetlands by digging deeper depressions, narrowing them and adding islands, and by changing the form of wetlands through siltation, producing shallower wetlands.

5.2.3.1 Desired Environmental Outcomes
- minimise structural changes to wetlands
- minimise disturbance to wetland morphology from off-site landform changes

5.2.4 Biology
Wetlands play a crucial role in the survival of numerous fauna and flora living within wetlands, as well as flora and fauna living adjacent to wetlands. Wetlands functions are frequently based on vegetation (species, coverage, survival), fauna (species, density, and habitat quality), sanctuary refuge value for fish, wildlife and waterfowl, and food chain production and production export to adjacent ecosystems (Kent, 1994, p57). Therefore to maintain wetland values, it is important that valuable wetland habitats be protected from clearing.

Many degraded wetland habitats on the Herbert River Floodplain have been infested with exotic plants. This can have a dramatic impact on the functioning of wetland systems, such as their ability to act as fisheries nurseries, and it is therefore important to minimise this impact on wetlands.

5.2.4.1 Desired Environmental Outcomes
- minimise the loss of wetland habitats
- preserve and enhance the quality of wetland habitats

Chapter 6:

PLANNING SOLUTIONS TO ACHIEVE DESIRED ENVIRONMENTAL OUTCOMES

6.0 INTRODUCTION

Following on from the definition of wetlands and the identification of desired environmental outcomes, it is now necessary to identify planning solutions that could be used to achieve these results. To do so, a range of planning and conservation techniques used by local authorities and management authorities across Queensland have been identified. They have been described in relation to their ability to conserve wetlands in a rural context. Collectively authorities utilise a suite of planning mechanisms for natural resource conservation, namely: regional planning programs; planning schemes (strategic plan and zoning and development control); performance standards and environmental monitoring; environmental impact assessments; financial incentives; retention of land through subdivision; bonus development/transferable development rights; vegetation protection ordinances; voluntary conservation agreements; land acquisition; property management planning; and best management practices.

6.1 REGIONAL WETLAND CONSERVATION PROGRAM

A regional wetland conservation program provides an overall framework for planning options or conservation methods to be incorporated into the planning scheme and additional conservation methods to implement strategies (refer figure 6.1). It can be achieved by developing a system of core protection areas surrounded by multiple use buffer zones. Noss (1994) concludes that this system offers the best opportunity for protecting sensitive species and intact ecosystems because it prevents the destruction of native biodiversity by changing land use allocations and management practices at a regional level. The basic components of a regional conservation program include core reserves, buffer zones and connectivity, and the most important considerations in the design and management of these systems are representation of all ecosystems, population viability of sensitive species and perpetuation of short term and long term evolutionary processes.

Table 6.1

REGIONAL WETLAND CONSERVATION PROGRAM
CORE WETLAND RESERVES Zone: Rural A: Conservation **Conservation Methods** • Land Acquisitions • Retention of Land through the subdivision process • Vegetation Protection Ordinances • Voluntary Conservation Agreements and Financial Incentives • Monitoring
BUFFER WETLAND RESERVES Zone: Rural B: Agriculture (Conditions - Agriculture remains an as of right use, however threshold to be reduced from 5ha) **Conservation Methods** • Voluntary Conservation Agreements • Bonus Development Rights • Environmental Impact Assessments • Performance Standards and Monitoring • Property Management Planning
Zone: Rural C: Intensive Agriculture (Conditions: Permitted Development Subject to Conditions) **Conservation Methods** • Performance Standards and Environmental Monitoring • Environmental Impact Assessments • Property Management Planning • Voluntary Conservation Agreements

6.1.1 Ecological Goals

Noss has defined several ecological goals of developing a regional conservation program to maintain the native biodiversity of a region. These are: to represent in a system of protected areas all native ecosystem types and stages across their natural range of variation; maintain viable populations of all native species in natural patterns of abundance and distribution; maintain ecological and evolutionary processes: maintain ecological and evolutionary processes (such as disturbance regimes, hydrological processes, nutrient cycles, and biology including predetation); allow for change (design and manage the system to be responsible to short term and long-term environmental change) and to maintain the evolutionary potential of linkages (Noss, 1994, p11).

Four approaches can be used to achieve these objectives and are identified in Table 6.1 below.

Table 6.2 (Source: Noss, 1994, p13)

Approaches to a Regional Wetland Conservation Program	
1	Identify and protect populations of rare and endangered species
2	Maintain healthy populations of species that play critical roles in their ecosystems (key-stone species) or that have pragmatic value as "umbrellas" (species that require large areas in to survive, and thus if protected will bring many species along with them) or "flagships" (charismatic species that serve as popular symbols for conservation)
3	Protect high-quality examples of all natural communities and
4	Identify and manage greater ecosystems or landscapes for both biodiversity conservation and sustainable human use

These four approaches to conservation must be pursued in concert if the full spectrum of biodiversity is to be protected (Noss, 1994, 13). Traditional strategies of protecting individual sites that support rare species or natural communities can work for plants and animals with small area requirements. However to conserve landscape mosaics, higher order expressions of biodiversity and to protect wide-ranging animals, small reserves conserved on a site by site approach are less effective because they often face greater external influences and often fail to retain the natural qualities for which they were set aside (Noss, 1994, p13).

6.1.2 Selection of Core Protection Areas, Primary Corridors and Buffer Areas

Selection of Core Protection Areas, Primary Corridors and Buffer Areas can be achieved through field inventory, remote sensing, and biogeographical research to determine the spatial distribution of biodiversity and wild areas, followed by an evaluation of which areas are most important to protect (Noss, 1994, p14). Core reserves and primary corridors in a regional network should enclose and link biogeographically critical areas in a continuous system of natural habitat wherever possible. Noss (1994) has identified critical steps in selecting core reserves and primary linkages and are identified in Appendix 2.

Mapping undertaken by the Department of Environment facilitates the division of the region into core and buffer wetland reserves. The mapping defines a range of vegetation communities based on predominant vegetation species, structure and composition, and soils and landform characteristics including frequency of inundation. From this information, it is possible to collapse the vegetation cover into a simpler set of units to guide planning. Two broad categories have been proposed: "wetlands" and land with "wetland affinity" and these can be translated into core and buffer wetland reserves. Core wetland areas ("wetlands") exhibit high wetland values (such as vegetation species, soil wetness, landform type, and frequency of inundation) and buffer areas ("wetland affinity") exhibit fewer wetland values. Division of habitat areas into these classes has been undertaken with the assistance of Ian Hisslop, Environment Officer, Bushland Management, Brisbane City Council. A list of predominant vegetation communities and their classification into core and buffer areas is provided in appendix 3.

By collapsing the vegetation into broad categories the accuracy of the maps will be reduced. As a result land may be defined as "wetlands" or "wetland affinity" when they possess no wetland values. Additionally simplification may result in the removal of areas possessing wetland values when they should be included. While this can be overcome through more detailed analysis and field truthing it is also important to remember that maps are produced as a tool to guide management and planning and will always be incorrect. Additionally, current pressures to develop planning guidelines now while there is a 12 month moratorium on sugar cane expansion requires maps to be developed quickly.

6.2 PLANNING SCHEMES

Local authorities are able to guide land use and development through local planning schemes. Planning schemes and policies regulate land in private ownership but has no power to bind the Crown (Bates, 1995). While planning schemes have historically been employed by urban authorities to manage development, they have typically had little effect in rural areas except to protect agricultural activities from other development activities (Johnson et al, 1996, p11). However, by providing local authorities with the power to control land use, planning schemes can be used to regulate agricultural activity and can also be used to achieve wetland conservation.

Planning schemes can be used to maintain core and buffer areas through the strategic plan, zoning plan and development control.

6.2.1 Strategic Plans

Strategic Plans are used by local authorities to guide future development in a manner that reflects the social, economic and environmental aspirations of the community. They establish the intent of the planning scheme and are usually expressed in terms of goals, objectives and implementation strategies (Johnson Shire Council, 1996). Strategic plans convert social, economic and environmental objectives into broad based spatial units to provide a framework for developer-led development approvals (Johnson et al, 1996, p11). In accordance with the provisions of the Local Government (Planning and Environment) Act, 1990 a Strategic Plan is to consist of the following three parts:

(1) A map identifying Preferred Dominant Land Uses for the Shire ;
(2) A statement of objectives for each Preferred Dominant Land Use (PDLU) for the management and progressive development of lands within the Shire. This statement is supported by criteria (eg: the type, scale or distribution of land uses) for the implementation of the Preferred Dominant Land uses and associated uses which may develop as an integral component of the dominant use; and
(3) Criteria for the implementation of the Plan (Local Government (Planning and Environment) Act, 1990) .

Therefore Preferred Future Dominant Land Uses (PFDLU) are the primary mechanism for the implementation of Strategic Plans. PFDLU's are not restrictions on use rights. They provide long term guidance for decision making on land use through the development control process (Johnson et al, 1996, p11). Core wetland reserves, primary corridors and buffer areas can be designated as a conservation preferred dominant land use on the strategic plan to guide appropriate development away from these areas in the future. This is not currently part of the strategic plan for Hinchinbrook Shire Council but it would improve conservation by providing an overall framework for the assessment of land use applications. The identification of areas where conservation is preferred provides a broad description of Councils policy and improves certainty for both council and the community as to the conservation framework. Without this individual development assessment would occur without regard to the cumulative impact they would have on wetlands.

6.2.2 Zoning

Local authorities control land use activity by 'zoning' land. Zoning plans divide the local authority area into a number of zones, define the intent of each zone, and determine what activities are permitted or restricted in each zone and on what general conditions. Land suitable for particular purposes is identified in a zone, inconsistent uses are prohibited and local authorities have discretionary powers to decide in particular cases if a proposed development is consistent or inconsistent with the purpose of that zone (Bates, 1995). In the case of discretional developments local authorities can place conditions on development approvals to preserve the intended character of a zone (Bates, 1995). The zoning process can be used to protect core wetland reserves, primary corridors and buffer areas by including wetland habitats in an environmental protection zone that incorporates several protection classes relating to the classification of wetlands as core reserves and primary corridors or buffer areas. Therefore the environmental protection zone can be divided into several categories which reflect the conservation value of the land and incorporate different land use requirements.

This system has been used by Brisbane City Council in the Non Urban Zone. Within the Non Urban Zone, three categories (A, B, and C) have been developed each providing different levels of control on land use. Category A is for land that contains prime habitats and places the greatest restrictions on use rights. Category B is designated for habitats that are not in prime condition but not in poor condition. Category C is used for land in poorer condition and enables the land to be rezoned to a higher intensity of use.

Category A can be used to protect core wetland reserves and primary corridors by placing the greatest limitations on use rights. The intent of this category would be to preserve land for nature conservation purposes and therefore uses in this category should be compatible with the sensitivity of natural resource values and should have minimal impact on the environment. Category B would be designated for habitats that are not in prime condition or have greater distributions and are therefore not considered to be as significant. While this category still emphasises the conservation of natural habitats, a greater number of activities are permitted. In this respect, Category B areas act as buffer to minimise impacts on Category A land. As a result it reflects a compromise between protecting the private property interest of the landowner and the public interest in the wetland. Category C is used for poor quality habitats and provides greater land use opportunities such as the rezoning of the land to a higher intensity of use.

The Hinchinbrook Planning Scheme currently does not incorporate an environmental protection zone. However the rural zone can be divided into three categories:
(1) Rural A - Conservation (for core wetland habitats)
(2) Rural B - Agriculture (for buffer wetland habitats)
(3) Rural C - Intensive Agriculture

Category A is to conserve core wetland reserves. As a result both agriculture and intensive agriculture would be prohibited in category A areas. Category B land may be able to support intensive agriculture , however planning approval would be needed to ensure the conservation value of the buffer is maintained. To ensure that wetlands are conserved, it is recommended that the maximum threshold for agriculture be reduced so that developments with potential to impact on the buffer reserves have to undergo development assessment. Category C land would be land that could be converted to intensive agriculture. Consequently, zoning can be used to achieve wetland conservation. To be most effective zoning would need to establish the framework for development assessment by specifying clearly the activities that require approval. In the proposed Rural B and C zones Intensive Agriculture would require a permitted development subject to conditions approval. Development applications would need to be accompanied by property management plans, and if the development proposes to modify a

wetland as defined in the scheme impact assessment should also accompany the application. Criteria for approval of development applications would be based on ensuring the desired environmental outcomes were achieved. Appraisal of development applications would be coordinated by Council and referred to technical experts for specific issues. Monitoring provisions should be implemented to ensure that the desired environmental outcomes are maintained through the life of the development.

6.2.3 Development Control

Strategic plans and zoning plans provide the framework for development control. The development control process is initiated when a person wants to develop, change the use of the land, or subdivide land (Bates, 1995, 193). Anyone wishing to undertake development must apply the local authority for permission. The criteria established in planning schemes are applied to proposals for specific development (Bates, 1995). Development control is the process of regulating rural uses to achieve wetland conservation. The process for development assessment within the rural zone has been discussed in Chapter Four. Briefly the draft Planning Scheme regulates primary industries by including it as a "permitted development subject to conditions" in the rural zone. This approach requires landowners to submit an application for approval by Council thereby providing the Council with the ability to condition intensive agriculture to achieve wetland conservation.

To be approved a development would need to demonstrate how it would maintain the quality of water in wetlands, maintain the hydrological regime of wetlands, minimise the impact of acid sulphate soils and other soil contaminants in wetlands, minimise sedimentation of wetlands, minimise the loss of wetland habitats and preserve and enhance the quality of wetland habitats. To achieve this allowable changes to environmental elements would need to be determined such as acceptable changes in water quality and the hydrological regime. They would take the form of guidelines and specific performance standards based on reflect sustainable management practices. These criteria need to be determined with the help of government agencies and local experts (McDonald and Bellamy, 1997).

6.2.4 Implications For Wetlands

Definition of core wetland reserves, primary corridors and buffer areas through mapping clearly identifies land subject to assessment against planning criteria. Mapping will also indicate those areas that require property management planning and those areas that require impact assessment. Council should be the lead agency for the appraisal of the applications, however for technical or specialist assessment, applications should be referred to agencies with expertise in particular issues.

6.3 PERFORMANCE STANDARDS

Performance based planning schemes are proactive in the sense that they anticipate environmental issues and establish performance standards that need to be maintained by developments. Performance standards are environmental requirements for project design and construction and are usually applied through a permit system. It is recommended that performance standards define the maximum permissible impact of specific uses on particular resources. "Threshold levels" or "acceptable limits of change" are often used to set the permissible levels which govern performance standards (Clark, 1996, p374).

Once performance standards have been established, planning applications are approved with the understanding that specific properties and characteristics of the natural system will continue to function in a prescribed manner after development. The developer can proceed with the project only if it can be proven that the natural system will continue to "perform" according to prescribed "standards". As a result, the developer can use their discretion to employ any

approach that will guarantee full function of the natural ecosystem after the project has been implemented. Examples of performance standards include the quantity of fish a pond shall produce, the quality of water that passes from a parcel of land, the amount of water flowing through an estuary, or the uptake of pollutants by a wetland (Clark, 1996, p373).

6.3.1 Implications For Wetlands

To maintain the ecological functions of wetlands, criteria for the approval of intensive agriculture needs to be established. This can be achieved through the development of performance standards. To be approved applications for intensive agriculture developments would need to achieve the desired environmental outcomes for hydrology, pedology, morphology and biology. Therefore planning criteria would need to define:

- acceptable levels of water quality in wetlands
- acceptable changes to the hydrological regime
- locations or conditions in which wetland loss is not acceptable
- locations of acid sulphate soils
- acceptable rates of erosion and sedimentation

Criteria for the approval of regulated uses

Performance conditions for water quality would be based on local knowledge of the impact that pollutants have on wetland systems or in the absence of local knowledge the use of standard water quality classifications such as Australian and New Zealand Conservation Council (ANZECC) Criteria. Performance criteria for the hydrological regime could be based on water inputs, outputs and flow rates. Specific criteria may need to be supplied by people with expert knowledge of the impact that changes to the hydrological regime will have on wetlands as these conditions are likely to vary depending upon the location of the wetlands on the floodplain. The assessment of wetland loss can be made against mapping that identifies critical habitats and buffer areas. Critical areas would need to be maintained however compromises may be made in buffer areas.

The assessment of acid sulphate soils would be undertaken for areas identified through mapping. Finally, performance conditions for erosion and sedimentation can also be based on local knowledge or in the absence of local knowledge the use of standard rates. These criteria would become guidelines and performance standards used to condition development. In addition, they need to be clearly established in the scheme to provide prior guidance to desired developments (McDonald and Bellamy, 1997).

6.4 ENVIRONMENTAL MONITORING

The conservation of wetlands can also be achieved through the monitoring of environmental indicators. Environmental monitoring can be associated with performance indicators and can be used to ascertain that mitigation measures are being implemented as agreed. Additionally monitoring can be used to warn agencies of unanticipated adverse impacts or sudden changes in impact trends, to warn when pre-selected impact indicators approach the pre-selected statistical level and to ensure that legal standards are not exceeded. Further monitoring can be used to verify estimated impacts and evaluate the effectiveness of implemented mitigation measures (Clark, 1996, p73).

Environmental monitoring can be used in the development assessment process. If local authorities approve a project with possible environmental impacts, environmental monitoring is used as an oversight process to ensure that mitigation and other counter measures are carried out according to the environmental conditions of the development permit (Clark, 1996, p73).

Monitoring can take two forms, Strategic and Tactical. Strategic monitoring is the "retrospective" or "hindsight" monitoring, which is often the main focus of the monitoring program. The object is to compare measurements of certain key characteristics of the environment both before and after project work is done so that an "environmental audit" can be made of the projects effects. This of course requires that "benchmark" information be collected before the project starts, to provide a statistically sound "baseline" (Clark, 1996, p73). Tactical monitoring is the "real-time" or "oversight" monitoring that occurs in conjunction with environmental management programs (EMP). It monitors the construction operation day by day to detect whether any major negative impacts are occurring. If problems are detected construction is stopped until the impact is remedied (Clark, 1996, 151).

6.4.1 Implications for Wetlands

Monitoring can be undertaken to ensure that performance standards are being complied with. Performance standards for wetlands that lend themselves to monitoring include water quality, changes to the hydrological regime can be monitored through water inputs, flow rates and outputs or number of fish species in wetlands. The Johnstone Shire Council has adopted monitoring to maintain surface water quality. This will enable the Shire to maintain acceptable water quality levels within wetland environments. A surface water classification system is to be applied to all the Shire's surface water systems and development within the catchment will be required to meet the water quality standards for the relevant class (Johnstone Shire Council, 1996). The water quality standards applying to the surface water classification system will be the Australian and New Zealand Environment and Conservation Council Water Quality Criteria for Fresh and Marine Waters (ANZECC) until such time as the State government adopts water quality standards applicable to the Shire. Until better information is available on the Shire's surface water systems, all systems will be required to meet water quality standards required for the protection of aquatic ecosystems (Johnstone Shire Council, 1996).

6.5 ENVIRONMENTAL IMPACT STATEMENTS

Environmental impact assessment (EIA) is a means of evaluating development proposals so that possible environmental impacts may be identified and mitigated. They are a tool employed by Local Government (Planning and Environment) Act to provide advice to decision-makers with respect to the environmental soundness of a development application. An environmental impact statement may be required in several circumstances. Under the Local Government (Planning and Environment) Act 1990, the Chief executive of the Department of Environment may, after due consultation with relevant agencies and local authorities, require applications in respect of designated development, as prescribed by regulation or specified in a local authorities planning policy to be supported by an EIS. In respect of other activities which need planning permission, and EIS may be required if the local authority is of the opinion that a proposal is for a 'relevant development' on land within or neighboring the Wet Tropics World Heritage Area the Wet Tropics Management Authority must be consulted.(Bates, 1995, p163).

The Draft Integrated Planning Bill 1997 features an Integrated Development Assessment System (IDAS) which integrates all State and local government assessment and approval process for development. Activities defined under the proposed act as assessable development require a development permit from the local authority. For developments defined as self-assessable development a permit is not required but it must comply with applicable codes and for exempt developments a permit is not required and development need not comply with codes or planning instruments (Queensland Department of Local Government and Planning, 1997, p74).

Under the proposed legislation the EIS process in the Planning and Environment Act is integrated with other assessment processes. This is achieved by requiring that the local authority determine first what supporting information needs to be provided with the application. This is

achieved in the 'acknowledgment period' in which the development manager sends the applicant an acknowledgment notice specifying among other things: which aspects of the development seeks approval, the names of referral agencies; whether the development requires impact assessment or code assessment (or both) and public notification requirements for impact assessment; any information requests from the development manager; if the development requires referral coordination; and any other development permits necessary to allow the development to be carried out (Queensland Department of Local Government and Planning, 1997, p79). If the information is insufficient to enable the full environmental impact of the proposed development to be assessed, the development manager or referral agencies can make additional information requests to the applicant.

6.5.1 Implications for Wetlands

Impact assessment procedures could be used for activities proposed in core wetland reserves, for activities proposed on lands containing potential acid sulphate soils as well as for activities that propose significant changes to the landscape and hydrological regime with the potential to impact on core and buffer wetland reserves. Impact assessment assists in the development control process by determining the impact development has on wetland areas.

6.6 RETENTION OF LAND FOR COMMUNITY BENEFIT DURING SUBDIVISION PROCESS

Where the applicant proposes to subdivide the land Council has the power to secure 10% towards parks contributions (Local Government (Planning and Environment) Act, 1990). If an applicant wanting to subdivide land that had been identified through mapping as containing core wetland habitats as well as buffer areas they could be surrendered to the Council as the parks contributions. Many Councils are already using this tool to add land with conservation value to the Crown estate. This is useful for assets that are conserved for community interests and common property resources such as riparian lands and wetlands (Creighton, Dickenson and Golden, 1994, p3).

6.7 FINANCIAL INCENTIVES

Financial incentives are another mechanism that can be used by local authorities to achieve wetland conservation. A range of incentives are available, including grants for conservation works, tax concessions and rate relief/differential rating.

6.7.1 Grants for Conservation Works

Financial assistance for farmers in the form of grants for conservation works can help improve the quality of wetland areas by minimising the cost of managing private land for public benefit. Grants for conservation works could involve standard payments (ie: so much per square hectare of wetland), it may be on the basis of meeting a fixed percentage of the cost incurred, or it may be in support of drawing up a conservation plan (Colman, 1994, p228).

6.7.2 Tax Concessions

Tax concessions can be used in return for conservation agreements. To implement tax concessions, the nature and extent of rehabilitation works to be undertaken by landholders may need to meet a series of defined criteria (Creighton, Dickenson and Golden, 1994, p2). Tax exemption needs to ensure that the condition of the management agreement is upheld and also that conservation agreements are transferred to new owners if the land is sold, or passed to inheritors (Colman, 1994, p229). Creighton, Dickenson and Golden (1994) state that "Mining companies are allowed 150% deduction for rehabilitation work. A similar scheme could be implemented for landholders.

6.7.3 Rate Relief/Differential Rating

Rate relief and differential rating are other financial incentives that can be used to encourage habitat retention and wetland preservation on private land. It establishes a specific zoning with accompanying covenant on the land title for lands set aside for various environmental purposes (Creighton, Dickenson and Golden, 1994, p3).

6.7.4 Implications for Wetlands

Financial incentives provide a sanction for wetland conservation. Preventing development on land is often not enough to achieve wetland conservation. Therefore financial incentives can be used in core and buffer areas to undertake the management or rehabilitation of wetlands. This is particularly important for wetlands that are not owned by the Crown.

6.8 BONUS DEVELOPMENT RIGHTS

Bonus development rights enable a parcel of land to be developed to a greater extent than could otherwise be achieved in that zone. They allow a portion of the site to be formally protected for wetland conservation purposes in return for allowing a higher density of use on the remaining portion of land (Johnstone Shire Council). Bonus development rights have been employed by the Johnstone Shire council to assist the Council conserve valuable environmental resources for private lands that are not already protected for conservation purposes (Johnstone Shire Council, 1996, D-18).

Council exercises its discretion in awarding Bonus Development Rights. Assessment of Bonus Development Rights needs to consider: the capacity of the habitat system to withstand the impacts of the proposed development and maintain its integrity and the potential for the proposed development to enhance and protect the core wetland areas (Johnstone Shire Council, 1996, D-18). Conditions can be attached to approvals for Bonus Development Rights. Through these conditions council can require: the declaration wetland habitats as protected areas through Local Laws; conservation agreements between the land owner and Council; revegetation of a portion of the site to re-establish the habitat function or maintain the wetland system; or the dedication of the land to public ownership for conservation purposes.

6.8.1 Implications for Wetlands

Bonus Development Rights can be used in the rural zone to formally protect core and to protect buffer wetland areas. Council can exercise its discretion and allow some limited loss of habitat where it would achieve conservation protection for the balance of the parcel of land. To achieve this the area to be foregone will be of least value compared to the balance of the habitat (extending beyond the property boundary of the subject site). Applications for Bonus Development Rights can be accompanied by a preliminary environment report or environment impact statement

6.9 VEGETATION PROTECTION ORDINANCES

Vegetation Protection Ordinances (VPO's) protect vegetation on publicly and privately owned land. They enable the Council to better protect natural areas. Vegetation protection ordinances do not prevent development approved under the town plan. Rather they provide for negotiation regarding the retention of significant vegetation. One of the greatest benefits of the ordinances is the ongoing education of landowners through the objection/application to clear process, allowing on-site assistance from Council officers. Brisbane City Council has tried and tested VPO's (Brisbane City Council). Important reasons for making an order are outlined in table _ below.

6.9.1 Nomination of VPO's

A flexible nomination model can be adopted which applies only to the most significant natural

areas. By using this model the most valuable natural assets can be protected without straining the financial resources of the Council. Protected areas will benefit from improved environmental values and increased property values. Five categories of protection can be developed that respond to the specific needs of landowners. These categories are individual trees; groups/stands of trees; vegetation of a particular class; vegetation of a particular species and all vegetation.

Table 6.3 (Brisbane City Council)

Reasons for Protection
• The vegetation has distinct scenic and landscape value • The vegetation is a wetland remnant • The vegetation forms an important wetland habitat • The vegetation is rare or endangered or is a habitat for endangered fauna or flora species. • The vegetation forms part of the original plant community and is a valuable natural habitat • The vegetation is of particular historical or cultural significance • The vegetation forms a wildlife corridor and vegetation links between natural habitat areas (eg: along the Herbert River) • The vegetation is important for erosion prevention and slope or bank stabilisation • The vegetation includes known koalas food trees and is important for koala protection, feeding and movement between habitat areas, and • The trees are important as a seed source for natural regeneration

6.9.2 Implications for Wetlands

Vegetation protection orders can be used to protect wetlands on private lands in buffer areas. They can be included as a condition of development or as a condition of Bonus Development Rights. In this way, the balance of land can be used for agricultural uses, however significant wetland habitat areas can be protected.

6.10 VOLUNTARY CONSERVATION AGREEMENTS

A 'conservation agreement' is a contract between the Minister for the Environment and the landholder or between the Council and the landholder. Conservation agreements determine how wetlands are to be managed and outline types of activities that can occur within wetlands. Each agreement is tailored to suit the specific management needs of the particular wetlands for example, conditions could be comprehensive or simply be directed at protecting a particular species of plant or animal.

A conservation agreement can be for a certain length of time (as determined by the landholder) or can be permanent and registered on the land title. Nature conservation and future generations will benefit most if agreements are added permanently to land titles (Brannock and Hutchinson, 1995).

6.10.1 Implications for Wetlands

Voluntary conservation agreements can be used to maintain the quality of wetlands on private land. They can be used in the development control process to influence the management of private land to achieve conservation objectives. They are particularly useful for core wetland reserves that are held in private ownership. Conservation agreements can include performance standards and environmental monitoring to maintain acceptable thresholds of change. Additionally conservation agreements can be included as a condition for Bonus Development Rights. Conservation agreements can also be linked to financial incentives.

6.11 LAND ACQUISITION AND RETENTION FOR NATURE CONSERVATION PURPOSES

Conservation of core habitats can be achieved through the acquisition of wetlands and regulation by specific management plans. Wetlands can be acquired and retained for nature conservation purposes by the Queensland Department of Environment as well as the Hinchinbrook Shire Council. Acquisitions are an important part of conserving key habitat areas. While the rights to subdivide and build upon land are controlled by planning legislation, the right to manage the land is still largely unfettered, yet the management of land is crucial to sustain the long term productive activity and natural ecosystems (Bates, 1995, [2.1]). Therefore land acquisition is an effective means of protecting the local environment because ownership and management by state or local bodies with a credible record is the most secure way of pursuing conservation policies (Bates, 1995, [2.1]; Coleman, 1994, 227). To be most effective land acquisition needs to be implemented in concert with Voluntary Conservation Agreements to ensure that wetlands on private land are protected until they are secured in public ownership (Creighton, Dickenson and Golden, 1994, p3).

6.11.1 Implications for Wetlands

Land acquisitions would be used for core wetland habitats and primary corridors to ensure their conservation.

6.12 PROPERTY MANAGEMENT PLANNING

Property Management Planning is a process for achieving improved resource management through action learning and self development, so that landholders take a strategic approach to planning their property. Property Management Plans (PMP's) integrates the farmers personal goals and vision, sustainable agricultural production and conservation of soil, water, flora and fauna, as well as physical financial and human resource goals which are required to achieve these in a variable climatic, marketing and social environment. Property management planning enables individuals to take voluntary action following an action learning process (Dawson, 1996, p328). At the farm level, ESD principles can be achieved through PMP's through the use of best management practices. In the Herbert River local cane assignment boards require applicants to submit a PMP with their application for new assignment. This information is reviewed by the board and relevant technical experts from Queensland Department of Primary Industries and the Queensland Department of Environment and Heritage (Johnson, et al, 1996).

6.12.1 Implications for Wetlands

Property management plans are an important tool for wetland conservation. They can be included in the development assessment process by requiring applicants to submit PMP's with applications for intensive agriculture. This will enable Council officers and technical experts from government agencies to determine the extent of changes that are being proposed and what impact that the it will have on wetlands. PMP's will also inform development assessors of the types of land management practices undertaken by applicants to minimise the impact of development on wetlands.

Chapter 7:

EVALUATION OF PLANNING OPTIONS

7.0 INTRODUCTION

The effectiveness of conservation options can be determined through evaluation. The evaluation that follows is broad and is based on an analysis of the existing use of conservation

options. Effectiveness is based on the ability of the planning options o maintain the ecological functions of wetlands, socio-political acceptability, administrative needs and the costs of implementing the planning provisions.

7.1 EVALUATION CRITERIA

7.1.1 Ecological Functions of Wetlands

To achieve the conservation of wetlands planning provisions need to ensure that the functions of wetlands are maintained or enhanced. This can be determined by evaluating the proposed provisions against the desired environmental outcomes determined for wetlands in Chapter 5 and summarised below in table 7.1. This will ensure that planning provisions maintain the key ecological functions wetlands including the hydrology, pedology, morphometry and biology.

7.1.1.1 Ecological Evaluation Criteria

The ecological criteria for evaluation is based on the desired environmental outcomes identified in Chapter five. These are summarised in Table 7.1 below.

Table 7.1 Ecological Evaluation Criteria

DESIRED ENVIRONMENTAL OUTCOMES	
HYDROLOGY	maintain water quality in wetlands
	maintain the hydrological regime of wetlands
PEDOLOGY	minimise the impact of acid sulphate soils and other soil contaminants in wetlands
MORPHOLOGY	minimise structural changes to wetlands
	minimise disturbance to wetland morphology from off-site landform changes
BIOLOGY	minimise the loss of wetland habitats
	preserve and enhance the quality of wetland habitats

7.1.2 Administrative Processes Associated with Planning Provisions

In rural authorities the administrative requirements of planning provisions can be significant barriers to achieving conservation and sustainable land management. Administrative requirements include staff hours, technical knowledge and skill as well as information needs. Hinchinbrook Shire is a small rural shire without qualified Town Planning staff. Therefore the administrative processes associated with the planning provisions need to consider the staffing limitations of the organisation. Consequently provisions that require extensive time to be devoted to implementation will be impractical given current resources.

Additionally, the level of knowledge and skill required to implement conservation provisions is of prime importance. Planning options that require technical skills beyond the capabilities of the local government to administer and monitor and beyond the scope of landowners to implement will be ineffective for wetland conservation. Therefore planning methods need to be comprehensive and soundly based ecologically but at the same time simple enough to be of practical use in the field by rural local authorities (Hill and Koslowski). Information requirements of planning provisions can also be a significant barrier to implementation. Information requirements differ for the different management options but could consist of wetland mapping, baseline water quality information, the location of acid sulphate soils, and the impact of different land management practices on wetlands.

Administrative Evaluation Criteria

- Time
- Knowledge and Skill
- Information

7.1.3 Socio-Political Criteria

Planning provisions need to be politically acceptable by both governments and the community and should try to educate and improve awareness of wetlands issues as well as promote sustainable land management practices. As has already been demonstrated the political acceptability of proposed planning provisions has significant implications on their implementation. The acceptability of different conservation mechanisms will vary between local governments, landowners and the community (Colman, 1994). Ultimately however, the policy options endorsed by Council will reflect community understanding of wetland issues as local governments are held accountable through the election process (Young, 1996). Therefore there is a direct link between promoting conservation mindedness and achieving political acceptability of environmental policies at the farm level (Colman, 1994, 235).

Consequently, planning provisions that encourage voluntary conservation and sustainable land management practices will assist in improving awareness of wetlands issues. As Colman states "planning tools based on a more antagonistic, regulatory relationship with farmers is sometimes a cause of resistance" (Colman, 1994, 235). This is particularly important as the regulation of agricultural activity by Council is a new concept in the Herbert. As a result provisions which generate antagonism will not be well received by the community in the short term and may also lead to long term resistance. A Comprehensive analysis of the political acceptability would require community and stakeholder consultation. Unfortunately this is beyond the scope of the study.

Socio-Political Evaluation Criteria

- Political Acceptability
- Promotion of Education and Awareness

7.1.4 Cost

Economic criteria are inextricably linked to socio-political criteria. Cost considerations are difficult to evaluate, especially at a broad scale. Considerations of cost include the short term financial costs of conserving and enhancing wetlands and the long term cost of not conserving wetlands. Several important issues include the opportunity costs associated with conservation and the issues over the distribution of costs. Firstly there are opportunity costs associated with wetland conservation as he conservation of wetlands is the cost foregone of farming that land. On the other hand there is an opportunity cost associated with wetland loss. The wetlands of the Herbert River Floodplain are of national significance. Therefore use of this land for agriculture is the foregone cost of conservation. Once wetlands are lost it is very expensive to try to recover or rehabilitate these areas.

Moral and ethical issues also arise over the distribution of costs. These issues are centred around the question of who should pay for the cost of conserving wetlands for public benefit on private land. While it is generally agreed that the cost of rehabilitating degraded habitats should be borne by those who degrade them, the whole community also needs to take financial responsibility for protecting the environment when the costs of doing so cannot be recovered by the use of market mechanisms (Johnson, Ebert, and Murray, 1997, p23). Colman comments that where extremely high values are attached to conserving specific habitats monetary cost becomes less important, and instruments which guarantee conservation are more efficient (Colman, 1994, p233).

Generally cost analysis is typically limited to the determination of the most cost effective conservation method for achieving a certain level of management. This considers administrative costs of staffing requirements to undertake conservation measures such as: development assessment; the assessment of bonus development rights and the monitoring or performance standards. Additionally administrative costs include the cost of obtaining the information

required for council to implement conservation methods. Cost analysis also considers the real cost of implementing conservation methods. This includes the cost to the community of acquiring land and providing financial incentives (Colman, 1994, p234).

Cost Evaluation Criteria
- administrative costs
- real cost of implementation

EVALUATION

7.2 REGIONAL CONSERVATION PROGRAM

7.2.1 Ecological Protection
The ability of the regional conservation program to maintain the ecological functions of wetlands is high as it establishes a system based on conserving the most significant habitat areas. Additionally uses are managed in buffer areas to protect the quality of core reserves. By taking a regional perspective the program provides the broad framework for development control and land use decisions that considers the impact of agricultural development on the regional distribution of wetlands. Additionally the regional conservation program is linked the other conservation methods to better manage core and buffer areas. For example the regional conservation program integrates land acquisitions and vegetation protection ordinances to conserve core areas and uses conservation agreements and bonus development rights in buffer areas. Through this system wetland functions in core areas are conserved and activities in buffer areas and beyond that have the potential to impact on wetlands are controlled.

7.2.2 Administrative Processes
Substantial information is required to select core and buffer reserves in the regional conservation strategy. This information would include remote sensing and mapping, field inventory, and biogeographical research to determine the spatial distribution of biodiversity and wild areas, followed by an evaluation of which areas are most important to protect (Noss, 1995, p14). The analysis and evaluation of this information would need to be undertaken by highly skilled technicians to produce the conservation program. Fortunately for the Herbert River Catchment most of this information already exists and is accessible to the Shire Council through the Herbert River Information Centre. Additional information that has been developed by the Department of Environment is also be useful for this program. Consequently information sharing between government organisations undertaking natural resource management and planning at different levels would improve co-ordination and make management more effective. The sharing of regional mapping would ensure that information is consistent between levels of government. However information sharing is currently a constraint to developing the regional wetland program.

Additionally the knowledge, skill and time required to implement a regional program is high because, in addition to providing the broad framework for environmental management, the program uses other conservation methods to implement it.

7.2.3 Socio-Political
The acceptability of this program is assumed to be moderate to high. Generally the community is demanding that state planning institutions and local government authorities respond to their environmental concerns and aspirations and act as a cohesive environmentally responsive resource management system (Bates, 1995). As the conservation program provides a framework for management that encompasses core wetland habitats, primary corridors and buffer areas and uses alternative methods to secure the protection of these areas, it is a resource management system. Furthermore, the regional conservation program integrates local and state planning

mechanisms for wetland protection. For example, conservation agreements and land acquisitions can be pursued by either the state or local governments. Additionally the regional conservation program establishes the framework for this to be undertaken in a coordinated and integrated manner with local government having the lead role.

The regional conservation program also has a role in education and awareness facilitated by key conservation methods used to implement the regional strategy, such as conservation agreements and property management planning.

7.2.4 Cost

Overall the program presents administrative costs of developing the program and generating maps. Additionally, the implementation of the regional program will involve administrative costs of implementing other conservation methods such as the assessment of development applications, bonus development rights, conservation agreements etc. The program will also involve real costs of conservation such as the cost to the community of acquiring land and the cost to landowners of managing wetlands and lost revenues from agriculture. The cost of not implementing a regional conservation program would also be high, as the framework for controlled and coordinated action would not be established making other conservation methods less effective.

PLANNING SCHEMES

7.3 STRATEGIC PLAN (A)

7.3.1 Ecological Protection

Strategic plans are spatial representations of broad future land uses and act as a framework to guide daily decision making on land uses. They are designed to provide the framework for development assessment in the Shire by using Preferred Dominant Land Uses for wetland habitats. They provide a general indication of the location of areas that are to be conserved and this needs to be taken into consideration in assessing development applications.

In itself the strategic plan is limited for detailed management of natural resources because its designations are broad in scale. While at least potentially it can address a wide range of objectives, it is primarily a guidance mechanism for development control, especially rezoning (Johnson et al, 1996, p11). Because of its scale, many small and fragmented wetland areas that contribute to the hydrological regime of the wetland would not be represented on the Strategic Plan. Additionally while the plan can influence future land use through Preferred Dominant Land Uses it is unable to influence the way the land is managed. While strategic plans are potentially beneficial and better than a planning system relying on zoning scheme and subdivision controls alone, they do not integrate with other spheres of government or the Queensland Sugar Corporation and consequently fall short of being true strategic visions and plans for managing development in a local area (Johnson et al, 1996, p11).

7.3.2 Administrative Processes

Strategic plans do not require significant additional administrative resources because it is part of the development assessment process currently undertaken by council. The level of skill required to assess applications under the strategic plan is much the same as current development assessment procedures, and the only information requirement is the Strategic Plan itself. The current strategic plan would need to be amended to incorporate a conservation preferred dominant land use and this may require additional staff hours or technical expertise, however overall there are few administrative requirements of this conservation method.

7.3.3 Socio-Political

It can be assumed that the political acceptability of strategic plans for conservation would be fair. This is because strategic plan destinations are broad and are intended to guide future development assessment. Additionally Preferred Dominant Land Uses are not intended to confer land use rights. Strategic plans would not significantly contribute to the improved awareness and understanding of wetlands issues or conservation methods as they are statements of policy intents and are not designed for community education.

7.3.4 Cost

A strategic plan is a broad policy document and consequently no direct costs would be imposed on the community or the landowner. However a conservation designation may restrict the development that can occur on that land in the future. In this respect a cost may be imposed on the landowner.

B. ZONING AND DEVELOPMENT CONTROL

7.3.5 Ecological

Zoning schemes have more scope than strategic plans and they place greater controls and restrictions on use rights. Zoning plans consider every allotment and therefore wetland areas can be identified and protected. Council can allocate land for intensive agriculture based on land capability and its compatibility with neighboring land uses. In addition the classification of the rural zone into three categories enables controls to reflect the wetland conservation value of the land.

Zoning schemes enforces conditions that can to be tailored to the specific needs of each application to maintain the ecological functions of wetland. This increased regulatory role enables council to regulate development to maintain water quality in wetlands; maintain the hydrological regime of wetlands; regulate development on acid sulphate soils; control rates of erosion; prevent structural changes to wetlands; and prevent wetland loss. Additionally conditions can be modified to reflect changes in information, technology and land management practices.

Zoning controls do not provide Council with the scope to influence land management once planning approval has been granted, other than by being able to police original approval conditions (Bates, 1995). In urban areas this is not a significant issue because conditions on development applications generally relate to the structure proposed to be constructed (ie: size, density, height, setbacks etc), and works that are required to be undertaken as part of the construction period. Once an urban project has been approved and built to the satisfaction of Council planning responsibilities usually cease. In contrast rural activities differ from urban activities in the sense that rural development is related to the improvement of land for intensive agriculture (ie: clearing land, constructing rural infrastructures) and the long term management of land and water resources for agricultural production (ie: land preparation, planting, pesticide and fertiliser application, and harvesting). Therefore unlike urban land uses, the impact of rural activities extends beyond the construction phase and requires the continued management of land and water resources.

Zoning has a limited ability to regulate the ongoing management of rural lands once the application has been granted. For example a condition can require that wetland vegetation is retained, however once the agricultural activity is established, it does not have the power to specify how the wetland is to be managed. The *Local Government (Planning and Environment) Act 1990* specifies that zoning schemes have regulatory force to ensure that conditions on development are complied with otherwise the applicant is in breech of the scheme and is liable for prosecution. However this process is disadvantageous because it means that the wetland

damage must occur before legal action can be taken (Anon, 1994, p1-6; Bates, 1995).

7.3.6 Socio-Political

The zoning of land for conservation may be met with some resistance because the regulation of intensive agriculture has not been implemented in the Herbert before and farmers generally resist controls on use rights (Hollick, 1991). However, this control may also be met with acceptance from members of the community who already understand the need to conserve wetlands. Zoning controls have a limited role in improving awareness of wetlands issues. Because zoning controls are prescriptive by nature they do not improve understanding of wetland issues or provide clear links with conservation objectives and appropriate management solutions.

7.3.7 Administrative Processes

The proposed regulation of agricultural land use activities coupled with the rapid expansion of the sugar industry will increase the number of development applications that need to be assessed by Council. As a result, Council will need to commit greater administrative resources to development assessment. In addition, greater skill will be required to ensure that development applications are conditioned to ameliorate potential environmental impacts and also to ensure that ecological processes are maintained. Referral of technical planning provisions to government agencies and criteria for development assessment established in the planning scheme should assist Council staff in this regard.

7.3.8 Cost

Landowners will incur greater costs through zoning control and development assessment. Depending on particular circumstances these costs could including having to prepare an Environmental Impact Statement, preparing a Property Management Plan and developing land management practices that will achieve prescribed standards. Additionally the administrative cost to council will also increase as a result of increased time required to assess Environmental Impact Statements and Property Management Plans and also to police provisions once approval has been granted.

7.4 PERFORMANCE STANDARDS AND ENVIRONMENTAL MONITORING (C)

7.4.1 Ecological

Performance Standards and Environmental Monitoring can be used to achieve ecological objectives by defining maximum limits that cannot be exceeded and by using monitoring to ensure that pre-determined limits are not exceeded. It provides greater scope to influence land management because the use of performance criteria requires land to be managed in a certain way to achieve environmental outcomes. Performance criteria can be developed to ensure that the desirable environmental outcomes are achieved. Examples include the requirement that water quality is maintained at a standard that will allow the continued functioning of aquatic habitats, or so that wetlands produce a prescribed number of fish (Clark, 1996). Monitoring is used to warn when pre-selected impact indicators reach the pre-selected statistical level. It an also be used to build up information on the environment and evaluate in land use practices with changes in wetlands over time (Clark, 1996).

Performance criteria and environmental monitoring are limited by the fact that levels need to reach threshold levels or need to be exceeded before legal action can be taken. Maintaining the ecological functions for wetlands may also be limited by the ability of monitoring to measure development impacts (Clarke, 1996). Additionally most wetlands have multiple surface water inputs and outputs which may also be difficult to administer. Further, many wetlands on the Floodplain are affected by groundwater and therefore diffuse source pollution carried in groundwater may be entering the wetland undetected (Rasin and Mitchell, 1996, p221).

7.4.2 Administrative Processes

The use of performance standards and environmental monitoring has high administrative requirements. To implement them Council staff need to understand the management problems and have the knowledge and skill to ensure that proposed developments will meet prescribed standards. Performance criteria established in the scheme would act as a checklist for development control, however an understanding of the issues is still vital for Council officers to understand the wetland systems and the impact that development can have on wetlands. This method of conservation also requires that Council staff posses a high level of knowledge and skill to develop criteria that will solve potential environmental impacts and to monitor and report on wetland impacts. Additionally performance standards and environmental monitoring require greater time to provide assistance to farmers to determine land management strategies that will maintain land management strategies, to monitor land and to revise strategies if they are ineffective. Both council resources and resources from other government departments for technical and specific issues will be required to implement performance standards and monitoring.

Monitoring has greater informational requirements. Baseline information is required to measure the environmental conditions and status of resources before a project is commenced. This may be a constraint to maintaining some wetland functions as baseline information may not be available. For example there is a lack of water flow data in some areas preventing accurate assessment of surface water resources and the monitoring of water quality in the past has been limited (Herbert River Catchment Coordinating Committee, 1996). Additionally monitoring information is required to measure the changes, if any, that occur after a project begins operating (Clark, 1996, p150).

7.4.3 Socio-Political

While performance criteria regulate land uses to achieve certain outcomes, it can be assumed that they will be well accepted because they are not overly prescriptive in nature. By establishing thresholds and standards, they enable landowners to tailor land management to suit their particular needs while maintaining the ecological functions of wetlands. Therefore they are less likely to be met with opposition than blatant restrictions on use rights.

Performance criteria and environmental monitoring have a significant role in education and awareness of wetlands issues by requiring farmers to undergo a learning process to work through management options and design criteria to achieve prescribed standards (Anon, 1994). Therefore to produce effective results that achieve performance standards, landowners need to understand the problem and what can be done to solve it. Additionally through monitoring landowners will learn of the impact that land management practices have on the environment.

7.4.4 Cost

The high administrative requirements of performance standards and environmental monitoring also incorporate higher costs. These include the cost of staff resources to assess applications against performance criteria and the financial cost of obtaining baseline information and in monitoring environmental indicators. Through performance standards landowners also have the scope to use the most cost effective measures to achieve wetland conservation.

7.5 ENVIRONMENTAL IMPACT STATEMENTS (D)

7.5.1 Ecological

Environmental Impact Statements (EIS) cannot conserve the ecology of wetlands by themselves. Rather they are a tool used to determine the impact of agriculture on core and buffer areas. EIS are a method of ensuring that environmental considerations obtain equal

weight in the decision-making process along with other traditional factors such as the social and economic advantages of a proposal. Environmental Impact Assessments do not introduce an environmental 'veto' power into the decision-making process however they can be responsible for the amendment or rejection of development proposals (Bates, 1995). Terms of Reference can be required for all environmental indicators to show the impact that development will have on the ecological integrity of the wetland and the impact the development will have on the regional wetland conservation strategy.

Theoretically Environmental Impact Assessments (EIA's) under the *Local Government (Planning and Environment) Act 1990* appear to establish a process to consider development within the carrying capacity of the environment. Practically this process has been inefficient in considering the cumulative impact of development on the environment. This has occurred because EIA's are considered individually at the project level resulting in the failure to adequately consider environmental issues within the broader regional framework. The integration of Environmental Impact Assessments with the regional conservation program should solve these problems providing a broader framework of environmental assessment.

7.5.2 Administrative Processes

Environmental Impact Statements require a high degree of technical and specific information. The amount and type of information required may vary depending on the nature of the environment, the scale of the development proposed, and therefore the particular Terms of Reference. In this regard EIS's are useful because they provide information in situations where there is little local knowledge of environmental resources or the particular impacts of certain developments. This information is to be provided by the applicant at their own expense.

The assessment of Environmental Impact Statements is undertaken by Council and referral agencies. This requires time greater staffing resources to undertake the assessment and analysis of the EIS. A high degree of knowledge and skill is also required by Council staff to evaluate the impact of the development on wetlands based on the findings of the EIS and to make recommendations about conditions or performance standards that may be required in response to the impacts and issues identified.

7.5.3 Socio-Political

Political acceptability of EIS can be assumed to be fairly high because it involves the investigation of the impact of a proposal and reflects growing community concern about the impact of developments on the environment. Environmental Impact Statements have large scope for education and awareness for the individual landholder but would have limited impact on the knowledge of issues community as a whole. By having to prepare and EIS, the landowner will learn of the potential impacts of the development and, through performance criteria or by modifying the proposal, how to overcome these impacts.

7.5.4 Cost

The cost of the preparing the EIS is borne by the applicant. The extent of costs will vary depending on the size of the development and the types of impacts it is likely to generate as this influences the Terms of Reference that need to be addressed in the EIS. An EIS can be expensive if the applicant needs to undertake technical studies to determine particular impacts. The opportunity cost of not preparing an EIS is that the potential environmental effects of development may not be determined or understood and therefore land use decisions would not be based on a full consideration of the impact of the development.

7.6 FINANCIAL INCENTIVES (E)

7.6.1 Ecological

Financial incentives can be used to influence the management of wetlands on private land. By entering into an agreement for reimbursement or other financial aid the landowner can be required to undertake certain management works or maintain wetlands to prescribed standards. In this way ecological outcomes for hydrology, pedology, morphology and biology can be included as part of the agreement for financial aid. Little information exists on the effectiveness of financial incentives in conserving wetlands. However It is assumed that landowners are more likely to undertake improved management practices or conservation if the costs of doing so can be met wholly or partially by financial incentives.

7.6.2 Administrative Processes

These methods would need to regularly monitored to ensure that the incentives are being used for the purposes established in the agreement, and so that payments adjusted or terminated if these is a change in the cost of management. A fair level of knowledge and skill is also required to ensure that the conservation works being undertaken as part of the agreement are appropriate to achieve the desired ecological outcomes of wetlands.

7.6.3 Socio-Political

The political acceptability of financial incentives is difficult to determine. On the one hand the community may argue against financial incentives because it is felt that the cost of conservation should be borne by those who cause the problems. This may be further aggravated if a wetland levy is imposed across the community. On the other hand the community may accept the need to assist landowners in managing the land for long term community benefit.

Financial incentives play an important role in improving the awareness of wetlands issues among landowners and has an educational role by promoting conservation land management practices. In addition, by providing financial assistance the number of farmers that actively participate in conservation may increase. However financial incentives have a limited role in improving general community awareness of wetlands issues.

7.6.4 Cost

This conservation method redistributes the cost of conserving wetlands. The cost of conservation is borne by the community rather than solely by the landowner. However conservation agreements qualifying for tax concessions involve little publicity and as a result the public may be unable to benefit fully from aspects of agreements designed to provide public goods (Clark, 1996). The administrative costs associated with financial incentives includes the cost of monitoring incentive programs.

7.7 RETENTION OF LAND THROUGH SUBDIVISION (F)

7.7.1 Ecological Criteria

The retention of land through the subdivision process can enable the conservation wetlands. Ten percent of the land proposed to be subdivided can be given to the Council as parks contributions. Land to be transferred to the Council can be part of the land proposing to be subdivided or it can be other land proposed by the applicant and accepted by the Local Government. This can be used to conserve wetlands by securing core or buffer wetland habitats. This then allows the effective management of wetlands by Council (Creighton, Dickenson and Golden, 1994, p3).

To ensure that land transferred to Council is effectively conserved this method would need to be undertaken as part of a management system to ensure that development on surrounding lands

was appropriately managed (Creighton, Dickenson and Golden, 1994, p3). The Local Government (Planning and Environment) Act specifies that a maximum of 10% of the total land area can be given in parks contributions. Therefore this process may be insufficient to conserve wetlands if the total area of the site occupied by wetlands is greater than 10% of the total site area.

7.7.2 Administrative Requirements

The transfer of the land does not incorporate significant administrative requirements as it is part of the development process. The information required to determine which areas are to be retained would be derived from the mapping that identifies core and buffer wetland reserves.

However once this land is transferred, Council needs to management of it for conservation purposes. This involves administrative requirements such as the development of management plans and then the maintenance and upkeep of these areas in the future. A high level of skill and knowledge is required to ensure that the ecological functions of wetlands are maintained.

7.7.3 Socio-Political

This process is assumed to be acceptable as it is currently part of the development process. It would ensure that lands intended to be conserved for public purposes is publicly accessible and managed by the Council. This process is not designed to promote education and awareness of wetlands issues across the shire but it could have a role depending upon the methods Council would use to manage these areas. For example Council could use the land as part of a wider educational program.

7.7.4 Cost

The landowner faces the cost of loosing land thereby forgoing the opportunity meet parkland contributions financially and use the land for other uses such as intensive agriculture. However as contributions are part of the Local Government (Planning and Environment) Act, there is a financial cost imposed on the landowner regardless of the method of payment. The cost of managing wetland areas is redistributed to. the community.

7.8 BONUS DEVELOPMENT RIGHTS (G)

7.8.1 Ecological Criteria

Bonus development rights help to secure core wetlands areas that are not already formally protected. Protection of core wetland habitats can be achieved by linking bonus development rights with other planning methods such as conservation agreements or rezoning of the land to a conservation zone to protect the ecological functions of wetlands (Young, 1996). This potentially facilitates the achievement of desired environmental outcomes. Bonus development rights involve an increase in density on a portion of the block. Therefore unless they are integrated within a management framework they have the potential to impact on the integrity of wetland habitats for example through water quality impacts and erosion and sedimentation. Additionally because they involve trade-offs, such as loss of some wetland habitats for the protection of other habitats, bonus development rights can result in the loss of wetlands habitats.

7.8.2 Administrative Requirements

Bonus Development rights have high administrative requirements. They need to be assessed by council on a case by case basis to determine the impact of the proposal on the environment. To achieve this a high level of technical and other information, such as property management plans, would be required to determine the impact of the uses on the ecological functions on adjacent wetlands. In addition, technical expertise and skill is required for Council to determine the maximum intensity of use that is sustainable and to determine appropriate conditions for

sustainable management.

7.8.3 Socio-Political

May be met with mixed responses from the community. On the one hand they appear to be a compromise between the development rights of the landowner and the conservation interests of the community. On the other hand, the community may also be concerned over the increase in intensity of use adjacent wetland habitats. Bonus Development rights have a role for education and awareness for landowners through the conditioning of BDR's. For example the use of performance standards and environmental monitoring would require farmers to undergo a learning process to work through management options and design criteria to achieve prescribed standards.

7.8.4 Cost

BDRs incorporate administrative costs of assessing the application and then monitoring to ensure that the development does not have an adverse impact on surrounding wetlands. There is also an opportunity cost for the community associated with the loss of wetlands for agricultural development. Landowners benefit through increased revenues from more intensive land use activities.

7.9 VEGETATION PROTECTION ORDINANCES (H)

Vegetation protection ordinances do not prevent development approved under the town plan. Rather they provide for negotiation regarding the retention of significant vegetation. One of the greatest benefits of the ordinances is the ongoing education of landowners through the objection/application to clear process, allowing on-site assistance from Council officers.

7.9.1 Ecological Criteria

Vegetation Protection Ordinances (VPO) are able to protect the biological functions of wetlands by protecting significant wetland habitats. They provide for negotiation regarding the retention of significant wetland vegetation. Different categories of protection can be awarded depending upon the conservation value of the wetlands. For land covered by a VPO the landowner needs to apply to damage or interfere with protected vegetation. Where agricultural land uses or practices are involved a property management plan will need to be included. The Council would use the advice of the Department of Primary Industries when making a decision on these issues (Brisbane City Council, p13).

Vegetation Protection Ordinances are an important support mechanism for land acquisitions as they protect the wetland vegetation until Council or the Department of Environment can secure these areas for formal protection. However vegetation protection ordinances do not have the power to influence the way these habitat areas are managed in the interim. For example they can not require the landowner control infestation of wetlands by exotic plants. Consequently they have a limited ability to achieve the other desired environmental outcomes for hydrology, pedology, and morphology.

7.9.2 Administrative Requirements

Like the method used by Brisbane City Council, Vegetation Protection Ordinances in the Herbert can be assessed by a committee made up of representatives independent of the Council and the final decision can be made by Council. Consequently the Council would not face any administrative requirements for the assessment of applications for VPO's. Council officers will need to assess the applications to clear vegetation. Technical information requirements can be provided by referral agencies such as the Queensland Department of Primary Industry, and additional information required to assess the applications to clear vegetation can be provided through a PMP.

7.9.3 Socio-Political

Vegetation Protection Ordinances are unlikely to cause strong community opposition because the steps leading up to the making of VPOs allow maximum community input both through the notification of the proposal by the Council and the objection period (Brisbane City Council, 1997). Additionally, VPO's do not prevent land development as landowners can still apply to clear vegetation through the application to clear land process.

VPO has a significant role in education and awareness. By requiring that areas of significant vegetation are protected, landowners and the community will begin to recognise their value. Additionally it provides ongoing education of landowners through the objection and application to clear process, allowing on-site assistance from Council officers (Brisbane City Council, p5).

7.9.4 Economic

Council will face increased administrative costs in terms of assessing applications to clear wetlands. Landowners will not be able to use wetlands for intensive agriculture without applying to Council first.

7.10 VOLUNTARY CONSERVATION AGREEMENTS (I)

7.10.1 Ecological Criteria

A Conservation Agreement allows the achievement of desired environmental outcomes by specifying what types of activities can occur in a wetland reserve. Agreements are tailored to suit the management needs of the particular area and as a result conditions can be comprehensive to achieve the specific management of hydrology, pedology, morphometry and biology. Alternatively conservation agreements can be directed at protecting a particular species of plant or animal. Conservation Agreements can protect wetlands for a certain length of time or indefinitely if registered on the land title. Coordinated conservation areas can be declared to jointly protect wetlands owned by several landowners (Conservation Strategy Branch, 1995). Conservation Agreements may need to be linked within a broader framework of conservation methods to ensure that conservation was being undertaken in the agreed manner. For example, it may need to be met with monitoring or financial incentives.

7.10.2 Administrative Requirements

The nature and terms of the conservation agreement will need to be based on an individual assessment by Council officers or the Department of Environment. Assessment would need to consider the particular values of plants and animals, any rare or threatened species, unique landform features and the location of the wetland in the relation to the regional wetland management program. Specific information would be needed to undertake this assessment. Additionally, knowledge of the impact that development may have would also be required to ensure that appropriate activities and management actions are established in the agreement.

7.10.3 Socio-Political

Conservation agreements have a significant role in increasing levels of knowledge and understanding because it requires landowners to contribute to improved management of wetlands (Johnson, Ebert and Murray, 1997, p21).

7.10.4 Cost

The cost to the landowner is the time required to negotiate management objectives and then to undertake the management of wetlands as agreed.

7.11 LAND ACQUISITION (J)

7.11.1 Ecological Criteria

Land acquisition is an effective method of conserving core wetland reserves because it enables Council or the Crown to protect the most valuable wetlands from unsustainable development. Additionally it enables the formulation of management plans to ensure the conservation of key ecological functions. Once land is formally protected it can be managed by Council to maintain the hydrology, pedology, morphometry and biology within the wetland environment (Creighton, Dickenson and Golden, 1994, p3). Ownership and management of wetlands by state or local bodies with good track records is the most secure way of pursuing conservation policies (Colman, 1994, 227). Acquisition provides the greatest level of control over wetland use and management.

Desired environmental outcomes can be achieved by maintaining wetland habitats in their current state and by rehabilitating them, ie: by removing exotic weed species. The effective management of wetlands in public ownership would also need to be integrated with other conservation measures and land use controls to ensure that surrounding development does not impact on the ecological integrity of wetlands (Bates, 1995, [2.1]).

7.11.2 Administrative Requirements

Land acquisition needs to be based on an assessment of core wetland reserves to conserve those areas that are most significant or most threatened. This requires Council or State Agency Officers to evaluate the appropriateness of current conservation methods for a particular wetland and the impact continued management arrangements would have on the wetland. Following assessment are the administrative processes of acquiring the land. This process requires technical knowledge to: understand the impacts on and threats to wetlands; to ensure that appropriate habitats are acquired; that management plans overcome threats and achieve the desired environmental outcomes; ensure that other conservation measures are implemented for land impacting on the wetland. Information will be required at the assessment stage, before acquisition has occurred, and more detailed information on the pressures and values of the wetland will be required at the management plan stage.

7.11.3 Socio-Political

Land acquisitions are likely to be met with resistance from landowners because they are the greatest infringement on property rights. Issues may also arise over the price paid to landowners for acquisition and this is related to issues with the present system of land valuation. For example Council or the Department of Environment may acquire wetlands at the unimproved value of land. However this price would not reflect the value of the land in conservation terms. In addition it does not consider the value that could be added to the land by improving it for agriculture. As a result this is likely to generate conflict over land acquisitions.

Through community education programs, land acquisition has the ability to improve awareness of wetlands issues and make people aware of the need to conserve them. This could be further enhanced if acquired land were to be used for educational through nature based recreation.

7.11.4 Cost

The cost of acquiring and then managing land is borne by the community however the extent of these costs will vary depending upon the scale of the acquisition program. It reflects the argument that the cost of managing land for community benefit should be borne by the community as a whole and not individual landowners. However, as mentioned above, landowners may also face short term costs through the acquisition process.

7.12 PROPERTY MANAGEMENT PLANNING (K)

7.12.1 Ecological Criteria

At the farm level, ESD principles have been recognised with the use of Property Management plans (PMP's). Property management planning can be used to conserve wetland habitats on rural property by providing a balance of achieving a managed ecosystem in which native flora and fauna species are maintained with the long term productivity of the land (Carey, 1991, p50). Adequate conservation of wetlands requires more than pockets of formally protected areas and it is impractical to reserve all land that contributes to wetland conservation. Wetlands will only continue to function if conserved in conjunction with the surrounding landscape ie: with riparian zones, remnants and corridors of vegetation and partially cleared pastoral lands (Carey, 1991, p50).

The contribution to nature conservation of land directly managed for agriculture is significant because it can influence the ecological functions of wetlands such as: water quality; the hydrological regime; soil erosion and sedimentation and pollution by acid sulphate soils, chemicals and pesticides. The conservation of wetlands through property management plans also has an important role to play in maintaining sustainable agricultural productivity. For example the management of wetlands by replacing exotic grasses with local native species helps to improve bank stability and reduces harborage areas for cane rats (Canegrowers, 1997).

Property management planning is effective because it enables landowners to use local knowledge to achieve the conservation of wetlands. It is based on the premise that landowners know their land better than any adviser and can contribute this knowledge to improved management. Further, landowners are more likely to take ownership of the plan and implement it if they have been involved in the planning process and agree with all aspects of the proposed plan (Carey, 1991).

7.12.2 Administrative Requirements

Property management plans are prepared by the landowner and rely heavily on technical information (Dawson, 1996). Technical information is required to identify the: identification of the capability of the land; the value of the resources; the basis for decisions about the allocation, use and management of the resources (to achieve economic, social and environmental benefits) (Dawson, 1996). Ingham has extensive technical information in the Herbert River Information Centre. However assistance may need to be provided by Council or the State Government to translate this information into management needs and options. For example assistance in determining ways of minimising erosion or maintaining water quality. PMPs would need to be assessed by Council and referral agencies when submitted to Council as part of the development assessment process. The assessment of PMPs requires knowledge of land management practices, their potential impact on wetlands and also improved practices, to ensure that property management plans achieve wetland conservation.

7.12.3 Socio-Political

Property management plans are becoming more popular and the Local Assessment Boards require that applicants submit a PMP with their application for new assignment (Johnson, et al, 1996). The use of property management plans as the basis for sustainable agriculture is strongly supported by the sugar industry as well as government agencies.

PMPs have a significant role in education and awareness. Property management planning is an action learning process that improves landowners skills in planning to achieve sustainable development and also improves commitment to the implementation of their plans (Carey, 1991, p33). Traditionally, farmers have been expected to adopt recommended farming practices which provided few perceived benefits to themselves or the community. The use of property

management plans facilitates voluntary strategies and cooperation based on information (Johnson, et al 1996, p14).

7.12.4 Economic

The cost of preparing the management plan lies with the landowner. However preparing a management plan also enables farmers to manage the land to sustain long term productive capability. Therefore property management plans can be used to integrate the landowners personal goals with conservation objectives.

Chapter 8:

LOCAL GOVERNMENT SOLUTIONS TO MANGROVE AND WETLAND CONSERVATION

8.0 INTRODUCTION

Conservation methods that can be used for wetland conservation include: the Strategic Plan; Zoning and Development Control; Performance Standards and Environmental Monitoring; Environmental Impact Statements; Financial Incentives; Retention of Land Through Subdivision; Bonus Development Rights; Vegetation Protection Ordinances; Voluntary Conservation Agreements; Land Acquisition; Property Management Planning. The effectiveness of these planning tools for rural environmental management has been evaluated based on their ability to maintain the key ecological functions of wetlands, socio-political acceptability, administrative needs and real cost of implementation (Refer Table 8.1). Based on this key management tools can be identified.

Table 8.1 Summary Table: Evaluation of Planning Options for a Regional Conservation Program

Planning Option	Achievement of Desirable Environmental Outcomes	Administrative Requirements	Socio-Political Acceptability	Cost of implementation
A	moderate	low	high	low
B	moderate/high	high	moderate	moderate/low
C	moderate/high	high	moderate	moderate
D	moderate/low	medium	high	low
E	moderate	moderate	moderate	high
F	high	moderate	high	moderate
G	low/moderate	moderate/high	moderate	moderate
H	moderate/high	moderate	moderate	moderate
I	high	high	high	moderate
J	high	moderate/high	moderate/low	high
K	high	moderate/high	high	low

KEY

A: Strategic Plan
B: Zoning and Development Control
C: Performance Standards and Environmental Monitoring
D: Environmental Impact Statements
E: Financial Incentives
F: Retention of Land Through Subdivision
G: Bonus Development Rights
H: Vegetation Protection Ordinances
I: Voluntary Conservation Agreements
J: Land Acquisition
K: Property Management Planning

8.1 RECOMMENDATIONS

Following the evaluation of planning options it is evident that there is not one single instrument that can achieve all the desired environmental outcomes of wetlands that has few administrative requirements, low real costs and high levels of political acceptability. From the analysis it is also evident that regulating new developments only through the planning process will not effectively deal with existing resource management problems because planning controls have little power to control existing unsustainable land uses and minor variations in those uses. Consequently planning controls by themselves will not achieve Ecologically Sustainable Development (McDonald and Bellamy, 1997, p1). Therefore to conserve wetlands, a range of measures need to be implemented that deal with the sustainable long term use of land and water resources.

To do this a system of resource management can be implemented that utilises range of planning and conservation tools to solve wetland issues. These planning and conservation tools need to be organised in a manner that identifies and protects core wetland habitats, provides an anticipatory framework to guide future land development and integrates this with methods that achieve sustainable resource management. In a rural context this can be achieved by adopting a regional system of wetland management. The regional program provides the overall management framework for wetland conservation based on core and buffer habitats. It facilitates the use of planning measures to guide land use changes, combined with other conservation methods to implement sustainable land management (refer table 8.2). As a result core wetlands are protected and land use is restricted and managed sustainably in buffer areas and beyond to ensure that desired environmental outcomes are achieved.

Table 8.2

REGIONAL WETLAND CONSERVATION PROGRAM
CORE WETLAND RESERVES Zone: Rural A: Conservation **Conservation Methods** • Land Acquisitions • Retention of Land through the subdivision process • Vegetation Protection Ordinances • Voluntary Conservation Agreements and Financial Incentives • Monitoring
BUFFER WETLAND RESERVES Zone: Rural B: Agriculture (Conditions - Agriculture remains an as of right use, however threshold to be reduced from 5ha) **Conservation Methods** • Voluntary Conservation Agreements • Bonus Development Rights • Environmental Impact Assessments • Performance Standards and Monitoring • Property Management Planning
Zone: Rural C: Intensive Agriculture (Conditions: Permitted Development Subject to Conditions) **Conservation Methods** • Performance Standards and Environmental Monitoring • Environmental Impact Assessments • Property Management Planning • Voluntary Conservation Agreements

The expanded role of the Hinchinbrook Shire Council into rural environmental planning introduces a whole new set of technical and political dimensions for which they may have little

training, no experience and few well developed precedents to guide the way (McDonald and Bellamy, 1997, p1). Additionally the small nature of organisation limits the staff resources that can be devoted to wetland conservation. Consequently not all measures that are potentially suitable can be practically implemented by Council and therefore several key methods need to be identified. Through evaluation the methods which can potentially provide the best protection of the ecological functions of wetlands are: zoning and development control; performance standards and monitoring; retention of land through the subdivision process; voluntary conservation agreements; land acquisition and property management planning. Therefore it is recommended that these measures be implemented for wetland conservation.

8.2 CONCLUSIONS

In conclusion, the wetlands of the Herbert River Floodplain are being threatened by the rapid expansion of the sugar industry and agricultural land management practices. Conservation of these natural resources has been ineffective because of fragmented institutional arrangements and a failure to address environmental issues in the rural land development process. Therefore the challenge facing the Hinchinbrook Shire Council is to regulate the continued expansion of the sugar industry, coordinate planning and land management between government agencies and encourage best practice land management.

Conservation of wetlands can be achieved partly through the Local Government (Planning and Environment) Act 1990 and the proposed Integrated Planning Act which provides local governments with the power to regulate land development. The underlining planning process will have some similarities with conventional urban based planning in terms of land use control, setting of performance standards and managing the development approval process. However in addition to this, rural based planning needs to address ecological and land resources issues and planning and management needs to be more site and local landscape specific (McDonald and Bellamy, 1997). However to effectively manage wetland resources, planning schemes and development control needs to be integrated with other conservation measures to achieve the ongoing management of land and water resources.

Potentially this can be achieved through the Strategic Plan; Zoning and Development Control; Performance Standards and Environmental Monitoring; Environmental Impact Statements; Financial Incentives; Retention of Land Through Subdivision; Bonus Development Rights; Vegetation Protection Ordinances; Voluntary Conservation Agreements; Land Acquisition; Property Management Planning (Refer Table 8.2). However practically, for a small rural shire it is recommended that key conservation tools be used that provide the best protection of wetland functions (Refer Table 8.3).

The implementation of such measures in rural shires is hindered by: the administrative limitations of the Council; the cost of implementation; lack of political support; conflicts with landowners over loss of use rights, injurious affection and potentially the need for compensation (McDonald and Bellamy, 1997, p1). Education and awareness programs have a significant role in overcoming many of these issues and is important for the protection of wetlands generally. Education at a policy and community level is vital to improve awareness of wetland functions and benefits and to provide information as to how conservation can be achieved in practice. Some of the suggested conservation methods lead councils into unexplored territory, such as the reliance on Property Management Plans and the application of Environmental Impact Assessments to small land development proposals (McDonald and Bellamy, 1997). Therefore training and development has a major role in implementation. Additionally community education and awareness of natural resource management problems can stimulate voluntary action.

Therefore, through a combination of statutory planning, sustainable land management practices and programs for education and awareness, wetland conservation can be achieved in a rural context.

Table 8.3

RECOMMENDED WETLAND CONSERVATION PROGRAM
CORE WETLAND RESERVES Zone: Rural A: Conservation **Conservation Methods** • Land Acquisitions • Retention of Land through the subdivision process • Voluntary Conservation Agreements • Monitoring
BUFFER WETLAND RESERVES **Zone: Rural B: Agriculture** (Conditions - Agriculture remains an as of right use, however threshold to be reduced from 5ha) **Conservation Methods** • Development Assessment • Environmental Impact Assessment • Voluntary Conservation Agreements • Performance Standards and Monitoring • Property Management Planning
Zone: Rural C: Intensive Agriculture (Conditions: Permitted Development Subject to Conditions) **Conservation Methods** • Development Control • Environmental Impact Assessment • Performance Standards and Environmental Monitoring • Property Management Planning • Voluntary Conservation Agreements

ACKNOWLEDGEMENTS

I would genuinely like to thank all the following people for their assistance with this project: Mike Bradby from the Department of Local Government and Planning; Michael Lusis from the Queensland Local Government Association of Queensland; The Hinchinbrook Shire Council; the Herbert River Catchment Coordinating Committee; the Hinchinbrook Reference Group; Andrew Johnson from the C.S.I.R.O; Ian Hisslop from Brisbane City Council, Carl Smith from the University of Queensland and Kim Michielin from Bryce Street. Special Thanks must go to my thesis supervisor Professor Geoff McDonald for his encouragement and guidance throughout the year.

Appendix 1:
Conditions Imposed by Local Board Under Section 142(4) of the Sugar Industry Act (1991)

1. Any use of assignment on the land the subject of this authorised transaction shall be utilised on land categorised as classes 1,2 or 3 by the Department of Primary Industries' land suitability criteria.
2. Any use of assignment on the land the subject of this authorised transaction excludes those areas of land which are:
    (a) Land categorised as classes 4 or 5 by the Department of Primary Industries' land suitability criteria.
    (b) Watercourse, natural drainage lines and preferential flow paths.
    (c) Wetlands, swamps, marshes, lagoons and lakes as defined by guidelines developed with QDPI and industry technical advisory agencies.
    (d) Mangrove areas and other areas naturally subject to tidal inundation. Areas below the 3 metre contour (Australian Height Datum) are unsuitable for the utilisation of assignment unless further advice and design in s provided by the QDPI Resource Management.
    (e) Riparian zones of 10 metres width along watercourses or, if applicable, such lesser width arising form the application of principles for riparian values adopted by the Herbert river Catchment CO-ordinating Committee. Adherence to QDPI Guidelines for sustainable Development on Floodplains is otherwise recommended.
3. (a) Any use of assignment on the land the subject of this authorised transaction excludes those parts of the land which do not have drainage works which comply with the Hinchinbrook Rural Drainage Plan (Cameron McNamara & Associates 1984), if applicable, or any other such standard as may be specified and/or approved by the BSES, CSR Technical staff, relevant Drainage Board and/or Water Management scheme in respect of the area in which the land is situated. (Copies of the Cameron McNamara report are available form the advisory agencies:- Hinchinbrook Shire Council, Herbert River District CANEGROWERS Executive, CSR Technical Field office, BSES, Herbert River Catchment Centre, and QDPI Resource Management).
    (b) Drainage works on, or associated with the assigned land are to be in accordance with the plan submitted at the time of application.
4. Any use of assignment on the land the subject of this authorised transaction excludes those parts of land where any works within or connecting to a watercourse, lake or spring have not been authorised by a relevant licence or permit under the Water Resources Act 1989 prior to any works, pursuant to the assignment, being undertaken.
5. Areas of the land the subject site of the authorised transaction which are known or identified to have acid sulphate characteristics shall not be used for the purposes of the assignment.
6. Where the slope of the land is 3% or steeper, the landholder must seek and adopt advice from the department of Primary Industries Land Use and Fisheries section on soil conservation measures for the land before it can be developed ans used for the purposes of the assignment.
7. A riparian zone of native vegetation of not less than 10 metres shall be maintained on each side of the existing watercourses and habitat corridor for mahogany gliders.

Appendix 2:
Process of Reconnaissance and Selection of Core and Buffer Areas in a Regional Land Conservation Strategy

The process involves field inventory, remote sensing, interpretation, and biogeographical research to determine the spatial distribution of biodiversity and wild areas, followed by an evaluation of which areas are most important to be protected. The next step, drawing lines on maps involves the identification of areas that are to be protected and areas to leave out. As not every hectare can be protected or restored, decisions must be made quickly about which areas are most valuable ecolgocially before they are altered irrevocably. Such decisions should not result in any area being trashed. Ideally all lands should be managed, at least in part for biodiversity. But some areas deserve and require more rigorous protection than others. This process of picking and choosing is called "conservation evaluation".

Core reserves and primary corridors in a regional network should enclose and link biologically critical areas in a continuous system of natural habitat whenever possible. Some critical steps in selecting core reserves and primary linkages in a land conservation network are as follows.

1. Select areas that, on the basis of field reconnaissance and interpretation of maps, aerial photographs or satellite images, appear to be roadless, undeveloped or otherwise in essentially natural condition. Centre proposed core reserve areas on these undeveloped areas. *A map of land ownership will show which of these areas are on public lands.*
2. Add roaded landscapes that are relatively undeveloped and restorable, expecially when adjacent to or near roadless areas. Addition of such areas is important to increase core reserve size and to link roadless areas into larger complexes or networks.
3. Map the distribution of rare species and community types in the region, *using state natural heritage program databases.* In some regions, mapping he destruction of rare species and communities might be the most practical first step in the network design process.
4. Draw polygons around clusters or constellations of rare species and community types. If not encompassed in core reserves proposed in steps 1 and 2, add these polygons to the system. Some wetlands will be naturally isolated and therefore linking them by corridors is unnecessary.
5. Obtain information (if available) to undertake a gap analysis on unprotected and under-protected vegetation types and centres of species richness in your region. The purpose of gap analysis is to provide information on representation of ecosystems and species in protected areas. Locate areas the contain vegetation types and centres of species richness that are not adequately protected in existing reserves. Add these areas to the network of sites if not already encompassed through steps 1-4.
6. The general locations of core reserves and some of the linkages have now been determined. The next step is to define boundaries more precisely, add more corridors so that sites that would be naturally linked would be reconnected and envelop the entire network in a matrix of buffer zones. To do this zoom in to the landscape scale (1:24 000 or larger) and refer to detailed road maps, landownership maps, land use information such as grazing allotments, proposed sugar industry expansion areas and wildlife maps such as Mahogany Glider Habitat areas and additional data, as available. This information will provide information as to the threats of wetland sites which need to be overcome. Using this information and knowledge of the land, based on field reconnaissance and maps, adjust proposed boundaries.
7. As part of the final proposal, indicate specific actions that must be taken to secure the system, including acquisitions, wilderness or other reserve designations on public lands etc.

Appendix 3:
Regional Wetland Program Core and Buffer Reserves

Vegetation mapping produced by the Department of Environment can be used to produce a regional wetland map. This involves division of the existing natural habitat in the region into Core and Buffer Wetland Reserves. This has been undertaken with the assistance of Ian Hisslop, Environment Officer, Bushland Management, Brisbane City Council. The following vegetation types have been classified into core and buffer reserves based on their wetland value. Vegetation marked with an "R" requires further investigation.

REGIONAL WETLAND CONSERVATION PROGRAM		
Vegetation Name (DoE)	**Category**	**Reserve Type**
Mangroves	**W**	Core
Mangroves (disturbed)	**W**	Core
Mangroves (regrowth)	**W**	Core
Treeless areas associated with Mangroves	**W**	Core

1. Integrated Catchment Management in Queensland

Since the inception of integrated catchment management (ICM) in Queensland, successful implementation has been largely impeded by the inability of catchment management groups to influence land use planning and management. Until relatively recently local governments have had a limited role in rural land use planning and in the management of natural resources generally (McDonald and Bellamy 1997). More specifically, ICM principles and catchment management issues have not traditionally been incorporated into or addressed by local planning schemes. Historically, local government planning schemes have been applied mostly to urban areas and to the expansion of urban related uses into rural areas. Local government has always been a significant provider of rural roads and is a key player in localised resource management matters such as drainage and water resources. The development and management of rural natural resources for agriculture and forestry, and the protection of environmental quality and nature conservation has been historically a state agency matter in Australia (McDonald and Bellamy 1997). Additionally the conservation and management of natural and rural lands has been achieved mostly through programs such as Landcare that foster voluntary changes in the way people use and manage their natural resources (ICM/Landcare Review Committee 1997). There is no specific legislation for ICM and consequently catchment management groups do not have the statutory power to legally implement management strategies (Queensland Department of Primary Industries 1993).

Partnerships between catchment management groups and local governments are beginning to be formed and as a result local governments are now beginning to take greater responsibility for the implementation of ICM principles and strategies. This is occurring through local government planning schemes and through locally funded ICM projects. These partnerships are the result of improved communication between catchment committees and local governments, a better understanding of the principles and objectives of ICM within local government and because of an improved recognition of the role of local government in the management of natural resources.

The use of local government planning schemes to facilitate the implementation of ICM strategies provides the focus for this report. The report reviews the evolution ICM planning by local governments and considers the advancements made by the Natural Heritage Trust (NHT) Project linking planning schemes with ICM strategies. It also reviews some of the key achievements of the Brisbane Waterways Management Plan. Specifically however the report provides a detailed consideration of the process for and outcomes of incorporating ICM into land use planning for the Herbert River Catchment in North Queensland. The Herbert River Catchment is selected as the focus for this review owing to its location in an area of great environmental significance, the impact that the rapid expansion of the sugar industry has had on the integrity of important environmental resources and the impact that future expansion may have on remaining resources. Furthermore, unlike most rural councils in Queensland, the Hinchinbrook Shire Council has begun to control rural development through the planning scheme to achieve more sustainable development outcomes. Additionally, the process of linking the planning scheme with the catchment management plan has helped to change the way key stakeholders view planning and environmental issues. In recognition of this important achievement the Hinchinbrook Shire Council was awarded the 1999 Landcare Local Government Award.

2. History of Local Government and Resource Management in Queensland

Local Government has a major role to play in implementing catchment management strategies as it is the major regulatory agency controlling land use and land use changes (Halliburton 1995). Local governments have an important role in implementing sustainability-based land use planning as it is estimated that perhaps 85% of land use decisions are made by local authorities (Nobbs, et al. 1995). As a result local authorities have an important role in bridging the implementation gap of the ICM program. Halliburton (1995) has identified several important advantages of implementing ICM at a local government level. Firstly, local government has significant opportunities to influence land use and land management through planning schemes. Secondly, local government is local. This is important as local ownership of problems, processes and solutions is a key to successful adoption of good catchment policies by landholders. Thirdly, political commitment by Local Government to ICM is necessary and helps provide a sense of local ownership. Political commitment is partially dependent on community knowledge, which can be fostered by Local Government. Finally, local government has a major role in information management and dissemination through involvement as a "clearing house" for research, through involvement in research design and in the production of information for catchment landholders.

2.1 ICM strategy and the role of local government

1991 Strategy for Integrated Catchment Management
In 1991 the Queensland State Government released an ICM strategy for Queensland that outlined the broad policy and structural arrangements. The strategy provides a framework for fostering cooperation and coordination between landholders and other resource users, community groups and government agencies from all levels (ie. federal, state and local) involved in the use and management of natural resources. It promoted ICM as a participative and consultative process with a strategic and planned approach to tackling important natural resource management issues (Bellamy, et al. 1998).

In identifying ways of implementing ICM, the 1991 strategy established the roles of relevant stakeholder groups including individuals, the community, local, state and commonwealth governments. The strategy determined that local government would play a key role in:

- Fostering community awareness and the formation of Catchment Care Groups;
- Contributing technical and financial support to Catchment Groups and Committees, on a voluntary basis and as resources permit;
- Participating in the development of catchment management strategies; and
- Contributing voluntarily to the implementation of catchment management strategies by considering incorporating relevant parts of these strategies in local authority plans, by-laws and administrative procedures and in their own field activities (Queensland Department of Primary Industries 1991).

1994 Natural Resource Management Discussion Paper
In 1994 a discussion paper on natural resource management (NRM) was released by the Queensland Department of Primary Industries (QDPI). It defined the policy position for NRM and established both regulatory and non-regulatory strategies to guide planning processes for the allocation and management of natural resources consistent with the principles of ecologically sustainable development (Queensland Department of Primary Industries 1994). The paper's objective was "to produce an integrated NRM policy with non-regulatory strategies and a minimum of legislation, and to integrate the existing natural resource legislation administered by DPI". The intent of the discussion paper was to provide the basis for the development of the Natural Resource Management Act. However a change in government stalled the development of this Act.

The strategy also highlighted the need to closely link and coordinate NRM policy with other policies and approaches for environmental protection, nature conservation, local government planning, management of leasehold land and native title (Queensland Department of Primary Industries 1994). It identifies a preference to amalgamate existing legislation within existing administrative arrangements, rather than create new agencies (McDonald and Shrubsole 1996). Therefore to implement ICM, the discussion paper suggests linking catchment management strategies with the plans policies and action programs (both voluntary and mandatory) of state, regional and local governments and community groups (Queensland Department of Primary Industries 1994).

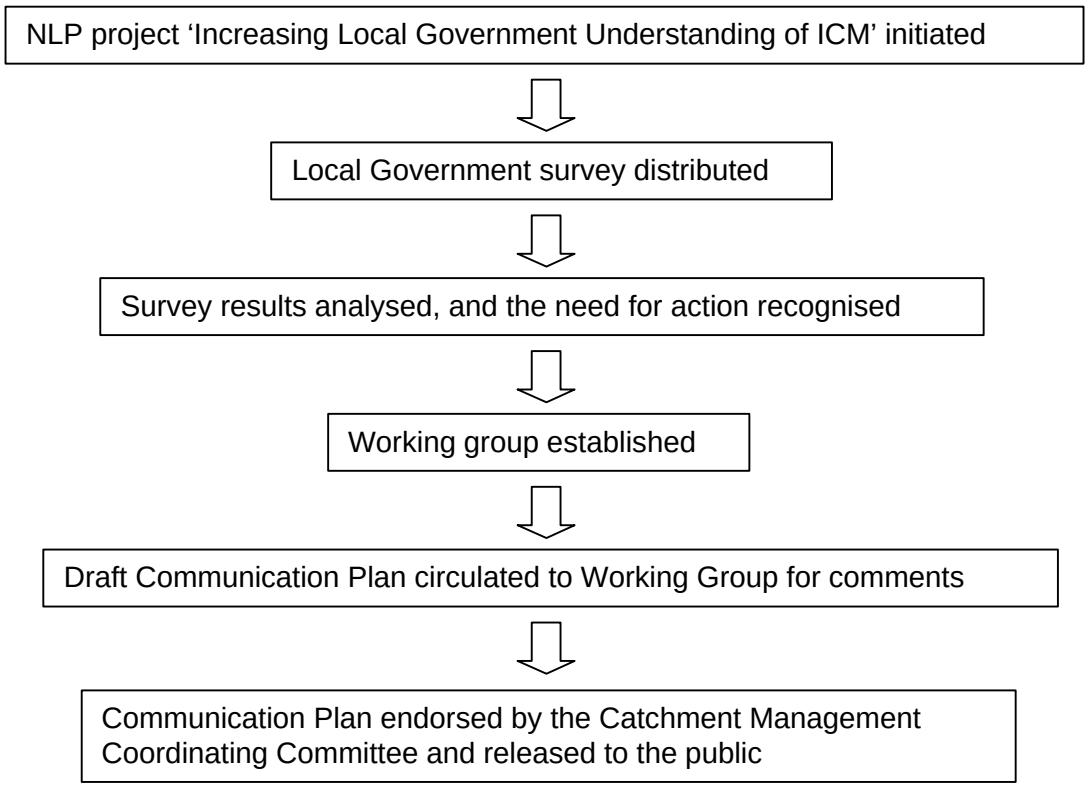
1996 Integrated Catchment Management Communication Plan

In 1996 the Department of Natural Resources produced the Local Government and Integrated Catchment Management Communication Plan. This plan further developed the government's 1994 policy position of integrating NRM within existing institutional arrangements and focused specifically on the important role of local government in the administration, coordination and implementation of natural resource management planning. The Communications Plan acknowledged that local governments are key players in the success of ICM because of their ability to influence local development and respond to social and economic change (Queensland Department of Natural Resources 1996).

The Communication Plan was developed as part of a project called 'Increasing local government understanding and involvement in ICM'. The plan development methodology is shown in Figure 1.

The Communication Plan sought to "increase the level of understanding of ICM concepts and provide best practice information for local government officers to solve real life catchment problems" (Queensland Department of Natural Resources 1996). It was targeted principally at local government due to their responsibility for tasks such as strategic planning, planning scheme preparation, development control, local area planning and provision of open space networks within local government areas (Queensland Department of Natural Resources 1996).

Figure 1. Process Used in the Development of the Communication



Source: (Queensland Department of Natural Resources 1996)

Achieving planning and development assessment from an ICM perspective is given urgent priority in the plan. The rationale being that local government planning schemes are the key to improving catchment management, yet planners have not always adequately addressed environmental and catchment issues through planning schemes. To facilitate the integration of ICM into planning and development assessment the communications plan confirms the need to:

- "show State and local government planners and elected representative involved in statutory planning and development assessment how to implement catchment management practices and policies
- identify and promote 'ICM best practice' guidelines for local government processes affecting land use
- enhance cooperation and coordination between CCCs and local and State governments through consultation and education
- improve catchment management processes (Queensland Department of Natural Resources 1996).

A specific action plan is developed in the Communication Plan to overcome these issues. Phase one involves a project officer working closely with CCCs landcare groups, industry and community interest groups to develop and implement ICM oriented local government planning schemes (Queensland Department of Natural Resources 1996). Critical tasks identified for this phase are to:

- identify and prioritise key issues which are identified by catchment management studies, catchment coordinating committees and local governments and which are addressed by local government through planning schemes;
- draft regulatory planning mechanisms that can be used by local government (particularly in planning schemes) to address ICM issues;
- review regulatory planning mechanisms for effectiveness and applicability to the issue and the area;

- negotiate incorporation of appropriate mechanisms in planning schemes; and
- develop and implement a monitoring and evaluation process for provisions incorporated in planning schemes (Queensland Department of Natural Resources 1996).

In Phase two , planning guidelines are prepared to resolve the issues and mechanisms and tools and implementation arrangements are researched. ICM policies are promoted and government officers are trained to apply and develop the policies (Queensland Department of Natural Resources 1996).

The outcomes of this project would therefore include:
- Local government planning schemes that effectively address catchment management issues;
- Land-use planners who are aware of and trained in, techniques to incorporate catchment management objectives into local government planning mechanisms;
- Catchment strategies and action plans that are more relevant to local government;
- Better acceptance, cooperation and coordination between CCCs and local and State governments;
- Improved and clearer recognition of the role of local government in ICM; and
- A training and education package for government planning officers and planning consultants (Queensland Department of Natural Resources 1996).

2.2 Linking Integrated Catchment Management and Local Government Planning Schemes: A Pilot Project

To overcome some of the implementation issues associated with ICM in Queensland and achieve planning and development assessment from an ICM perspective, a project was initiated in 1997 that aimed at linking catchment management strategies and local government planning schemes. It was based on the urgent priority strategy in the Communications Plan regarding improved linkages between local planning and catchment management. The project received National Heritage Trust (NHT) funding and was partnered by the Department of Natural Resources, Local Government Association of Queensland, Department of Communication and Information, Local Government and Planning, Landcare and Integrated Catchment Management.

The project "Linking ICM and Local Government Planning Schemes" sought to demonstrate how councils and catchment committees could successfully work together to identify catchment issues and implement planning solutions through local government planning mechanisms (Lusis 1999a). Implementation of this project has been via three stages. The first stage focussed on linking ICM strategies and planning schemes in four case study areas. The second stage involves the preparation of good practice guidelines for councils and catchment committees, and stage three, involves training and education programs for catchment committees, councils and other relevant organisations.

The Noosa, Warwick, Bulloo and Herbert River Catchments were the case study ares used for stage one. At the project conception stage, the local councils in all study areas were developing new planning schemes. For each case study area a reference group consisting of representatives from local government, the catchment coordinating committee and community stakeholder groups, drove the catchment management and local government planning processes. The specific roles of the reference groups were to:
- identify the ICM issues to be addressed by the project;
- develop the issues through workshops to assess current information;
- appoint consultants to provide information on the ecological issues and possible planning solutions;
- review the ecological findings and range of planning solutions;
- agree on preferred amendments to be made to the planning scheme and presented the final report to Council for endorsement in principle;

- monitor the public review process; and
- evaluate the success of the case study as a model to solve catchment issues (Lusis 1999a).

The Case study process was completed in 1998 bringing to an end the first of the three stages in this project. A brief description of the catchment issues and planning solutions for each of the case study areas is outlined below.

Four River Case Studies
The Bulloo ICM Reference Group's case study sought to incorporate aspects of the management of intensive agricultural development within the catchments of the Bulloo, Paroo and Wilson rivers and Cooper Creek in the Bulloo Shire Planning scheme (Lusis 1999a).

The reference group established that future land use and resource management for the Four River Region:
- Depends on the well being and economic soundness of the Bulloo community;
- ensures future development does not prejudice the continued natural/organic beef production industry;
- seeks guarantees that water allocation from the river systems and the Great Artesian Basin will not impact upon the sustainability of these natural systems; and
- fosters a responsible tourism industry, which emphases on education and awareness of the region's values (Lusis 1999a).

The ecological report identified the following environmental pressures requiring further action:
- over-grazing on native pastures;
- visitor impact on popular camping sites;
- exploitation of native fish;
- uncontrolled flows from the Great Artesian Basin Due to uncapped bores; and
- The need for additional input by the local community to regional development (Lusis 1999a).

However, the ecological report also found that the Cooper Creek, Wilson and Bulloo Rivers are generally in their natural state and contain only native fish species. The report identified how cooperative action is successfully addressing contemporary issues such as pest management, the capping of bores and the establishment of water reticulation systems for grazing animals (Lusis 1999a).

In terms of the status of catchment management planning in the case study area, progress is also being made towards forming a catchment coordinating committee for the Bulloo River, which encompasses part of Bulloo and Quilpie Shires. A steering committee was formed in September 1997 to create local awareness of and support for catchment management and to develop an issues paper which will highlight the needs of the catchment and possible directions the community may take with ICM. Steering Committee members have participated in landcare group meetings, shire pest management planning workshops, and developing media releases and posters (Lusis 1999b). A survey has been developed and circulated throughout the catchment to identify key stakeholder groups, identify the major issues in the catchment and to find out people's perceptions about and interest in forming a catchment coordinating committee (Lusis 1999b).

In terms of local government planning mechanisms, resource management and land use planning in the Bulloo Shire Planning Scheme is principally achieved through the provisions of the council's strategic plan and development requirements imposed on specific development proposals as conditions of approval (Lusis 1999b). The scheme also includes council's aims and objectives and associated provisions in respect of intended environmental, community and rural management outcomes (Lusis 1999b).

To integrate ICM objectives into the scheme, several amendments were proposed by the reference group. The proposed amendments to the Bulloo Shire Planning focus on rural land management, development requirements, and the rural planning strategy (Lusis 1999a). The planning scheme provisions for grazing and agricultural activities now include:

- permitting grazing as a right, but limiting grazing density to sustainable stocking rates;
- treating all other animal husbandry activities, including grazing beyond sustainable levels, as intensive animal husbandry, which requires the approval of council;
- defining "Intensive agriculture" as "…any agriculture in which water, chemicals and other productivity boosters are applied, and which has the potential to harm the environment or human health; and
- permitting agriculture as a right, provided it does not constitute intensive agriculture (Lusis 1999b).

This means that the scheme identifies grazing activities "as of right" and defines all other rural activities as intensive agriculture thereby requiring council consent. The amendments also include new criteria for Council to assess future development applications (Lusis 1999a). These amendments have been approved by Council and endorsed by the community.

Condamine River Catchment Case Study

The Condamine River Case study sought to incorporate aspects of the management of the riparian zone and flood plains of the upper Condamine River catchment into the Warwick Shire Planning Scheme. The Warwick ICM Reference Group agreed that the priority issues to be investigated in terms of how they may be addressed in the planning scheme included:

- providing for a healthy stream and riverine ecosystem;
- improving the water quality in watercourses in the upper catchment;
- enhancing the physical and biological values of the riparian zone, flood plains and watercourses;
- improving the biodiversity of riparian and flood plain fauna and flora; and
- integrating flood mitigation controls (Lusis 1999a).

The health of the Condamine River catchment is vital to the downstream health of the Murray-Darling Basin. The ecological report identified the following pressures upon the Condamine River:

- flood plain development;
- requests for increases in water extraction;
- poor management of stock access to watercourses; and
- stormwater run-off from urban areas and intensive husbandry sites (Lusis 1999a).

The State of the Rivers for the upper Condamine Catchment concluded that the overall condition of the river was good along 13%, moderate along 43%, poor along 41%, and very poor along 3% of the River. Initiatives to address the pressures include a water allocation management plan (using a whole of catchment approach), and Warwick Shire Council's environment management plan for waste (including water, oil, packaging and refuse) (Lusis 1999a).

The Condamine Catchment Management Association, is responsible for overseeing the implementation of its management strategy which was endorsed by the Catchment Management Coordinating Committee and DNR in 1997. The Committee has been involved in the recognition of issues and the coordination of technical support so it can help regional organisations achieve long-term management solutions. Its achievements include:

- implementing the priority actions of the Condamine Catchment Strategic Plan during 1998;
- publishing and promoting the Riparian Zone Management Manual for application throughout the catchment;

- initiating 10 soil conservation projects with the support of four local government authorities; and
- being closely associated with landcare groups based in Allora (which are addressing issues in Dalrymple Creek), and Glengallan and Rosenthall (which combine to address issues across the shire) (Lusis 1999e).

By the end of 1999, CCMA will have completed a comprehensive review of the Condamine Catchment Strategic Plan. It will also be working with local communities to develop sub-catchment action plans. The focus of the CCMA consultation is to encourage the community to write the action plans by considering local soil, water vegetation and fauna issues. It is anticipated that more than 30 sub-catchment action plans will have been prepared in the Condamine Catchment by October (Lusis 1999e).

The reference group has integrated catchment management into the planning scheme. Warwick Shire Council was one of the first Shires in Queensland to prepare a planning scheme under the Integrated Planning Act (IPA) of 1997. Therefore the planning provisions suggested in the planning scheme reflect the system of planning and management established under the IPA. One of the purposes of the IPA is to promote ecological sustainability by seeking to balance and integrate the protection of ecological processes and natural systems, and economic development and the maintenance of the cultural, economic, physical and social well being of people and communities. Similarly the Council has addressed ecological sustainability, economic development, shire image and cultural heritage, and community and physical infrastructure in the scheme (Lusis 1999e). Five ICM-related desired environmental outcomes were developed each with performance indicators and measures to achieve the required outcome. These planning provisions provided the foundation for one of the four parts of the new Warwick Shire Council Planning Scheme (Lusis 1999a). In 1999, Warwick Shire Council embarked on an extensive consultation program for the new Warwick Shire Planning Scheme with the local stakeholder groups (Lusis 1999e).

Noosa River Catchment Case Study

The Noosa River ICM Reference Group aimed to incorporate planning solutions for the management of riparian lands into the Noosa Shire Planning scheme. The ecological report prepared as part of the project found that the pressures on the riparian lands were attributed to increasing residential, industrial and agricultural activities in the shire as well as poor development practices. This has facilitated increasing sediment, nutrient and pesticide levels via stormwater run-off, as well as ongoing clearing of riparian vegetation, drainage of wetlands and building on flood plains (Lusis 1999a).

The planning report provided a range of complementary statutory and voluntary measures that could be used to address new development within the riparian lands of the Shire. From a planning perspective the approach provides flexibility for Council by setting both general and specific objectives in place within the Noosa Strategic Plan and Planning Scheme (Lusis 1999a).

The planning report influenced the development of Councils strategic plan. Following extensive government industry, and community consultation, Noosa Shire Council completed its strategic plan for the shire in 1997. The strategic plan has a life to 2005 and has three broad levels: strategic vision, strategic aims and implementation provisions by locality. It is also guided by four overarching principles: character and lifestyle, environment, economic principles and social principles (Lusis 1999d)

Noosa Shire Council will review its vegetation management local laws in 1999. The new provisions are anticipated to apply over the whole shire; currently local laws apply only to the coastal area, rural towns and a number of individual properties. Community consultation is preceding the preparation of the new system. The council has credited the case study as being instrumental in determining the suitable measures for assessing tree removal proposals in riparian locations (Lusis 1999d).

Noosa Shire Council has developed two maps to assist the community in identifying the riparian areas of the shire. The first map identifies the riparian areas of the Noosa River catchment and the following ecological characteristics:

- areas immediately alongside the river, creek and stream banks;
- areas surrounding the four lakes;
- wetlands linked to the river system; and
- vegetation communities which have clear links to the river system (Lusis 1999d).

The riparian areas in the first map are modified in the second map to illustrate how the planning scheme would be implemented. The following sites are excluded from the second map.

- areas where management is controlled by state agencies;
- areas where the effect of any new controls would be limited; and
- small and isolated areas (Lusis 1999d).

This approach has allowed the Council to focus on a workable range of issues that need to be addressed, identify the most appropriate statutory or voluntary measure to use to address each issue and set in place general and specific objectives to address each issue (Lusis 1999d).

The Noosa Shire is currently in the process of amending its planning scheme to become consistent with new provisions of the Integrated Planning Act. As these changes are completed, the council will commence consultation on likely policy changes to scheme provisions that affect land sues and earthworks in riparian areas. The council has used the case-study process and the planning report as the source on how the planning scheme can be used to address issues of riparian and land management (Lusis 1999d).

Noosa Shire Council commenced Stakeholder meetings in March 1999, prior to the public review in mid 1999. The case study successfully explored the mechanisms available to the catchment committee and Noosa Council for addressing catchment issues through the planning process (Lusis 1999d).

Herbert River Catchment Case Study

The Hinchinbrook Shire ICM Reference Group sought to incorporate elements of the management of wetlands, riparian lands and drainage systems into the Hinchinbrook Shire Planning scheme (Lusis 1999a). The reference group agreed that successful land use planning is a marriage between the conservation of locally important natural resources and the sustainable cane growing for the local economy (Lusis 1999a).

The ecological report found that the shire is rich in natural fauna, but that many of the species are under pressure attributed to a range of human activities and natural phenomena. Findings included:

- 56 species of native animals, 13 of high conservation interest
- 47 resident species of water birds, and 17 species of migratory birds, 24 under some level of threat
- 43 species of fish in the fish habitat areas, but declining diversity further up the flood plain (Lusis 1999a).

The planning report provided a series of amendments to the Hinchinbrook Shire Strategic Plan and Planning Scheme. The effect of the amendments will mean that where a landowner intends to use land for intensive agriculture and where part or all of the land suitable for cane growing is considered Class 4 or 5, contains a known wetland, fish habitat or abuts a fish habitat, is in an active coastal area, is below 3m AHD, is a Wet Tropics area, or a known mahogany glider habitat, then a town planning impact assessment application and approval is required from the Hinchinbrook Shire Council (Lusis 1999a).

The Hinchinbrook Community endorsed these planning scheme amendments in January 1999 (Lusis 1999a).

2.3 Brisbane Waterways Management Plan

While catchment management planning has been applied in many rural contexts in Queensland, there are few examples of catchment plans for urban environments. The Brisbane River and Moreton Bay Water Management Plan is the first Queensland example of an integrated catchment plan focussing predominantly on urban land uses. The 1998 Brisbane Waterways Management Plan presents an integrated framework for the management of the environmental, social, cultural and economic aspects of the waterways of the Brisbane River and Moreton Bay Catchment. Spatially, the Waterways Management Plan encompasses the Brisbane, Bremer, Pine, Caboolture, Logan, Albert, and Stanley Rivers and Warrill, Tingalpa and Lockyer Creeks, as well as the other creeks and ground waters that flow into these three rivers and Moreton Bay (Brisbane River Management Group 1998).

In the development of the Waterways Management Plan the Brisbane River Management Group (BRMG) worked closely with the Brisbane River and Moreton Bay Wastewater Management Study (BRMBWMS). The BRMBWMS was initiated in 1994 to produce a water quality management strategy for the Moreton Bay waterways including the tidal sections of the Brisbane, Bremer, Pine and Caboolture Rivers and associated creeks (Brisbane River Management Group 1998). The Waterways Management Plan is a joint publication of the two groups (Brisbane River Management Group 1998).

The Waterways Management Plan takes a regional approach to catchment management. It is linked to several priority actions of the 1998 SEQ2001 Regional Framework for Growth Management and it provides a model approach for waterways management and water quality performance criteria for south east Queensland. It is also linked to a range of regional or geographically based programs and projects undertaken by State and local government and other agencies which will influence waterways planning and management in the Brisbane River and Moreton Bay Catchment (Brisbane River Management Group 1998). Examples include:

- environmental and land use planning for the Port of Brisbane;
- the Brisbane Gateway Ports Area Strategy;
- the Regional Coastal Management Plan for South East Queensland Maroochy Shire to Gold Coast City);
- the Moreton Bay Marine Park Zoning Plan;
- the Queensland Fisheries Management Authority's management planning in Moreton Bay; and
- the natural Resource Management Strategy for South East Queensland (Brisbane River Management Group 1998).

The management strategies and actions developed in the Waterways Management Plan relate to four major outcome areas, namely water quality and ecological health, livelihoods and resources, waterways celebration, and livability and lifestyle (Brisbane River Management Group 1998). To achieve these outcomes, the plan identifies specific actions for developing coordinated waterways management, stakeholder consultation, communication and education (Brisbane River Management Group 1998).

The Waterways Management Plan also acknowledges that coordination with local and regional planning activities is essential to achieve catchment management objectives. At the planning level in South East Queensland, five layers of planning need to be linked for effective catchment management. These include:

- *1998 Regional Framework for Growth Management;*
- *Regional Management Plans*: for example the 1998 Waterways Management Plan, Regional Coastal Management Plan;

- *Specific Topic/Outcome Plans*: strategies and actions to deal with important outcome areas ie: Moreton Bay Catchment 1998 Water Quality Management Strategy and Implementation Program Plans;
- *Local Catchment Council Plans*: local strategies and actions for specific local government areas or catchments; and
- *Local Area/Site Plans*: specific detailed plans or actions that refer to a single location such as facility upgrade plans, or plans for improving a riverside park (Brisbane River Management Group 1998).

Formal linkage between the Waterways Management Plan and local government planning has already been established through the Brisbane City Council "City Plan". The City Plan is the new IPA planning scheme for Brisbane and is currently undergoing an extensive phase of public consultation. Council clearly makes a strong commitment to achieving catchment management principles and objectives in the City plan through:

- The *Vision*;
- *Desired Environmental Outcomes, performance indicators and strategies* for natural environment and waterways and the green space system;
- *General assessment processes* for greenspace areas including conservation, parkland, sport and recreation, environmental protection and rural areas;
- *Planning Scheme Policies* for acid sulfate soils, environmental impact assessment, management of urban stormwater quality, and natural assets;
- *Codes and related provisions* for acid sulfate soils, biodiversity, greenspace, outdoor sport and recreation, parks, stormwater management, waste water management, waterways, and wetlands; and
- *Local Planning Policies.*

3. Integrated Catchment Management and Local Government Planning in the Herbert

The Herbert River Catchment drains an area of approximately 1,0000km^2 to the Coral Sea and is the largest of the river systems located in Australia's sub-humid to humid tropical north-east (Refer Map 1). With its source 8km north-east Herberton, (1070m asl) the Herbert River winds 340km to its mouth, 7km north of Halifax (Herbert River Catchment Coordinating Committee 1996). Topographically, the catchment can be divided into three distinct sections. The upper catchment, (the Tablelands) is approximately 6,000km^2 and is bounded to the north and west by the Great Dividing Range and to the east by the Cardwell Range. In the intermediate catchment, (the central ranges, approximately 1,000km^2) below Gleneagle (179km downstream) the River changes direction and flows south-east for 70 km through a deep gorge before entering the lower catchment. The lower catchment, or coastal lowlands (3,000km^2) is bounded on the north by the Cardwell Range and on the south by the Seaview Range (Johnson and Murray 1997). The Lower catchment contains the Floodplain and delta of the Herbert River and is characterised by reworked alluvial soils. The floodplain consists of flat and relatively low lying terrain which is subject to regular inundation from flooding (Herbert River Catchment Coordinating Committee 1996). The Herbert River Delta is a major feature of the Queensland coast (Johnson and Murray 1997). The alluvial floodplain of the Herbert River, is one of the most intensively cultivated districts in the state, being a highly significant sugar-producing region that produces approximately 20% of Australia's sugar. It has a set of chronic but not acute resource management issues, most important being those associated with water management, flooding, drainage, river system quality as well as nature conservation for remnant terrestrial habitat and wetlands (McDonald and Bellamy 1997). The administrative boundary of the Hinchinbrook Shire Council is also contained within the lower section of the catchment.

Mahogany Glider Habitat, mangroves, wetlands, riparian lands and other important habitat areas of the Herbert River Catchment are of national and local significance. However the distribution of such environmental resources has been dramatically reduced since European Settlement. Conservation of many important environmental resources has been ineffective in the past owing to fragmented management arrangements, a failure to address environmental issues in the rural land development process and limited ability to control harmful land management practices. The greatest threats to these areas at present are associated with the rapid expansion of the sugar industry.

Until relatively recently this expansion was not managed adequately and consequently one of the key challenges facing the Herbert catchment was to regulate the further expansion of the Sugar Industry and incorporate environmental objectives into the rural land development process. Other issues that had hindered the management and conservation of these important areas in the past included the poor coordination of institutional arrangements poor information and knowledge about environmental issues and possible solutions and limited political will to take a stand against inappropriate rural development. Freehold land rights issues have also been a significant barrier preventing the regulation of rural land for environmental purposes. Traditionally there has been far less control over rural land use and management and statutory land use controls tend to be regarded by farmers as an infringement of their property rights. Additionally, as local governments are held accountable by way of election, the extent to which local governments are prepared to intervene in development activity (ie: by imposing statutory controls on land use) are guided by the willingness of the community to support that intervention. The extent of intervention is also the subject of many debates between planners, economists and politicians (Vella 1997). Consequently the major focus in the past in the Herbert catchment has been on river management issues, especially issues relating to flooding and drainage associated with the major river systems. Solutions have generally been seen to be engineering works for example, works to mitigate flooding and drainage issues rather than private land use controls and land management strategies (McDonald and Bellamy 1997).

Given these environmental and social issues, recent progress in the Herbert River basin, administered by two local governments, Hinchinbrook and Herberton Shires, provides a good case study of the evolution of the role of local government in natural resources management.

3.1 Catchment Management in the Herbert

ICM commenced in the Herbert Catchment in March 1993 with the establishment of the Herbert River Catchment Coordinating Committee (HRCCC) on a voluntary basis by local community interests. The impetus for its formation was the recognised need for better community participation in decision-making relating to river management issues. The HRCCC's stated objectives are to:

- coordinate government agencies and the community to pursue common goals;
- seek community involvement in catchment management;
- identify and rectify natural resource degradation;
- promote ways to prevent and reduce natural resource degradation;
- promote the wise use of all natural resources within the Catchment;
- identify key indicators of biodiversity and monitor as a measure of catchment health;
- encourage the retention of significant natural habitats within the Catchment (Hinchinbrook Shire Council 1997).

The HRCCC activities since formation have primarily focussed around:

(i) single-issue activities to get 'runs on the board' rather than issues of strategic importance (eg., promotion of owl boxes for pest control);
(ii) being a referral agency for proposed projects and other catchment activities by state and local government (eg., SIIP proposal, Hinchinbrook Shire Planning Scheme);
(iii) the formulation of a draft Herbert River Catchment Management Plan for public review and comment;
(iv) brokering funding for others to undertake natural resource management activities in the catchment (eg., for recent round of NHT funding) (McDonald and Bellamy 1997).

In 1996 a Draft Catchment Management Strategy was produced for the Herbert River.

3.2 Local Government in the Herbert River Catchment

Several local government areas have boundaries that overlap with the Herbert River Catchment. Hinchinbrook Shire Council is the only local government area that is completely within the Herbert River Catchment. The boundary of the Hinchinbrook Shire roughly corresponds with the alluvial floodplain of the Herbert River. The upper part of the catchment forms part of the Herberton Shire Council. Other Shire Councils with control over small sections of land include the Thuringowa Shire in the southern part of the catchment, and the Johnson Shire in the upper part of the catchment.

The Hinchinbrook Shire Council (HSC) has been involved in resource development of since its foundation in 1933 in many and various ways. The HSC is a partner in the Drainage Board gazetted in 1977, in a number of voluntary boards for sub-catchments and of the Herbert River Information Centre, which was established in 1996.

1984 Town Planning Scheme

The first planning scheme in Hinchinbrook Shire was gazetted in 1984. The 1984 Scheme did not include a strategic plan (Sinclair Knight Merz 1998) and its spatial extent was roughly aligned to the urban township of Ingham. Consequently the 1984 plan provided the Council little opportunity to facilitate natural resource management through planning mechanisms.

1997 Town Planning Scheme

In 1996 the Hinchinbrook Shire Council resolved to prepare a new planning scheme. Planning Consultants were appointed to the task and a draft scheme was made available for public consultation at the end of 1996. The Scheme was gazetted in 1997. The spatial extent of the new scheme was extended to encompass the entire Hinchinbrook Shire Council area, thereby providing Council with the ability to control development across the whole shire for the first time. This also provided Council with the ability to control natural resource management and rural development. The intention of the planning scheme was to provide Council with greater control over rural development. This was to be achieved through the Strategic Plan, regulation of agricultural uses and wetland conservation (McDonald and Bellamy 1997). The 1997 scheme facilitated greater management of freehold land for nature conservation purposes.

Council clearly made a strong commitment to natural resource management in the 1997 Town Plan. This is demonstrated through the Broad Aim of the Strategic Plan which seeks "To provide a framework to facilitate the continuing use and development of the Shire's resources according to sound environmental and catchment management practices, and, to promote the diversification of the Shire's economic base, for the long-term benefit of the community" (Hinchinbrook Shire Council 1997). The overall thrust of the Strategic Plan, as reflected in the broad aim and the broad strategies, was to promote environmentally and economically sustainable development for the long-term benefit of the community and successive generations (Hinchinbrook Shire Council 1997; McDonald and Bellamy 1997).

In addition, Council's obligation to catchment management was also established in the scheme through three broad Integrated Catchment Management objectives. The first was "to identify and designate the catchments and sub catchments of the Herbert River which lie wholly or partly within the Shire' (Hinchinbrook Shire Council 1997). This was to be implemented through the assessment of planning and development proposals on the basis of the catchment system and potential impacts of development upon the natural resource of that system. Catchment management strategies and specific catchment data are to be "taken into account" in the assessment of any planning proposal (McDonald and Bellamy 1997).

Objective two was "to ensure that, as a result of the development and use of land no environmental impacts affect any lands elsewhere within a catchment designated in this Strategic Plan" (Hinchinbrook Shire Council 1997). This will be implemented by a commitment of having "regard for and shall implement the principles of ICM" and the "may refuse to support any proposal which will generate unacceptable effects upon any land...", and "may require the preparation of an EIA" where detrimental downstream effects or impacts are possible" (McDonald and Bellamy 1997).

The third Objective was "to promote sensitive and sustainable land use practices through the development process" (Hinchinbrook Shire Council 1997). This will be implemented by requiring and encouraging "all development and land uses... to adopt sound management practices so as to minimise, mitigate and contain the impacts on the land, water and biological resources of the catchment system". Additionally "the Council may refuse to support any proposal which would prejudice the long-term values of the resources within the catchment system affected" (McDonald and Bellamy 1997).

Zoning controls and development assessment

The 1997 Shire Council has adopted a simple zoning scheme which divides the local authority into five zones these being Public Purposes, Rural, Town, Village, Special Activities (Hinchinbrook Shire Council 1997). The planning scheme does not include any zone with the primary intent being to conserve natural resources. This limits the scheme's ability to protect core wetland areas.

Regulation of agricultural uses
The draft-planning scheme has sought to regulate agriculture to achieve Integrated Catchment Management objectives. The regulation of agriculture has been achieved by defining 'agriculture' and 'intensive agriculture' as separate land uses requiring different approval processes.

'Agriculture' is defined in the scheme as:

> *"the use of land, and buildings on the land, for the purposes of producing primary products from cropping, grazing or stock, and horticulture including the use of the land for an ancillary activity necessary for the conduct of the principal use."*

Intensive' Agriculture' is defined in the scheme as:

> *The use of land for the intensive production of crops, such as but not limited to sugarcane, at rates of production beyond the natural capability of the land where the land is irrigated for such purposes and relies upon the regular and systematic application of fertilisers and other chemicals.*
>
> *The term includes the establishment of any infrastructure necessary for the conduct of the use. The term does not include small-scale agriculture conducted on premises or a site less than 5 hectares in area ".*

McDonald and Bellamy (1997) write that the separation of the two rural uses could create confusion unless unambiguously defined (McDonald and Bellamy 1997).

Designated Uses Requiring Approval
Agriculture is a "permitted development" in the rural zone. As a result, the land can be used for agriculture (as defined) and for small-scale agriculture conducted on premises or a site less than five hectares in area (as defined for Intensive Agriculture) without needing to apply to Council for approval. This impacts on wetland conservation as sites of less than five hectares can possess wetland values that are worthy of conservation and in the case of small wetland habitats, can have an important role in the hydrological regime of the Herbert River Floodplain. However Council will have no control over the development of these sites. Clearly very small areas should not require regulation, but setting the minimum threshold too high could allow many significant developments to go unregulated (McDonald and Bellamy 1997).

In the Rural Zone intensive agriculture is defined as a "permitted development subject to conditions". Consequently Council has discretionary power to assess an application for intensive agriculture and apply conditions where necessary (Bates 1995). Council cannot refuse a permitted development subject to conditions. However it does have the power to impose conditions on development to achieve wetland conservation. Development assessment is initiated when the applicant applies to council if they propose to "use the land for the intensive production of crops, such as, but not limited to sugarcane, at rates of production beyond the natural capacity of the land where the land is irrigated for such purposes and relies upon the regular and systematic application of fertilisers and other chemicals. Additionally development assessment is initiated when an applicant seeks to develop infrastructure associated with intensive agriculture. This means that when an applicant wants to convert to sugar cane or establish infrastructure for the growing of sugar cane they need to apply to council for permission However this raises the question of what will be used for the definition of 'infrastructure'. Rural infrastructure differs from urban infrastructure and confusion may be created if this definition is not clear. As it currently stands, the definition could potentially include structures from farm sheds to access roads (even if they are dirt roads) and farm drains.

Neither agriculture nor intensive agriculture required consent application under the planning scheme. Consent applications are different to permitted development applications in the application process and the options available to council in assessing the application. Firstly the proposal needs to be advertised

to give the public the chance to comment on it. The range of issues that need to be considered by Council is greater including: whether the environment would suffer any unacceptable impact caused by the proposal; and if all objections which have been duly lodged within the prescribed time against the granting of consent by the Council. In accordance with the Local Government (Planning and Environment) Act, 1990, Council can grant consent; refuse to grant consent; or grant consent subject to reasonable and relevant conditions. Therefore unlike permitted development applications, Council can refuse to grant consent and therefore if a proposed development poses unacceptable effects on wetlands, it can be refused. Terms for refusal are also established in the scheme and those relevant to wetland conservation include if: flood mitigation, drainage of filling works required within the site would adversely affect surrounding land; the proposal will have an unacceptably long-term effect upon the environment; the proposal would be in conflict with any provisions of the Strategic Plan in effect in respect of the subject land.

Criteria for the approval of regulated uses
The planning scheme does not establish any criteria to facilitate development assessment or establish criteria for the approval of regulated uses. As a result it does not provide guidelines, performance standards or best practice for relevant environmental issues, natural resource protection, water quality and quantity issues. The planning scheme does not specify what changes can be made to drainage and flood regimes. These conditions need to be specified in planning documents in such as way to give clear prior guidance as to desired developments (McDonald and Bellamy 1997).

Assessment of development applications against criteria
When determining conditions for intensive agriculture the planning scheme states that Council is to consider the character of the proposed development in relation to: the character of development on the adjoining land and in the locality; the adequacy of any proposed landscaping; the retention of existing vegetation and buffers to adjoining land and roads; the provision for storage and disposal of waste; the provisions of the planning scheme including the strategic plan and any Local Planning Policy of the Council, relevant to the application. However because no criteria has been established the scheme just identifies general considerations.

The planning scheme had the potential to achieve the effective conservation of wetland resources, yet in reality this was not facilitated by the words of the scheme. Council's strong commitment to ICM and radical regulation of agricultural development is to be commended. However, it did not take the next step and develop the details needed to make the plan implementable (McDonald and Bellamy 1997). The scheme did not include performance conditions or development criteria to assist development assessors achieve wetland conservation, yet it is particularly important that these tools are included in planning scheme, especially for Shires such as Hinchinbrook, where there is no professional planner on staff. Therefore it is imperative that the implementation framework reflects best practice and considers obstacles such as the capability of the Local Government (McDonald and Bellamy 1997).

Submissions to the Scheme
As previously mentioned, a draft scheme was made available for public consultation at the end of 1996. Submissions were received from the Herbert River Catchment Coordinating Committee, Herbert River Canegrowers, the Environmental Protection Agency (Department of Environment at the time) and the Department of Natural Resources. While the submissions generally supported the plan's commitment to ICM they also criticised the scheme for failing to provide criteria to guide the development assessment process and thereby achieve these goals. The submissions also criticised the scheme for not appropriately reflecting the policies, programs and plans of state government departments and local resource management groups in the designation of lands and for failing to bring them on board as referral agents for environmental impact assessment. Other recommendations made through submissions included the use of the geographic data held in the Herbert River Information Centre to

map suitable and unsuitable development areas and the suggestion that greater attention be focused on community consultation and education in the plan preparation process. Summaries of these issues and others raised in the submissions are included in Appendix 1.

3.3 The Linking Process

The Hinchinbrook ICM reference group had 14 members, bringing together a number of community stakeholders. The Group consisted of:

- five representatives from Hinchinbrook Shire Council;
- five representatives from the catchment committee;
- the senior planning officer of the North Queensland Department of Communication, Information, Local Government and Planning
- a CSIR project director
- the NHT project manager
- the ICM project officer.

Through the reference group, stakeholders were forced together to discuss and identify the issues that were of greatest importance to them and their constituents and also to the catchment as a whole. From this, four priority catchment management issues were identified. The project then sought for ways of dealing with these issues through the planning scheme. The four issues included:

- riparian vegetation management on all stream banks;
- addressing the filling of urban land for residential and rural residential development and rural wetlands for intensive agricultural purposes;
- establishing a farm drainage system;
- the need to develop a strategy for the future construction and maintenance of local roads (Lusis 1999c).

The reference group conducted most of its business between march 1997 and June 1998. A final meeting was convened in November 1998 to evaluate the success of the case study (Lusis 1999c).
